IV. CONCLUSION

In this work, the new hybrid algorithm, called HDPH, is proposed to achieve a robust algorithm with a good solution quality by combining the three well-known algorithms, DE, PSO and HS. The performances of chosen algorithms are based on the parameter selection. Therefore, all combination of parameter values are tested for each function for all three algorithms and the results that are tabulated are selected as the best values obtained through all possible trials. However, in the HDPH algorithm the parameters are chosen randomly in the given ranges which make the algorithm easier to implement. Even with this kind of simplification in HDPH algorithm, the good performance is verified. Also, the experimental results have shown that, when both solution quality and robustness of an algorithm are taken into consideration, in most of the test functions, HDPH is more robust than the other three algorithms. At the same time, HDPH, for many functions analyzed, has similar or even better solution quality than the three algorithms that composes it. Hence, the proposed hybrid algorithm, HDPH, makes use of the features of the three algorithms and has similar or better solution quality with high robustness to random initialization of the population.

Computer Science & Network Systems

CSNS is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to more technical aspects of computer science and related disciplines. The CSNS area spans themes ranging from hardware issues close to the discipline of computer engineering via software issues tackled by the theory and applications of computer science and to communications issues of interest to distributed and network systems. Events that constitute CSNS are:

- CANA'2013 - Computer Aspects of Numerical Algorithms
- MMAP'2013 - International Symposium on Multimedia Applications and Processing

Computer Aspects of Numerical Algorithms

Numerical algorithms are widely used by scientists engaged in various areas. There is a special need of highly efficient and easy-to-use scalable tools for solving large scale problems. The workshop is devoted to numerical algorithms with the particular attention to the latest scientific trends in this area and to problems related to implementation of libraries of efficient numerical algorithms. The goal of the workshop is meeting of researchers from various institutes and exchanging of their experience, and integrations of scientific centers.

Topics

- Parallel numerical algorithms
- Novel data formats for dense and sparse matrices
- Libraries for numerical computations
- Numerical algorithms testing and benchmarking
- Analysis of rounding errors of numerical algorithms
- Languages, tools and environments for programming numerical algorithms
- Numerical algorithms on GPUs
- Paradigms of programming numerical algorithms
- Contemporary computer architectures
- Heterogeneous numerical algorithms
- Applications of numerical algorithms in science and technology

***Abstract*—The aim of the paper is to analyze the potential of the mixed precision iterative refinement technique for the WZ factorization. We design and implement a mixed precision iterative refinement algorithm for the WZ factorization with the use of the single (a.k.a. float), double and long double precision. For random dense square matrices with the dominant diagonal we report the performance and the speedup of the solvers using different machines and we investigate the accuracy of obtained solutions. Additionally, the results (performance, speedup and accuracy) for our mixed precision implementation based on the WZ factorization were compared to the similar ones based on the LU factorization.**

I. Introduction

SOLUTION of linear systems of equations of the form:

$$\mathbf{A}\mathbf{x} = \mathbf{b}, \qquad \text{where} \quad \mathbf{A} \in \mathbb{R}^{n\times n}, \quad \mathbf{b} \in \mathbb{R}^{n}, \qquad (1)$$

is an important and common problem in engineering and scientific computations. One of the direct methods of solving a dense linear system (1) is to factorize the matrix $\mathbf{A}$ into some simpler matrices — and then solving simpler linear systems. The most known factorization is the LU factorization. In this work we study another form of the factorization, namely the WZ factorization. In [5], [6], [7] we showed that there are matrices for which applying the incomplete WZ preconditioning gives better results than the incomplete LU factorization and we also showed the use of the WZ factorization for Markovian models.

One of quite known techniques to accelerate computations is the mixed precision iterative refinement. The iterative refinement is a well-known concept and it was analyzed by [11], [13], [12]. The mixed precision iterative refinement technique is used for the high performance computing [2], for example, for the solution of dense linear systems [3] — the LU factorization was considered among others, for accelerated block-asynchronous iteration methods [1].

The idea of such a refinement is that we perform the most time-consuming computations with the use of the low precision and then we improve the accuracy of the solution with the use of the high precision — by the iterative refinement. The mixed precision method uses properties of modern computer architectures where the single precision computations are about twice faster than the double precision ones — and the same can be observed for the memory access for both precisions.

Here we will modify the WZ solver to use the mixed precision approach. The aim of the paper is to analyze the potential of the mixed precision iterative refinement technique for the WZ factorization. We design and implement a mixed precision iterative refinement algorithm for the WZ factorization and compare its performance, speedup and accuracy with the pure implementation of the WZ factorization with the use of the float, double and long double precisions. We also compare it to an analogous LU solvers (pure ones and with the mixed precision).

The content of the paper is following. In Section II we describe the idea of the WZ factorization [8], [14] and the way the matrix $\mathbf{A}$ is factorized to a product of matrices $\mathbf{W}$ and $\mathbf{Z}$ — such a factorization exists for every nonsingular matrix (with pivoting) what was shown in [8].

Section III provides some mathematical background by outlining the idea of the iterative refinement algorithm.

In Section IV we describe the mixed precision iterative refinement technique for the WZ factorization. We present the algorithm for matrices which can be factorized without pivoting, for example, strictly diagonally dominant ones (as it was proved in [8]) and we give details about the implementation of the mixed precision iterative refinement for the WZ factorization.

In Section V we present the results of our experiments. We analyze the performance of our algorithm and its speedup. We study the influence of the size of the matrix on the achieved numerical accuracy.

Section VI is a summary of our experiments.

II. WZ Factorization

Here we describe shortly the WZ factorization usage to solve (1). The WZ factorization is described in [8], [10]. Assume that the $\mathbf{A}$ is a square nonsingular matrix. We are to find matrices $\mathbf{W}$ and $\mathbf{Z}$ that fulfill $\mathbf{WZ} = \mathbf{A}$ and the matrices $\mathbf{W}$ and $\mathbf{Z}$ consist of the following columns $\mathbf{w}_i$ and rows $\mathbf{z}_i^T$

This work was partially supported within the project N N516 479640 of the Ministry of Science and Higher Education of the Polish Republic (MNiSW) "Modele dynamiki transmisji, sterowania zatłoczeniem i jakością usług w Internecie".

978-83-60810-53-8/$25.00

respectively:

$$\begin{aligned}
\mathbf{w}_i &= (\underbrace{0,\ldots,0,1}_{i}, w_{i+1,i},\ldots,w_{n-i,i},0,\ldots,0)^T \\
&\quad \text{for} \quad i=1,\ldots,m,\\
\mathbf{w}_i &= (\underbrace{0,\ldots,0,1}_{i},0,\ldots,0)^T \\
&\quad \text{for} \quad i=p,q,\\
\mathbf{w}_i &= (\underbrace{0,\ldots,0}_{n-i+1}, w_{n-i+2,i},\ldots,w_{i-1,i},1,0,\ldots,0)^T \\
&\quad \text{for} \quad i=q+1,\ldots,n,\\
\mathbf{z}_i^T &= (\underbrace{0,\ldots,0}_{i-1}, z_{ii},\ldots,z_{i,n-i+1},0,\ldots,0) \\
&\quad \text{for} \quad i=1,\ldots,p,\\
\mathbf{z}_i^T &= (\underbrace{0,\ldots,0}_{i-1}, z_{i,n-i+1},\ldots,z_{ii},0,\ldots,0) \\
&\quad \text{for} \quad i=p+1,\ldots,n,
\end{aligned}$$

where

$$\begin{aligned}
m &= \lfloor (n-1)/2 \rfloor,\\
p &= \lfloor (n+1)/2 \rfloor,\\
q &= \lceil (n+1)/2 \rceil.
\end{aligned}$$

(see also Figure 1).

After the factorization we can solve two linear systems:

$$\begin{aligned}
\mathbf{W}\mathbf{y} &= \mathbf{b},\\
\mathbf{Z}\mathbf{x} &= \mathbf{y}
\end{aligned}$$

(where $\mathbf{c}$ is an auxiliary intermediate vector) instead of one (1).

III. Refinement

Let $\mathbf{x}_{cr}$ be the exact solution of the system (1):

$$\mathbf{A}\mathbf{x}_{cr} = \mathbf{b} \tag{2}$$

and $\mathbf{x}_{cm}$ be the machine-computed solution, thus with some rounding error — which we denote by $\mathbf{e}$ (all $\mathbf{x}_{cr}$, $\mathbf{x}_{cm}$, $\mathbf{e}$ are vectors of the size n).

Then, we can write:

$$\mathbf{x}_{cm} = \mathbf{x}_{cr} - \mathbf{e} \tag{3}$$

Let

$$\mathbf{r} = \mathbf{b} - \mathbf{A}\mathbf{x}_{cm} \tag{4}$$

be a residual vector for the not exact solution $\mathbf{x}_{cm}$. Using (3) for $\mathbf{x}_{cm}$ in (4) we get:

$$\mathbf{r} = \mathbf{b} - \mathbf{A}(\mathbf{x}_{cr} - \mathbf{e})$$

and then (from (2)):

$$\mathbf{r} = \mathbf{A}\mathbf{e}. \tag{5}$$

Now, we can compute the error vector $\mathbf{e}$ from a linear system (5) and find a new, better solution of (1):

$$\mathbf{x}'_{cm} = \mathbf{x}_{cm} + \mathbf{e}.$$

However, the vector $\mathbf{e}$ as a solution of (5) is also prone to rounding errors, so the new $\mathbf{x}'_{cm}$ is also not exact — although better — and it can be further improved iteratively with the same process. This routine is known as the iterative refinement.

Algorithm 1 describes steps of such an iterative refinement for the solution of the linear system (1), with the use of the WZ factorization. The computational complexity is also given for every step. The stop condition is given by the infinity norm of the residual vector:

$$||\mathbf{r}||_\infty = \max_{1\le i\le n} |r_i|,$$

and the refinement stops when there is no further improvement (that is why we return $\mathbf{x}$, not $\mathbf{x}'$).

Algorithm 1 The iterative refinement technique for the WZ factorization

Require: $\mathbf{A}$, $\mathbf{b}$
Ensure: $\mathbf{x} \leftarrow \mathbf{A}^{-1}\mathbf{b}$

10:	$\mathbf{r} \leftarrow \mathbf{A}\mathbf{x}' - \mathbf{b}$	$\{O(n^2)\}$
11:	$\varepsilon' \leftarrow ||\mathbf{r}||_\infty$	$\{O(n)\}$
12:	**if** $\varepsilon' \ge \varepsilon$: **return** $\mathbf{x}$	$\{O(1)\}$
13:	$\mathbf{x} \longleftrightarrow \mathbf{x}'$	$\{O(1)$, only references swapped$\}$
14:	$\varepsilon \leftarrow \varepsilon'$	$\{O(1)\}$
15:	**end loop**	

IV. Mixed Precision

The next algorithm, Algorithm 2, describes the use of the mixed precision technique with the iterative refinement of the solution. Every step is also labeled with its precision.

The only operations performed with the use of the double (or long double) precision are:

- matrix-vector operations with the complexity $O(n^2)$ — Steps 7 and 15 (computing the residual vector);
- vector operations with the complexity $O(n)$ — Steps 8, 16 (computing the norm) and 14 (applying the correction);
- scalar operations with the complexity $O(1)$ — Steps 17 and 19;
- conversions — almost all with the complexity $O(n)$ — the only exception ($O(n^2)$) is Step 1, but it is done only once, before the loop.

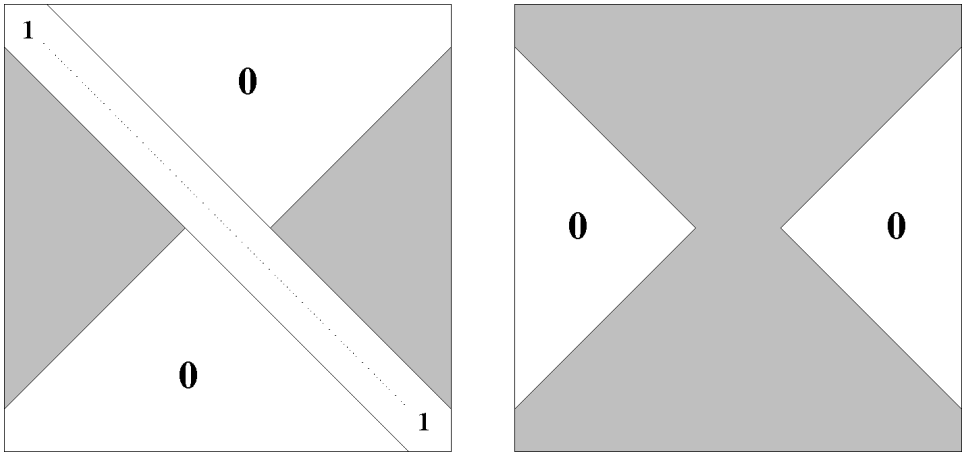

Fig. 1. Structures of the matrices $\mathbf{W}$ (left) and $\mathbf{Z}$ (right)

Algorithm 2 The mixed precision iterative refinement technique for the WZ factorization

Require: $\mathbf{A}_d$, $\mathbf{b}_d$
Ensure: $\mathbf{x}_d \leftarrow {\mathbf{A}_d}^{-1}\mathbf{b}_d$

1: $\mathbf{A}_s \leftarrow \mathbf{A}_d$ {conversion}
2: $\mathbf{b}_s \leftarrow \mathbf{b}_d$ {conversion}
3: $\mathbf{W}_s\mathbf{Z}_s \leftarrow \mathbf{A}_s$ {$O(n^3)$, single}
4: Solve the equation $\mathbf{W}_s\mathbf{y}_s = \mathbf{b}_s$ {$O(n^2)$, single}
5: Solve the equation $\mathbf{Z}_s\mathbf{x}_s = \mathbf{y}_s$ {$O(n^2)$, single}
6: $\mathbf{x}_d \leftarrow \mathbf{x}_s$ {conversion}
7: $\mathbf{r}_d \leftarrow \mathbf{A}_d\mathbf{x}_d - \mathbf{b}_d$ {$O(n^2)$, (long) double}
8: $\varepsilon \leftarrow ||\mathbf{r}_d||_\infty$ {$O(n)$, (long) double}
9: **loop**
10: $\mathbf{r}_s \leftarrow \mathbf{r}_d$ {conversion}
11: Solve the equation $\mathbf{W}_s\mathbf{y}_s = \mathbf{r}_s$ {$O(n^2)$, single}
12: Solve the equation $\mathbf{Z}_s\mathbf{p}_s = \mathbf{y}_s$ {$O(n^2)$, single}
13: $\mathbf{p}_d \leftarrow \mathbf{p}_s$ {conversion}
14: $\mathbf{x}'_d \leftarrow \mathbf{x}_d + \mathbf{p}_d$ {$O(n)$, (long) double}
15: $\mathbf{r}_d \leftarrow \mathbf{A}_d\mathbf{x}'_d - \mathbf{b}_d$ {$O(n^2)$, (long) double}
16: $\varepsilon' \leftarrow ||\mathbf{r}_d||_\infty$ {$O(n)$, (long) double}
17: **if** $\varepsilon' \geq \varepsilon$: **return** $\mathbf{x}_d$ {$O(1)$, (long) double}
18: $\mathbf{x}_d \longleftrightarrow \mathbf{x}'_d$ {$O(1)$, only references swapped}
19: $\varepsilon \leftarrow \varepsilon'$ {$O(1)$, (long) double}
20: **end loop**

All the other computations are single precision ones.

We denote the matrices and vectors stored in the (long) double precision with the $_d$ subscript and the matrices and vectors stored in the single precision with the $_s$ subscript. So, the input data are the matrix $\mathbf{A}_d$ and the vector $\mathbf{b}_d$ ((long) double precision). The output vector $\mathbf{x}_d$ is also stored in the (long) double precision.

The coefficient matrix $\mathbf{A}_d$ is converted to the single precision for the WZ factorization and denoted as $\mathbf{A}_s$. Some vectors in the algorithm are also converted between single and (long) double precision (that is why we have: $\mathbf{b}_d$ and $\mathbf{b}_s$; $\mathbf{x}_d$ and $\mathbf{x}_s$; $\mathbf{r}_d$ and $\mathbf{r}_s$; $\mathbf{p}_d$ and $\mathbf{p}_s$).

The method used in Algorithm 2 can give a significant improvement for the solution of a linear system, because the cost of every iteration is very small comparing to the cost of the factorization.

The disadvantage of this approach is a lot larger memory requirement — a great deal of data are to be duplicated in both precisions. It consumes up to 50% more memory than it is used in usual double precision solution.

V. Numerical Experiments

In the experiment, we analyze how the use of the mixed precision iterative refinement techniques for the WZ factorization influences the performance, the speedup and the accuracy of the WZ solver for the linear equation system. In this section we test the performance, the speedup and the accuracy on three devices of different architectures. Additionally, we compare properties of the WZ solver with the LU solver. For both kinds of factorization we consider five implementations:

- a traditional single precision implementation;
- a traditional double precision implementation;
- a traditional long double precision implementation;
- a mixed precision implementation with double precision refinement (denoted as mix(double));
- a mixed precision implementation with long double precision refinement (denoted as mix(long double)).

The former three are made according to Algorithm 1 and the latter two are made according to Algorithm 2. All the implementations were sequential (single-threaded).

All the computations were carried out for dense random matrices with a dominant diagonal. The sizes of the matrices were from 500 up to 9000.

A. Environment

The architectures used for tests are shown in Table I. All the machines worked under the Debian GNU/Linux 6.0 operating system and the programs were compiled with the use of the GCC compiler (ver. 4.7.2, compiler command: `g++ -O3`).

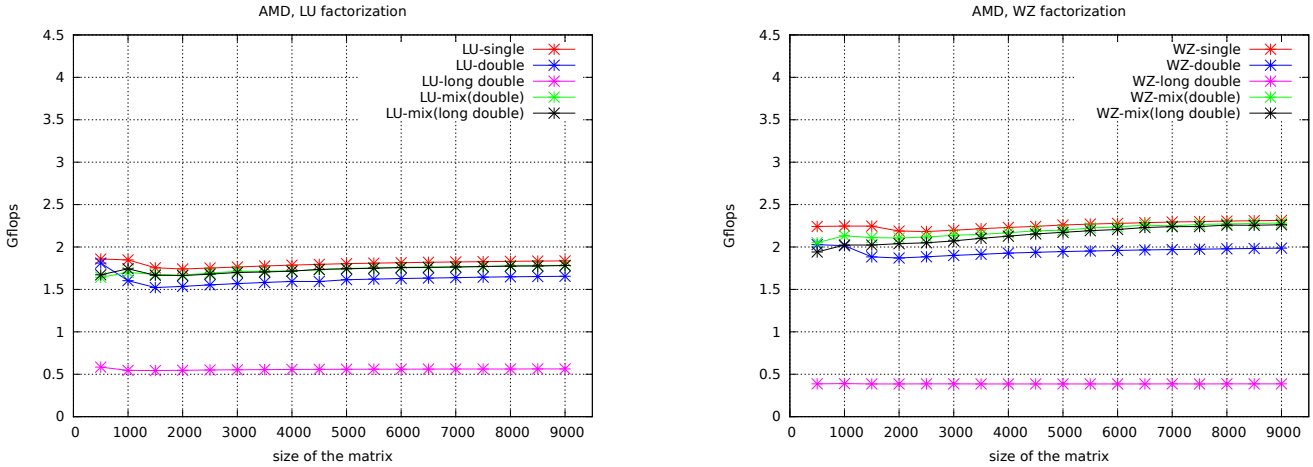

Fig. 2. The performance of the LU (left) and WZ (right) solver on the AMD architecture

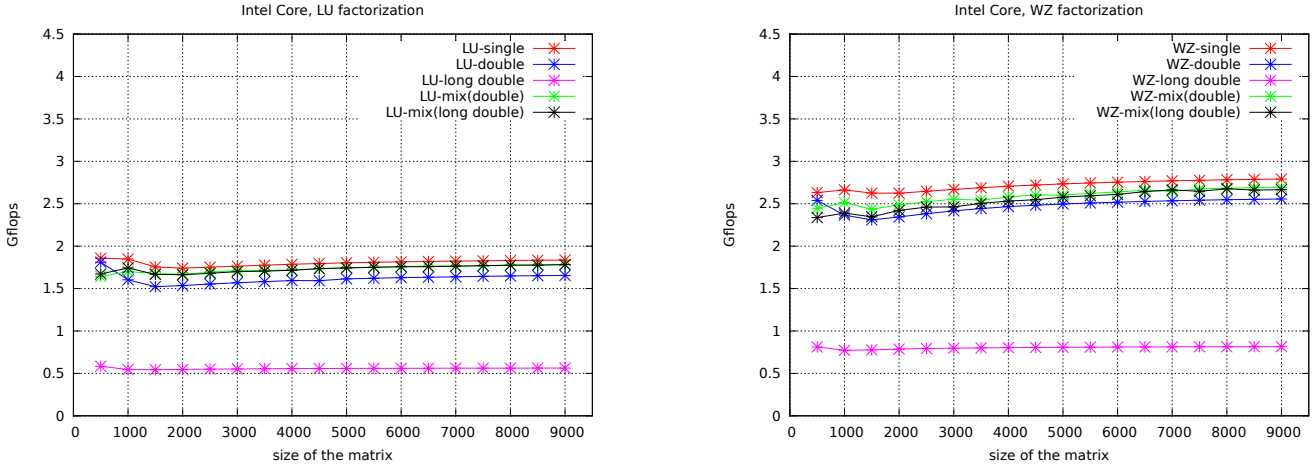

Fig. 3. The performance of the LU (left) and WZ (right) solver on the Intel Core architecture

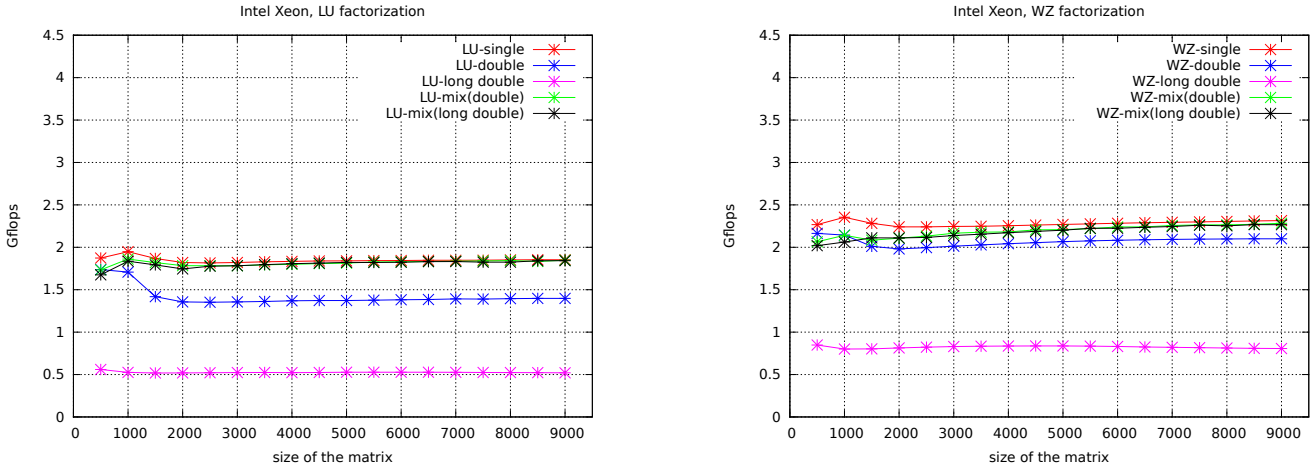

Fig. 4. The performance of the LU (left) and WZ (right) solver on the Intel Xeon architecture

B. Performance

Figures 2, 3, 4 show the performance of the single-core implementations of the LU and WZ solvers on the given architectures. The performance is based on the number of floating-point operations in the LU solver $\left(\frac{2}{3}n^3 + \frac{1}{2}n^2 - \frac{7}{6}n\right)$.

We see that:

- the architecture has almost no impact on the performance — however, not mixed implementations on AMD are somewhat slower;
- the size of the matrix has no impact on the performance, either;
- the WZ solver performs better than the LU solver;
- the long double implementation is always the slowest, the others perform quite similarly — even (what is very important) the mix(long double) implementation.

C. Speedup

Figures 5, 6, 7 show the speedup of the same implementations. We labeled our speedups by S(F)-P where:

- F $\in \{$LU, WZ$\}$ is the kind of the factorization used;
- P $\in \{$double, long double$\}$ is the precision of the result.

Thus, S(F)-P denotes the speedup achieved by the mix(P) implementation over the P implementation — while both are conducted with the use of the F factorization.

We see that:

- the architecture has some impact on the speedup: the best is for the AMD architecture — because that architecture gives somewhat slower performance for double and long double implementations;
- for very small problem sizes, the cost of even a few iterative refinement iterations is high compared to the cost of the factorization and thus, the mix(double) implementations are less efficient than the double ones;
- the LU solvers have higher speedups than the WZ solvers for all architectures — because the original LU solver performs slightly worse than the WZ one;
- if the problem size is big enough, the mix(double) implementation can provide a speedup of up to 1.3 and the mix(long double) — even up to 7.

D. Accuracy

Figures 8, 9, 10 show the accuracy of the implementations. We define the measure of the accuracy as

$$\text{accu} = -\log_{10} ||\mathbf{Ax} - \mathbf{b}||_\infty.$$

We see that:

TABLE I
HARDWARE PROPERTIES OF THE TEST MACHINES

AMD	CPU	AMD FX-8120 3.1 GHz
	Host memory	16 GB
Intel Core	CPU	Intel Core I7 2670QM 2.2 GHz
	Host memory	8 GB
Intel XEON	CPU	Intel Xeon X5650 2.67GHz
	Host memory	48 GB

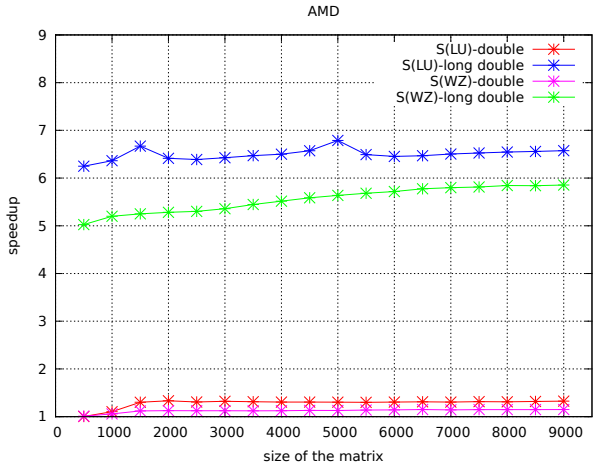

Fig. 5. The speedup of the LU and WZ solvers on the AMD

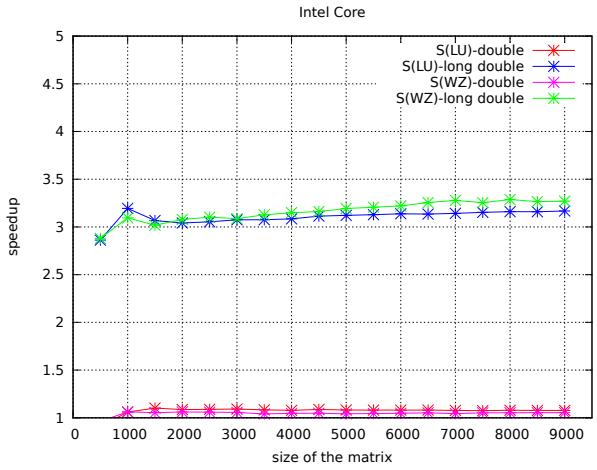

Fig. 6. The speedup of the LU and WZ solvers on the Intel Core

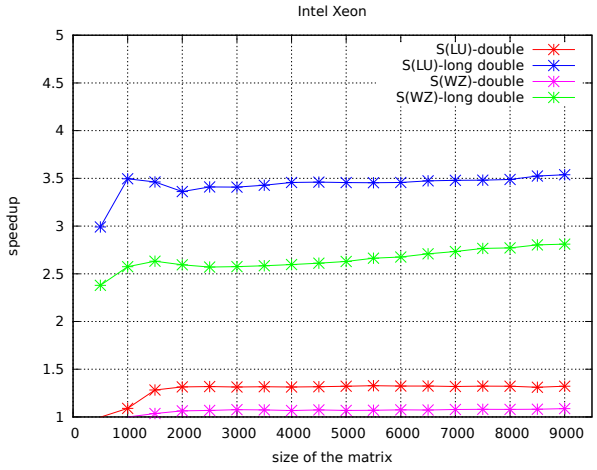

Fig. 7. The speedup of the LU and WZ solvers on the Intel Xeon

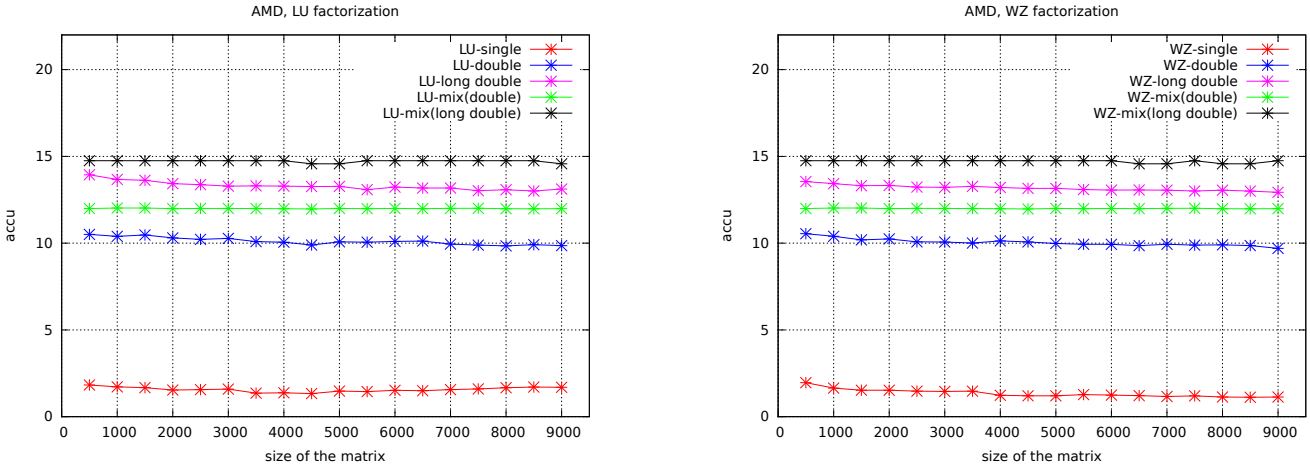

Fig. 8. The accuracy of the LU (left) and WZ (right) solver on the AMD architecture

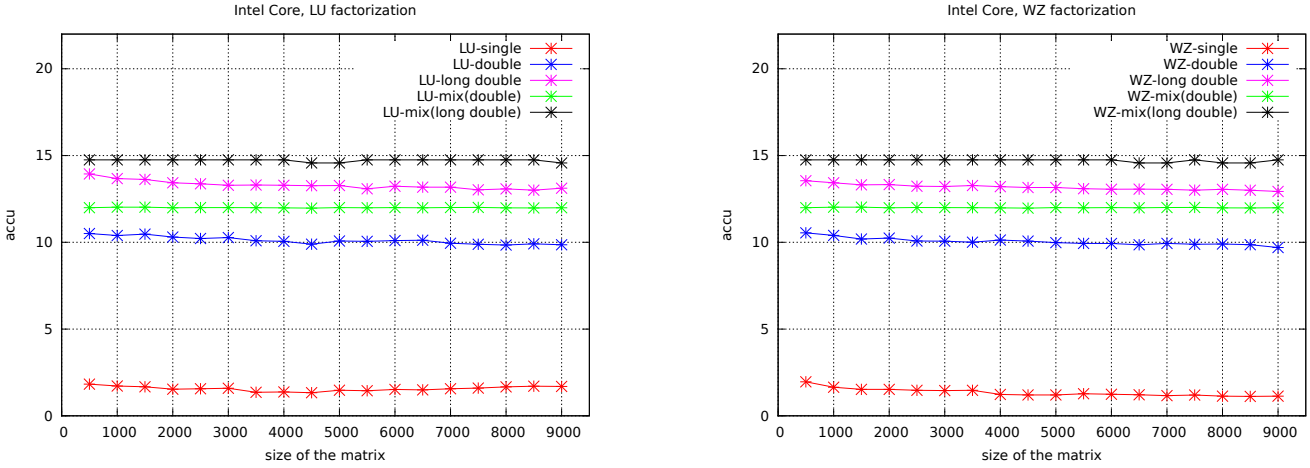

Fig. 9. The accuracy of the LU (left) and WZ (right) solver on the Intel Core architecture

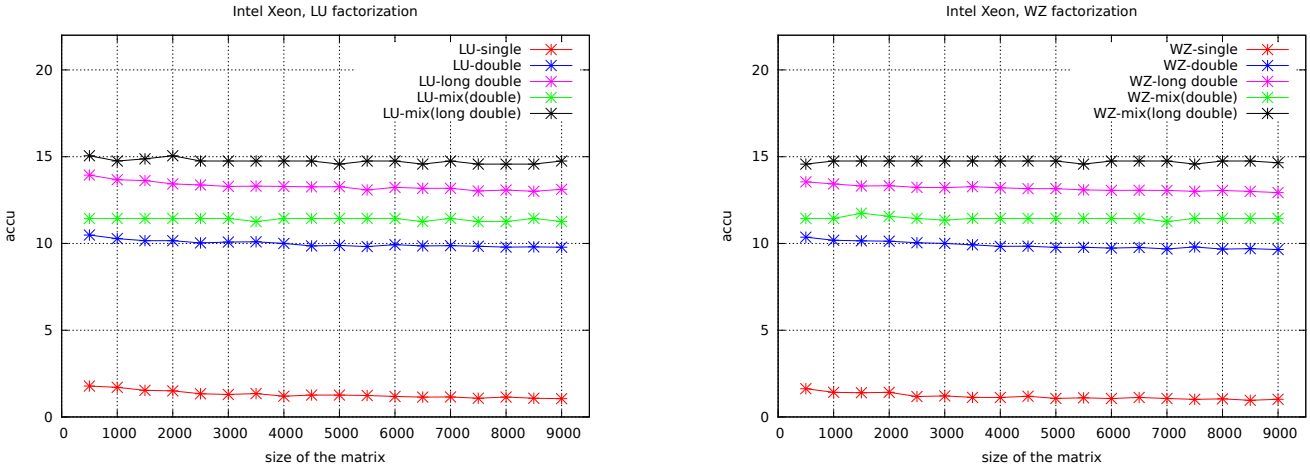

Fig. 10. The accuracy of the LU (left) and WZ (right) solver on the Intel Xeon architecture

- the architecture has no impact on the accuracy;
- the size of the matrix and the type of the factorization has almost no impact on the accuracy, either;
- the worst accuracy we get is (of course) for the single implementation; the best (about 10^{-15}) — for the long double one;
- the mixed precision significantly improves the accuracy.

The number of iterations needed for our mixed precision method to outdo the accuracy of the (long) double precision solver is not too high and is about 5–6 iterations, somewhat less on the AMD architecture (about 3–4 iterations).

VI. Conclusion

In this article we described an iterative refinement algorithm for the WZ solver with the use of the mixed precision technique and investigated properties of this new algorithm. We compared the mixed precision iterative refinement for the WZ factorization with a similar algorithm for the LU factorization.

Both the types of algorithms gave similar accuracy. However, the performance was better for the WZ solvers but the higher speedup was achieved for the LU solver.

These experiments show that the mixed precision iterative refinement method can run faster than the (long) double precision solver — delivering the same (or even better) accuracy as the (long) double precision one for both the factorizations. Moreover, the experiments also show that the mixed precision iterative refinement method for the long double precision solver is much faster than the traditional one (up to 7 times) — with the same or better accuracy.

The results do not depend significantly on the size of the matrix.

The approach presented here causes a significant acceleration of solving the linear systems with the use of direct methods and we think that the similar problems on different architectures (as GPU, for example) could be also improved.

***Abstract*—In this paper we describe a parallel implicit method based on radial basis functions (RBF) for surface reconstruction. Practical applicability of RBF methods is hindered by their high computational demand, that requires the solution of linear systems of size equal to the number of data points. The implementation of our method relies on parallel scientific libraries and is designed for exploiting Graphic Processor Units (GPUs) acceleration. The performance of the proposed method in terms of accuracy of the reconstruction and computing time shows that RBF interpolation can be very effective for large scale surface reconstruction problems.**

I. Introduction

MANY applications in engineering and science need to build accurate digital models of real-world objects defined in terms of *point cloud data*, *i.e.* a set of scattered points in 3D. Typical examples include the digitalization of manufactured parts for quality control, statues and artifacts in archeology and arts [12], human bodies for movies or video games, organs and anatomical parts for medical diagnostic [4] and terrain elevation models for simulations and modeling [16]. Modern 3D scanners are able to acquire point clouds containing millions of points sampled from an object. The process of building a geometric model from such point clouds is usually referred to as *surface reconstruction*.

There are several approaches to reconstruct surfaces from 3D scattered datasets. Generally, such methods fall into two categories [17]: Delaunay-based methods and implicit surface methods. Delaunay triangulation, and other related approaches like Voronoi diagrams, are widely used in digital elevation modeling, and their core numerical problem is a nearest neighbor interpolation [2]. Implicit surface modeling is mostly popular in describing complex shapes and interactive graphical operations. Level set methods [24], moving least square methods [11], variational implicit surfaces [21] and adaptively sampled distance field [9] are recent developments in that field. In this paper, we present an implicit surface method based on radial basis functions (RBFs). In the 1980's, Franke [8] firstly used radial basis functions to interpolate scattered point cloud and proved accuracy and stability of such methods. In this approach, an implicit surface is constructed by calculating the weights of a linear combination of a set of radial basis functions that interpolates the given data points.

Practical applicability of RBF methods is hindered by their computational demand, since they require the solution of a linear system of size equal to the number of data points and current 3D data scanners allow the acquisition of tens of millions points of an object surface.

High Performance Computing is a natural solution to provide the computational power required in such large scale problems [15]. Here, we propose an RBF surface reconstruction method designed for a massively multi-core architecture, namely Graphics Processing Units (GPUs) [18]. Recently, GPUs have been effectively exploited to improve the performance of software tools in several scientific applications, such as computational fluid dynamics, molecular dynamics, climate modeling [6], [7], [10]. The core of our method is the construction of an RBF interpolant. We are not aware of RBF interpolation algorithms for GPU. To our knowledge, the most efficient parallel algorithm for RBF interpolation on multiprocessor clusters is PetRBF [22]. PetRBF exhibits $\mathcal{O}(N)$ complexity, requires $\mathcal{O}(N)$ storage, and scales excellently up to a thousand processes. Our proposed method relies on PetRBF and one of our main contributions consist in developing an improved version of PetRBF for surface reconstruction and GPU acceleration. Moreover, we show how to make a suitable choice of the algorithm parameters for accurate reconstruction from synthetic, real or incomplete datasets. The paper is organized as follows. In Section II we deal with some mathematical preliminaries about implicit surfaces and RBF interpolation. In Section III, first we briefly recall main features of PetRBF, then we describe our method and illustrate our GPU implementation strategy. Section IV contains a discussion on the results of numerical experiments for assessing accuracy and performance of the method. Final conclusions are reported in Section V.

II. Preliminaries

In this section we recall basic ideas underlying implicit surface reconstruction and define the related RBF interpolation problem.

978-83-60810-53-8/$25.00

A. Implicit Surface Reconstruction

Given a point cloud

$$\mathcal{X} := \{(x_i, y_i, z_i) \in \mathbb{R}^3, i = 1, \ldots, N\}$$

belonging to an unknown surface $\mathcal{M}$, *i.e.* $\mathcal{X} \subset \mathcal{M}$, the goal is to find another surface $\mathcal{M}^*$ which is a reconstruction of $\mathcal{M}$. In the implicit surface approach, $\mathcal{M}$ is defined as the surface of all points $(x, y, z) \in \mathbb{R}^3$ that satisfy the implicit equation

$$f(x, y, z) = 0 \tag{1}$$

for an unknown function f. A way to approximate f is to impose the interpolation conditions (1) on the point cloud $\mathcal{X}$. However, the use of those interpolation conditions only leads to the trivial solution given by the identically zero function, whose zero surface is $\mathbb{R}^3$. Therefore, the key for finding an approximation of the function f is to use additional significant interpolation conditions, *i.e.* involving from off-surface points (where $f \neq 0$). This ensures the existence of a non trivial interpolant $\mathcal{P}_f$, whose zero surface contains a meaningful surface $\mathcal{M}^*$. This approach leads to a surface reconstruction method which consists of three main steps:

1) off-surface points generation;
2) interpolant model identification on the extended dataset;
3) computation of the zero iso-surface of the interpolant.

1) Off-surface points generation:

A common practice [20] is to consider the set of surface normals $\mathbf{n}_i = (n_i^x, n_i^y, n_i^z)$ to the surface $\mathcal{M}$ at points $\mathbf{x}_i = (x_i, y_i, z_i)$. If these normals are not explicitly known, there are techniques and tools[1] that allow to estimate them. Given the oriented surface normals ($\mathbf{n}_i$ and $-\mathbf{n}_i$), the extra off-surface points can be generated by marching a small distance δ along the normals. So for each data point, $\mathbf{x}_i = (x_i, y_i, z_i)$ two additional off-surface points are obtained. The first lies "outside" the surface $\mathcal{M}$ and is given by

$$\begin{aligned}(x_{N+i}, y_{N+i}, z_{N+i}) &= \mathbf{x}_i + \delta \mathbf{n}_i = \\ &= (x_i + \delta n_i^x, y_i + \delta n_i^y, z_i + \delta n_i^z);\end{aligned}$$

the second point lies "inside" and is given by

$$\begin{aligned}(x_{2N+i}, y_{2N+i}, z_{2N+i}) &= \mathbf{x}_i - \delta \mathbf{n}_i = \\ &= (x_i - \delta n_i^x, y_i - \delta n_i^y, z_i - \delta n_i^z).\end{aligned}$$

The union of the sets $\mathcal{X}_\delta^+ = \{\mathbf{x}_{N+1}, \ldots, \mathbf{x}_{2N}\}$, $\mathcal{X}_\delta^- = \{\mathbf{x}_{2N+1}, \ldots, \mathbf{x}_{3N}\}$, and $\mathcal{X}$ gives the overall set of points on which the interpolation conditions are assigned (see Fig. 1). The set $\mathcal{X}_\delta^+$ implicitly defines a surface $\mathcal{M}_\delta^+$ which passes through its points. Analogously, $\mathcal{X}_\delta^-$ defines the surface $\mathcal{M}_\delta^-$. Those two surfaces can be considered as external and internal to $\mathcal{M}$, respectively. The value of δ represents a small step size, whose specific magnitude may be rather critical for a good surface reconstruction [3]. In particular, if δ is chosen too large, this results in self intersecting $\mathcal{M}_\delta^+$ or $\mathcal{M}_\delta^-$ auxiliary surfaces. In our implementation we fix δ to 1% of the side of the bounding box of the data, as suggested in [23].

[1]package ply.tar.gz provided by Greg Turk, available at http://www.cc.gatech.edu/projects/large_models/ply.html

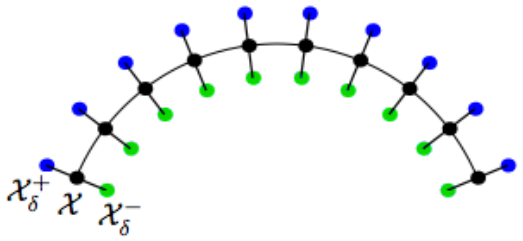

Fig. 1. Extended data set. In black points from $\mathcal{X}$, in blue points from $\mathcal{X}_\delta^+$ and in green points from $\mathcal{X}_\delta^-$

2) Interpolant model identification on the extended dataset:

This step consists in determining a function $\mathcal{P}_f$ whose zero contour (iso-surface $\mathcal{P}_f = 0$) interpolates the given point cloud data $\mathcal{X}$, and whose iso-surface $\mathcal{P}_f = 1$ and $\mathcal{P}_f = -1$ interpolate $\mathcal{X}_\delta^+$ and $\mathcal{X}_\delta^-$, respectively, *i.e.*

$$\mathcal{P}_f(x_i) = \begin{cases} 0 & i = 1, \ldots, N \\ 1 & i = N+1, \ldots, 2N \\ -1 & i = 2N+1, \ldots, 3N \end{cases} \tag{2}$$

The values of ± 1 for the auxiliary data are assigned in an arbitrary way. Such choice does not affect the quality of the results. Here we are interested to the zero iso-surface of $\mathcal{P}_f$.

3) Computation of the zero iso-surface of the interpolant:

In order to evaluate the $\mathcal{P}_f$ zero iso-surface and visualize it, we simply evaluate the interpolant $\mathcal{P}_f$ on a dense grid in a bounding box containing the point cloud. This approach leads to some undesired artifacts, since there are points in the bounding box which do not belong to $\mathcal{M}^*$. A way to overcome this drawback and display only $\mathcal{M}^*$ consists in evaluating the interpolant in a small *surrounding* volume of the surface $\mathcal{M}$. This set is denoted as $\mathcal{M}_{ext}^\varepsilon = \{\mathbf{x} \in \mathbb{R}^3 : \ d(\mathbf{x}, \mathcal{M}) \leq \varepsilon\}$, where $d(\mathbf{x}, \mathcal{M}) = \inf_{\mathbf{y} \in \mathcal{M}} \|\mathbf{y} - \mathbf{x}\|$. For a small enough value of ε, it holds that

$$\mathcal{M}^* \approx \mathcal{M}_{ext}^\varepsilon \cap \mathcal{S}_0,$$

where $\mathcal{S}_0$ is the zero iso-surface of $\mathcal{P}_f$.

B. RBF interpolation

Given a set of N distinct points $(x_j,\ y_j)$, $j = 1, \ldots, N$, where $x_j \in \mathbb{R}^s$ and $y_j \in \mathbb{R}$, the scattered data interpolation problem consists in finding an interpolant function $\mathcal{P}_f$ such that:

$$\mathcal{P}_f(x_j) = y_j,\ j = 1, \ldots, N. \tag{3}$$

In the univariate setting ($s = 1$), the interpolant $\mathcal{P}_f$ is usually chosen in a suitable function space. A common approach assumes the function $\mathcal{P}_f$ as a linear combination of certain basis functions B_j

$$\mathcal{P}_f(x) = \sum_{j=1}^{N} c_j B_j(x). \tag{4}$$

In a multivariate setting ($x_j \in \mathbb{R}^s,\ s > 1$), the problem is more complex. As stated by the *Mairhuber-Curtis* theorem [5], [13], in order to have a well-posed multivariate scattered data interpolation problem, it is not possible to fix in advance the basis $\{B_1, \ldots, B_N\}$, since the basis functions must depend on the data sites x_j.

The data dependent space for RBF interpolation can be easily generated by means of the radial functions:

$$B_j \equiv \Phi_j = \varphi(\|x - x_j\|).$$

The points x_j to which the basic function φ is shifted are usually referred to as *centers*. While there may be circumstances that suggest to choose these centers different from the data sites one generally picks the centers to coincide with the data sites.

In fact, a practical interpolation problem consists of two subproblems: finding the interpolant $\mathcal{P}_f$ and evaluating it on an assigned set of points. The coefficients c_j in (4) are obtained by imposing the interpolation conditions (3)

$$\mathcal{P}_f(x_i) = \sum_{j=1}^{N} c_j \varphi(\|x_i - x_j\|) = y_i,\ i = 1, \ldots, N.$$

This leads to solve the linear system of equations $Ax = b$ in (5).

Given a set of M points $\xi = \{\xi_1, \xi_2, \ldots, \xi_M\}$, the evaluation of the interpolant $\mathcal{P}_f$ on ξ can be computed as a matrix-vector product (6).

It is well known that in order to have a well-posed problem (5), the matrix A must be non-singular. Unfortunately, a complete characterization of the class of all basic functions φ that generate a non-singular matrix for an arbitrary set $\mathcal{X} = \{x_1, \ldots, x_N\}$ of distinct data sites is still lacking. The situation gets better in case of *positive definite matrices*, that are always non-singular. Popular radial basis functions Φ_j, that give rise to positive definite interpolation matrices, are summarized in Table II-B. We focused our work on the gaussian function, as in [22].

III. GPU Parallel Surface Reconstruction

A brief description of the surface reconstruction algorithm is reported below:

Algorithm 1 Surface Reconstruction

Requirements:
point cloud $\mathcal{X}$, surface normals $\mathbf{n}_i$,
evaluation grid ξ

1: compute extended data set:
$\mathcal{X}_{ext} = \mathcal{X} \bigcup \mathcal{X}_\delta^+ \bigcup \mathcal{X}_\delta^-$ by using $\mathbf{n}_i$;
2: find the interpolant $\mathcal{P}_f$ on $\mathcal{X}_{ext}$;
3: evaluate $\mathcal{P}_f$ on ξ;
4: render the surface;

Steps 1 and 2 have been already discussed in §II.A. Step 3 requires a matrix-vector multiplication as stated in §II.B and the rendering step can be simply accomplished using either the MATLAB `isosurface` feature or other specific tools. The most computationally expensive step is the second one, that requires the solution of a system of $3N$ linear equation, where N is the initial point cloud size. In the following, we describe a parallel scheme for solving this RBF interpolation linear system.

A. Parallelization scheme

In handling problems with a large number of data points, as in surface reconstruction from clouds of millions of points, the large amount of memory storage can become a critical point. As the problem size grows, parallelization on distributed memory architectures becomes necessary. Domain Decomposition is a useful parallelization strategy for large scale interpolation, since the solution of the original system is built up by solving a set of smaller subproblems that interact through their interfaces. Below, we briefly overview the parallelization strategy of PetRBF, in a 3D setting. Let Ω be a 3D domain containing the point cloud and let partition Ω in overlapping sub-domains $\Omega_k,\ k = 1, \ldots, S$. Moreover, let $\tilde{\Omega}_k$ denote the empty intersection portions of subdomains Ω_k (see Fig. 2). The solution of the RBF interpolation linear system

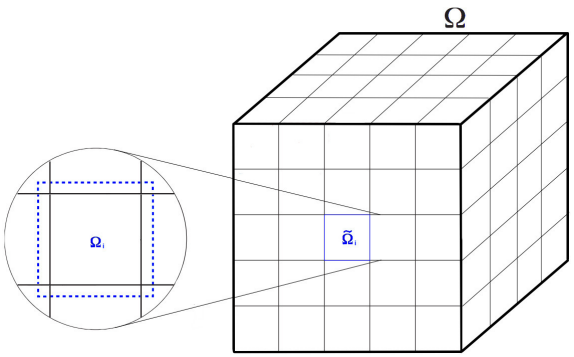

Fig. 2. Illustration of the Domain Decompostion Method.

$Ax = b$ on the whole domain Ω can be obtained through an iterative method consisting in sequentially solving, for any Ω_k, the linear (sub)system $A_k x_{\Omega_k} = b_{\Omega_k}$, where A_k, x_{Ω_k} and b_{Ω_k} are the entries in A, x, and b belonging to the sub-domain Ω_k, respectively. If at each iteration the solution on the entire domain is updated simultaneously after the solutions on every sub-domain are computed, we have an *additive* Schwarz method. Moreover, if the entries of x_{Ω_k} which are outside of the subdomain $\tilde{\Omega}_k$ are discarded after the calculation on each subdomain Ω_k, a *restricted additive* Schwarz method (RASM) in defined. RASM is known to converge faster than additive Schwarz, and requires less communication in a parallel setting. Notice that solving smaller systems of equations has the same effect of a preconditioning technique, and then RASM can be used in combination with any iterative method. PetRBF uses a Krylov subspace methods, namely the Generalized Minimum Residual (GMRES).

If the basis functions exhibit negligible global effects then A can be considered a band matrix, so that the matrix-vector

$$\underbrace{\begin{bmatrix} \varphi(\|x_1-x_1\|) & \varphi(\|x_1-x_2\|) & \cdots & \varphi(\|x_1-x_N\|) \\ \varphi(\|x_2-x_1\|) & \varphi(\|x_2-x_2\|) & \cdots & \varphi(\|x_2-x_N\|) \\ \vdots & \vdots & \ddots & \vdots \\ \varphi(\|x_N-x_1\|) & \varphi(\|x_N-x_2\|) & \cdots & \varphi(\|x_N-x_N\|) \end{bmatrix}}_{A} \cdot \underbrace{\begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_N \end{bmatrix}}_{x} = \underbrace{\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_N \end{bmatrix}}_{b} \tag{5}$$

$$\begin{bmatrix} \mathcal{P}_f(\xi_1) \\ \mathcal{P}_f(\xi_2) \\ \vdots \\ \mathcal{P}_f(\xi_M) \end{bmatrix} = \begin{bmatrix} \varphi(\|\xi_1-x_1\|) & \varphi(\|\xi_1-x_2\|) & \cdots & \varphi(\|\xi_1-x_N\|) \\ \varphi(\|\xi_2-x_1\|) & \varphi(\|\xi_2-x_2\|) & \cdots & \varphi(\|\xi_2-x_N\|) \\ \vdots & \vdots & \ddots & \vdots \\ \varphi(\|\xi_M-x_1\|) & \varphi(\|\xi_M-x_2\|) & \cdots & \varphi(\|\xi_M-x_N\|) \end{bmatrix} \cdot \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_N \end{bmatrix} \tag{6}$$

TABLE I
EXAMPLES OF RADIAL BASIS FUNCTIONS.

RBF	Φ	
Poisson radial function	$\frac{J_{s/2-1}(\|x-x_j\|)}{\|x-x_j\|^{s/2-1}}$	$s \geq 2$
Inverse Multiquadric	$(1+\|x-x_j\|^2)^{-\beta}$	$\beta > \frac{s}{2}$
Matèrn function	$\frac{K_\alpha(\|x-x_j\|)\|x-x_j\|^\alpha}{2^{\beta-1}\Gamma(\beta)}$	$\alpha = \beta - \frac{s}{2} > 0$
Whittaker function	$\int_0^{+\infty}(1-\|x-x_j\|)_+^{k-1}t^\alpha e^{-\beta t}dt$	$k = 2,3,\ldots, \quad \alpha = 0,1,\ldots$
Gaussian function	$\frac{1}{\sqrt{2\pi}\sigma}e^{\frac{-\|x-x_j\|^2}{2\sigma^2}}$	$\sigma > 0$

product, which is the predominant operation in GMRES, can be computed somewhat locally. Using a gaussian function as the basic function, it holds that A has the following entries:

$$A_{ij} = \frac{1}{\sqrt{2\pi}\sigma}\exp\left(\frac{-\|\mathbf{x}_i-\mathbf{x}_j\|^2}{2\sigma^2}\right). \tag{7}$$

Since the gaussian function decays rapidly, for a suitable choice of σ, the entries of A in (6) which correspond to the interaction of distant points can be neglected. Such resulting sparsity of A depends on the relative size of the domain compared to the standard deviation σ of the gaussian. If σ is kept constant while the size of the domain increases with N, the calculation load will scale as $\mathcal{O}(N)$. The communication required to compute $A_k x_{\Omega_k}$ is also restricted to a constant number of entries corresponding to neighbor points. Therefore, RASM entails a high level of parallelism at each GMRS iteration, and a good scalability for surface reconstruction problems with a domain size as large as hundreds (or even thousands) of σ [22].

A remarkable implementation feature of PetRBF is the use of the parallel numerical library PETSc (Portable, Extensible Toolkit for Scientific Computation) [1]. All vectors and matrices can be distributed via PETSc routines in a such way that each process stores only a local portion of data. In particular, this can be done by defining x and b as `Vec` PETSc objects. Overlapping and non-overlapping sub-domains can be handled by means of index sets (`IS`). A PETSc `IS` object is a global index that identifies the entries in each sub-domain and is distributed among the processes in the same way as the vectors. Recalling that the interpolation matrix has entries which depends only on the vector x of data sites and σ in the gaussian (eq. 7), it turns out that A can be represented as a `MatShell` PETSc object, that allows to perform matrix computations in a matrix-free way, i.e. without actually storing the matrix. Inner products, norms, and scalar products are computed by specific PETSc routines, and the solution of the linear system is obtained by calling the `KSPSolve` PETSc solver.

B. GPU implementation

Our basic idea consists in using the new PETSc GPU feature in the latest version of PETSc [1]. In fact, we have developed an improved version of PetRBF that extends the original code to GPU environments. GPU support to PETSc has been introduced by means of the CUDA framework and exploits the open source libraries THRUST [19] and CUSP [14]. THRUST is a collection of data parallel primitives that provide high level abstractions to describe efficient computations on GPU. CUSP is a sparse linear algebra toolkit for performing matrix operations and solving linear systems via CUDA on GPUs. They allows a transparent access to the GPU, without radically changes to the existing source code of PETSc. In PETSc GPU, two new subclasses `VecCUSP` and `MatCUSP` of the `Vector` and `Matrix` classes have been defined, which in turns rely on CUBLAS, CUSP, and THRUST routines to perform matrix and vector operations on the GPU. CUSP natively supports several sparse matrix formats:

- Coordinate list (COO)
- Compressed Sparse Row (CSR)
- Diagonal (DIA)
- ELLPACK (ELL)
- Hybrid (HYB)

It is worth noting that in PETSc GPU by using the routines `VecSetType()` and `MatSetType()` we can select the desired sparse matrix format simply with the command line option `-mat_cusp_storage_format <format>`, and switch from a CPU version to a GPU version by means of the command line parameters `-vec_type cusp` and `-mat_type aijcusp`.

Our GPU parallel implementation of the implicit surface reconstruction method in Algorithm 1 focuses on steps 2 and 3, i.e. construction of the RBF interpolant for the extended dataset (2), and evaluation of such RBF interpolant on a given set of evaluation points. The most expensive operation in step 2 is the matrix-vector multiplication at each iteration of the RASM preconditioned GMRES. The choice of a suitable PETSc object for the sparse matrix A turns out to be crucial for the efficiency of the implementation of step 2 on the GPU. According to the results of specific experiments, we decided to use the Diagonal (DIA) sparse matrix format in CUSP, and the related CUSP sparse matrix operations. Besides taking advantage of very reliable and efficient CUSP routines, the resulting code exhibits a very low overhead for data transfer from host memory (CPU) to device memory (GPU). By contrast, in implementing step 3 we represented the matrix A as a `MatShell` PETSc object and then we used the CUDA kernel reported in Algorithm 3 below. This choice is justified by the fact that the matrix-vector multiplication in the evaluation step must be performed only once, so that the time needed to compute the non-zero entries of A, using the Algorithm 2 as in step 2, would nullify all the advantages of the efficient CUSP routines. Moreover, our CUDA kernel makes use of the shared memory portion of the device memory, whose low latency improves the performance of the computation.

Algorithm 2 Pseudo-code for the construction of the interpolation matrix

1: **for each** subdomain Ω_i **do**
2: **for each** point x_i in the subdomain Ω_i **do**
3: **for each** point x_j in the truncation area of Ω_i **do**
4: Set $A_{ij} = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(\frac{-\|x_i - x_j\|^2}{2\sigma^2}\right)$
5: **end for**
6: **end for**
7: **end for**

IV. Experimental results

In this section we present some results of our method for surface reconstruction. The results were computed using a system equipped with an Intel Core i7-940 CPU (2,93 GHz, 8M Cache). The middleware framework is OS Linux kernel 2.6.32-28 and PETSc developer version 3.3.

First, we investigate the impact of the parameter σ on the quality of reconstruction. As we showed in §III.B, our method is very efficient for small values of σ compared to the domain size. However, besides efficiency, even the quality of the result also depends on the values of σ. This is because the accuracy

Algorithm 3 CUDA code for the evaluation step

```
__shared__ float sharedXi[BLOCK_SIZE];
__shared__ float sharedGi[BLOCK_SIZE];
int bx = blockIdx.x;
int tx = threadIdx.x;
int i = blockIdx.x * BLOCK_SIZE +
threadIdx.x;
float pf = 0;
float coeff = 0.5f/(sigma*sigma);
for (unsigned int m = 0; m <
(col-1)/BLOCK_SIZE+1; m++) {
sharedXi[tx] = Xi[m*BLOCK_SIZE + tx];
__syncthreads();
for (unsigned int k = 0; k <
BLOCK_SIZE; k++) {
dx = Xj[i]-sharedXi[k];
pf += sharedGi[k]*exp(-(dx*dx)*coeff;}}
Pf[i] = pf/M_PI*coef;
```

of the interpolation model depends on the ratio between the density of the point cloud and σ.

The experiments carried out in [22] were designed only for equally-spaced lattice point distributions, and the point density was measured by the spacing h between the points. In that case, a good choice of σ, in terms of performance and accuracy, is that yielding $h/\sigma \approx 1$.

For non-uniform unorganized data, more appropriate density measures can be devised. One is the so-called *separation distance* defined as

$$q_{\mathcal{X}} = \frac{1}{2} \min_{i \neq j} \|x_i - x_j\|_2. \tag{8}$$

As shown in Fig. 3, $q_{\mathcal{X}}$ geometrically represents the radius of the largest (hyper)sphere that can be drawn around each point in such a way that no (hyper)sphere intersects the others; that is why it is sometimes called *packing radius*. Another measure, popular in approximation theory, is the so-called *fill distance*:

$$h_{\mathcal{X},\Omega} = \sup_{x \in \Omega} \min_{x_j \in \mathcal{X}} \|x - x_j\|_2. \tag{9}$$

It indicates how well the set $\mathcal{X}$ fills the domain Ω. A geometric interpretation of the fill distance is given by the radius of the biggest empty (hyper)sphere that can be placed among the data sites in Ω (see Fig. 3); for this reason, it is also referred to as *covering radius*. Hence for scattered data, using (8) and (9), the heuristic "optimal" ratio $h/\sigma \approx 1$ can be expressed as follows:

$$\sigma \approx 2q_{\mathcal{X}} \tag{10}$$

and

$$\sigma \approx h_{\mathcal{X},\Omega}\sqrt{2}. \tag{11}$$

A. Tests on synthetic dataset

The experiments on synthetic dataset deal with a sphere, that allows to easily calculate (8) and (9). In order to perform

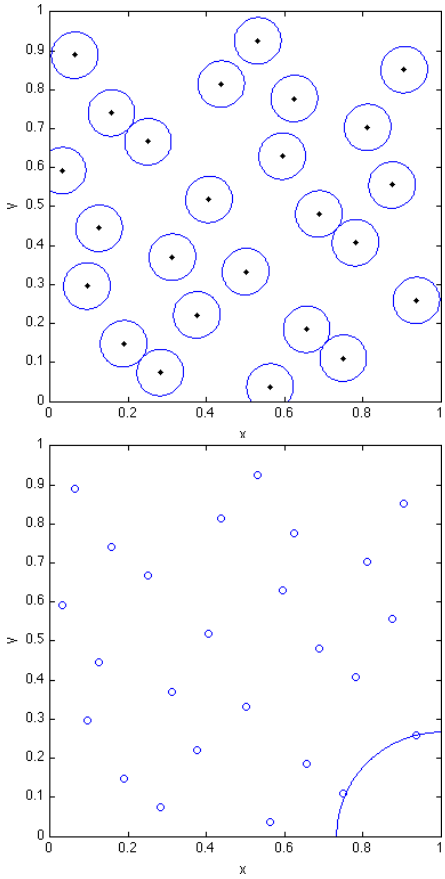

Fig. 3. Geometric interpretation of separation distance (on the left) and fill distance (on the right) for 25 Halton points on the domain $\Omega = [0,1]^2$ ($q_{\mathcal{X}} \approx 0.0597$ and $h_{\mathcal{X},\Omega} \approx 0.2667$).

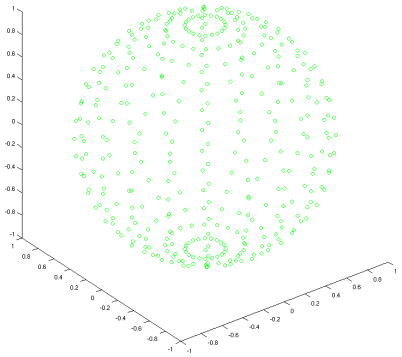

Fig. 4. 382 point cloud from the unit sphere centered in the origin.

a test consistent with a real dataset, the widely scattered point cloud in Fig. 4 was selected.

As shown in Fig. 5 (top left), a too small value of σ leads to a surface that actually interpolates the given point cloud but whose reconstruction quality is unsatisfactory. Notice that, even using (10) as in [22], one couldn't achieve a better result (see Fig. 5, top right). On the contrary, by using (11) and increasing the value of σ (see Fig. 5, bottom left) the quality of the reconstruction improves up to the desired level (see Fig.

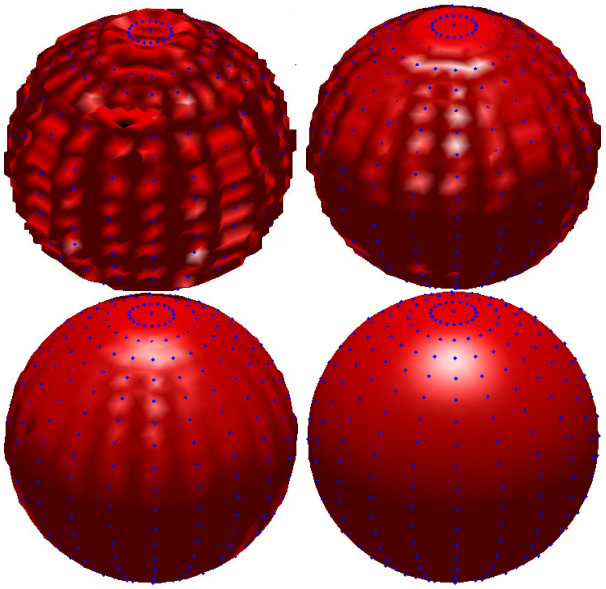

Fig. 5. Reconstructed sphere for different values of σ. (from left to right $\sigma = 0.025$, $\sigma = 2q_{\mathcal{X}} = 0.048$, $\sigma = 0.065$, $\sigma = h_{\mathcal{X},\mathcal{M}}\sqrt{2} = 0.157$)

5, bottom right). It is interesting to note that for intermediate values of σ, though the quality is not globally satisfactory, it appears to be locally adequate, mainly in those parts of the surface where the points are at a distance $d \approx \sigma$.

1) Tests on incomplete data:

We assessed the sensitivity of our method to the lack of information by means of an incomplete dataset. We began with a dataset composed of 50% randomly chosen points from the previous dataset; Fig. 6 shows the new the point cloud. In this case, it turns out that an "optimal" value of σ is

$$\sigma = h_{\mathcal{X},\mathcal{M}}\sqrt{2} = 0.328.$$

This optimal value corresponds to the actual fill distance for the new dataset and provides a successful reconstruction of the sphere (see Fig. 6, bottom). We remark that the old value $\sigma = 0.157$ would lead to a reconstructed surface which is not the desired sphere (see Fig. 6, top).

Another interesting test deals with a point cloud belonging to the (upper) semi-sphere:

$$\mathcal{M}^+ = \{(x,y,z) \in \mathbb{R}^3 : \ x^2 + y^2 + z^2 = 1, z \geq 0\}.$$

If we set $\sigma = h_{\mathcal{X},\mathcal{M}^+}\sqrt{2} = 0.157$, then we can reconstruct the $\mathcal{M}^+$ surface (see Fig.7, top) from which the dataset was extracted. If we assume that the point cloud came from the whole sphere $\mathcal{M}$, then the value of the fill distance would change to $h_{\mathcal{X},\mathcal{M}} = \sqrt{2}$. The latter value of the fill distance gives an optimal value of $\sigma = h_{\mathcal{X},\mathcal{M}}\sqrt{2} = 2$, which leads to the reconstruction of the whole sphere, as shown in Fig. 7, bottom.

B. Tests on real dataset

We briefly discuss the results of some tests concerning real dataset, namely the Stanford Bunny model. This is composed

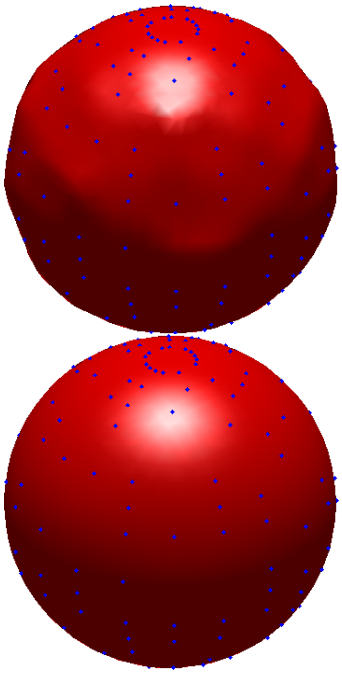

Fig. 6. Reconstructed sphere from incomplete data. (on the left $\sigma = 0.157$ and on the right $\sigma = h_{\mathcal{X},\mathcal{M}}\sqrt{2} = 0.328$)

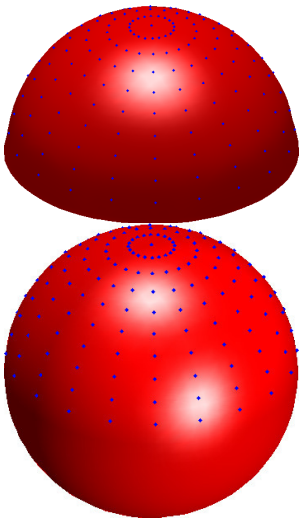

Fig. 7. Reconstructed surface from upper semi-sphere data. (on the left $\sigma = h_{\mathcal{X},\mathcal{M}^+}\sqrt{2} = 0.157$ and on the right $\sigma = h_{\mathcal{X},\mathcal{M}}\sqrt{2} = 2$)

of $N = 8171$ points, giving an extended dataset of $N_{ext} = 3N = 24513$ points. In order to select a suitable value of σ, we need to calculate the value of the fill distance for the given dataset. On real datasets, where the geometry of the surface is either unknown or very complex, this task can be a real challenge. Recalling that the fill distance measures the data density in the membership domain, we introduce a new measure defined as

$$h_{max} = \max_j \min_{i \neq j} \|x_i - x_j\|_2.$$

This represents the largest value of the distances between each point and its nearest neighbor point. For a dataset without multiple *connected components*, the fill distance can be approximated by

$$h_{\mathcal{X},\mathcal{M}} \approx h_{max}\sqrt{2}. \tag{12}$$

As in the case of synthetic dataset, a too small value of σ results in a low quality reconstructed surface (see Fig. 8, top left)), intermediate values lead to reconstructions which are adequate only where there is a high density of points (see Fig.8, top right), while the choice (12) of $\sigma \approx h_{\mathcal{X},\mathcal{M}}$ provides the best result (see Fig. 8, bottom).

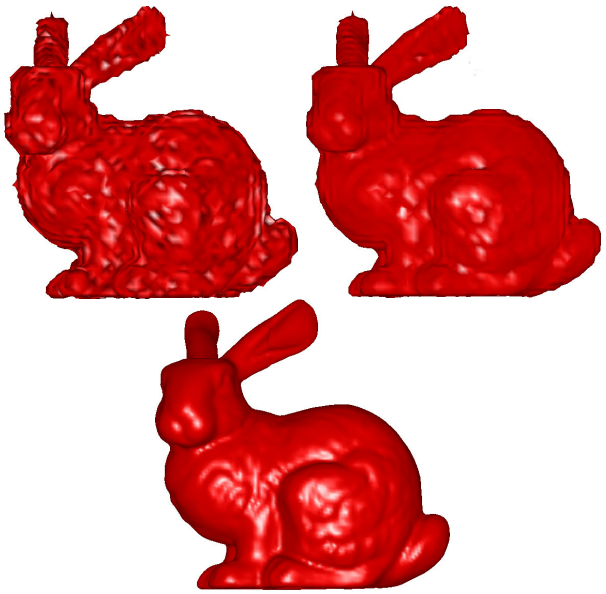

Fig. 8. Reconstructed bunny for different values of σ. (from left to right $\sigma = 0.0007$, $\sigma = 0.0012$ and $\sigma = h_{max} \approx h_{\mathcal{X},\mathcal{M}}\sqrt{2} = 0.0033$)

C. Tests on performance

We report some results on the performance of the GPU implementation of our method compared to its CPU implementation. CPU times refer to the execution on one core of the i7-940 CPU, and GPU times refer to execution on the Nvidia Fermi C1060 GPU, with 4Gb of RAM. The middleware software consists of PETSc developer version 3.3, compiled with GPU support, CUDA release 4.2, CUSP version 0.3.0 and THRUST version 1.5.2.

We have used synthetic point clouds of increasing size number N, i.e with an increasing the density. Since we want to emphasize the advantages in exploiting the GPU, we choose a constant value of σ ($\sigma = 0.157$). Notice that if the value of σ scaled with the density, then the problem would scale as $\mathcal{O}(N)$, giving rise to a less noticeable GPU acceleration.

In Tab. II, we report the execution times on a single CPU and a single GPU, and also the resulting speed-ups for the interpolant construction (step 2 of the reconstruction algorithm), varying the size N of the dataset. To make a fair comparison, we fixed the number of iterations in GMRES to 50. Results

in Tab. II show that, even though the RASM preconditioner is not available in CUSP, the GPU implementation achieves a 6.6 sped-up.

TABLE II
SPEED-UPS FOR THE INTERPOLANT CONSTRUCTION STEP ON GPU.

N	CPU	GPU	Speed up
1323	0,67551	0,1404	4,81
4686	34,567	5,6472	6,12
15625	451,75	71,57	6,31
24036	5398,4	815,09	6,63

In Tab. III we reported the execution times on CPU and GPU, and the resulting speed-ups for the interpolant evaluation (step 3), varying the size N of the point cloud and the size M of the evaluation grid. As expected, these execution times are substantially lower than those obtained for the step 2, but in this case the GPU is fully exploited and larger speed-ups are achieved.

TABLE III
SPEED-UPS FOR THE EVALUATION STEP ON GPU.

$M\backslash N$		1323	4686	15625	24036
15625	CPU	0,11571	0,20605	0,78172	0,97539

	GPU	0,59846	1,7525	6,4671	7,9468
	Speed up	**25,09**	**24,06**	**24,76**	**25,09**

V. CONCLUSION

We proposed a parallel method based on radial basis functions for surface reconstruction on GPU. Our implementation relies on GPU-parallel scientific libraries, in order to take full advantage of the computing power of the GPU device. We showed that reconstruction quality and performance of the method are strongly related to the gaussian RBF parameter σ. We proposed an optimal heuristic estimate of such parameter based on suitable density measures of the point cloud. Finally, the observed speed-ups and running times confirm that the RBF interpolation can be a very effective approach to solve large scale surface reconstruction problems.

***Abstract*—Relativistic numerical hydrodynamics is an important tool in high energy nuclear science. However, such simulations are extremely demanding in terms of computing power. This paper focuses on improving the speed of solving the Riemann problem with the MUSTA-FORCE algorithm by employing the CUDA parallel programming model. We also propose a new approach to 3D finite difference algorithms, which employ a GPU that uses surface memory. Numerical experiments show an unprecedented increase in the computing power compared to a CPU.**

I. Motivation

NUMERICAL hydrodynamics has been used in many scientific and engineering applications for decades, mostly due to its relative simplicity. Even a complicated, dynamic system can be described with a small set of relatively simple hyperbolic conservation laws in this framework. All the information about the physical properties of a system is contained in a single equation of state, which is the relationship between the thermodynamic properties of the analyzed system. Knowledge of the details of the interactions that take place on the microscopic level is not required. However, there is one strong assumption underlying the use of hydrodynamics: the system has to be at least in the local thermodynamic equilibrium, which means that the thermodynamic quantities for any point are approximately constant around that point.

Recently relativistic hydrodynamics has been applied in studies of a new field of physics: high energy nuclear science. The goal of high energy nuclear science is to study the interactions between the basic constituents of matter; quarks and gluons. In normal conditions, quarks and gluons are bound together to form nucleons: protons and neutrons. However, the forces binding quarks together can be subjected to a sufficiently high energy density, leading to a transition from ordinary nuclear matter to a new state, where quarks and gluons behave like quasi-free particles. Such a *soup* of quarks and gluons is called a Quark-Gluon Plasma (QGP), and it is hypothesized to have existed in the early universe, a few millionths of a second after the Big Bang. The energy density of nuclear matter created in relativistic heavy ion collisions at the Relativistic Heavy Ion Collider (RHIC) at Brookheaven National Laboratory, or the Large Hadron Collider (LHC) at CERN, is sufficiently high that a phase transition to a QGP is expected in such reactions.

In the collisions of heavy nuclei at RHIC or LHC, a decrease in the amount of nuclear matter occurs with exposure to the extreme energy density. The first phase of collisions consists of interactions with a large momentum transfer. Then the system expands, equilibrates and forms the QGP. Relativistic hydrodynamics can then be employed to extract the properties of the QGP. Relativistic ideal fluid dynamics has indeed been used in the theoretical modeling of the QGP and remarkable agreement between experimental data and simulations has been found, leading to the unexpected conclusion that *hot* nuclear matter behaves like a nearly frictionless liquid (i.e. with extremely low viscosity) [1], [2].

The initial success of relativistic hydrodynamics stimulated further development of the numerical codes needed for a more precise understanding of the fundamental properties of the quark and gluon dynamics in the QGP.

Firstly, fully (3+1)-dimensional simulations (3 spatial dimensions + time) are necessary to describe the system's evolution without any assumptions regarding its symmetries. Such numerical problems are well defined and numerical methods are available; however, (3+1)-dimensional simulations are extremely expensive in terms of computing power. Moreover, the fluctuations in the pre-QGP phase might have an impact on the dynamics of the QGP, therefore *event-by-event* studies (where an *event* is a single collision between heavy ions) with fluctuating initial conditions and with a large amount of statistics are of particular interest and require a fast and efficient computer code. Furthermore, studies of jets (which are narrow beams of particles with a high momentum) and their propagation through the hot nuclear medium can provide information about the fundamental properties of the QGP (transport coefficients, for instance). However, such studies require an accurate representation of relativistic flows and shock waves. This requires a larger numerical grid in the simulations, which in turn increases the computing time

This work was supported in part by Dean's Grant (2012) at the Faculty of Physics Warsaw University of Technology

978-83-60810-53-8/$25.00

needed significantly.

Due to all these factors, there is a constantly increasing demand for computing resources in relativistic hydrodynamics simulations. Graphics Processing Unit (GPU) computing is a promising solution for this problem, and offers an unprecedented increase in computing power compared to standard CPU simulations. In this paper, we present the concept of an implementation of 3+1 ideal hydrodynamics simulations carried out on a GPU using an NVIDIA CUDA framework and test results for selected physics problems.

II. Equation System for the Riemann Problem

A. Hydrodynamics Equations

Equations of relativistic hydrodynamics can be written in a conservative form:

$$\frac{\partial U}{\partial t}+\frac{\partial F(U)}{\partial x}+\frac{\partial G(U)}{\partial y}+\frac{\partial H(U)}{\partial z}=0 \qquad (1)$$

where $U=(E,M_x,M_y,M_z,R)$ is a vector of conserved quantities in the *laboratory rest frame*, E is the energy density, M_i is the momentum density in the i-th Cartesian coordinate and R is a conserved charge density (e.g. a baryon number). F,G,H are vectors of fluxes of those quantities in the x,y,z directions, defined as:

$$F(U)=\begin{pmatrix}(E+p)v_x\\ M_xv_x+p\\ M_yv_x\\ M_zv_x\\ Rv_x\end{pmatrix}$$

$$G(U)=\begin{pmatrix}(E+p)v_y\\ M_xv_y\\ M_yv_y+p\\ M_zv_y\\ Rv_y\end{pmatrix} \qquad (2)$$

$$H(U)=\begin{pmatrix}(E+p)v_z\\ M_xv_z\\ M_yv_z\\ M_zv_z+p\\ Rv_z\end{pmatrix}$$

where v is the velocity and p is pressure, defined by an equation of state: $p=p(e,n)$; e and n are the energy and charge density in the *fluid rest frame* (i.e. in a frame where velocity vanishes, $v=(0,0,0)$).

B. Numerical Scheme

In numerical applications, all continuous fields have to be represented in a finite number of degrees of freedom, e.g. on a fixed numerical grid. In our program we use a finite-difference scheme on a Cartesian grid. Since non-conservative methods (i.e. methods based on non-conservative variables) have been shown to fail (do not converge to a correct solution) if a shock wave is present in the solution [3], a conservative method is used.

There are two standard approaches to solving the problem (1): *dimensional splitting* and a *finite volume method*. Derivation of dimensional splitting methods is based on Taylor series expansions and may give incorrect results for discontinuous solutions [4], thus a finite volume method was chosen. For a three-dimensional problem, such a scheme reads:

$$\begin{aligned}U^{n+1}_{i,j,k} &= U^n_{i,j,k}+\frac{\Delta t}{\Delta x}\left(F_{i-\frac12,j,k}-F_{i+\frac12,j,k}\right)\\ &+\frac{\Delta t}{\Delta y}\left(G_{i,j-\frac12,k}-G_{i,j+\frac12,k}\right)\\ &+\frac{\Delta t}{\Delta z}\left(H_{i,j,k-\frac12}-H_{i,j,k+\frac12}\right)\end{aligned} \qquad (3)$$

where $U^n_{i,j,k}$ represents a conserved quantity at the discrete time t_n; Δt and Δx, Δy, Δz are time and space steps, respectively, and $F_{i-\frac12,j,k}$, ... , $H_{i,j,k+\frac12}$ are numerical fluxes through cell boundaries.

The central point of a particular scheme is the construction of intercell fluxes $F_{i-\frac12,j,k}$, ... , $H_{i,j,k+\frac12}$. There are two distinct approaches to this problem: the *upwind* and *centered* schemes.

The main feature of upwind schemes is that they explicitly exploit information about wave propagation contained in the equations, usually by solving a one-dimensional Riemann problem locally. The accuracy of such schemes is highly dependent on the choice of a particular Riemann solver, which should ideally be *complete* (i.e. take into account all characteristic fields present in the exact solution).

On the other hand, centered methods do not solve the Riemann problem directly, and therefore are usually simpler and more general, at the cost of accuracy (given that there is a complete Riemann solver available).

In order to obtain a general and accurate algorithm, we use a hybrid MUSTA (MUlti-STAge) approach [5], [6]. This utilizes a centered flux in a predictor-corrector loop, solving the Riemann problem numerically, i.e. without using a priori information about waves.

The algorithm in a one-dimensional case is as follows:

1) In order to calculate flux $F_{i+\frac12}$ we introduce auxiliary variables $U^{(l)}_L$ and $U^{(l)}_R$ and their fluxes $F^{(l)}_L$ and $F^{(l)}_R$.
2) Set $U^0_L=U_i$, $U^0_R=U_{i+1}$.
3) Calculate $F^{(l)}_L=F(U^{(l)}_L)$ and $F^{(l)}_R=F(U^{(l)}_R)$ using (1).
4) Calculate $F^{(l)}_{i+\frac12}$ using a centered flux, $U^{(l)}_L$, $U^{(l)}_R$, $F^{(l)}_L$ and $F^{(l)}_R$. If l reached a predefined value, stop.
5) Solve Riemann problem locally:

$$\begin{aligned}U^{(l+1)}_L &= U^{(l)}_L-\tfrac{\Delta t}{\Delta x}\left(F^{(l)}_{i+\frac12}-F^{(l)}_L\right)\\ U^{(l+1)}_R &= U^{(l)}_R-\tfrac{\Delta t}{\Delta x}\left(F^{(l)}_R-F^{(l)}_{i+\frac12}\right)\end{aligned} \qquad (4)$$

6) Go back to step 3.

One drawback to using such an algorithm is that it is numerically more expensive than other, more conventional, algorithms, for instance the SHASTA (SHarp And Smooth Transport Algorithm) [7], [8].

As a centered flux, we used the FORCE (First ORder CEntered) scheme:

$$F^{\text{force}}_{i+\frac{1}{2}} = \frac{1}{2}\left(F^{\text{lw}}_{i+\frac{1}{2}} + F^{\text{lf}}_{i+\frac{1}{2}}\right) \tag{5}$$

where $F^{\text{lw}}_{i+\frac{1}{2}}$ is the Lax-Wendroff type flux (in terms of MUSTA auxilliary variables):

$$F^{\text{lw}}_{i+\frac{1}{2}} = F\left(\frac{1}{2}(U_L + U_R) - \frac{1}{2}\frac{\alpha\Delta t}{\Delta x}(U_R - U_L)\right) \tag{6}$$

and $F^{\text{lf}}_{i+\frac{1}{2}}$ is the Lax-Friedrichs type flux:

$$F^{\text{lf}}_{i+\frac{1}{2}} = \frac{1}{2}(F_L + F_R) - \frac{1}{2}\frac{\Delta x}{\alpha\Delta t}(U_R - U_L) \tag{7}$$

In a three-dimensional case $\alpha = 3$, but other values may also be considered.

To achieve second order accuracy in space and time, we extend our algorithm with MUSCL-Hancock scheme. The basic idea of this scheme is to use more cells to interpolate inter-cell values and evolve them half a time step. The algorithm is:

1) Replace cell average values U^n_i by a piece-wise linear function inside i-th cell:

$$U_i(x) = U^n_i + \frac{(x - x_i)}{\Delta x}\Delta_i \tag{8}$$

where Δ_i is a slope vector and will be defined later. In the local coordinates the points $x = 0$ and $x = \Delta x$ correspond to boundaries of the cell $x_{i-\frac{1}{2}}$ and $x_{i+\frac{1}{2}}$. The values at these points are $U^L_i = U^n_i - \Delta_i/2$ and $U^R_i = U^n_i + \Delta_i/2$.

2) Propagate U^L_i and U^R_i by a time $\frac{1}{2}\Delta t$:

$$\begin{aligned}
\tilde{U}^L_i &= U^L_i + \frac{1}{2}\frac{\Delta t}{\Delta x}(F(U^L_i) - F(U^R_i)) \\
&\quad + \frac{1}{2}\frac{\Delta t}{\Delta y}(G(U^L_i) - G(U^R_i)) \\
&\quad + \frac{1}{2}\frac{\Delta t}{\Delta z}(H(U^L_i) - H(U^R_i)) \\
\tilde{U}^R_i &= U^R_i + \frac{1}{2}\frac{\Delta t}{\Delta x}(F(U^L_i) - F(U^R_i)) \\
&\quad + \frac{1}{2}\frac{\Delta t}{\Delta y}(G(U^L_i) - G(U^R_i)) \\
&\quad + \frac{1}{2}\frac{\Delta t}{\Delta z}(H(U^L_i) - H(U^R_i))
\end{aligned} \tag{9}$$

3) Use $\tilde{U}^L_i$ and $\tilde{U}^R_i$ as U^0_L and U^0_R in MUSTA.

A simple choice for the *slope* Δ_i in (8) is:

$$\Delta_i = \frac{1}{2}(U^n_{i+1} - U^n_{i-1}) \tag{10}$$

which indeed results in a second-order accurate algorithm. However, as predicted by Godunov's theorem, it has the unpleasant effect of producing spurious oscillations in the vicinity of strong gradients.

To solve this issue, a number of flux limiting and slope limiting methods have been proposed. We employed a slope limiting method; instead of Δ_i as in (10) we use:

$$\tilde{\Delta}_i = \xi(r_i)\Delta_i \tag{11}$$

in (8), where ξ is called the *slope limiter*, and r_i is defined as:

$$r_i = \frac{U_i - U_{i-1}}{U_{i+1} - U_i} \tag{12}$$

There are a number of possible choices for ξ, each with its own characteristics and features. One possibility is the MINBEE limiter:

$$\xi_{\text{mb}}(r) = \max(0, \min(1, r)) \tag{13}$$

and there is another, called SUPERBEE:

$$\xi_{\text{sb}}(r) = \max(0, \min(2r, 1), \min(r, 2)) \tag{14}$$

Introducing non-linearity in the scheme provides less oscillations near high gradients and retains good accuracy in smooth areas of the solution.

III. Implementation Notes

A. GPUs – an Overview

Recent developments in GPU technology have transformed them into very powerful devices offering a notable speed increase compared to traditional CPUs in high performance computing. The reason behind this lies in the difference in structure between these two processors. GPUs use many more resources for arithmetic operations at the expense of cache and flow control.

The basic idea of a GPU is that it is built around an array of Streaming Multiprocessors (SMs). Compute Unified Device Architecture (CUDA) allows a programmer to define a special function *kernel* which is executed on a GPU device by a number of threads which are organized into blocks. Each thread block executes in parallel on a single SM independently and in undefined order.

CUDA threads can access several memory spaces. *Global memory*, which has a very big latency, can be accessed by all the threads. Threads within one block can cooperate through *shared memory*. Shared memory is expected to be much faster than global memory and many applications benefit from using it. Registers, whose limited number is distributed to threads by a streaming multiprocessor, offer the lowest latency. By default, all the variables are placed in registers for as long as the latter are available. When there is a lack of registers, other variables go in the local memory which resides in device memory and provides the same high memory latency. This is called *register spilling* and causes a notable slow down for applications.

The main drawback of shared memory is its limited size (48 KB in contemporary GPUs). This is sufficient for many applications, but for others - such as image processing where millions of pixels are transformed in parallel - it is not. For such cases data may be put into texture memory which resides in device memory and is cached in the texture cache. As a

result, data read from texture memory cost one read from global memory on cache miss, and give almost immediate access otherwise. The texture cache is optimized for 2D spatial locality. Texture memory offers only data reading while surface memory offers both read and write operations.

Threads are executed in groups of 32 parallel threads called warps, of which all execute the same instruction scheduled by the warp scheduler. If, due to conditional sentences, different threads within a warp follow different paths, then the scheduler visits each path taken sequentially, disabling threads that are not active in the current path. This is called branching and effects slow down in execution.

A common bottleneck for many GPU applications is memory access latency due to the limited size of cache, especially when using global device memory. However, those latencies can be hidden by a warp scheduler. At every instruction issue time, a warp scheduler selects a warp that is ready to execute its next instruction, if any, and issues the instruction to the active threads of the warp. It can easily be seen that CUDA performs this most effectively when there are plenty of threads to be executed.

B. Data Organization

GPUs have recently been widely used for many advanced computations. Typical examples have involved 3D finite difference computations using the most popular sliding-window approach, which operates using shared memory [9] - [12]. Some papers have also studied using texture memory to optimize the solution in fluid dynamics [13], [14].

In our approach surface memory is applied to hold the simulation data. Surface memory retains all the benefits of texture memory, but it also works in write mode. It is available for NVIDIA GPUs with a compute capability of 2.x or higher. Currently, surface memory does not support double precision floating-point arithmetic and all the calculations are done solely in single precision.

Surface memory offers several benefits over the popular sliding-window approach. Due to the limited size of shared memory, only a limited amount of the data can be held in it and hence loop tiling has to be performed. An input grid is divided into smaller blocks (*tiles*) that fit into shared memory, the threads copy these parts of the data from global to shared memory and perform computations in the latter. Thus, the shared memory can be seen as a manually managed cache. It can easily be noticed that this results in data access redundancy which can be computed using the formula $(n * m + k(n + m))/(n*m)$, where n and m stand for a block's size and k is the order of stencil [10]. In contrast to shared memory, which is highly limited in size, the maximum number of elements we can bound to surface memory is 65536x32768x2048 [15]. Therefore, in practice surface memory is limited only by its size and in most cases all the data can be kept in surface memory.

Surface memory allows the algorithm to decrease register usage. In our approach, the numerical scheme requires a single cell to contain more than one simple variable. When we multiply the size of a cell by the number of cells needed in stencil computation it is easy to notice that the registers are quite heavily used in this algorithm.

Using surface memory it is also easier to modify and test different numerical schemes. Code which uses shared memory is usually dedicated to just one kind of stencil. Changing the order or *direction* of the stencil results in changing many lines of code. In the case of surface memory, since all data are held in it and global indexing is used, this change may be done at once and handling special cases is kept to a minimum. Hence, it is a more general approach.

C. GPU Algorithm

In this section we present the idea behind the algorithm which uses surface memory.

Algorithm 1 Data processing schema for a thread (i, j) and an order-4 stencil computation

```
for n in 1..N do
  for k in 3..Z-Dimension −2 do
    Load neighbor cells from surface memory.
    Compute cell U(i, j, k).
    Write result to surface memory.
    Synchronize threads.
  end for
end for
```

The presented algorithm was built based on the idea of the sliding-window algorithm. All threads work on a 2D *xy*-slice of the grid, benefiting from optimization for the 2D spatial locality of surface memory, and iterate through the *Z*-axis. The *Compute cell* method refers to the MUSTA-FORCE algorithm. In this algorithm we use two surfaces which are employed alternately for read/write operations. It is possible to use just one surface but this would put more pressure on registers and require additional synchronizations. Since memory usage is not a problem in our simulation we decided to stay with two surfaces being used.

IV. Experimental Results

We examined the performance of the parallel GPU code and compared it to the performance of the sequential CPU code. The goal of our research was just to verify the usefulness of GPUs for solving equations of relativistic hydrodynamics and to approximate the order of magnitude of the possible speed-up. Therefore, we measured the time needed to perform the simulations on a single GPU and a single CPU core. This allowed us to estimate the time required to perform massive physics simulations.

The numerical experiments were executed on an Intel Pentium B960, 2.2 GHz processor with an NVIDIA GeForce 610 1 GB graphics card with Compute Capability 2.1. The figures show the time taken for a hydrodynamic simulation, using the MUSTA-FORCE algorithm approach for various configurations of input data.

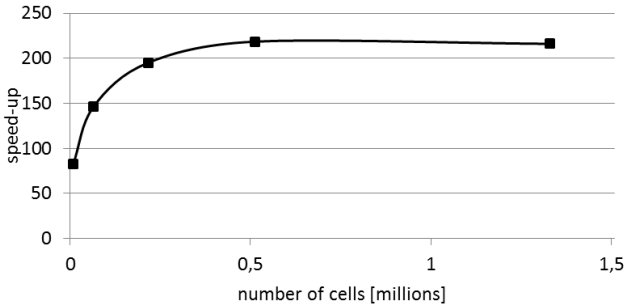

Fig. 1. The speed-up gained by using surface memory compared to CPU implementation for the MUSTA-FORCE algorithm as a function of the total number of cells

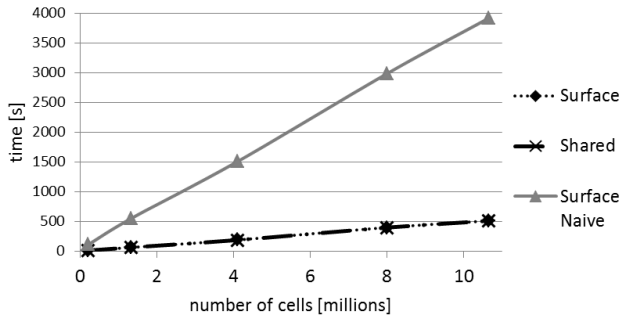

Fig. 2. Execution time for shared memory and surface memory approaches for 100 steps of the MUSTA-FORCE algorithm as a function of the total number of cells

With the GPU, the tests were carried out for 100 time steps of the MUSTA-FORCE algorithm, using grids of dimensions 60^3, 110^3, 160^3, 200^3, and 220^3. A single cell, containing a vector U, occupies 20 bytes of memory. The maximum grid that fitted within the memory limitations was 240^3.

The simulations on the CPU were conducted on smaller grids. We interrupted the calculations for grids when the time exceeded a few hours, because it would have taken days to perform massive tests on the CPU.

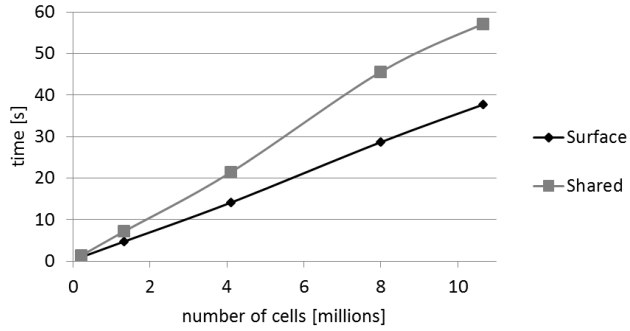

Fig. 3. Execution time for 100 steps of a generalized 3D finite difference algorithm

Fig. 1 shows the acceleration factor gained by using a GPU instead of a CPU. The GPU implementation speed-up is over 200 for bigger numbers of cells. For a grid of size 110^3, the GPU simulation took 1 minute while the CPU required over 3 hours. This proves that finite difference computations are a perfect example of an algorithm that fits the parallel computation concept. The whole algorithm can easily be divided into small parts that single threads can perform in parallel.

Note that the simulation on the CPU is very slow. The estimated effort for 100 time steps and a grid with 220 cells in each dimension is almost 30 hours. Such large grids are necessary in the case of studies of ultra-relativistic flows and strong shocks. Moreover, event-by-event simulations require samples of thousands of such simulations (events). Because of this, the total computing time needed for such analysis (assuming 1,000 events) amounts to as much as 3 years, which makes such a study extremely hard, if not impossible, without parallel computing. This example illustrates how expensive, in terms of computation and memory usage, relativistic hydrodynamic simulations are.

The next thing we examined was various implementations on a GPU. Fig. 2 presents a comparison between the execution time for the sliding-window algorithm using shared memory, and surface memory implementations. For shared memory we used a 16x16 data tile, which we found to be the most effective size. The first, naive surface memory implementation used exactly the same approach as with the shared memory algorithm. Thus it can be concluded that surface memory is about 8 times slower. The revised version of the algorithm with surface memory, presented in section 3c, used all its benefits - keeping all data in surface memory, lower usage of registers, and smaller branching. It decreased the simulation time significantly. As a result the timing of the surface memory and sliding-window approach turned out to be almost identical.

Profiling of the application showed that here we are faced with register spilling which causes a serious slow down. This is due to the fact that the MUSTA-FORCE and MUSCL algorithms we have used, both use many temporary cells interpolated during computations. Now, when there only a maximum of 63 registers per thread, and each cell takes 5 of them, a lot of data need to be kept in local memory. Usage of local memory instead of registers is one of the biggest limitations in current GPUs. Our tests showed that just increasing the size of a single cell kept in memory without any other extra computation cost, made the time of simulation increase 5-fold.

Since one of our goals was to evaluate the effectiveness of the surface memory approach for 3D finite difference computations we prepared another version of the application, which performs an interpolation between the cells instead of the whole MUSTA-FORCE algorithm. Fig. 3 shows that the sliding-window approach is more than 50% slower than the surface algorithm. This proves our thesis that the results in Fig. 2 are affected by register pressure. Profiling of this

application shows that achieved occupancy is higher for the surface algorithm (0.45 instead of 0.32), there is lower usage of registers (in the surface algorithm all data is kept in registers while in the second approach 8 variables are also kept in local memory), and that there is a slightly smaller number of branches (12.5% instead of 14.5% on average). These numbers and the test results prove that despite the fact that surface memory is slower than shared memory, the benefits it offers allow the application to achieve better performance.

V. Conclusion

In this paper the possibilities of using GPUs for developing a solver for the Riemann problem have been examined. We studied two methods of 3D finite difference computation – a sliding-window algorithm using shared memory and our new approach based on surface memory.

First of all, the GPU proved to be a good choice for 3D finite difference computations. Such a problem scales perfectly with parallel computations and thus is very effective. Our implementation is over 200 times faster than a sequential implementation on a CPU. This number shows that graphics cards offer greater computational power for problems that can be divided into independent subproblems.

We have investigated the usefulness of our novel approach using surface memory. Because the amount of memory available is very big all the data can be kept in surface, which thus decreases data redundancy and pressure on registers. On the other hand, shared memory is in general faster than surface memory. As a result, in our application using the MUSTA-FORCE algorithm, both implementations have very comparable speeds. However, as we showed, the results were affected by register spilling caused by the high memory cost of the algorithm used. To investigate the effectiveness of surface memory in 3D finite difference methods we prepared a simplified version of an algorithm that minimized register usage. As a result, the surface memory approach turned out to be faster than the one with the sliding-window approach. It should also be stressed that surface memory implementation is more general and, in contrast to the shared memory approach, can easily be changed to use any other kind and order of isotropic, or anisotropic, stencil in any direction.

In this paper we showed that GPUs are very effective for hydrodynamics simulations in comparison to CPUs. The current GPU implementation allows a device to perform a massive number of simulations in a reasonable time. This was previously impossible, even in our preliminary parallel CPU implementation with the use of a cluster computer and MPI. The designed GPU algorithm, based on surface memory, is easy to modify and proved to be a valuable new tool for high energy nuclear science.

***Abstract*—The paper considers application of the AVX (Advanced Vector Extensions) technique to improve the performance of the PARFES parallel finite element solver, intended for finite element analysis of large-scale problems of structural and solid mechanics using multi-core computers. The basis for this paper was the fact that the *dgemm* matrix multiplication procedure implemented in the Intel MKL (Math Kernel Library) and ACML (AMD Core Math Library) libraries, which lays down the foundations for achieving high performance of direct methods for sparse matrices, does not provide for satisfactory performance with the AMD Opteron 6276 processor, Bulldozer architecture, when used with the algorithm required for PARFES. The procedure presented herein significantly improves the performance of PARFES on computers with processors of the above architecture, while maintaining the competitiveness of PARFES with the Intel MKL *dgemm* procedure on computers with Intel processors.**

I. Introduction

THE PARFES (Parallel Finite Element Solver) is a sparse direct method for solving linear equation sets with sparse symmetric matrices, which arise when the finite element method is applied to structural and solid mechanics problems, is presented in [7], [8]. The method is developed to be used in FEA software focused on multi-core shared memory computers. PARFES supports core mode (CM) as well as two out of core modes – OOC and OOC1. In the core mode, the solver only utilizes random access memory (RAM), demonstrating good performance and speed up when the number of threads increases. If the dimension of the problem exceeds the RAM capacity, the method switches to the OOC mode, in which disk storage is used, and the amount of I/O operations is minimal. Performance and speed up deteriorate slightly compared to the CM. If the amount of RAM is not sufficient for the OOC mode, PARFES switches to OOC1. In this mode, the number of I/O operations is greatly increased; however, the RAM amount requirements are low. The performance and speed up degrade significantly, but this method allows solving problems of several million equations using desktop and laptop computers.

The option to use disk memory is the advantage of PARFES compared to PARDISO (Parallel Direct Solver), which is described in [16] and presented in the Intel MKL library [11]. Although PARDISO formally supports the OOC mode, practice showed that in this mode, this method is considerably inferior both to PARFES, and the multifrontal method where small tasks are concerned [1], [5], [10], and simply crashes when used for larger problems [7], [15].

In contrast to the multifrontal method, PARFES demonstrates significantly higher performance and speed up, and smaller RAM requirements (in OOC1 mode) [7], [8].

This paper describes further development of PARFES for the use with Intel AVX instructions [14] that implement computation vectorization elements with 256-bit registers, allowing to perform four multiplications or four additions of double type values in one CPU cycle.

It was discovered that the *dgemm* matrix multiplication procedure as implemented in Intel MKL 11.0 [12] does not provide for satisfactory performance of PARFES on a computer with a 16-core AMD Opteron 6276 CPU 2.3/3.2 GHz processor, Bulldozer architecture. For test 1: $\mathbf{C} = \mathbf{C} - \mathbf{A}\cdot\mathbf{B}$, where $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ are 8 000 × 8 000 square matrices, the performance of this procedure is 3 958 MFLOPS with a single thread and 35 013 MFLOPS with 16 threads. The performance of the same procedure as implemented in ACML 15.2.0 (AMD Core Math Library) [2] is 14 203 MFLOPS and 94 852 MFLOPS respectively.

However, when solving test 2 (Fig. 1, 2) it was found that the performance of this algorithm degrades (see Table 1), and the threads run in the OS kernel mode for a considerable amount of time.

```
#pragma omp parallel for
for(ib=0; ib<Nb; ++ib)
{
    ip = omp_get_thread_numb();
    Cib = Cib − Aib·B;
}
```

Fig.1 Algorithm for test 2

Matrices $\mathbf{C}$ and $\mathbf{A}$ have a block structure (Fig. 2), *ip* is the thread number, and *ib* is the block number. Inside the loop, the single-treaded version of the *dgemm* procedure (ACML [2]) is used. The arrows indicate the packing of data in the respective matrices.

This work was supported by Narodowy Centrum Nauki on the basis of decision DEC-2011/01/B/ST6/00674.

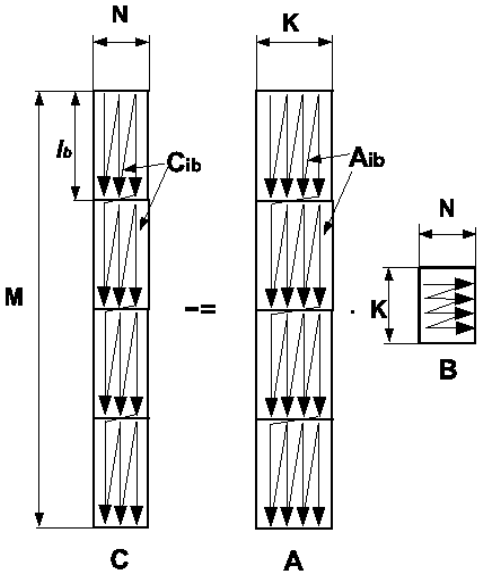

Fig. 2 Structure of **A**, **B**, **C** matrices in test 2

Test 2 is a good simulation of the PARFES correction procedure [7], [8], when the *jb* block-column (matrix **C**) is updated by the *kb* block-column (matrix **A**) located to the left of the former.

Thus, it was decided to develop a new procedure, *microkern_8x4_AVX*, which would allow achieving high performance with processors that support AVX instructions on the × 64 platform.

II. Factorization Stage

A.Problem definition

Let us consider the direct method for solving linear equation sets.

$$\mathbf{KX} = B,\quad K = K^T,\quad X = \{x_i\},\quad B = \{b_i\},\quad i \in [1, nrhs], \quad (1)$$

where **K** is the symmetric sparse stiffness matrix; **X** and **B** are solution vectors and right-hand parts for multiple load cases; and *nrhs* is the number of right-hand parts. The decomposition is sought in the form of

$$K = L \cdot S \cdot L^T, \quad (2)$$

where **L** is the lower triangular matrix and **S** is the sign diagonal that summarizes the Cholesky decomposition method into a class of indefinite matrices. After factorization (2), forward substitution, diagonal scaling and back substitution are carried out:

$$\begin{aligned} L \cdot Y &= B \rightarrow Y \\ S \cdot Z &= Y \rightarrow Z \\ L^T \cdot X &= Z \rightarrow X \end{aligned} \quad . \quad (3)$$

B.Sparse matrix analysis

First of all the adjacency graph for nodes of the finite element model is reordered to reduce the number of non-zero entries in the factorized stiffness matrix. The number of non-zero entries and the non-zero structure of the sparse lower triangular matrix **L** depend on the reordering method used [3].

Each node of FE model, which has *dof* degrees of freedom, produces a dense submatrix with the dimensions *dof* × *dof*. Therefore, the physical formulation of the problem leads to the division of the original sparse matrix into dense submatrices of relatively small dimensions. To achieve high performance, we should enlarge the dimension of these blocks, and do so in a way that provides for the minimal number of zero entries appearing as the result of such procedure. To this end, we use the algorithm presented in [8]. As a result, matrix **L** is divided into dense rectangular blocks, and the blocks located on the main diagonal are filled completely. The blocks located below the main diagonal may be filled either completely or partially. Memory is not allocated to empty blocks, and for partially filled blocks, only non-zero rows are taken into consideration (Fig. 3).

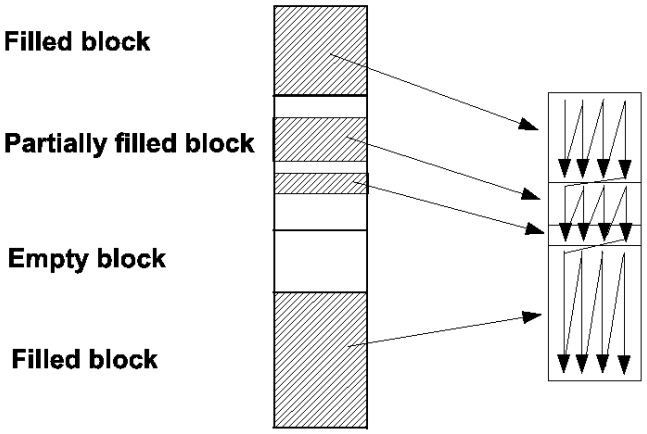

Fig.3. Block-column consisting of empty, partially and completely filled blocks. The packing of data in column major storage is shown to the right.

A more detailed description of the method is provided in [7], [8].

C.Numerical factorization

The algorithm used in this method of left-looking block factorization for the CM mode is shown in Fig. 4, 5.

Factorization is performed in a loop going over *jb* block-columns, the current block column *jb* is corrected by the fully factored block columns located to the left (p.2). Nb is the number of block-columns (p. 1, Fig. 5).

To avoid a situation when two or more threads attempt to modify the same block $\mathbf{A}_{ib,jb}$ in a *jb* block-column, all blocks of current block row are mapped to the same thread. To evenly distribute the processor load, the weight of each block row is calculated (the number of non-zero elements in this block-row), the block rows are sorted in the descending weight order, and then mapped to the threads alternately; with that, the current block row is assigned to the thread with the currently-minimal amount of computation.

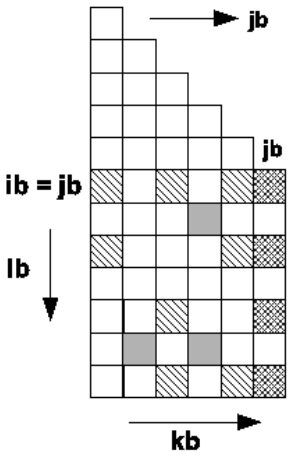

Fig. 4. Left-looking factorization of jb block-column. All block-columns located to the left of jb (kb < jb) are fully factorized.

1. **do** *jb=1,Nb*
2. update of block-column *jb*
prepare parallel tasks Q[*ip*] for update of block-column *jb*
#pragma omp parallel
while(Q[*ip*])
$\{\mathbf{L}_{jb,kb}, \mathbf{L}_{ib,kb}, kb\} = (Q[ip]/\{\mathbf{L}_{jb,kb}, \mathbf{L}_{ib,kb}, kb\})$
$\mathbf{A}_{ib,jb} = \mathbf{A}_{ib,jb} - \mathbf{L}_{ib,kb} \cdot \mathbf{S}_{kb} \cdot \mathbf{L}_{jb,kb}^T$
$(kb \in List_k[jb];\ ib \in L_{kb})$
end while
end of parallel region
end of update
3. factoring of block-column *jb*
$\mathbf{A}_{jb,jb} = \mathbf{L}_{jb,jb} \cdot \mathbf{S}_{jb} \cdot \mathbf{L}_{jb,jb}^T$
#pragma omp parallel for $(ib \in L_{jb})$
$\mathbf{L}_{jb,jb} \cdot \mathbf{S}_{jb} \cdot \mathbf{L}_{ib,jb}^T = \mathbf{A}_{ib,jb}^T \rightarrow \mathbf{L}_{ib,jb}^T$
end of factoring
4. prepare *List_k* for block-columns, which are located
to the right of block-column *jb* and will be updated by it
end **do**

Fig. 5. Looking-left block factorization algorithm

As a result, a queue of tasks Q[*ip*] is created for each *ip* thread, *ip* = 0, 1, …, *np*-1, *np* is a number of threads. Each queue element $\{\mathbf{L}_{jb,kb}, \mathbf{L}_{ib,kb}, kb\}$ contains pointers to the factorized matrix blocks $\mathbf{L}_{jb,kb}$, $\mathbf{L}_{ib,kb}$ and the *kb* index of the sign diagonal block $\mathbf{S}_{kb}$. The *jb* block-column is corrected only by those block-columns that have non-zero blocks $\mathbf{L}_{jb,kb}^T$ in the block row *ib* = *jb* (*kb* ∈ *List_k*[*jb*]).

In the parallel region each thread runs a *while* loop going over its own queue of tasks Q[*ip*] until it is exhausted.

The nearest element is popped from the queue and immediately deleted: $\{\mathbf{L}_{jb,kb}, \mathbf{L}_{ib,kb}, kb\} = (Q[ip]/\{\mathbf{L}_{jb,kb}, \mathbf{L}_{ib,kb}, kb\})$. Then, the task $\mathbf{A}_{ib,jb} = \mathbf{A}_{ib,jb} - \mathbf{L}_{ib,kb} \cdot \mathbf{S}_{kb} \cdot \mathbf{L}_{jb,kb}^T$ is performed. Conditions *ib* ∈ $\mathbf{L}_{kb}$ and *ib* = ∈ $\mathbf{L}_{jb}$ mean that the *ib* index accepts only those values that correspond to the non-zero blocks in the *kb* and *jb* block-columns respectively.

The details of this algorithm are presented in [7].

To ensure high performance, we can use the *dgemm* matrix multiplication procedure, or the microkern_8x4_AVX procedure presented in this paper.

When the *jb* block-column is completely corrected, it is factorized (p.3), and then the *jb* index is pushed to the *List_k* block-column list, which will be updated by the *jb* block-column at the next factorization steps (p. 4).

Therefore, performance at the numerical factorization stage is mainly determined by the performance of the matrix multiplication procedure. Test 2 (see Fig. 1, 2) simulates correction of the *jb* block-column by block-columns located to the left of it. Therefore, this was the test mainly used to test out the microkern_8x4_AVX procedure. Following [6], we will refer to the procedure microkern_8x4_AVX, whose code is written based on the AVX instructions, as microkernel.

D.Microkernel microkern_8x4_AVX

The proposed approach uses the same idea as in the development of the microkernel, based on SSE2 [6], [9], [10]. To achieve high performance, it is necessary to use cache blocking, register blocking, computing vectorization, data repacking in order to reduce the number of cache misses, and to unroll the inner loop to maximize the use of the processor pipelines. Since in the PARFES method, the maximum dimension of block l_b is 120, the l_b, K, N dimensions do not exceed this value. Therefore, division of matrices $\mathbf{A}_{ib}$, **B** and $\mathbf{C}_{ib}$ into blocks (cache blocking) is not required, and the dimension of TLB (translation look aside buffer) will not be exceeded [6].

Modern processors supporting AVX have 256-bit YMM registers, and 16 registers are available on the ×64 platform. Four floating-point double precision words can be loaded into each register, and four additions or four multiplications are carried out per each clock of processor. The register blocking diagram for the ×64 platform is shown in Fig. 6.

The result is stored in 8 registers intended for the elements of matrix $\mathbf{C}_{ib}$. Two registers are used for elements of matrix $\mathbf{A}_{ib}$, one register – for elements of matrix **B** and one register is required to store the intermediate multiplication results. The block dimension is $m_r \times n_r = 8 \times 4$. When the inner loop runs, the elements of matrices $\mathbf{A}_{ib}$ and **B** are repacked to ensure their locations in neighboring RAM addresses. This reduces the number of cache misses and allocates the data in the cache extremely densely. We denote: **AA = repack($\mathbf{A}_{ib}$), BB = repack(B),** where **Dest = repack(Source)** means repacking from array **Source** to array **Dest** (Fig. 6, bottom). The elements of matrices $\mathbf{A}_{ib}$, **B** and $\mathbf{C}_{ib}$ are located in the RAM column-major storage. Prefetch instructions are applied to hide memory system latency.

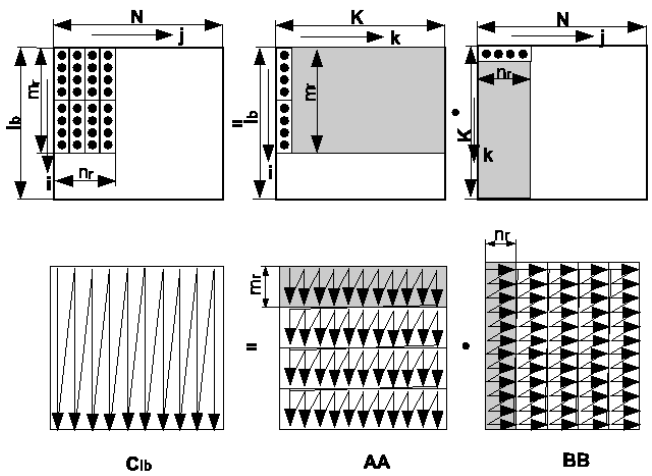

Fig. 6. Diagram of register blocking (top) and data repacking (bottom)

The AVX is used to accelerate the transmission of data when matrices $\mathbf{A}_{ib}$, **B** are repacked into arrays **AA** and **BB** respectively. The pseudo code presenting the microkern_8x4_AVX procedure is shown in Fig 7.

1. **Procedure Pack_BB: B = repack(BB)** (fig. 6, bottom).

2. **Procedure microkern_8x4_AVX:**

$\mathbf{C}_{ib} = beta \cdot \mathbf{C}_{ib} + alpha \cdot \mathbf{A}_{ib} \cdot \mathbf{B}$ (in the future index *ib* is omitted)

AA = repack(A)

```
for(j=0; j<N; j+=nr)
{
   //pBB0 = BB+K*j;  //point to current
   //vertical pane of BB
    for(i=0; i<lb; j+=mr)
    {
      pAA=AA+i*K; //point to current
                  //horizontal pane of AA
      pC=C+ldc*j+i; //point to Cij, ldc =
                    //lb.
      pBB = pBB0;

      //move Cij, Ci+1,j, … , Ci+7, j to cache
      //untill CPU run internal loop
      //move Ci,j+1, Ci+1,j+1, … , Ci+7, j+1 to cache
      //untill CPU run internal loop
      _mm_prefetch((const char *)(pC+ldc),

```

Fig. 7. microkern_8x4_AVX

Here, for ease of understanding the basic idea of the method, we consider only the case when M is a multiple of m_r, N multiple of n_r, and K is a multiple of 16. In the real microkernel, submatrices of dimension $M_1 \times K$ and $K \times N_1$ are extracted from matrices **A** and **B**, where M_1 and N_1 assume the greatest value with the following limitations: ($M_1 \le M$) ^ (M_1 % m_r) = 0, ($N_1 \le N$) ^ (N_1 % n_r) = 0, where a%b means that the remainder after the division of a by b is zero. Therefore, matrices $\mathbf{A}_{ib}$, **B** are divided into blocks, in which the largest submatrices are a multiple of m_r and n_r respectively. The YMM register blocking scheme (Fig. 6) is applied specifically for these submatrices. For the remaining small submatrices, simpler multiplication methods are used.

Matrix B is repacked in a separate procedure, allowing us to use it only once for each *kb* block-column. To produce register blocking, indexes i, j are increased by increments of m_r, n_r correspondingly. The pointers pAA and pBB are set to the beginning of the horizontal strip of matrix AA and the vertical strip of BB (Fig. 6, 8), before loops with indexes i, j are initiated.

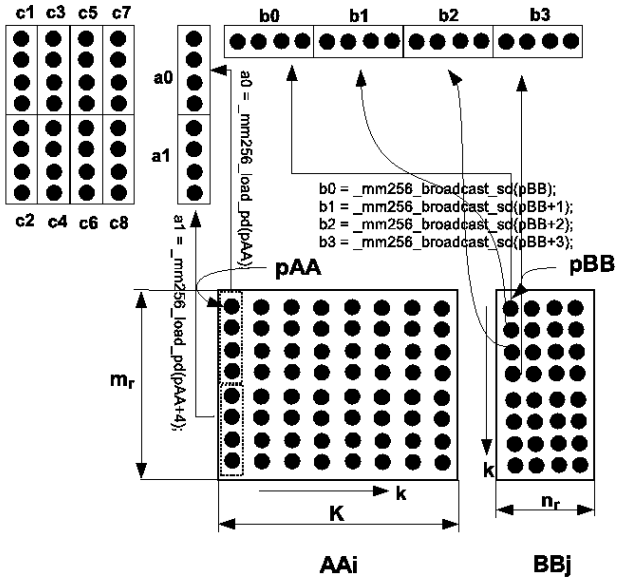

Fig. 8. Map of YMM register's loading

Registers c1 through c8 are zeroed before the loop with index *k* is started. The inner loop with index k is unrolled 16 times. The eight consecutive elements of array **AA** (the entire column of horizontal strip – Fig. 6) are loaded into registers a0, a1 by means of the instruction _mm256_load_pd(...). Each of the four consecutive elements of array **BB** (the entire vertical strip row) is sent to registers b0, b1, b2, b3 correspondingly, by means of the instruction _mm256_broadcast_sd(...) (Fig. 7, 8). As a result, the first element from the vertical strip row is found four times in register b0, the second – four times in register b1, etc.

The contents of register a0 are multiplied by the contents of register b0, and the result is placed into register mul – instruction mul = _mm256_mul_pd(a0, b0). Instruction c1 = _mm256_add_pd (c1, mul) adds up the contents of registers c1 and mul, and sends the result into register c1. Then, the contents of register a1 are multiplied by the contents of register b0, and the result is added to the contents of register c2. The contents of registers a0, a1 are multiplied by b1, and the results are added to the contents of registers c3, c4, etc. respectively. At the end of the loop with index *k*, registers c1 through c8 contain the fully computed elements of the $m_r \times n_r$ block of matrix $\mathbf{C}_{ib}$, which constitute the result of multiplying the horizontal strip $m_r \times K$ of matrix $\mathbf{A}_{ib}$, repacked into array **AA**, by the vertical strip $K \times n_r$ of matrix **B**, repacked into array **BB**.

This result is multiplied by scalar factor *alpha*. If the *beta* coefficient is non-zero, the 8 elements c_{ij}, $c_{i+1,j}$, ..., $c_{i+7,j}$ are loaded into registers a0, a1 by using _mm256_loadu_pd(...). The elements of matrix $\mathbf{A}_{ib}$ are loaded from array **AA** by using instruction _mm256_load_pd (...), because memory for array **AA** is allocated with a 32 byte alignment. Memory for matrix **C** is allocated without the 32 byte alignment, so here we use the _mm256_loadu_pd (...). The elements of matrix **C** held in registers a0, a1 are multiplied by factor *beta* and added to the contents of registers c1 and c2. Then, eight elements from the next column of matrix $\mathbf{C}_{ib}$ – $c_{i,j+1}$, $c_{i+1,j+1}$, ..., $c_{i+7,j+1}$ are loaded into registers a0 and a1, multiplied by factor *beta*, and added to the contents of registers c3, c4, etc. Transition to the next column of matrix $\mathbf{C}_{ib}$ is made by offsetting $ldc = l_b$ of pC pointer. While the current iteration is running, the prefetch instruction is applied to transmit the elements of matrix $\mathbf{C}_{ib}$ from RAM to the cache, as required for the next iteration of the loop with index *i*.

As a result, registers c1 through c8 hold the accumulated result of *alpha*·**AA**i***BB**j+*beta*·**CC**ij, where **AA**i, **BB**j are, respectively, the horizontal strip of matrix $\mathbf{A}_{ib}$, determined by the value of index *i*, and the vertical strip of matrix **B**, defined by the value of index *j*, and **CC**ij – the corresponding block of matrix $\mathbf{C}_{ib}$. Instructions _mm256_storeu_pd (...) unload data from registers c1 through c8 to the corresponding elements of matrix $\mathbf{C}_{ib}$.

III. Numerical results

A. Test 2

The results of test 2, described in the introduction (Fig. 1, 2), have been obtained on two computers and are shown in Table 1.

The first computer has a 16-core AMD Opteron 6276 CPU 2.3/3.2 GHz processor, 64 GB DDR3 RAM, and runs Windows Server 2008 R2 Enterprise SP1, 64 bit. The second computer has a 4-core Intel i7 2760QM CPU 2.4/3.5 GHz processor, 8 GB DDR3 RAM, and runs Windows 7 Professional SP1, 64 bit.

For the ACML 15.2.0 procedure, column for computing on 16 threads (the computer with AMD processor) contains two values: the first (41 469 MFLOPS) corresponds to solving the problem by parallelizing only within the *dgemm* procedure, using its multi-threaded version; while the second (10 061 MFLOPS) – to the use of the single-threaded version of *dgemm* in a parallel OpenMP loop. The first value is used to estimate the top performance of the AMD Opteron 6276 CPU for this test, since the ACML library is best adapted to AMD processors. The second value confirms that the *dgemm* procedure from the ACML library does not work properly in the mode required by PARFES.

A comparison of the results (Table 1) showed that the proposed microkern_8x4_AVX procedure successfully solved this problem on the computer with AMD Opteron 6276 processor, as well as on the computer with Intel i7 2760QM processor.

Next, we consider two real-life problems, taken from the collection of SCAD Soft – a Software Company (www.scadsoft.com) developing software for civil engineering. SCAD is FEA software, which is widely used in the CIS region and has a certificate of compliance to local regulations.

I. Problem 1

A design model of multistorey building contains 2 546 400 equations, consists of triangular, quadrilateral shell finite elements, as well as spatial frame ones (Fig. 9).

The original stiffness matrix contains 27 927 845 nonzero entries, and lower triangular factorized matrix – 1 124 085 204 nonzero entries. METIS reordering method [13] has been used.

The duration and performance of the factorization stage is presented in Table 2. As in the preceding example, the *dgemm* procedure from the Intel MKL 11.0 library does not achieve the desired performance on the computer with AMD Opteron 6276 processor. The *dgemm* procedure from the ACML library works well on a single thread, but when PARFES implements multithreading, the procedure is not performing its task. The microkern_8x4_AVX procedure proposed in this paper demonstrates good results with a single thread as well as during multi-threading. It is interesting to note that on a computer with Intel i7 2760QM processor, this procedure was not inferior to the *dgemm* procedure from the Intel MKL 11.0 library.

B. Problem 2

A design model of soil-structure interaction problem contains 2 989 476 equations (Fig. 10, 11) and consists of triangular, quadrilateral shell finite elements, as well as spatial frame and volumetric finite elements simulating the behavior of the ground.

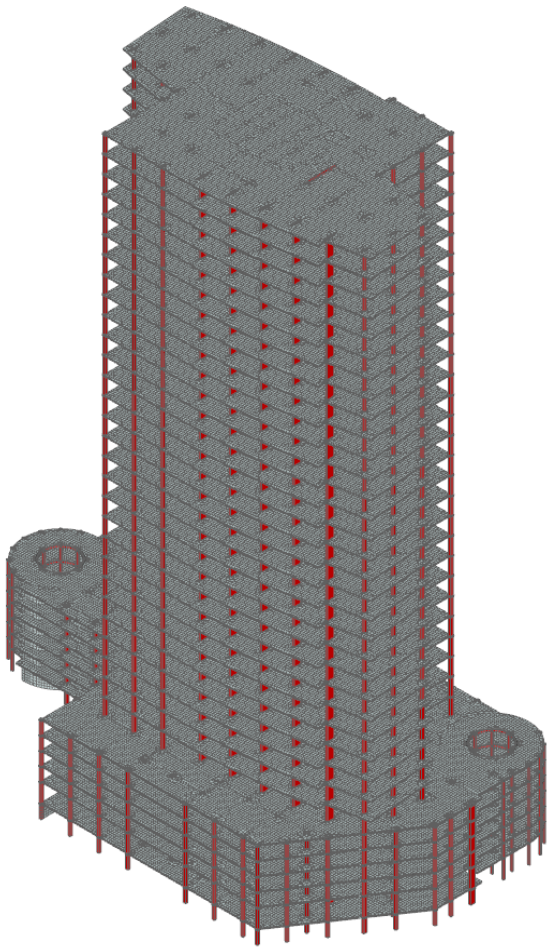

Fig. 9. Problem 1. Design model of multistorey building (2 546 400 equations).

This problem is very challenging for direct methods, because the soil prism, simulated by volumetric finite elements, generates a relatively dense part of a sparse matrix. Of all the methods available for reordering – the minimum degree algorithm MMD [4], the nested dissection method ND [3], the parallel section method [3] in conjunction with the MMD – the most efficient method for this task is METIS [13]. The number of nonzero elements in original matrix is 68 196 176 and in the lower triangular matrix – 4 966 055 936 (37 GB).

The duration of the numerical factorization phase and the performance obtained on the computer with AMD Opteron 6276 processor is shown in Table 3. The solution of this problem on the computer with Intel i7 2760QM processor and 8 GB of RAM was not effective due to the small amount of core memory. PARFES was run in the OOC1 mode, performing a large number of I/O operations. For this reason, performance analysis of the matrix multiplication procedure is not applicable.

The suggested microkernel procedure is slightly inferior to the *dgemm* procedure from the ACML 15.2.0 library on a single thread, but greatly outperforms it on 16 threads. In all cases, the proposed procedure is faster than the *dgemm* procedure from Intel MKL.

TABLE 1.
PERFORMANCE (MFLOPS) OF ALGORITHM **C = C – A·B** FOR MATRICES M × N × K = 2 000 000 × 120 × 120 (A – MATRIX M × K, B – K × N, C – M × N)

Procedure	AMD Opteron 6276 CPU 2.3/3.2 GHz		Intel i7 2760QM CPU 2.4/3.5 GHz	
	Single thread	16 threads	Single thread	4 threads
dgemm MKL 11.0	2 377	24 945	17 921	40 563
dgemm ACML 15.2.0	6 837	41 469 / 10 061	–	–
microkern_8x4_AVX	6 373	50 571	17 582	41 025

TABLE 2.
PROBLEM 1. DURATION (S) AND PERFORMANCE (MFLOPS) OF PARFES ON THE NUMERICAL FACTORIZATION STAGE (PROBLEM 1)

Procedure	AMD Opteron 6276 CPU 2.3/3.2 GHz				Intel i7 2760QM CPU 2.4/3.5 GHz			
	Single thread		16 threads		Single thread		4 threads	
	Duration, s	Perform.	Duration, s	Perform.	Duration, s	Perform.	Duration, s	Perform.
dgemm MKL 11.0	1 139	3 619	160	25 789	330	12 554	191	21 787
dgemm ACML 15.2.0	718	5 743	542	7 628	–	–	–	–
microkern_8x4_AVX	753	5 477	118	34 843	294	14 196	157	27 649

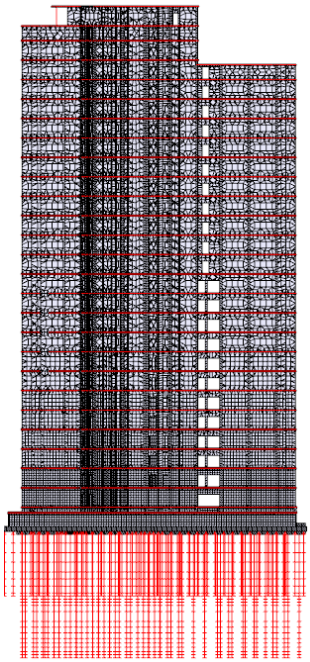

Fig. 11. The pile foundation (ground is hidden)

TABLE 3.
PROBLEM 2. DURATION (S) AND PERFORMANCE (MFLOPS) OF PARFES ON THE NUMERICAL FACTORIZATION STAGE. COMPUTER WITH AMD OPTERON 6276 PROCESSOR (PROBLEM 2)

Procedure	Single thread		16 threads	
	Duration, s	Performance, MFLOPS	Duration, s	Performance, MFLOPS
dgemm MKL 11.0	18 992	3 138	2 123	28 068
dgemm ACML 15.2.0	12 871	4 630	10 897	5 476
microkern_8x4_AVX	13 541	4 400	1 481	40 216

The speed up with the increase in the number of processors is depicted in Fig. 12.

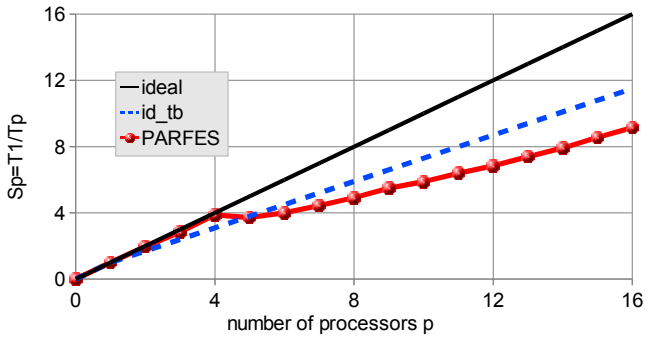

Fig. 12. Speed up with the increase in the number of threads. Ideal – the ideal speed up, id_tb – the ideal speed up on processors with Turbo Core support, PARFES – the real speed up.

The straight line of the "ideal" speed up passes through the points {0, 0}, {1, 1}, {2, 2}, … . This means that if the problem is solved using p threads, we would like to solve it p times faster than when using one thread. The id_tb curve approximates the ideal speed up for processors that support the Turbo Core mode – when a small number of cores is loaded, the processor increases the clock frequency, and when the number of loaded cores increases, reduces the frequency to the nominal value of 2.3 GHz. This curve is represented by a square parabola passing through the points {0, 0}, {1, 1}, {16, 11.5}. The ordinate of the last point was obtained as 16 × (minimum clock frequency of the processor) / (maximum clock frequency of the processor) = 16·3.2/2.3 = 11.5.

When using up to 4 threads, the speed up of PARFES is almost perfect. We explain the anomaly at p = 5 by the features of the Turbo Core control on this processor, because testing of PARFES on computers with different processors [7], [8] does not produce such behavior. The speed up of the method when p > 4 is stable up to p = 16, although lower than for the id_tb curve.

IV. Conclusion

Developing the microkernel procedure, based on AVX, in the parallel direct solver PARFES designed to solve problems of structural and solid mechanics that arise as a result of applying the finite element method, significantly accelerates matrix factorization on computers with AMD Opteron 6276 processor, Bulldozer architecture, while maintaining high performance and competitiveness with the Intel MKL *dgemm* procedure on computers with Intel processors.

***Abstract*—Recent developments in computational sciences, involving both hardware and software, allow reflection on the way that computers of the future will be assembled and software for them written. In this contribution we combine recent results concerning possible designs of future processors, ways they will be combined to build scalable (super)computers, and generalized matrix multiplication. As a result we propose a novel library of routines, based on generalized matrix multiplication that facilitates (matrix / image) manipulations.**

I. Introduction

SINCE the early 1990's one of the important factors limiting computer performance became the ability to feed data to the, increasingly faster, processors. Already, in 1994 authors of [1] discussed problems caused by the increasing gap between the speeds of memory and processors. Their work was followed, among others, by Burger and Goodman ([2]), who were concerned with the limitations imposed by the memory bandwidth on the development of computer systems. In 2002, P. Machanick presented an interesting survey ([3]) in which he considered the combined effects of doubling of processor speed (predicted by Moore's Law) and the 7% increase in memory speed, when compared in the same time scale.

The initial approach to address this problem was through introduction of memory hierarchy for data reuse (see, for instance, [4]). In addition to the registers, CPUs have been equipped with small fast cache memory. As a result systems with 4 layers of latency were developed. Data could be replicated and reside in (1) register, (2) cache, (3) main memory, (4) external memory. Later on, while the "speed gap" between processors and memory continued to widen, multi-processor computers gained popularity. As a result, systems with an increasing number of latencies have been built. On the large scale, data element could be replicated and reside in (and each subsequent layer means increasing / different latency of access): (1) register, (2) level 1 cache, (3) level 2 cache, (4) level 3 cache, (5) main memory of a (multi-core / multi-processor) computer, (6) memory of another networked computer (node in the system), (7) external device. Obviously, such complex structure of a computer system resulted in need for writing complex codes to efficiently use it. Data blocking and reuse became the method of choice for solution of large computational problems. This method was applied not only for multi-processor computers, but also computers with processors consisting of multiple computational units (e.g. cores, processors, etc.). In this context, let us note that as the number of computational units per processor is systematically increasing, the inflation adjusted price of a processor remains the same. As a result, the price per computational operation continues to decrease (see, also [5]).

While a number of approaches have been proposed to deal with the memory wall problem (e.g. see discussion of 3D memory stacking in [6]), they seem to only slow down the process, rather than introduce a radical solution. Note that, introduction of multicore processors resulted in (at least temporary) sustaining the Moore's Law and thus further pushing the performance gap (see, [3], [7]). Here, it is also worth mentioning recent approach to reduce memory contention via data encoding (see, [8]). The idea is to allow for hardware-based encoding and decoding of data to reduce its size. Since this proposal is brand new, time will tell how successful it will be. Note, however, that also this proposal is in line with the general observation that "computational hardware" (i.e. encoders and decoders) is *cheap*, and should be used to reduce volume of data *moved* between processor(s) and memory.

Let us now consider one of the important areas of scientific computing – computational linear algebra. Obviously, here the basic object is a matrix. While, one dimensional matrices (vectors) are indispensable, the fundamental object of majority of algorithms is a 2D, or a 3D, matrix. Upon reflection, it is easy to realize that there exists a conflict between the structure of a matrix and the way it is stored and processed in most computers. To make the point simple, 2D matrices are rectangular (while 3D matrices are cuboidal). However, they are *stored* in one-dimensional memory (as a long vector). Furthermore, in most cases, they are *processed* in a vector-oriented fashion (except for the SIMD-style array processors). Finally, they are sent back to be *stored* in the one-dimensional memory. In other words, data arrangement natural for the matrix is neither preserved, nor taken advantage of, which puts not only practical, but also theoretical limit on performance of linear algebra codes (for more details, see, [9]).

Interestingly, similar disregard to the natural arrangement of data concerns also many "sensor systems." Here, the input image, which is square or rectangular, is read out serially,

978-83-60810-53-8/$25.00

pixel-by-pixel, and is send to the CPU for processing. This means that the transfer of pixels destroys the 2D integrity of data (an image, or a frame, start to exist **not** in their natural layout). Separately, such transfer introduces latency caused by serial communication. Here, the need to transfer large data streams to the processor may prohibit their use in applications, which require (near) real-time response [10]. Note that large data streams exist not only in scientific applications. For instance modern digital cameras capture images consisting of 22.3×10^6 pixels (Cannon EOS 5D Mark III [11]) or even 36.3×10^6 pixels (Nikon D800 [12]). What is even more amazing, recently introduced Nokia phone (Nokia 808 PureView [13]) has camera capturing 41×10^6 pixels.

For the scientific / commercial sensor arrays, the largest of them seems to be the 2-D pixel matrix detector installed in the Large Hadron Collider in CERN [14]. It has 10^9 sensor cells. Similar number of sensors would be required in a CT scanner array of size approximately $1m^2$, with about 50K pixels per $1cm^2$. In devices of this size, for the (near) real-time image and video processing, as well as a 3-D reconstruction, it would be natural to load data directly from the sensors to the processing elements (for immediate processing). Thus, a focal-plane I/O, which can map the pixels of an image (or a video frame) directly into the array of processors, allowing data processing to be carried out immediately, is highly desired. The computational elements could store the sensor information (e.g. a single pixel, or an array of pixels) directly in their registers (or local memory of a processing unit). Such an architecture has two potential advantages. First, cost can be reduced because there is no need for memory buses or a complicated layout. Second, speed can be improved as the integrity of input data is not destroyed by serial communication. As a result, processing can start as soon as the data is available (e.g. in the registers). Note that proposals for similar hardware architectures have been outlined in [15], [16], [17]. However, all previously proposed focal-plane array processors were envisioned as a mesh-based interconnect, which is good for the local data reuse (convolution-like simple algorithms), but is not proper to support the global data reuse (matrix-multiplication-based complex algorithms).

Separately, it has been established that computational linear algebra can be extended through the theory of algebraic semirings, to subsume large class of problems (e.g. including a number of well known graph algorithms). The theoretical mechanism is named Algebraic Path Problem (APP). As shown, for instance, in ([18]), there is an interesting link between the arithmetical fused multiply and add (FMA) operation, which is supported in modern hardware, and the FMAs originating from other semirings that are not. Specifically, if it was possible to modify the standard FMA to include operations from other semirings (in a way similar to the proposals of KALRAY; [19]), and thus develop a generalized FMA, it could be possible to speed-up large class of APP problems at least 2 times ([18]).

Let us now assume the existence of a computational unit that satisfies the above requirements: (1) accepts input from the sensor(s) and transfers it directly to its operational registers / local memory; (2) is capable of generalized FMA operations. The latter requirement means that such FMA should store (in its registers) constants needed to efficiently perform FMA operations originating from various semirings. Let us name it the *extended generalized FMA; EG FMA*. Recall, that the cost of computational units (of all types) is systematically decreasing ([5]). Therefore, cost of the *EG FMA* unit should not be much higher than that of a standard FMAs found in today's processors. Hence, it is easy to imagine m(b)illions of them "purchased" for a reasonable price. As stated above, such *EG FMAs* should be connected into a square array that will match the shape of the input data. Let us now describe how such system can be build.

II. Mesh-of-tori interconnection topology

Since early 1980's a number of topologies for supercomputer systems have been proposed. Let us omit the unscalable approaches, like a bus, a tree, or a star. The more interesting topologies (from the 1980's and 1990's) were:

- hypercube – scaled up to 64000+ processor in the Connection Machine CM-1,
- mesh – scaled up to 4000 processors in the Intel Paragon,
- processor array – scaled up to 16000+ processor in the MassPar computer,
- rings of rings – scaled up to 1000+ processors in the Kendall Square KSR-1 machines
- torus – scaled up to 2048 units in the Cray T3D

However, all of these topologies suffered from the fact that at least some of the elements were reachable with a different latency than the others. This means, that algorithms implemented on such machines would have to be asynchronous, which works well, for instance, for ising-model algorithms similar to [20], but is not acceptable for a large set of computational problems. Otherwise, extra latency had to be introduced by the need to wait for the information to be propagated across the system.

To overcome this problem, recently, a new (*mesh-of-tori*; *MoTor*) multiprocessor system topology has been proposed ([21], [22]). The fundamental (*indivisible*) unit of the *MoTor* system is a μ-Cell. The μ-Cell consists four computational units connected into a 2×2 doubly-folded torus (see, Figure 1). Logically, an individual μ-Cell is surrounded by so-called membranes that allow it to be combined into larger elements through the process of cell-fusion. Obviously, collections of μ-Cells can be split into smaller structures through cell division. In Figure 1, we see total of 9 μ-Cells logically fused into a single macro-μ-Cell consisting of 4 μ-Cells (combined into a 2×2 doubly folded torus), and 5 separate (individual) μ-Cells. Furthermore, in Figure 2 we observe all nine μ-Cells combined into a single system (a 3×3 doubly folded torus). Observe that, when the 2×2 (or 3×3) μ-Cells are logically fused (or divided), the newly formed structure remains a doubly folded torus. In this way, it can be postulated that the single μ-Cell represents the "image" of the whole system. While in earlier publications (e.g. [22], [23], [24], [25]

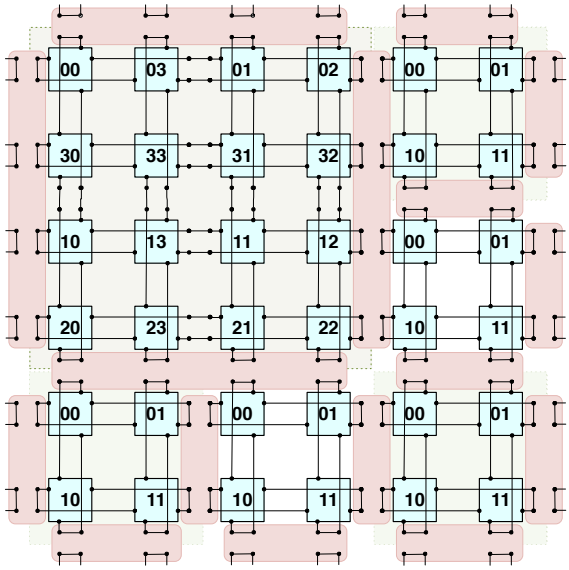

Figure 1. 9 μ-Cells fused into a single 2×2 "system," and 5 separate μ-Cells

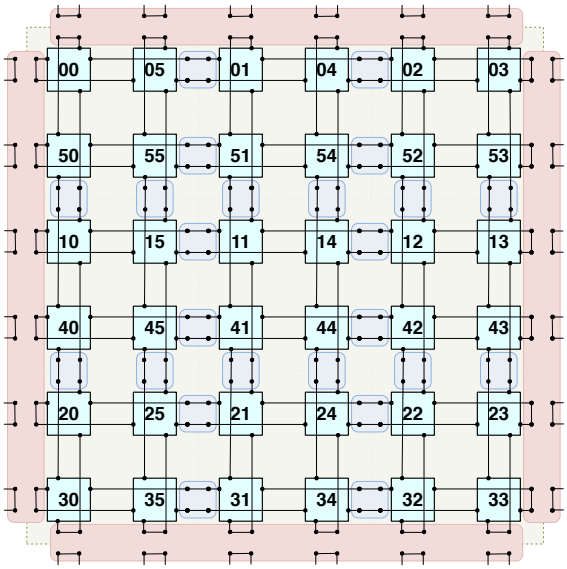

Figure 2. 9 μ-Cells fused into a single 6×6 EG FMA system

the computational units were mostly treated as "theoretical entities," in the context of this paper we assume that each one of them is the *EG FMA* described above. However, analysis of cell connectivity in Figure 1 shows that the model *EG FMA* proposed in the previous section has to be complemented by four interconnects that allow construction of the *MoTor* system. Therefore, from here on, we will understand the *EG FMA* in this way. Furthermore, we will keep in mind that the *MoTor* architecture is build from *indivisible* μ-Cells, each consisting of four, interconnected into a doubly folded torus *EG FAMs*.

Let us now observe that the proposed *MoTor* topology has similar restriction as the array processors from the early 1990's. To keep its favorable properties, the system must be square. While this was considered an important negative (flexibility limiting) factor in the past, this is no longer the case. When the first array processors were built and used, arithmetical operations and memory were "expensive." Therefore, it was necessary to avoid performing "unnecessary" operations (and maximally reduce the memory usage). Today, when GFlops costs about 50 cents (see, [5]) and this price is systematically dropping, and when laptops come with 8 Gbytes of RAM (while some cell phones come with as much as 64 Gbytes of flash memory on a card), it is data movement / access / copying that is "expensive" (see, also [26]). Therefore, when matrices (images) are rectangular (rather than square), it is reasonable to assume that one could just pad them up, and treat them as square. Obviously, since the μ-Cell is a single indivisible element of the $MoTor$ system, if the matrix is of size $N \times N$ then N has to be even.

Observe that there are two sources of inspiration for the $MoTor$ system: (i) matrix computations, and (ii) processing data from, broadly understood, sensor arrays (e.g. images). Furthermore, we have stated that the extended generalized FMA can contain a certain number of data registers to store (a) the needed scalar elements originating from various semirings, (b) elements of special matrices needed for matrix transformations (see, below), as well as (c) data that the FMA is to operate on. However, we also consider the possibility that each FMA may have a "local memory" to allow it to process "blocks of data." This idea is based on the following insights. First, if we define a pixel as " the smallest single component of a digital image" (see, [27]), then the data related to a single pixel is very likely to be not larger than a single 24 bit number. Second, in early 2013 the largest number of FMA units combined in a single computer system was 5.2×10^6. This means that, if there was a one-to-one correspondence between the number of FMA units and the number of "sensed pixels" then the system could process stream of data from a 5.2 Megapixel input device (or could process a matrix of size $N \simeq 2200$).

Let us now consider, development of the *MoTor*-based system. In the initial works, e.g. in [22], links between cells have been conceptualized as programmable abstract links (μ-Cells were surrounded by logical membranes that could be fused or divided as needed, to match the size of the problem). Obviously, in an actual system, the abstract links and membranes could be realized logically, while the whole system would have to be hard-wired to form an actual $MoTor$ system of a specific size. Therefore to build a large system with M^2 μ-Cells (recall the assumption that the mesh will constitute a square array), it can be expected that their groups will be combined into separate "processors," similarly to multicore / multi-FMA processors of today. As what concerns cell fusion and division, it will be possible to assemble sub-system(s) of a needed size, by logically splitting and/or fusing an appropriate

number of cells within the $MoTor$ system. However, it is worthy to stress that, while the theoretical communication latency across the mesh-of-tori system is uniform, this may not be the case when the system will be assembled from processors constituting logical (and in some sense also physical) macro-μ-Cells. In this case it may be possible that the communication within the processor (physical macro-μ-Cell) will be slightly faster than between processors. Therefore, the most natural split would be such that would involve complete macro-μ-Cells (processors). However, let us stress that, the design of the mesh-of-tori topology does not distinguish between the connections that are "within a chip" and "between the chips." Therefore, the communication model used in the algorithms described in [22], [23], and considered in subsequent sections, is *independent* of the hardware configurations.

Finally, let us consider the input from the sensor array (or sending a matrix) into the mesh-of-tori type system. As shown in [22], any input that is in the canonical (square matrix) arrangement, is not organized in a way that is needed for the matrix processing in a (doubly folded) torus. However, adjusting the data organization (e.g. to complete a 2D $N \times N$ DFT), requires 2 matrix multiplications (left and right multiplication by appropriate transformation matrices, see below). These two multiplications require $2N$ time steps on a *MoTor* architecture. Next, after the processing is completed, the canonical arrangement can be restored, by reversing the original transformation. Here, again, two multiplications are needed and their cost is $2N$ time steps. For the details about the needed transformations and their realizations as a triple matrix multiplication, see [22].

III. Data manipulations in a $MoTor$ system

Let us summarize points made thus far. First, we have refreshed arguments that there is an unfulfilled need for computer systems that (1) have focal-plane I/O that, among others, can feed data from sensors directly to the operand registers / memory of extended FMA units (generalized to be capable of performing arithmetical operations originating from different semirings), (2) operate on matrices treating them as square (or cuboidal, e.g. tensor) objects, (3) are developed in such a way that (i) minimizes data movement / access / copying / replication, (ii) maximizes data reuse, and (iii) is aware of the fact that arithmetical operations are cheap in comparison with any form of data "movement." Such systems are needed not only to process data originating from the Big Hadron Collider, but also for everyday electronics. Here, it is worth mentioning that virtual reality and 3D media (part of the new enterprises, so called *creative industries*) are in the latter category, illustrating where the computational power is going to be needed in an increasing rate, beyond the classic domains of scientific computing.

Second, we have briefly outlined key features of the, recently proposed, mesh-of-tori topology, which has some favorable features and naturally fits with the proposed *EG FMAs*. Furthermore, we have pointed to some issues that are likely to be encountered in the development of (large-scale) $MoTor$ based systems. Let us now assume, that the, just proposed, $MoTor$ computer systems have been built. In ([22], [23], [25]) it was shown that a large number of matrix operations / manipulations can be unified through the use of a generalized matrix multiply-and-update (MMU) operation. However, in this context it is important to realize that one more problem we are facing today is the increasing complication of codes that are being developed to take advantage of current computer architectures (see, for instance [28], [26]). This being the case, a return to simplicity is needed. In the remaining sections of this paper we will illustrate how a MATLAB / MATHEMATICA style (meta-level) approach can be used to build a library of matrix manipulation operations that, among others, can be implemented on the proposed $MoTor$ computer architecture. This library will be uniformly based on the "fused" matrix multiply-and-update (MMU) operation.

A. Basic operations

To proceed, we will use the generalized matrix multiply and update operation in the form (as elaborated in [28]):

$$\mathtt{C} \leftarrow \mathtt{MMU}[\otimes, \oplus](\mathtt{A}, \mathtt{B}, \mathtt{C}) : \mathtt{C} \leftarrow \mathtt{C} \oplus \mathtt{A}^{\mathtt{N/T}} \otimes \mathtt{B}^{\mathtt{N/T}}. \qquad (1)$$

Here, A, B and C are square matrices of (even) size N (recall the, above presented, reasons for restricting the class of matrices); while the $\otimes, \oplus$ operations originate from a scalar semiring; and $\mathtt{N/T}$ specify if a given matrix is to be treated as being in a canonical (`N`) or in a transposed (`T`) form, respectively.

In what follows, we present a collection of matrix / image manipulations that can also be achieved through matrix multiplication. While they can be implemented using *any* matrix multiplication algorithm, we use this as a springboard to further elaborate the idea of *MoTor* system, and a library of routines that can complement it. Note that, for simplicity of discussion (and due to the lack of space), in what follows we only discuss the special case when a single *EG FMA* stores scalar data elements. However, as discussed in [22], [23], [25], [24] all matrix manipulations can be naturally extended to blocked algorithms. Therefore, we actually do not contradict our earlier assumption that each *EG FMA* holds a block of data (e.g. pixel array, or a block of a matrix).

1) Reordering for the mesh-of-tori processing: Let us start from the above mentioned fact that the canonical form of the matrix (image) fed to the $MoTor$ system through the focal-plane I/O is not correct for further (parallel) processing on a doubly folded torus. As shown in [23], the proper format can be obtained by corresponding linear transform through two matrix-matrix multiplications. Specifically, matrix product in the form $M \leftarrow R \times A \times R^T$, where A is the original / input $(N \times N)$ matrix that is to be transformed, M is the matrix in the format necessary for further processing on the mesh-of-tori system, and R is the format rearranging matrix (for details of the structure of the R matrix, consult [23]). Taking into account the implementation of the generalized MMU, proposed in [28], the needed transformation is:

$$M = R \cdot A \cdot transpose(R). \quad (2)$$

Note that on the $MoTor$ system: (a) operation $R \cdot A$ is performed in place and requires N time steps, (b) operation $A \cdot transpose(R)$ is performed in place, requires N time steps and is implemented as a parallel matrix mutiplication with a different data movement (operation scheduling) that the standard multiplication. In other words, the matrix arrangement remains unchanged and well-known problems related to row vs. column matrix storage (see, for instance, [29]) do not materialize (for more details, see [30]).

Observe that when instantiating the $MoTor$ system, it is assumed that appropriate matrix R will be pre-loaded into the macro-μ-Cell, upon its creation. In earlier work, see for instance [28] and references to earlier work of S. Sedukhin collected there, it was assumed that the generalized FMA will store in its operand registers the (scalar) constants originating from implemented semiring(s) and representing elements $\bar{0}$ and $\bar{1}$. Here, we assume that, in addition to the separate operand registers dedicated to each $\bar{0}, \bar{1}$ element originating from the semiring implemented in the hardware, in a separate operand register an appropriate element of a transformation matrix needed to perform operations summarized in this paper will be pre-loaded. It is in this way, that the matrix R will be pre-loaded into the $MoToR$ system.

Observe that in the $MoTor$ system, the size of the "logical" system (macro-μ-Cell) can vary with time and be changed through cell fusion and division. This means that, after a group of μ-Cells is fused (split), some of the "transformation matrices" will have to be re-instantiated. However, this will not concern matrices like `ONES` (see, below) that preserve format during cell fusion / division. Nevertheless, matrix R will have to be re-initialized each time cells are fused / divided. We summarize these considerations, for the "special matrices" identified in this paper, in Table I.

When considering the implementation of the transformation, observe that the information about the R matrix does not need to be known to the user (only to the implementer). This being the case, we can define the $Canonical\_to\_MoTor$ function that will have as its input the matrix A in the canonical form, and as its output matrix M in the form ready to use in the $MoTor$ system. This function will perform operations from equation 2, while hiding matrix R from the user. Obviously, an inverse function $MoTor\_to\_Canonical$, that will perform operation $A \leftarrow R^T \cdot M \cdot R$ (with the same matrix R), will restore the matrix to its original (canonical) format in $2N$ time steps. Obviously, these two functions make sense only in the context of the $MoTor$ system. Specifically, such transformations can be performed on any computer system, but they are useless if that system has a different topology.

2) Row and column permutations: It is a well known fact, that row and column permutations can be represented as matrix-matrix multiplications. Specifically, permutation of rows of matrix A is achieved through left hand side multiplication by an appropriate matrix P ($A' \leftarrow P \cdot A$), while column permutation is achieved through the right hand side multiplication by an appropriate matrix Q ($A' \leftarrow A \cdot Q$). Both matrices P and Q are identity matrices, with two elements (corresponding to appropriate rows or columns) modified. While the matrix multiplication is typically treated as a convenient notation used in theoretical linear algebra, in computational practice row and column permutations are usually implemented as vector operations. However, in the $MoTor$ approach, row and column permutations will be achieved through actual $N \times N$ matrix multiplication, performed in place, in $O(N)$ time steps.

As far as the implementation is concerned, matrix P will be initially stored in the meta-μ-Cell as a copy of the identity matrix(I). Note that this means that this matrix will be actually represented in separate operand registers of appropriate *EG FMAs*. Let us now introduce function $Row\_permute(A, i, j)$. This function, when called, will send information to appropriate four *EG FMAs* $((i,i), (j,j), (i,j), (j,i))$ to flip their values from $\bar{0}$ to $\bar{1}$ and vice-versa. Depending on the implementation, this should be achieved in no more than 4 time steps. Next, the actual matrix multiplication will be performed. Finally, the four processing units (belonging to matrix P) that changed their values, will revert to the original ones (again, in no more than 4 time steps). The same approach will be used in the case of column permutation (function $Column\_permute(A, i, j)$). Observe that, while there exist algorithms that ask for ($A' \leftarrow P \cdot A \cdot Q$), these two operations (left and right side multiplication) do not have to be performed simultaneously (in this paper we do not consider a more general case of performing concurrently triple matrix multiplications). This means that actually, we do not need to store two separate matrices P and Q. All that is needed is a single `PERMUT` matrix than can be used by the implementer to support both operations (this matrix is not being made available to the user). Potential use of the actual identity matrix (in place of the separate `PERMUT` matrix) needs to be further considered, before such decision could be made. As what concerns the effect of cell fusion and splitting, it should be obvious from Figures 1 and 2 that it is during this process it is necessary to reinitialize both the identity and the `PERMUT` matrices.

3) Scalar data replication (broadcast): Let us now consider replication of a data element across all processors in the system (operation that in MPI [31] is known as *MPI_BCAST*). As shown in [23], this can be achieved through two matrix multiplications. The appropriate triple has the form $B \leftarrow$ `LBCAST` $* D *$ `RBCAST`, where B is the resulting matrix with all of its elements equal to the replicated one; D is a zero matrix with the element to be replicated in position $d(i, j)$; `LBCAST` is a matrix with all zeros except of the ones in column i; and `RBCAST` is a zero matrix with ones in row j. Obviously, on the $MoTor$ system (since the broadcast involves 2 matrix multiplications) it will be completed in place, in $2N$ time steps.

Based on the material presented thus far, we propose the following implementation of broadcast of a selected element across all processors of a $MoTor$ system. Assume that ma-

trices LBCAST and RBCAST are zero matrices with ones in column 1 and row 1 respectively. Furthermore, matrix D is a copy of the $\bar{0}$ matrix, which is going to be used in both multiplications. In the first step, the selected element is send to the *EG FMA* located in position $(1,1)$ of the $MoTor$ system and stored in the operand register corresponding to $D(1,1)$. Next, the MMU operation is invoked twice ($B \leftarrow$ LBCAST $*\, D *$ RBCAST) within a $ElBcast$ function, which has the form: $ElBcast(element)$, where the $element$ specifies element that should be replicated. As a result, in $2N$ time steps, the selected element is replicated to all elements of matrix B and thus made available across the $MoTor$ system. Finally, the $D(1,1)$ element is zeroed. Note that, while matrices LBCAST and RBCAST have to be reinstantiated, the matrix D, being a copy of the zero matrix remains unchanged during cell fusion / division. Possibility of use of the actual zero matrix, instead of matrix D has to be further evaluated. Obviously, matrices LBCAST and RBCAST are available only to the implementer, while being hidden from the user.

4) Global reduction and broadcast: The next matrix operation that can be formulated in terms of matrix multiplications, is the *global reduction and broadcast*. As seen in [23], when the standard arithmetic is applied, and matrix A is multiplied from both sides by a matrix of ones (matrix with all elements equal to one, let us name it ONES), then the resulting matrix will have its elements equal to the sum of all elements of A. On a mesh-of-tori system, this can be implemented in place, in $2N$ time steps, when the matrix ONES is available (preloaded) in all *EG FMAs* of the system.

However, recall that our approach is based on use of the generalized MMU. Thanks to this, we can apply operations originating from different semirings. Here, particularly interesting would be semirings, in which the addition and multiplication operations are defined as $(\times, max)$ or $(\times, min)$. In this case, the "generalized reduction and broadcast" operation is going to consist of two generalized MMUs (represented in notation from the equation 1):

$$\texttt{MMU}[\otimes,\oplus](\texttt{A},\texttt{ONES},\texttt{TEMP}) : \texttt{TEMP} \leftarrow \texttt{TEMP} \oplus \texttt{A} \otimes \texttt{ONES};$$
$$\texttt{MMU}[\otimes,\oplus](\texttt{ONES},\texttt{TEMP},\texttt{RESULT}) :$$
$$\texttt{RESULT} \leftarrow \texttt{RESULT} \oplus \texttt{ONES} \otimes \texttt{TEMP}.$$

Here, operations $[\otimes,\oplus]$ are defined in an appropriate semiring, while matrices TEMP and RESULT are initialized as copies of the $\bar{0}$ matrix (zero matrix for a given semiring). Finally, ONES is a matrix of all ones, where the "one" element originates from a given scalar semiring (its element $\bar{1}$).

Under these assumptions it is easy to see that we can define at least three functions that will have the same general form, while being based on different semirings: $AddBcast$ – realizing summation of all elements in a matrix and broadcasting the result to all processors (function based on the standard arithmetic); $MaxBcast$ finding the largest element in a matrix and broadcasting it to all processors (based on the $(\times, max)$ semiring); and $MinBcast$ finding the smallest element in the matrix and broadcasting it to all processors (based on the $(\times, min)$ semiring). Each of these functions will be completed in place, in $2N$ time steps, through 2 generalized matrix multiplications. Observe that, for all practical purposes, matrix ONES does not have to be instantiated. It consists of $\bar{1}$ elements that, according to our assumptions, are already stored in operand registers of the *EG FMAs*. Finally, note that (regardless of the way it will finally be instantiated in the *MoTor* system) matrix ONES is independent of the size of the macro-μ-Cell and remains unchanged and available after cell fusion / division operation. As previously, all information about very "existence" of matrices ONES and TEMP, and initialization of matrices TEMP and RESULT is going to be hidden from the user.

B. Matrix (image) manipulations

Let us now consider three simple matrix *manipulations* that can be achieved with help of matrix multiplication. While they are presented as matrix operations, their actual value can be seen when the underlying matrices represent images (e.g. each matrix element represents a pixel, or a block of pixels).

1) Upside-down swap: Image (matrix) upside down swap can be achieved by multiplying the matrix from the left hand side by the $SWAP$ matrix, which has the following form:

$$SWAP = \begin{vmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{vmatrix}$$

Obviously, we assume that on the $MoTor$ system, matrix SWAP will be instantiated when macro-μ-Cell(s) will be created (appropriate elements will be stored in separate operand registers of the *EG FMAs*). However, it will not be made available to the user. This means that the upside-down swap will be achieved by calling a $UDswap(A)$ function, and completed in place, in N time steps. Matrix SWAP will have to be re-initialized after each μ-Cell fusion or division.

2) Left-right swap: The left-right image (matrix) swap can be achieved the same way as the upside-down swap, with the only difference being that the image matrix A is going to be multiplied by the SWAP matrix from the right hand side. Therefore, on the $MoTor$ system, the left-right swap will be completed in place, in N time steps, by calling the $LRswap(A)$ function. All the remaining comments, concerning the SWAP matrix, presented above, remain unchanged.

3) Rotation: Interestingly, combining the two swaps into a single operation (multiplication of a given image / matrix A from left and right by the matrix SWAP) results in rotation of the matrix / image A by $180°$. Obviously, from the above follows that on the $MoTor$ system, this operation can be completed in place, in $2N$ steps using two matrix multiplications, by calling an appropriately defined $Rotate(A)$ function.

IV. Towards library of matrix multiplications based data manipulations

Let us now summarize the above considerations from the point of view of development of a library of operations that can be performed on matrices / images though generalized matrix

Table I
SUMMARY OF FUNCTIONS PROPOSED FOR THE LIBRARY

Functionality	Function	Matrices	Re-instantiate
Reorder Canonical to $MoTor$	$Canonical\_to\_MoTor(A)$	R	yes
Reorder $MoTor$ to Canonical	$MoTor\_to\_Canonical(A)$	R	yes
Row permutation	$Row\_permute(A,i,j)$	PERMUT	yes
Column permutation	$Column\_permute(A,i,j)$	PERMUT	yes
Replication	$ElBcast(element)$	LBCAST, RBCAST, D	yes & no
Addition and broadcast	$AddBcast(A)$	ONES	no
Max and broadcast	$MaxBcast(A)$	ONES	no
Min and broadcast	$MinBcast(A)$	ONES	no
Upside-down swap	$UDswap(A)$	SWAP	yes
Left-right swap	$LRswap(A)$	SWAP	yes
Rotation by 180°	$Rotate(A)$	SWAP	yes

multiplication. In Table I we combine proposals presented thus far. There, we present the functionality, the proposed function name, the "special matrices" that have to be instantiated within the *MoTor* system to complete the operations, and information if these matrices have to be reinitialized after μ-cell fusion / splitting operation. Observe that, while the first two functions are directly connected with the *MoTor* architecture, the remaining ones can be seen as "system independent." In other words, they can be implemented for any computer architecture, taking full advantage of the underlying architecture.

This latter observation deserves further attention, and some points have to be made explicit. Only the transformations from the canonical to the $MoTor$ format and back are $MoTor$ architecture specific. The remaining functions are system independent. While the above considerations have in mind the $MoTor$ architecture, the proposed functions use only matrix multiplication and thus can be implemented to run on any computer architecture, using its best of breed matrix multiplication algorithm. This being the case, and taking into account discussion presented in Section I, it may be desirable to implement functions from Table I on existing computers, using state-of-the-art matrix multiplication algorithms and consider their efficiency.

A. Object oriented realization

Let us now recall that our main goal is to consider functions from Table I in the context of the *MoTor* architecture. However, we also see them as a method of simplifying code writing (by introducing matrix operations represented in the style similar to that found in MATLAB / MATHEMATICA). This being the case we assume that there may be multiple ways of implementing these routines, and that they are likely to be vendor / hardware specific. Nevertheless, at the time of writing of this paper, object oriented programming is one of more popular ways of writing codes in scientific computing and image processing. Furthermore, this means the possible trial implementations, suggested above, are likely to be tried using this paradigm. This being the case, we have decided to conceptualize the top-level object-oriented representation of the library of routines from Table I. Since different OO languages have slightly different syntax (and semantics), we use a generic notation, distinguishing information that needs to be made available in the interface and in the main class. We start from the interface (see, also [28]).

```
/* T - type of matrix element */

interface Matrix_interface {
        public Matrix 0(n) {/*generalized zero matrix*/}
        public Matrix I(n) {/*generalized identity matrix*/}
        public Matrix operator + /*generalized  A+B*/
        public Matrix operator * /*generalized A*B*/
        public Matrix Canonical_to_Motor(A);
        /*reordering for themesh-of-tori processing*/
        public Matrix Motor_to_Canonical (A);/*inverse of
        the reordering for the mesh-of-tori processing*/
        public Matrix transpose(A);
        {/*transposition of matrix A*/}
        /*generalized permutation of column / row
                i and j in matrix A*/
        public Matrix Column_Permut (A,i,j);
        public Matrix Row_Permut (A,i,j);
        /*generalized element broadcast*/
        public Matrix ElBcast(element);
        public Matrix AddBcast (A);/*generalized summation
        of all elements of A and broadcast*/
        /*broadcast the largest element of A*/
        public Matrix MaxBcast (A);
        /*broadcast the smallest element of A*/
        public Matrix MinBcast (A);
        /*Matrix (Image) Manipulation*/
        public Matrix UDswap (A);/*upside-down swap*/
        public Matrix LRswap (A);/*left-right swap*/
        /*image vertical rotation*/
        public Matrix Rotate (A);...
}
```

Just defined interface is to be used with the following class *Matrix*. This class summarizes the proposals outlined above.

```
class Matrix inherit scalar_Semiring
                implement Matrix_interface {
  T: type of element;/*double, single,...*/
  private Matrix R (n);/*matrix for MoTor
        transformation*/
  private Matrix ONES (n) /* matrix of ones*/
  private Matrix PERMUT(i,j,n)/*identity matrix
       with interchanged columns i and j*/
  //anti-diagonal matrix of ones
  private Matrix SWAP (n)
       // Methods
  public Matrix 0(n) {/*0 matrix*/}
  public Matrix I(n) {/*identity matrix*/}
  public Matrix transpose(A:Matrix){
                /*MMU-based transposition of A*/}
  public Matrix operator + {A,B:Matrix}
                {return MMU(A,I(n),B,a,b)}
  public Matrix operator * {A,B:Matrix}
                {return MMU(A,B,matrix_0,a,b)}
  public Matrix Column_Permut (A,i,j){
                 return MMU(PERMUT(i,j,n),A,O(n))}
  public Matrix Row_Permut(A,i,j){
                return MMU(A,PERMUT(i,j,n),O(n))}
```

```
    public Matrix Canonical_to_Motor (A){
                M = R * A * transpose(R);
                return M}
    public Matrix UDswap (A);/*upside-down swap*/
                {return MMU(O(n),SWAP,A)}
    public Matrix LRswap (A);/*left-right swap*/
                {return MMU(O(n), A,SWAP)}
          /*image vertical rotation*/
          public Matrix Rotate (A);
                {A=MMU(O(n),SWAP,A);
                 return MMU(O(n),A,SWAP)}
          ...
    private MMU(A,B,C:Matrix(n)){
      return "vendor/implementer specific
          realization of MMU = C + A*B where
      + / * are from class scalar_Semiring"}
...
}
```

Obviously, just defined class and interface allow us to write codes in the suggested manner. Here, the matrix operations (image manipulations) can be performed by calling very simple functions, and hiding all implementation details from the user.

V. Concluding remarks

The aim of this paper was to reflect on current trends in computational sciences. We have focused our attention on selected trends in hardware and software design, to visualize possible designs of future processors and ways they will be combined to build scalable (super)computers. In this context, the mesh-of-tori architecture is one of the more promising concepts for design of large-scale computer systems. This provided us with background, against which we have considered the role of generalized matrix multiplication. As a result we proposed a novel library of routines, based on generalized matrix multiplication that allows for data (matrix / image) manipulations. In the future we plan to implement the proposed library on the virtual *MoTor* system.

***Abstract*—IEC 61131-3 standard defines five languages for programming industrial controllers. They support both textual and graphical development approaches. In case of Function Block Diagram graphical language, diagrams consist of a set of elements connected with lines, which have various length and shape. Development of an editor supporting diagrams design involves implementation of an algorithm, which is able to automatically find a suitable connection between blocks. In the paper an appropriate application of A* algorithm is proposed. The authors have ensured that the proposed solution is efficient and work smoothly. Relations between implementation details and performance are discussed. Achieved results caused that the mechanism has been introduced into graphics editors available in CPDev engineering environment for programming controllers.**

***Index Terms*—A* algorithm, graphics editors, IEC 61131-3, searching path.**

I. Introduction

GRAPHICS editors for various diagrams allow the user to create connections between symbolic blocks. The simplest approach is to draw an exact line or polyline by the user. It can be cumbersome and lead to errors, especially when the block, which is a start or end point for the connection, is moved later, because the connection is not updatable. A better solution is to draw connections between blocks automatically and also update them when necessary, without user attention. This scenario makes creation of the diagram easier and limits a number of errors. It is consistent with a process of diagram creation that starts from designing the first working version of control algorithm, without focusing on legibility of the diagram, and then moving elements to get more readable design that is easier to understand and maintain.

To implement such an approach, a dedicated algorithm is required. It complies with some rules corresponding to the diagram type (e.g. restrictions on overlapping lines and crossing other blocks) and takes into account user preferences (directions changed rarely). Moreover, the algorithm should determine all paths on the fly, immediately after creating or moving an element.

Results obtained during research caused an implementation of the mechanism of automatic connections finding in graphics editors inside the CPDev engineering environment. They work smoothly also on devices with limited resources and allow the designer to create and modify connections in almost imperceptible way. A process of updating connections between multiple elements typically takes only a few milliseconds.

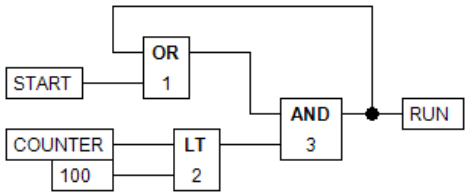

Fig. 1. FBD program that represents the following formula: $RUN = (RUN \vee START) \wedge (COUNTER < 100)$.

In this paper, the algorithm with an application for Function Block Diagram (FBD) graphical language from IEC 61131-3 standard is presented. The article is organized as follows. The second section reviews FBD language and CPDev engineering environment. A problem of path searching in a graph with analysis of A* algorithm modifications is described in the third section. The results of measurements and a short information about test software is presented in the fourth section.

II. FBD in CPDev engineering environment

Third part of the IEC 61131 standard [1] defines five programming languages for industrial controllers. Textual languages include ST (Structured Text) and IL (Instruction List). FBD (Function Block Diagram) and LD (Ladder Diagram) are graphical, while SFC (Sequential Function Chart) is mixed and requires parts implemented in other languages.

In the paper, the authors focus on FBD, that is a graphical language allowing users to create control programs in a visual way. POUs (Program Organization Units, i.e. programs, function blocks, and functions) defined in this language consist of rectangles that represent variables, constants, instances of function blocks, and functions. All of them are connected with lines as shown in Fig. 1.

Graphical languages benefit from visual programming. Their features include legibility of diagrams, easiness of program understanding or modification, and a possibility of attaching printouts directly to the documentation. Engineering tools (e.g. Beckhoff TwinCAT [2], CoDeSys [3], Control Builder F [4]) contain graphics editors that allow users to design programs graphically. They support drawing and

978-83-60810-53-8/$25.00

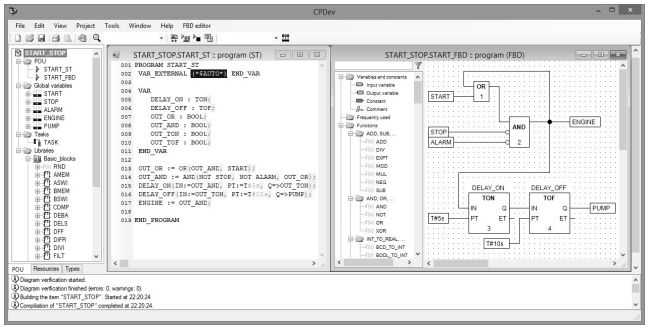

Fig. 2. CPDev IDE with editors of ST and FBD languages.

updating connections between blocks automatically, using some proprietary solutions, without any clues of the used algorithms and implementation details. Development of the CPDev engineering environment required another solution, thus the authors proposed using the A* algorithm with some adjustments and tuning of parameters, as described later.

CPDev (Control Program Developer) is an engineering environment [5] developed in the Department of Computer and Control Engineering at Rzeszow University of Technology (Poland). It can be used for programming PLC, and PAC controllers, mini-DCSs [6], and secure NCS systems [7], according to IEC 61131-3 standard [1]. The CPDev environment is universal and generates code in the form that can be executed on various target platforms, including AVR, ARM, x86, and FPGA. It is achieved by using a virtual machine executing an intermediate code [8]. The environment is open for controller constructors and engineers that can implement low-level procedures and add them to the virtual machine. Developers using CPDev can create own libraries with POUs and reuse them in multiple projects. CPDev consists of several parts, including integrated development environment (Fig. 2), compilers, translators, configuration tools, testing application [9], and visualization mechanism [10]. CPDev has been applied for ship control and monitoring systems from Praxis Automation Technology B.V. (Leiderdorp, the Netherlands) [11] and for small PAC controller in measurement-and-control systems from LUMEL S.A. (Zielona Gora, Poland) [12].

All kinds of POUs, i.e. programs, function blocks, and functions, can be created using CPDev graphics editors [13]. They are equipped with typical functionalities such as basic edition operations (adding, moving, copying, pasting), translation to ST code, conversion to XML format, and printing accordingly to a template. The editors provide also an execution mode to run programs with support of tracing variable values and breakpoints.

Automatic connection finding is one of the most important features. It generates a connection between two elements on the diagram (variables, functions, or function blocks) automatically. Therefore, the user can focus on implementation of the control software, without paying special attention to connections. In CPDev graphics editors the lines are drawn automatically, just after selecting the beginning and the end of the connection. The problem can be interpreted as finding a path in a graph. However, some simplifications and modifications have to be done due to short time requirement.

III. Path searching in a graph

The problem of finding the shortest path in a graph is one of typical problems in discrete mathematics [14]. The classical approach, like the Dijkstra algorithm [15], focuses on examining all possible paths to find the shortest one. However, such a solution is not performance efficient. As an extension to the classical approach, a number of BFS (*Best-First Search*) algorithms have been proposed. For the problem specified above, the authors have chosen the A* algorithm [16], which combines traditional approach (similar to Dijkstra's) and heuristic one involving a metric. The A* algorithm requires estimation of a distance between the current node and the target for every node in a graph. Such a distance must be predicted in an optimistic way, i.e. real distance cannot be shorter than estimated. Numerous modifications of A* algorithm have been described [17], as well as applications including finding optimal routing in wireless sensor networks [18], [19], shortest road on a map [20], or even solving motion correspondence problem in computer vision [21].

Basically, the A* algorithm in every step tries to go the most promising way, i.e. chooses such a neighbor node that is close both to the current track and to the target node. At first, estimated distance from the target is calculated for every node, denoted as *H score*. While traversing the graph, real distances from the start node to neighbors of the current one are evaluated. The *G score* for every node reflects the distance from the start point via the shortest path already examined. The G score for every node can be updated later if a shorter path to this node is found. The *F score* is a sum of G and H scores. It represents estimated cost of using this node while directing to the target. In every step a node with the lowest F score from so-called *open set* (containing nodes to be traversed) is selected, and added to the *closed set* (nodes already traversed).

Implementation of such an algorithm requires consideration of some data structures for these sets. Ordinary lists or hashtables can be used, but heaps or binary search trees (simple BST or self-balancing, e.g. red-black trees RBT) [22] usually turn out better. Selection of a node with the minimal F score from the open set (which is a priority queue) is one of the most time consuming parts in A* algorithm. The worst case computational complexity of such an operation is $O(n)$ for tables, $O(\log n)$ for balanced BST or RBT, and $O(1)$ for min heap. Choosing F score as a key for a complex data structure improves performance, but checking if the set already contains the node, by using structure with coordinates of the node as a key, is more convenient. Similarly, adding or removing a node from complex data structures, as well as updating their F score (and position in the structure) takes significantly more time. Thus, choosing the most efficient structure, as well as its key, in a given case requires some tests, as shown in the following section.

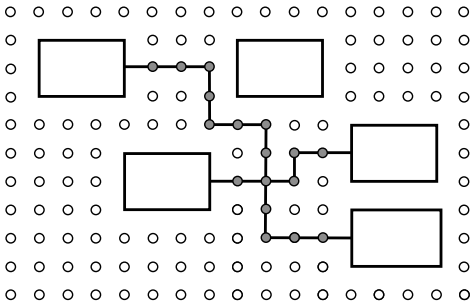

Fig. 3. Generated graph nodes.

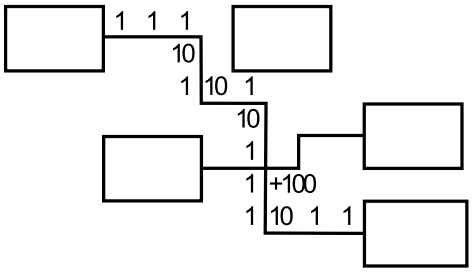

Fig. 4. Calculation of the path cost.

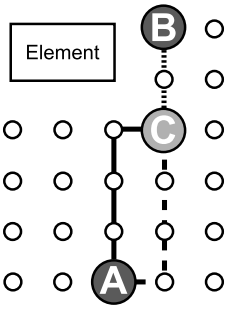

Fig. 5. Variants of the path between A and B nodes.

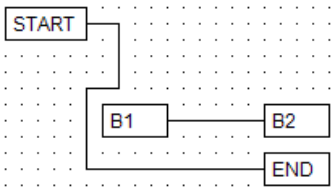

Fig. 6. Connections found with line cost intersection 50.

Another possibility for closed set implementation is addition of marks indicating whether the node has been already traversed. Such marks are included in internal class representation of the nodes. Thus, an additional data structure is unnecessary, which simplifies the implementation.

Finding an appropriate connection between elements in FBD diagrams can be considered as solving the shortest path problem in a graph. The connection should meet the following requirements:

- be found every time if elements are placed on the diagram correctly,
- pass round elements placed earlier,
- limit a number of intersections with other lines,
- change direction rarely,
- support additional margin around elements.

In our solution such a graph is created automatically. The nodes are simply diagram grid points, as shown in Fig. 3. Elements placed on the diagram (variables, functions, and function blocks) remove some nodes from the graph. Arcs connect the nodes vertically and horizontally, according to the neighborhood of the grid points. Initially weights of all arcs are equal. The start and end nodes (in the graph) are defined by positions of the elements, which should be connected.

A structure of the graph, which nodes represent grid points, is suitable for searching the shortest path using A* algorithm. The Manhattan (taxicab) distance is a natural choice for heuristic function to estimate a connection cost in such a case. The distance is calculated according to the formula $d(n_1, n_2) = |x_1 - x_2| + |y_1 - y_2|$, where $n_i = (x_i, y_i)$ denotes node i with coordinates x_i and y_i. Among other metrics, that could be also considered, the maximum (Chebyshev) one seems also promising, calculated as $d(n_1, n_2) = \max(|x_1 - x_2|, |y_1 - y_2|)$.

In order to find an optimal connection some additional conditions must also be considered while analyzing the diagram. Firstly, connection lines can not overlap, and can cross only when necessary. Overlapping can be easily solved by removing the arcs in the graph, which connect nodes representing fields that are already parts of any line. Crossing can be reduced by adding a high penalty for the G score. Secondly, lines in the diagram should go straight and change direction rarely. It can be achieved by setting an appropriate penalty on the G score, depending on a direction of actual path. An example of path cost calculation according to these rules is shown in Fig. 4.

It is worth mentioning, that G score rules sometimes lead to calculating different costs for a path between two nodes, depending on the previous path. Such a case is shown in Fig. 5. Considering the paths between A and B nodes, the algorithm can choose either one marked by a solid line or by dashed. In both cases the connection crosses C node. Two paths between A and C have the same cost, but the cost of the path between C and B is different, depending on the previous path. If the solid line between A and C is chosen, the connection changes direction in C towards B, thus some penalty for the G score is added.

A method for adding nodes to the structure representing the open set is another issue. In every step one node with the lowest F score in the open set is selected, but sometimes there may be many nodes with the same minimal F score. Selection of the node in such a case depends on the order of adding nodes in previous steps. There are several possibilities to be considered. New nodes can be added before or after previous ones, and they can be unsorted or sorted by direction. Such modifications affect searching time and shape of resulting path.

The costs of line intersection and direction change have

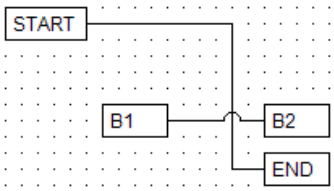

Fig. 7. Connections found with line cost intersection 5.

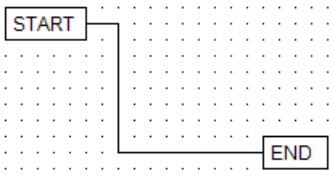

Fig. 8. Connection found with Manhattan metric.

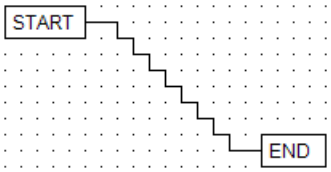

Fig. 9. Connection found with Maximum metric.

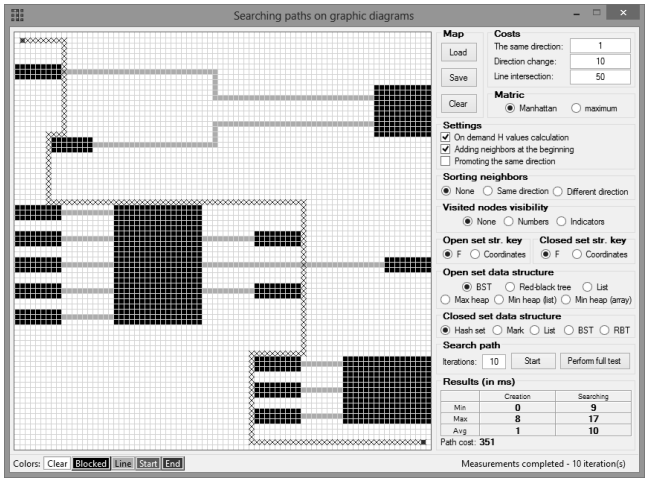

Fig. 10. The application for testing the mechanism of connection finding.

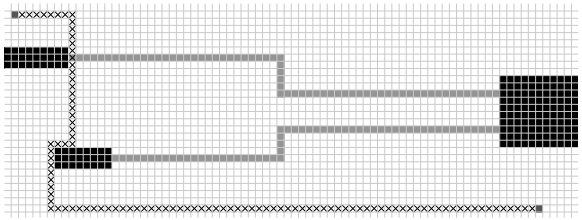

Fig. 11. The simple map for testing the mechanism of connection finding.

also an impact on the final path (Fig. 6, 7). If penalty for crossing a line is huge (as in Fig. 6), intersections will be avoided, but the path will go by roundabout way. The metric influences a shape of the path as well (Fig. 8, 9). For maximum metric the algorithm tries to minimize the distance in one of coordinates, the longest first. Such a metric can lead to generating ”stairs shaped” connection (Fig. 9) when a penalty for changing direction is low. Selection of appropriate cost values to find reasonable compromise in general case is not trivial.

IV. Test software and performance results

A. Test software

Test results have been measured using a dedicated software with user interface shown in Fig. 10. That makes it possible to adjust settings and perform measurements for various combinations of parameter values. All tests are run on the map implemented as a matrix of integer values. They represent current states of fields: *start*, *end*, *blocked*, *line*, or *clear*. Available settings include:

- cost values (e.g. direction change or line crossing)
- open set data structure (BST, RBT, list, max heap, and min heap)
- closed set data structure (hash set, mark, list, BST, and RBT)
- keys for open and closed set structure (F value or coordinates)

The testing application consists of two parts, i.e. map and settings panel. In the example from Fig. 10, the map presents a connection found by the mechanism between the start element (top-left) and the end (bottom-right). Some other elements, like blocks and variables from diagrams, are shown as black rectangles. They are connected by gray lines.

The measurements have been performed for a number of data sets, including simple and complex (Fig. 11, 12–15, respectively). The results have been calculated for various metrics, costs, structures, and keys for open and closed sets.

B. Simple map

The simple example from Fig. 11 consists of three blocks. Two of them represent input variables and the third one is an instance of function block. There are two lines from inputs to the block. The algorithm has to find a path between the start element (top-left) and the end (bottom-right) one. It is clear that for specified values of parameters the algorithm tries to avoid crossing lines, even if it requires to change direction and apply a longer path.

Improving performance is one of the most important reasons for testing the mechanism of finding connections. The results are presented in Table I. Following abbreviations have been assumed: *F* indicates F value, *C* – coordinates, *HS* – hash set structure, *Heap* – min heap structure, *Man* – Manhattan metric, and *Max* – Maximum metric. Cost is equal to 191 in all cases. Tests have been performed on PC with 2,5 GHz processor. Even for the simple example (Fig. 11) required times are different and depend on parameters, mainly on open and closed

TABLE I
RESULTS OF TESTING THE MECHANISM OF FINDING CONNECTIONS FOR THE SIMPLE MAP.

#	Open set		Closed set		Metr.	Required time [ms]
	Str.	Key	Str.	Key		
1	RBT	F	Mark	-	Man	0
2	BST	F	Mark	-	Man	1
3	BST	F	Mark	-	Max	1
4	RBT	F	Mark	-	Max	1
5	BST	F	HS	any	Man	1
6	RBT	F	HS	any	Man	1
7	Heap	F	Mark	-	Man	1
8	BST	F	BST	C	Man	3

10	BST	F	RBT	F	Man	20
11	Heap	F	HS	F	Max	45
12	RBT	F	List	F	Max	64
13	List	F	List	C	Max	74
14	BST	F	BST	F	Man	118
15	List	C	BST	F	Man	125
16	Heap	C	BST	F	Max	174

set structures, as well as their keys. The metrics do not have such an important impact. The mechanism allows to calculate the path in the fastest way by using RBT or BST structures of the open set, and mark or hash set as a structure of the closed set (Table I, rows 1-6). The performance is significantly decreased by using a list or min heap as a structure of the open set, and BST, RBT, or list as a structure of the closed set (Table I, rows 15-16).

As mentioned in Section III, the results can be explained by internal concepts of various data structures and their computational complexity. In case of the open set it is important to select data structure that performs well while adding or removing an item, checking whether the structure contains specified item, or selecting an element with minimum value. For the closed set, only two operations should be well supported, i.e. adding an item and checking whether the structure contains specified item. Choosing a suitable combinations of structures for the open and closed sets significantly increases overall performance of the mechanism.

C. Complex map

The complex map (Fig. 12–15) consists of sixteen elements from the FBD diagram, i.e. ten input variables, three output variables, and three instances of function blocks. All of them are connected in more complicated way than before. The performance results for finding connections are presented in Table II. Cost is equal 351 in all cases.

The results confirm conclusions from the previous example. Again, the mechanism performs well with RBT or BST as a structure of the open set (Fig. 16), and with mark or hash set as a structure of the closed set (Fig. 17). However, differences between required times are higher, because significantly more operations must be performed while searching. In this case, the best combination of parameters finds the connection in 1 ms, but the worst in 781 ms.

TABLE II
RESULTS OF TESTING THE MECHANISM OF FINDING CONNECTIONS FOR THE COMPLEX MAP.

#	Open set		Closed set		Metric	Required time [ms]
	Str.	Key	Str.	Key		
1	RBT	F	Mark	-	Man	1
2	BST	F	Mark	-	Man	2
3	BST	F	HS	F	Man	3
4	RBT	F	HS	F	Man	3
5	Heap	F	Mark	-	Man	3
6	BST	F	RBT	C	Man	5
7	Heap	F	RBT	F	Max	103
8	Heap	F	BST	F	Max	781

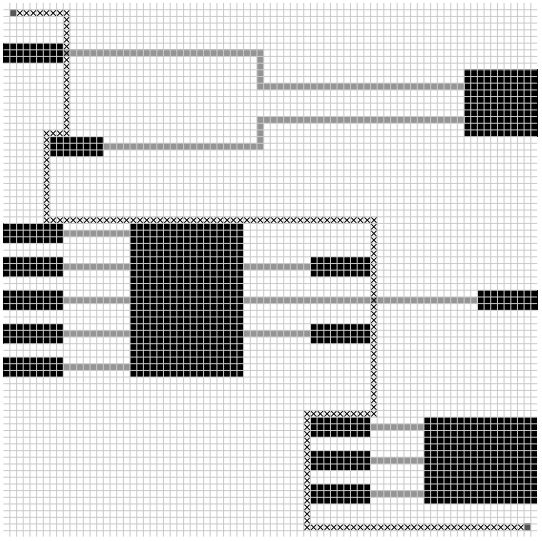

Fig. 12. Connections found for the Manhattan metric and 50 as a cost of line intersection.

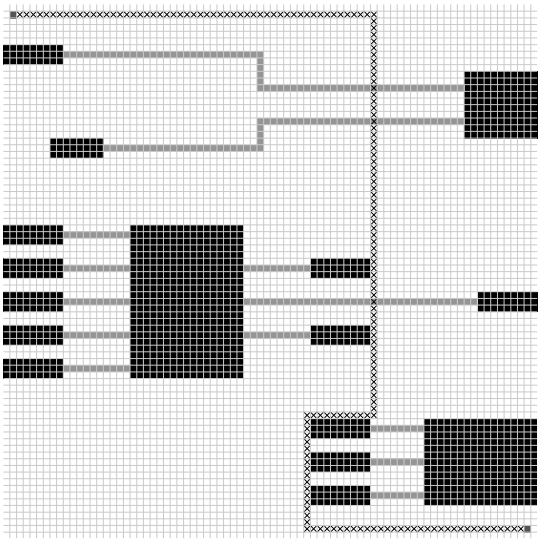

Fig. 13. Connections found for the Manhattan metric and 20 as a cost of line intersection.

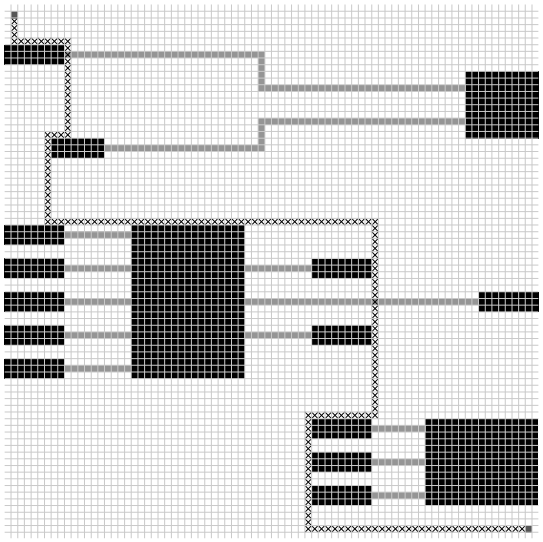

Fig. 14. Connections found for the Maximum metric and 50 as a cost of line intersection.

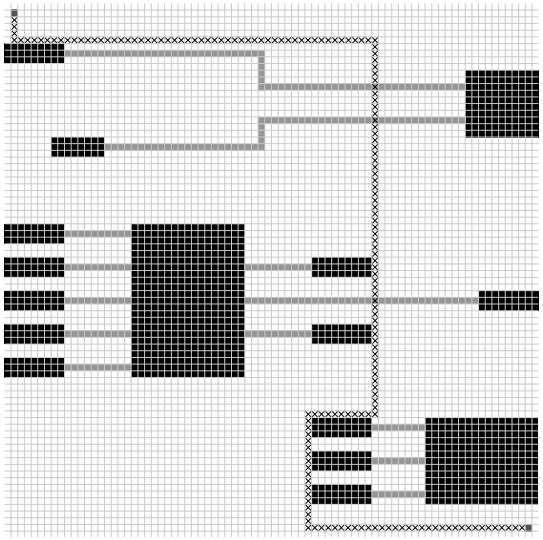

Fig. 15. Connections found for the Maximum metric and 20 as a cost of line intersection.

Using a proper open set structure (for fixed closed set structure) improves performance even a few times (Fig. 16). The difference is also seen in case of mark and hash set as structures of the closed set (Fig. 17). The mark can lead up to 50% increase of performance. Choosing a key for the closed set structure also affects performance, but only in case of structures other than mark.

A comparison between four combinations of structures of open and closed sets (RBT or BST, mark or hash set), depending on the metric, is shown in Fig. 18. The difference in case of the complex map is not high between BST and RBT used as the open set. Performance for mark and hash set as structures of the closed set is also similar. There is a difference in average time required to find connection when

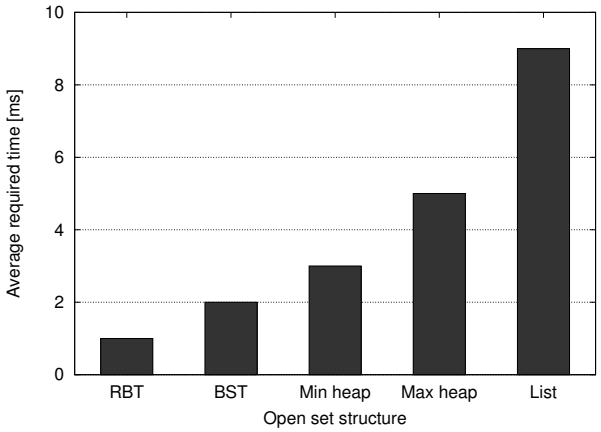

Fig. 16. Average required time for finding connection by open set structure (mark, F value as closed set structure and key, Manhattan metric).

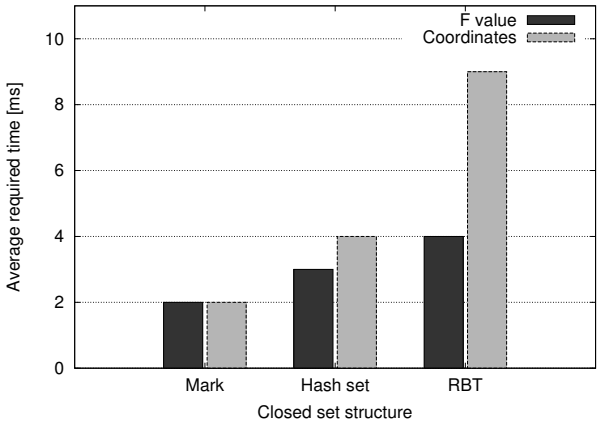

Fig. 17. Average required time for finding connection by closed set structure, open and closed set keys (BST as open set structure, Manhattan metric).

the mechanism uses Manhattan and maximum metrics. It is caused mainly by a different number of fields analyzed during searching. The difference is specific to the map.

Parameters have an impact not only on performance, but also on the path found. Depending on the metric and costs, it can change a direction more or less frequently, promote variants without crossing other lines, or even promote a specific direction. Differences are presented in Figs. 12–15 on a set of maps for the complex example.

The first connection (Fig. 12) is found for the Manhattan metric and 50 as a cost of crossing other lines. In this case the algorithm avoids crossings even by changing directions more frequently (see the top left part). In the second connection (Fig. 13) the cost of crossing is smaller and equals to only 20. It promotes crossing other lines instead of changing direction. Because of it, the first half of the connection differs significantly from the previous case. Similar conclusions can be made for the third and fourth connections (Figs. 14, 15), however, shape of the connection is different. The change

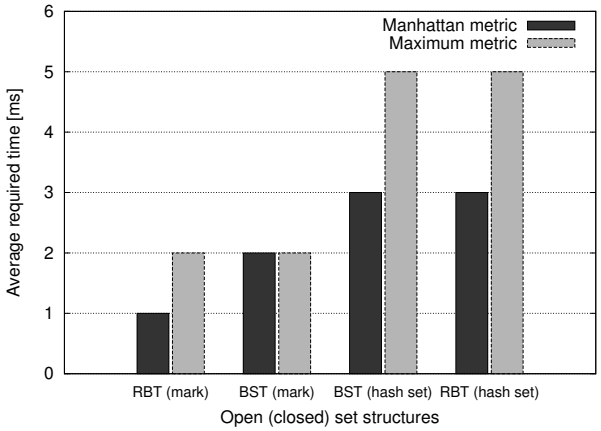

Fig. 18. Average required time for finding connection, depending on metric, open and closed set structures, with F values as keys.

is caused by the metric, either Manhattan (Figs. 12, 13) or maximum (Figs. 14, 15). The authors empirically found that values about 10-20 for direction change and 20-50 for line crossing give satisfactory results in case of FBD and LD diagrams.

V. Conclusion

The problem of finding a suitable path in a graph is typical in discrete mathematics. However, its application in FBD graphic diagrams to automatically find connections between elements requires some additional research and discussion. The mechanism meets a set of requirements which contain an execution in short time allowing to use on devices with limited resources. It supports a process of almost imperceptible updating and redrawing connections after moving any block on the diagram. Thus, the developer can easily adjust design of the diagram after creation of the first working version of POU. It can significantly increase legibility of the diagram and makes it easier to understand, modify, and maintain. Taken assumptions caused some modifications and tuning of the A* algorithm. As measured, values of parameters have significant impact on performance, length, and shape of the connection.

In the paper the authors considered some implementation details of A* algorithm, created a dedicated software for performance testing, and presented conclusions. The measurements indicate data structures that are efficient for the A* algorithm, and group of structures with performance problems. An impact on the shape of connection depending on path costs and metric is also described. All of these aspects are combined to tune properly the mechanism of finding connections in IEC 61131-3 Function Block Diagram editor implemented in the CPDev engineering environment.

***Abstract*—Through the last decades multigrid methods have been used extensively in the solution of large sparse linear systems derived from the discretization of Partial Differential Equations in two or three space variables, subject to a variety of boundary conditions. Due to their efficiency and convergence behavior, multigrid methods are used in many scientific fields as solvers or preconditioners. Herewith, we propose a new algorithm for N-body simulation, based on the V-Cycle multigrid method in conjunction with Generic Approximate SParse Inverses (GenAspI). The N-body problem chosen is in toroidal 3D space and the bodies are subject only to gravitational forces. In each time step, a large sparse linear system is solved to compute the gravity potential at each nodal point in order to interpolate the solution to each body and through the velocity Verlet method compute the new position, velocity and acceleration of each respective body. Moreover, a parallel version of the multigrid algorithm with a truncated approach in the parallel levels is utilized for the fast solution of the linear system. Furthermore parallel results are provided which depict the efficiency and performance for the proposed multigrid N-body scheme.**

I. Introduction

LET US consider the Partial Differential Equation (PDE) describing the gravity potential in a domain Ω, [19]:

$$\Delta\Phi = 4\pi G\rho, (x, y, z) \in \Omega \quad (1)$$

subject to Dirichlet boundary conditions

$$\Phi = 0, (x, y, z) \in \vartheta\Omega \quad (1.a)$$

where Ω denotes the region where the problem resides, $\partial\Omega$ is the boundary of the region, G is the Gravitational constant and ρ is the mass density in each nodal point computed by the mass of the neighboring bodies.

Applying the Finite Difference method, with the seven point stencil, for the PDE (1)-(1.a) results in solving a seven diagonal linear system,

$$A\varphi = f, \quad (2)$$

where A is a large sparse diagonally dominant symmetric matrix, f is the right hand side vector consisting of the forcing term and respective boundary conditions and φ is the gravity potential at each nodal point.

The linear system (2) derived from the discretization of the 3D PDE can be solved by the multigrid method. Multigrid methods have been used extensively, during the last decades, in a variety of scientific fields such as Computational Fluid Dynamics, Computational Economics and Partial Differential Equations, due to their near optimal computational complexity and convergence behavior, [3, 4, 5, 10, 15, 16, 17, 18, 21, 23, 24]. Multigrid methods are based on the observation that the low-frequency components of the error are not effectively damped by a stationary iterative method. However, the high frequency components of the error are quickly reduced towards zero within the first few iterations, [3, 4, 21]. In order to handle the low frequency components of the error, multigrid methods utilize a grid hierarchy consisting of coarser levels with higher mesh size (h) and by projecting the finer problem to the coarser levels the lower frequency components are becoming more oscillatory and can be damped efficiently by a stationary iterative solver. The vectors required in each level are transferred between the respective grid with the use of two operators: the prolongation and the restriction operator, which transfer vectors from coarser to finer grids and vice versa, [3, 4, 21]. The sequence in which the coarser grids are visited and the respective coarse grid corrections to the solution are obtained is referred to as the cycle strategy, [3, 4, 21]. A 3D Geometric multigrid hierarchy is depicted in Figure 1. In order to accelerate the convergence of the multigrid method the Dynamic Over / Under Relaxation (DOUR) scheme is used, [18], in conjunction with the GENeric Approximate SParse Inverse (GenAspI) matrix, as the smoother for the multigrid method, [8].

Approximate inverses have been used as preconditioners for various iterative schemes due to their inherent parallelism and convergence behavior, [5, 11, 12, 13, 20]. Moreover, approximate inverses have been used effectively in conjunction with the multigrid method for a variety of problems, [5, 9, 10, 14]. Recently, classes of Generic Approximate Inverses have been proposed, [8,14], that can handle any sparsity pattern of the coefficient matrix A, based on Incomplete LU factorization with zero fill-in. Unlike their predecessors, [11, 12, 13, 20], these Generic schemes are not limited by the structure of the coefficient matrix or the method used for the discretization and produce approximate inverses with sparsity patterns, based on Powers of Sparsi-

978-83-60810-53-8/$25.00

fied Patterns (PSM's), [6, 7], using adequate dropping strategies to further sparsify the initial sparsity pattern of the coefficient matrix A, thus leading to sparser more efficient approximate inverses. The GenAspI matrices are then computed using a modified procedure introduced in the GENeric Approximate Banded Inverses class (GenAbI), [14], according to an a priori known sparsity pattern. The GenAspI matrices are used as preconditioners in the damped Richardson scheme, in conjunction with the DOUR scheme, and V-cycle strategy to derive the GenAspI-MGV method which is used to obtain the gravity potential in each time step of the N-body simulation scheme proposed. The parallelization of the GenAspI-MGV method is performed with a new approach where the lower order levels are executed sequentially in order to avoid overhead in levels with low computational cost.

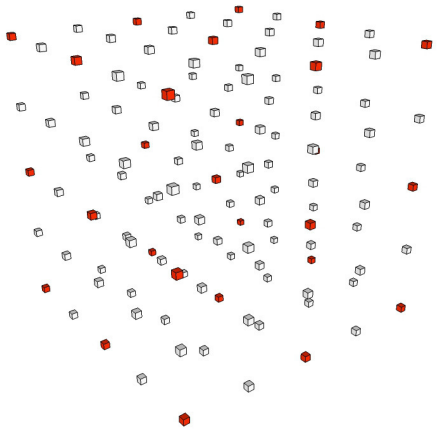

Fig. 1 Grid hierarchy of a three-dimensional PDE discretized with the Finite Differences method for mesh size h=1/2 (red points) and h=1/4 (red and white points).

The N-body simulation is a simulation of a dynamical system of particles, under the influence of, mainly the gravitational force. N-body simulations have become a fundamental tool in the study of complex physical systems, [19]. Starting from a basic physical interaction (e.g., gravitational, Coulomb) one can follow the dynamical evolution of a system of bodies, which represent the phase-space density distribution of the system. The greater the number of the particles used on the simulation results in more accurate and complete results, [19]. There are a lot of methods that can be used to calculate such kind of forces in a confined space. A direct approach to the problem called particle-particle simulation (P-P) assumes that on a simulation containing N bodies, there are N×(N-1) force pairs (Newtonian gravitation), [19]. This direct approach to the problem scales with $O(N^2)$ complexity, where N denotes the number of bodies, rendering the scheme restrictive for large values of particles.

Herewith, we propose a new scheme for computing the gravity potential and thus the forces in the bodies, using the Particle Mesh method and the GenAspI-MGV method to accelerate the solution of the linear system. The Particle Mesh method neglects the close interactions between particles and takes into account only the dynamics of superparticles consisting of a great number of particles. The density of these masses is then added according to weights computed from the distance of each node to the grid points surrounding each respective particle resulting in the rhs vector of the linear system (2). The assignment of the respective weights in each nodal point is performed using the Cloud in Cell (CIC) method, [19]. The linear system is solved using an iterative method and the potential is computed at the cell centers. Finally, by integrating the equations of motion through the Verlet integrator, [22], the new position of each particle is computed. Repeating the aforementioned process leads to the simulation of the system of particles. The Particle Mesh method is efficient due to the fact that the nodal points are, in general, less than the number of particles and thus a large number of pairing forces is not computed. Moreover, the low computational complexity of the mutligrid method utilized in each time step for the solution of the linear system renders the algorithm efficient especially for increasing numbers of particles.

The proposed N-body algorithm is parallelized using OpenMP. OpenMP is a collection of directives available for a variety of languages including C/C++/Fortran used to parallelize programs for Symmetric Multi-Processing Units.

Finally, numerical results on the performance and convergence behavior of the proposed GenAspI-MGV schemes are given for solving three-dimensional N-body simulation problems.

II. Multigrid Method In Conjunction With Generic Approximate Sparse Inverses

The multigrid method, especially in the last decades, is used extensively by the scientific community in the fields of computational physics, computational fluid dynamics and financial engineering due to its near-optimal complexity and its convergence behavior, [3, 4, 5, 9, 14, 15, 16, 17, 21, 23, 24].

Multigrid methods are composed by four distinct components: Smoothers, Prolongation and Restriction operators and Cycle strategy. The smoothers are an essential component of the multigrid algorithm and are used to obtain the respective corrections for the solution on each level. Smoothers are stationary iterative methods that can be described by the following relation, [4,5,21,23],

$$x_l^{(k+1)} = x_l^{(k)} + \omega M_l\left(b_l - A_l x_l^{(k)}\right),\ k = 0,1,2,.... \quad (3)$$

where l denotes the level in which the smoother is applied, M_l is the preconditioner to the Richardson's iterative method and ω is the damping parameter with values between 0 and 2. In case where the $M_l=D_l^{-1}$, the iterative scheme (3) results in the Damped Jacobi method, [4, 21, 23]. Substituting $M_l = \left(M_{lfill}^{drptol}\right)_l$, where $\left(M_{lfill}^{drptol}\right)_l$ is the l-th level Generic Approximate Sparse Inverse with lfill levels of fill and drptol drop tolerance results in the proposed parametric smoothing scheme. The Generic Approximate Sparse Inverse

(GenAspI) is inherently parallel and can be adjusted by modifying the drptol and lfill parameters.

A. Generic Approximate Sparse Inverse smoothing

Let us consider the ILU(0), [1], factorization of a matrix A,

$$\mathrm{A=LU+E} \tag{4}$$

where E is the error matrix and L and U are the lower and upper factors of the matrix A, retaining the same profile. In order to compute the GenAspI matrix a sparsity pattern must be known a priori. The approximate inverse sparsity pattern is computed through Powers of Sparsified Matrices (PSMs) of the filtered version of the coefficient matrix, [6,7]. Let the sparsified version of the matrix A be described as follows,

$$\tilde{A}_{\mathrm{ij}}=\begin{cases}1,\mathrm{i==j\ and}\ \left|\left(D^{-1/2}\mathrm{AD}^{-1/2}\right)_{\mathrm{i,j}}\right|>\mathrm{drptol}\\ 0,\mathrm{otherwise}\end{cases} \tag{5}$$

where D is a diagonal matrix such that

$$D_{\mathrm{ii}}=\begin{cases}|A_{\mathrm{ii}}|,|A_{\mathrm{ii}}|>0\\ 1,\mathrm{otherwise}\end{cases} \tag{6}$$

and drptol is the so called drop tolerance, [6,7]. The coefficient matrix A is sparsified with the process described by equation (5), which denotes the normalization of each element with the diagonal element, [6,7]. Then each element is compared in absolute value against a given drop tolerance in order to withhold or discard the element. The sparsification process is succeeded by the augmentation of the sparsity pattern by raising it to powers denoted by lfill, [6,7]. The remaining nonzero elements of the coefficient matrix represent the strong connections (neighbors) of each element, by considering the equivalent graph of the matrix, [6,7]. The k–th row of the ℓ –th level sparsity pattern $\tilde{\mathrm{A}}^{\ell}$ can be computed as $\tilde{\mathrm{A}}^{\ell}_{\mathrm{k,:}}=\tilde{\mathrm{A}}_{\mathrm{k,:}}\tilde{\mathrm{A}}^{\ell\text{-}1}$, which denotes that the k–th row of the $\tilde{\mathrm{A}}^{\ell}$ pattern is composed by "fusing" the non–zero indices of columns in the rows of $\tilde{\mathrm{A}}^{\ell-1}$ corresponding to the nonzero columns of the k–th row of the sparsified coefficient matrix $\tilde{A}$, [6,7]. By increasing the levels of fill the approximate inverse tends to the exact inverse of the linear system. The algorithm for the computation of an approximate inverse sparsity pattern is given in [6,7,8]. More information concerning the approximate inverse sparsity patterns can be found in [6,7].

The GenAspI matrix is computed, according to the sparsity pattern defined by the previous procedure, by solving recursively the following system, [8],

$$UM^{lfill}_{drptol}=I\ \ \text{and}\ \ M^{lfill}_{drptol}L=0 \tag{7}$$

where L and U are the lower and upper triangular factors computed by the ILU(0), [1], factorization, (4). The GenAspI algorithm has been presented in [8]. The complexity of the GenAspI algorithm in terms of its nonzero elements and its order can be shown to be $\approx(3/4)\left(nnz(M)^2/n\right)-(3/8)\left(nnz(M)\right)+(5/8)n$ multiplications and $\approx(3/4)\left(nnz(M)^2/n\right)-(3/2)\left(nnz(M)\right)+(3/4)n$ additions, [8].

The GenAspI matrix could be used in conjunction with the iterative scheme (3) in order to derive a parametric parallel smoother. The proposed smoother is inherently parallel because the smoothing procedure is limited to matrix – vector multiplication while complex orderings and parallel algorithmic schemes are avoided. In order for a smoother to be effective the smoothing property must be satisfied, [4, 15, 16, 17, 21, 23]. The smoothing property has been proven for the Optimized Banded Generalized Approximate Inverse (OBGAIM) matrix, [9]. Equivalently, the smoothing property can be proven for the GenAspI matrix. Moreover, sharp estimates for the convergence of multigrid algorithms, for generalized smoothing, have been proven by Bank and Douglas in [2]. Furthermore, Hackbusch has proven the optimal values for the damping parameter for various iterative schemes and various PDEs, [15, 16, 17]. It can be observed that the resulting scheme requires a damping parameter ω, which cannot be defined optimally for every problem. In order to tackle the problem of the value of the damping parameter, the Dynamic Over/Under Relaxation (DOUR) algorithm is used, [18]. The DOUR scheme is predictor – corrector scheme that dynamically determines the value of ω to ensure convergence of the smoothing scheme.

Let us consider the equivalent expression for the relaxation scheme (3),

$$x_l^{(\mathrm{k+1})}=\mathrm{x}_l^{(k)}+\omega\left(S\left(x_l^{(k)}\right)\text{-}\mathrm{x}_l^{(k)}\right) \tag{8}$$

where $S\left(x_l^{(k)}\right)=\mathrm{x}_l^{(k)}+\left(M^{\mathrm{lfill}}_{\mathrm{drptol}}\right)_l\left(f_l\text{-}\mathrm{A}_l x_l^{(k)}\right)$.

By applying the predictor–corrector scheme, [18], we have

$$\tilde{x}_l^{(k)}=\mathrm{x}_l^{(k)}+\omega\left(S\left(x_l^{(k)}\right)\text{-}\mathrm{x}_l^{(k)}\right) \tag{9}$$

$$x_l^{(\mathrm{k+1})}=\mathrm{x}_l^{(k)}+\kappa\left(\Delta x_l^{(k)}\right),\ \Delta x_l^{(k)}=\tilde{x}_l^{(k)}\text{-}\mathrm{x}_l^{(k)} \tag{10}$$

where

$$\kappa=\frac{\left\langle \Delta x_l^{(k)},\mathrm{b}_l\text{-}\mathrm{A}_l\tilde{x}_l^{(k)}\right\rangle}{\left\langle \Delta x_l^{(k)},\mathrm{A}_l\Delta x_l^{(k)}\right\rangle} \tag{11}$$

From (8), (9), (10) and (11) we obtain

$$x_l^{(\mathrm{k+1})}=\mathrm{x}_l^{(k)}+\omega_e\left(S\left(x_l^{(k)}\right)\text{-}\mathrm{x}_l^{(k)}\right),\ \omega_e=\omega(1+\kappa) \tag{12}$$

where ω_e is the effective relaxation parameter and equation (12) is the proposed iterative scheme, [18]. The equation (12) denotes a two stage non-stationary approximate inverse smoother. Further information and convergence analysis of the DOUR algorithm were given in [18].

B. Transfer Operators

The transfer operators are special operators that are used to transfer vectors from coarser to finer grids and finer to coarser grids. The transfer operators for the multigrid method are the restriction and prolongation operators. The

restriction operator is used to transfer vectors from finer to coarser grids. An effective choice for the restriction operator is the full-weighting, which for the three-dimensional case, [21], can be expressed by the following stencil,

$$R=\frac{1}{64}\left[\begin{bmatrix}1&2&1\\2&4&2\\1&2&1\end{bmatrix}^{2h}\begin{bmatrix}2&4&2\\4&8&4\\2&4&2\end{bmatrix}^{2h}\begin{bmatrix}1&2&1\\2&4&2\\1&2&1\end{bmatrix}^{2h}\right]_h$$

It can be observed that both for the two-dimensional and three-dimensional case the elements of the coarse vector are the weighted average of their neighbors in the finer grid. The prolongation operator is an interpolation procedure used to transfer vectors from coarser to finer grids. An effective choice for the prolongation operator is the tri-linear interpolation. For three-dimensional problems the tri-linear interpolation can be expressed by the following stencil, [21]

$$\mathrm{P}=\frac{1}{16}\left[\begin{bmatrix}1&2&1\\2&4&2\\1&2&1\end{bmatrix}^{\mathrm{h}}\begin{bmatrix}2&4&2\\4&8&4\\2&4&2\end{bmatrix}^{\mathrm{h}}\begin{bmatrix}1&2&1\\2&4&2\\1&2&1\end{bmatrix}^{\mathrm{h}}\right]_{2\mathrm{h}}$$

The full-weighting operator and the tri-linear interpolation operator are related through the Galerkin condition $[P]=c[R]^T$, thus simplifying the mapping on the data, [4, 21]. Transfer operators occupy about 30% of the total computational work of the multigrid algorithm, thus choosing higher order interpolation schemes may lead to excessive computational cost at no extra gain in the convergence behavior, [4, 21]. The prolongation and restriction operators for the proposed schemes are in sparse matrix representation and thus the transfer operation between the levels is limited to matrix "times" vector multiplication and their parallelization is covered by the parallelization of the matrix-vector multiplication. Further information concerning the transfer operators can be found in [3, 4, 21, 23].

C. Cycle Strategy

The cycle strategy is the last component of the multigrid method. The cycle strategy refers to the sequence in which the grids are visited and the respective corrections are obtained, [4,21,23]. The most commonly used cycle strategy is the V-Cycle where the method descends to coarser level executing ν_1 smoother iterations in each level and then the method ascends executing ν_2 iterations in each level. The V-Cycle strategy is depicted in Figure 2.

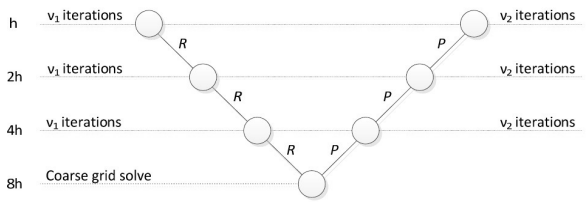

Fig. 2 The multigrid V – Cycle for four levels with ν_1 pre-smoothing iterations and ν_2 post-smoothing iterations.

The V-Cycle is parallelized only in the higher order levels to ensure the efficiency of the scheme, because lower order levels possess computational effort comparable to the parallelization overhead produced during the procedure of creating and detaching threads present in the parallel computation. Thus, levels with many nodes are computed in parallel using multiple threads, however levels with lower order are executed sequentially. As the number of levels is increased the sequential part is occupying lesser computational effort compared to higher order levels, thus increasing the speedup and efficiency of the proposed scheme.

The Parallel truncated V-Cycle multigrid algorithm with GenAspI parallel smoothing is the following, [4,21,23],

$$v^h \leftarrow \mathrm{MGV}\left(A^h,\left(M^{\mathrm{lfill}}_{\mathrm{drptol}}\right)^h,\mathrm{v}^h,\mathrm{f}^h,\mathrm{l}\right) \quad (13)$$

if l is the coarsest level

$$\text{relax}\left(A^{\mathrm{lh}},\left(M^{\mathrm{lfill}}_{\mathrm{drptol}}\right)^{\mathrm{lh}},\mathrm{v}^{\mathrm{lh}},\mathrm{f}^{\mathrm{lh}}\right)\ \nu_3\ \text{times} \quad (14)$$

else

if order (n) large enough

where ν_3 denotes the iterations for the inexact solution on the coarsest level. The prefix "P" denotes the parallel version of the method used. More information concerning the V-Cycle strategy as well as more Cycle schemes can be found in [3,4,21,23].

III. Particle Mesh Method Based On Multigrid Iterative Scheme

The Particle Mesh method (PM), introduced by Hockney in [19], significantly reduces the computational cost of N-body simulation algorithms in cosmological simulations of large scale structure formations. The PM method is based on the computation of the forces of the so-called "superparticles", which are composed by large formations of smaller particles and react together through their gravitational force as a whole.

In the PM method each particle contributes to the density of the concentrated mass along the grid points. Thus, each particle contributes to the neighboring points of the mass by a fraction analogous to the distance of the body from the surrounding nodes. The most commonly known method for adding the contribution of each body to the density of mass in the region is the Nearest Grid Point (NGP), [19]. The NGP method, however, increases the overall error of the PM scheme, because bodies inside a single cell share the same acceleration and force without considering the position of the particle. In order to decrease the computational error introduced during the discretization or the interpolation, the multilinear interpolation is used, namely Cloud in Cell (CIC), [19]. The Cloud In Cell method is used to interpolate the contribution of mass to every nearby grid point and raises significantly the accuracy of the computations. For the computation of the mass density of a particle with mass m_p located at (x_p, y_p, z_p) the Cloud In Cell (CIC) method is used and the respective mass densities for the eight surrounding grid points are given by equations (27), [19].

The grid points where each respectable mass contributes are depicted in Figure 3.

Let us consider the PDE (1) subjected to Dirichlet boundary conditions (1.a), discretized with the Finite Differences method and solved with the parallel GenAspI-MGV method. The solution of the resulting linear system provides the gravity potential in each point of the mesh.

$$\begin{aligned}
\rho_{i,j,k} &= \frac{m_p}{h^6}(h-\Delta_{pi})(h-\Delta_{pj})(h-\Delta_{pk}) \\
\rho_{i,j,k+1} &= \frac{m_p}{h^6}(h-\Delta_{pi})(h-\Delta_{pj})(\Delta_{pk}) \\
\rho_{i,j+1,k} &= \frac{m_p}{h^6}(h-\Delta_{pi})(\Delta_{pj})(h-\Delta_{pk}) \\
\rho_{i,j+1,k+1} &= \frac{m_p}{h^6}(h-\Delta_{pi})(\Delta_{pj})(\Delta_{pk}) \\
\rho_{i+1,j,k} &= \frac{m_p}{h^6}(\Delta_{pi})(h-\Delta_{pj})(h-\Delta_{pk}) \\
\rho_{i+1,j,k+1} &= \frac{m_p}{h^6}(\Delta_{pi})(h-\Delta_{pj})(\Delta_{pk}) \\
\rho_{i+1,j+1,k} &= \frac{m_p}{h^6}(\Delta_{pi})(\Delta_{pj})(h-\Delta_{pk}) \\
\rho_{i+1,j+1,k+1} &= \frac{m_p}{h^6}(\Delta_{pi})(\Delta_{pj})(\Delta_{pk})
\end{aligned} \tag{27}$$

The gravity potential is acquired from the solution of the linear system and the acceleration g is computed by the following equation, viz.

$$g = -\nabla\Phi = -\left(\frac{\partial\Phi}{\partial x}, \frac{\partial\Phi}{\partial y}, \frac{\partial\Phi}{\partial z}\right) \tag{28}$$

The computation of the acceleration in the center of the cells is commencing by using centered differences to retain the accuracy of the computed results. For the x-direction the acceleration can be computed by the following equation,

$$\frac{\partial\Phi}{\partial x} \approx \frac{\Phi_{i+1,j,k} - \Phi_{i-1,j,k}}{2\mathrm{h}} + O\left(h^2\right) \tag{29}$$

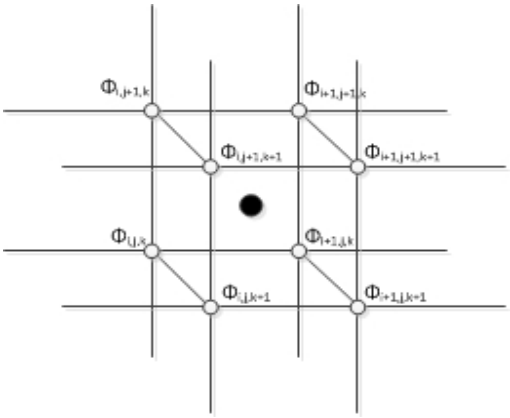

Fig. 3 Neighboring points in a three-dimensional cell of mesh size h.

The acceleration in the centers of the cells is interpolated back to the particles using the CIC method. Applying the CIC method for a particle in the three-dimensional space results in the following formula for the acceleration, [19],

$$\begin{aligned}
g_p = {} & \kappa_1 g_{i,j,k} + \kappa_2 g_{i,j,k+1} + \kappa_3 g_{i,j+1,k} + \kappa_4 g_{i,j+1,k+1} \\
& + \kappa_5 g_{i+1,j,k} + \kappa_6 g_{i+1,j,k+1} + \kappa_7 g_{i+1,j+1,k} \\
& + \kappa_8 g_{i+1,j+1,k+1}
\end{aligned} \tag{30}$$

where

$$\begin{aligned}
\kappa_1 &= (h-\Delta_{pi})(h-\Delta_{pj})(h-\Delta_{pk}) \\
\kappa_2 &= (h-\Delta_{pi})(h-\Delta_{pj})(\Delta_{pk}) \\
\kappa_3 &= (h-\Delta_{pi})(\Delta_{pj})(h-\Delta_{pk}) \\
\kappa_4 &= (h-\Delta_{pi})(\Delta_{pj})(\Delta_{pk}) \\
\kappa_5 &= (\Delta_{pi})(h-\Delta_{pj})(h-\Delta_{pk}) \\
\kappa_6 &= (\Delta_{pi})(h-\Delta_{pj})(\Delta_{pk}) \\
\kappa_7 &= (\Delta_{pi})(\Delta_{pj})(h-\Delta_{pk}) \\
\kappa_8 &= (\Delta_{pi})(\Delta_{pj})(\Delta_{pk})
\end{aligned} \tag{31}$$

while the Δ operator denotes the difference between the two points as denoted by the subscripts.

The acceleration of each mass is subject to weights computed by the distances from the nodal points of the grids. To compute the final displacement of a body, the equations of motion have to be integrated. In this article the velocity Verlet integrator is utilized due to its low computational cost and $O(h^2)$ accuracy, [22]. The Verlet integration of the equations of motion leads to the following equations,

$$\vec{x}(t+\Delta t)=\vec{x}(t)+\vec{u}(t)\Delta t+\frac{1}{2}\vec{a}(t)\Delta t^2 \qquad (32)$$

$$\vec{u}(t+\Delta t)=\vec{u}(t)+\frac{1}{2}\left(\vec{a}(t)+\vec{a}(t+\Delta t)\right)\Delta t \qquad (33)$$

where $\vec{u}, \vec{a}, \vec{x}$ are the three-dimensional vectors of the velocity, the acceleration and the position, respectively. This process is repeated according to the chosen time step and the maximum time of the simulation. It should be noted that particles cannot escape from the domain because the region is forced to be toroidal. The parallelization of the method is simplified and based on loop level parallelism using OpenMP, because the proposed schemes are mainly composed of matrix-vector multiplications and vector-vector computations. Further information concerning the Particle Mesh method can be found in [19].

IV. Numerical Results

In this section the applicability and performance of the proposed scheme is demonstrated by simulating the 3D spaces with different numbers of particles.

The numerical tests were performed on a Dual Socket AMD Opteron Processor 6128 HE, with 16GB RAM, running Ubuntu Linux 12.04.1.

The domain chosen for the simulations was the unit cube. The time step for the method was set to 0.001 and the simulation was executed for 10 consequent time steps.

The 3D region chosen was 10 parsec in each direction and the masses of the bodies were chosen to be 10^{32} kg. These variables were normalized in order to model the system on the unit cube.

The termination criterion was set to $\|r_i\|<1e\text{-}10\|r_0\|$. The pre-smoothing and post-smoothing steps were set to $\nu_1=2$ and $\nu_2=2$. The drop tolerance for the computation of the GenAspI matrices was set to drptol=0.0. The method for lfill=1 presented the fastest performance and required 7 iterations to converge to the desired tolerance. The levels below n=343 were executed sequentially because the computational overhead exceeds the computational effort required in order to obtain the coarse grid corrections.

In Table 1, the overall performance of the designed simulation algorithm based on the GenAspI-MGV method for various numbers of bodies, various numbers of threads and various resolutions, is presented. In Table 2, the speedups of the designed simulation algorithm based on the GenAspI-MGV method for various numbers of bodies, various numbers of threads and various resolutions, are presented. In Table 3, the efficiency of the designed simulation algorithm based on the GenAspI-MGV method for various numbers of bodies, various numbers of threads and various resolutions, is presented.

It should be noted that the preprocessing cost of the designed simulation algorithm concerning the computation of the Generic Approximate Sparse Inverses for resolutions h=1/16 and h=1/32 was t_{pre}=0.030093 seconds and t_{pre}=0.248670 seconds respectively, which is several orders less than the computational time needed for the model problems rendering the method efficient by slightly enlarging the computational cost.

V. Conclusion

The proposed schemes were proven experimentally effective for various choices of bodies and resolutions. Additionally, it should be stated that the proposed scheme presented satisfactory scalability as the number of particles increases and resolution is refined. Research efforts are under way to improve the parallel performance of the method with new hybrid schemes. Moreover, new computational schemes that will enhance convergence behavior and accuracy of the simulation are under further research.

***Abstract*—When there is a need to store a sparse matrix into a file system, is it worth to convert it first into some space-efficient storage format? This paper tries to answer such question for the adaptive-blocking hierarchical storage format (ABHSF), provided that the matrix is present in memory either in the coordinate (COO) or in the compressed sparse row (CSR) storage format. The conversion algorithms from COO and CSR to ABHSF are introduced and the results of performed experiments are then presented and discussed.**

I. Introduction

SPARSE matrices are commonly present in computer memory in storage formats that provide high performance of the matrix-vector multiplication operation. Considering a generic sparse matrix without any particular pattern of its nonzero elements, such storage formats are usually not space-optimal [1]–[3]. If we need to store such a matrix in a file, we have two options:

1) either to store the matrix in its *in-memory storage format* (IMSF), in which is the matrix stored in a computer memory;
2) or to store it in some *space-efficient storage format* (SESF), which additionally requires to perform the conversion between these formats.

Question 1. *Which of these two options will take less time?*

The second option should result in a smaller file and hence its faster store operation. However, the price paid for that is the overhead of the conversion algorithm.

Let S_{IMSF} and S_{SESF} denote the amount of memory required to store a matrix in particular IMSF and SESF, respectively. The time that will be saved when storing the matrix in a file system in SESF instead of IMSF will be

$$t_{\text{saved}} = \frac{S_{\text{IMSF}} - S_{\text{SESF}}}{\text{file system I/O bandwidth}}. \quad (1)$$

Let further t_{overhead} denote the running time of the conversion algorithm between IMSF and SESF. Storing a matrix in SESF will pay off if $t_{\text{saved}} > t_{\text{overhead}}$.

The answer to Question 1 is especially important for high performance computing (HPC) applications where matrices are distributed among P processors of a massively parallel computer system (MPCS). Let L_{IMSF} and L_{SESF} denote the amount of memory required to store a local part of a matrix in IMSF and SESF, respectively, on a particular processor. If the distribution of matrix nonzero elements among processors is well-balanced, then $L_{\text{IMSF}} \approx S_{\text{IMSF}}/P$ and $L_{\text{SESF}} \approx S_{\text{SESF}}/P$, and we can rewrite (1) to

$$t_{\text{saved}} \approx \frac{L_{\text{IMSF}} - L_{\text{SESF}}}{\text{file system I/O bandwidth}} \times P. \quad (2)$$

As the size of a computational problem, and therefore the size of a given sparse matrix, varies, then:

- L_{IMSF} (and hence L_{SESF} as well) is more or less constant, since it is limited by the amount of physical memory available to a single processor on a given MPCS.
- $\boldsymbol{t_{\text{overhead}}}$ **is approximately constant**, since the IMSF-to-SESF conversion algorithm is executed independently by all processors on their local parts of the matrix (of size L_{IMSF}).
- The file system I/O bandwidth—at least its listed maximum value—is constant.
- The number of processors P varies.
- $\boldsymbol{t_{\text{saved}}}$ **varies**, according to (2), **proportionally to** $\boldsymbol{P}$.

Thus, we may expect that as the size of a computational problem grows, beyond some point it will be faster to store a sparse matrix to a file system in SESF instead of IMSF.

In this paper, we focus on situations where the IMSF is either the *coordinate* (COO) or the *compressed sparse row* (CSR) storage format [4, Section 3.4], [5, Section 4.3.1] and the SESF is the *adaptive-blocking hierarchical storage format* (ABHSF) [2]. These formats are introduced in more details in Section II. We have developed conversion algorithms from COO and CSR to ABHSF, which are presented in Section III. The experiments performed with these algorithms are then described and the results discussed in Section IV.

Note that within the context of this paper, by a *storage format* we mean the way how sparse matrices are stored in computer memory (physical/disk), by a *file format* we mean the way how sparse matrices are stored in files (in a particular storage format), and by a *storage scheme* we mean a storage format at a block level for ABHSF.

II. Data Structures

Let A be an $m \times n$ sparse matrix with z nonzero elements. The COO storage format consist of 3 arrays of size z that contain row indexes, column indexes, and values of the nonzero elements of A. We can thus define a data structure `COO` that stores A in the COO storage format as follows:

structure `COO` := {
- m, n: matrix size;
- z: number of nonzero elements;
- $rows[]$: row indexes of nonzero elements;
- $cols[]$: column indexes of nonzero elements;
- $vals[]$: values of nonzero elements;

}.

Note that we accompany a data name with [] if the data is meant to be an array.

The advantages of the COO storage format are its clear concept, simple usage, and no requirement for the order of matrix nonzero elements. Its drawback is relatively high amount of memory needed for storing A, i.e., high S_{COO}.

If we order matrix nonzero elements according to the increasing row index, we can modify the COO storage format such that we substitute the array of row indexes by the array of positions of each row data in the remaining two arrays. Such approach results in the CSR storage format, which can be defined by the following data structure:

structure `CSR` := {
- m, n: matrix size;
- z: number of nonzero elements;
- $colinds[]$: column indexes of nonzero elements;
- $vals[]$: values of nonzero elements;
- $rowptrs[]$: offsets of places where data of each row in the $colinds$ and $vals$ arrays start;

}.

Since the array $rows[]$ of `COO` is of size z and the array $rowptrs[]$ of `CSR` is of size m (usually $m+1$ for the sake of simpler implementation), and since $z \gg m$ usually holds for real-world sparse matrices, the CSR storage format typically requires considerably less amount of memory for storing A when compared with COO, i.e., $S_{\text{CSR}} < S_{\text{COO}}$.

ABHSF is a two-level hierarchical storage format (see Figure 1) based on partitioning a matrix into $\lceil m/s \rceil \times \lceil n/s \rceil$ blocks of size $s \times s$ and storing each nonzero block in its space-optimal storage scheme. This approach can considerably reduce the memory requirements for storing sparse matrices when compared not only with COO and CSR but also with other fixed-scheme hierarchical storage formats.

We consider the following storage schemes within this text:

1) **dense:** all block elements are stored including zeros,
2) **bitmap:** only nonzero block elements are stored and their structure is defined by a bit map,
3) **COO:** equivalent of the COO storage format at a block level,
4) **CSR:** equivalent of the CSR storage format at a block level.

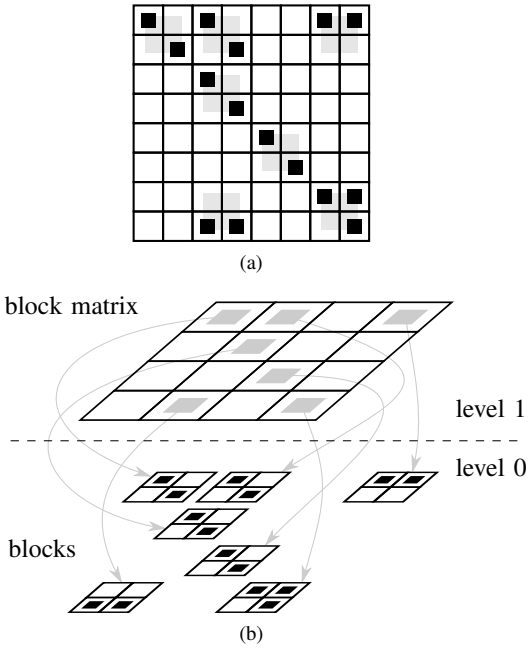

Fig. 1: An 8×8 matrix (a) represented as a hierarchical data structure with 2×2 blocks (b).

The optimal block size s for a particular matrix is application dependent, however, block sizes between 64 and 256 provide best results in general.

We can define a data structure `ABHSF` that stores A in the ABHSF format as follows:

structure `ABHSF` := {
- m, n: matrix size;
- z: number of nonzero elements;
- s: block size;
- $brows[]$: row indexes of nonzero blocks;
- $bcols[]$: column indexes of nonzero blocks;
- $zetas[]$: the number of nonzero elements of nonzero blocks;
- $schemes[]$: optimal storage scheme tag of nonzero blocks;
- $bitmap[]$: a bit map;
- $lrows[]$: row indexes local to a block;
- $lcols[]$: column indexes local to a block;
- $lrowptrs[]$: offsets of places where data of each row of a block start;
- $vals[]$: values of the elements of nonzero blocks;

}.

More details about ABHSF are beyond the scope of this paper, however, they were presented by Langr et at. [2].

Let `BLOCK` be an auxiliary data structure used for storing data of a single nonzero block, defined as follows:

structure `BLOCK` := {
- $brow$: row index of a block within A;
- $bcol$: column index of a block within A;

$zeta$: a number of block nonzero elements;
$lrows[]$: local row indexes of nonzero elements;
$lcols[]$: local column indexes of nonzero elements;
$lvals[]$: local values of nonzero elements;
}.

III. Algorithms

We further suppose that all indexes are 0-based (as used in the C/C++ programming languages).

A. Conversion from COO to ABHSF

The pseudocode of the conversion process from COO to ABHSF is presented as Algorithm 1. It is based on the successive gathering and processing of data for each nonzero block. To optimize this process, the nonzero elements of A are first sorted, at line 5, according to the key represented by the following quadruple with left-to-right significance of its elements:

$$\Big(\lfloor coo.rows[i]/s \rfloor, \lfloor coo.cols[i]/s \rfloor, coo.rows[i] \bmod s, coo.cols[i] \bmod s\Big). \quad (3)$$

Such ordering puts the nonzero elements of each nonzero block into a continuous chunks within the arrays of the `COO` data structure. Consequently, the conversion can be performed within a single iteration over matrix nonzero elements (lines 7–21).

The ProcessBlock procedure, which stores data of a single nonzero block into the `ABHSF` data structure at line 20, is defined in Section III-C.

B. Conversion from CSR to ABHSF

The pseudocode of the conversion process from CSR to ABHSF is presented as Algorithm 2. It is based on the same principle as Algorithm 1, i.e., on the successive gathering and processing of the data of individual nonzero blocks. However, this process is here more complicated, since we cannot simply reorder the matrix nonzero elements according to (3), as in Algorithm 1. Therefore, instead of iterating over matrix nonzero elements, Algorithm 2 iterates over all blocks (loops at lines 5 and 15) and for each block it tries to obtain its nonzero elements. If there are any, they are then processed by the ProcessBlock procedure as well.

C. Processing Blocks

The ProcessBlock procedure stores data of a single nonzero block into the `ABHSF` data structure. Its pseudocode is shown as Algorithms 3.

We assume that the `ABHSF` data structure represents an open file and that all updates into this data structure will be directly translated into corresponding updates of its file representation. Within the pseudocode, we regard all `ABHSF` arrays as file output streams/virtual dynamic arrays to which the elements are successively *appended*.

The space-optimal storage schemes for blocks are selected at line 1 line by comparing their memory requirements, which were defined by Langr et al. [2] as functions (1a)–(1d). According to the optimal storage scheme, the block data are then stored into the `ABHSF` data structure as follows:

- **dense** (lines 7–17): The procedure iterates over all elements of a block. If the corresponding nonzero element is found, then its value is appended to the $vals[]$ array of the `ABHSF` data structure. Otherwise, 0 is appended instead.
- **bitmap** (lines 19–30): The procedure iterates over all elements of a block. If the corresponding nonzero element is found, then its value is appended to the $vals[]$ array of the `ABHSF` data structure and 1 is appended to the $bitmap[]$ array. Otherwise, 0 is appended to the to the $bitmap[]$ array instead.
- **COO** (lines 32–36): The procedure iterates over nonzero block elements and appends their row/column indexes and values to the corresponding arrays of the `ABHSF` data structure.
- **CSR** (lines 38–50): The procedure iterates over nonzero block elements and appends their column indexes and values to the corresponding arrays of the `ABHSF` data structure, while it also constructs the array $lrowptrs[]$ of positions of data for each row of a block.

Note that to ProcessBlock work properly, the nonzero elements in the input `BLOCK` data structure need to be ordered according to growing row index and for each row according to the growing column index. Both Algorithm 1 and Algorithm 2 conform to this requirement.

IV. Experiments and Discussion

We have designed and performed experiments to evaluate the suitability of storing sparse matrices in files in ABHSF. Within these experiments, same matrices were stored in the COO, CSR, and ABHSF storage formats into files based on the HDF5 file format [6] so that particular data from the `COO`, `CSR`, and `ABHSF` data structures were stored as HDF5 attributes and data sets.

Within our implementation, the `ABHSF` data structure represented an open file, i.e., all updates to its data were directly translated into updates of corresponding file attributes and data sets. The data types for data sets containing indexes were always chosen to be unsigned integer data types of minimal possible bit width. All floating-point numbers were stored in files in single precision.

For all the experiments, we used the block size $s = 256$, which generally provides reasonable results for a wide range of matrices, as shown by Langr et al. [2]. To achieve maximum performance, we implemented experimental programs so that:

- All HDF5 data sets were chosen to be *fixed-size*. The conversion algorithms hence needed to be executed twice. Within the first *dry run*, the sizes of data sets were computed. Within the second run, data were actually written into them. (Sorting of elements in Algorithm 1 was performed only once within the dry run.)
- All updates of HDF5 data sets were buffered. We used buffers of size 1024 elements for each data set.

Algorithm 1: Conversion from COO to ABHSF

Input: coo: `COO`; s: integer
Output: $abhsf$: `ABHSF`
Data: $block$: `BLOCK`; $k, brow, bcol$: integer

```
1  abhsf.m ← coo.m
2  abhsf.n ← coo.n
3  abhsf.z ← coo.z
4  abhsf.s ← s
5  sort the coo.rows, coo.cols, and coo.vals arrays all at once according to (3)
6  k ← 0
7  while k < coo.z do                                          // iterate over nonzero elements
8      block.brow ← ⌊coo.rows[k]/s⌋
9      block.bcol ← ⌊coo.cols[k]/s⌋
10     block.zeta ← 0
11     while ⌊coo.rows[k]/s⌋ = block.brow and ⌊coo.cols[k]/s⌋ = block.bcol do   // while element is in the actual block
12         block.lrows[block.zeta] ← coo.rows[k] mod s
13         block.lcols[block.zeta] ← coo.cols[k] mod s
14         block.lvals[block.zeta] ← coo.vals[k]
15         block.zeta ← block.zeta + 1
16         k ← k + 1                                           // go to next nonzero element
17         if k ≥ coo.z then break
18
19     end
20     ProcessBlock(block, abhsf)                              // store block data into the ABHSF structure
21 end
```

- All the *bitmap*, *lrows*, *lcols*, and *lrowptrs* arrays from the `ABHSF` data structure were implemented in files as a single data set.

Reasoning for the listed decisions is beyond the scope of this paper. However, they all originated from results of our complementary tests and measurements.

A. File Sizes for Benchmark Matrices

First, we compared sizes of files for different matrices that emerged in real-world scientific and engineering applications. All used *benchmark matrices* were taken from *The University of Florida Sparse Matrix Collection* (UFSMC) [7]. We tried to choose matrices from different computational domains and therefore with different structural properties. Their list together with their characteristics is presented in Table I, where z' denotes the relative number of nonzero elements in percents, i.e., the inverse measure of sparsity of a matrix.

We stored matrices in HDF5-based files in the COO, CSR, and ABHSF storage formats. We further refer to these options as HDF5-COO, HDF5-CSR, and HDF5-ABHSF, respectively. The results are presented in Figure 2 where the file sizes are relative (in percents) to the HDF5-ABHSF option. For comparison, we also included the sizes of compressed (`.mtx.gz`) and uncompressed (`.mtx`) files in the Matrix Market file format [8], in which matrices are originally published in UFSMC.

The main conclusion from these results is that for all benchmark matrices, HDF5-COO resulted in files about twice as big as HDF5-ABHSF and HDF5-CSR resulted in files about 1.4 times bigger than HDF5-ABHSF. Therefore, **if we convert matrices to ABHSF, we can save a considerable amount of file system capacity.**

Unfortunately, we cannot simply compare the results for the text-based Matrix Market file format and the binary-based HDF5 file format, since in the text-based file formats, the floating-point values are generally represented in various precisions. However, note that for some matrices the smallest files were achieved for the compressed Matrix Market file format. This effect was caused by the fact that in these special cases, many matrix elements had identical floating-point values, which led to high efficiency of text compression. HDF5 also allows to compress data, which should reduce the sizes of data sets containing repeated floating-point values. We have, however, not tested this possibility.

B. Parallel Experiments

The matrices in UFSMC are of smaller sizes suitable for sequential rather than parallel processing. Since we did not find any suitable scalable HPC application able to generate very large sparse matrices, we simulated such matrices by parallel generation of random block matrices. The developed generating algorithm works as follows:

1) an *imaginary* global matrix is partitioned into P submatrices,
2) each submatrix is further treated by a single processor,
3) each submatrix is partitioned into blocks,

Algorithm 2: Conversion from CSR to ABHSF

Input: csr: CSR; s: integer
Output: $abhsf$: ABHSF
Data: $block$: BLOCK; $k, brow, bcol, firstrow, lastrow, nrows, row, lrow$: integer; $from$, $remains$: integer array

```
1  abhsf.m ← csr.m
2  abhsf.n ← csr.n
3  abhsf.z ← csr.z
4  abhsf.s ← s
5  for brow ← 0 to ⌈csr.m/s⌉ − 1 do                                   // iterate over block rows
6      firstrow ← brow · s
7      if firstrow + s ≤ csr.m then nrows ← s
8      else nrows ← csr.m − firstrow
9
10     lastrow ← firstrow + nrows − 1
11     for row ← firstrow to lastrow do                               // for each row of a block row find out:
12         from[row − firstrow] ← csr.rowptrs[row]                    // position of data to be processed
13         remains[row − firstrow] ← csr.rowptrs[row + 1] − csr.rowptrs[row]   // number of elements to be processed
14     end
15     for bcol ← 0 to ⌈csr.n/s⌉ − 1 do                               // iterate over block columns
16         block.brow ← brow
17         block.bcol ← bcol
18         block.zeta ← 0
19         for row ← firstrow to lastrow do                           // for each row of a block row
20             lrow ← row − firstrow
21             while remains[lrow] > 0 and csr.colinds[from[lrow]] < (bcol + 1) · s do
                                                                      // while elements belong to the actual block
22                 block.lrows[block.zeta] ← lrow
23                 block.lcols[block.zeta] ← csr.colinds[from[lrow]] − bcol · s
24                 block.lvals[block.zeta] ← csr.vals[from[lrow]]
25                 block.zeta ← block.zeta + 1
26                 from[lrow] ← from[lrow] + 1
27                 remains[lrow] ← remains[lrow] − 1
28             end
29         end
30         if block.zeta > 0 then ProcessBlock(block, abhsf)
                                                                      // store block data into the ABHSF data structure
31     end
32 end
```

4) each block becomes nonzero with some probability,
5) each nonzero block contains a random number of nonzero elements,
6) each nonzero element is assigned a random row/column index and a random value.

We further set up the generator so that:

- $L_{\text{COO}} \approx 600$ MB, therefore submatrices took about 600 MB each when stored in COO (the typical amount of physical memory per processor is 1–2 GB on contemporary MPCSs).
- Resulting matrices contained nonzero blocks of various properties, thus various storage schemes were generally space-optimal for them.
- Processors used different seeds for their instances of a pseudorandom number generator to produce different submatrices. However, these seeds were preserved in time, thus each processor generated the very same submatrices through all experiments.

The parallel experiments were carried out in the following steps:

1) Each processor generated a random submatrix and stored it in memory either in COO or in CSR.
2) All processors stored their submatrices to a file system in the original IMSF, which resulted in HDF5-COO or HDF5-CSR files.
3) All processors stored their submatrices to a file system in the ABHSF storage format utilizing either Algorithm 1 or Algorithm 2, which resulted in HDF5-ABHSF files.

Algorithm 3: PROCESSBLOCK(b, a)

Input: $block$: BLOCK; $abhsf$: ABHSF
Output: $abhsf$: ABHSF
Data: $scheme$: scheme tag; k, row, col: integer

```
scheme ← space-optimal storage scheme for block block   // functions (1a)–(1d) defined by Langr et al. [2]
append block.brow to abhsf.brows
append block.bcol to abhsf.bcols
append scheme to abhsf.schemes
append block.zeta to abhsf.zetas
if scheme = dense then                                  // optimal scheme is dense
    k ← 0
    for row ← 0 to abhsf.s − 1 do                       // iterate over all block elements
        for col ← 0 to abhsf.s − 1 do
            if k < block.zeta and block.lrows[k] = row and block.lcols[k] = col then   // if element exists
                append block.lvals[k] to abhsf.vals     // store its nonzero value
                k ← k + 1
            else
                append 0 to abhsf.vals                  // otherwise store 0
            end
        end
    end
else if scheme = bitmap then                            // optimal scheme is bitmap
    k ← 0
    for row ← 0 to abhsf.s − 1 do                       // iterate over all block elements
        for col ← 0 to abhsf.s − 1 do
            if k < block.zeta and block.lrows[k] = row and block.lcols[k] = col then   // if element exists
                append block.lvals[k] to abhsf.vals     // store its nonzero value
                append 1 to abhsf.bitmap                // and 1 to bit map
                k ← k + 1
            else
                append 0 to abhsf.bitmap                // otherwise store 0 to bitmap
            end
        end
    end
else if scheme = COO then                               // optimal scheme is COO
    for k ← 0 to block.zeta − 1 do                      // iterate over block nonzero elements
        append block.lrows[k] to abhsf.lrows            // and store them into COO storage scheme
        append block.lcols[k] to abhsf.lcols
        append block.lvals[k] to abhsf.vals
    end
else if scheme = CSR then                               // optimal scheme is CSR
    row ← 0
    for k ← 0 to block.zeta − 1 do                      // iterate over block nonzero elements
        while row ≤ block.lrows[k] do                   // and store them in the CSR storage scheme
            append k to abhsf.lrowptrs
            row ← row + 1
        end
        append block.lcols[k] to abhsf.lcols
        append block.lvals[k] to abhsf.vals
    end
    while row ≤ abhsf.s do                              // align final rows if needed
        append block.zeta to abhsf.lrowptrs
        row ← row + 1
    end
end
```

TABLE I: The list of the benchmark matrices used for the performed experiments.

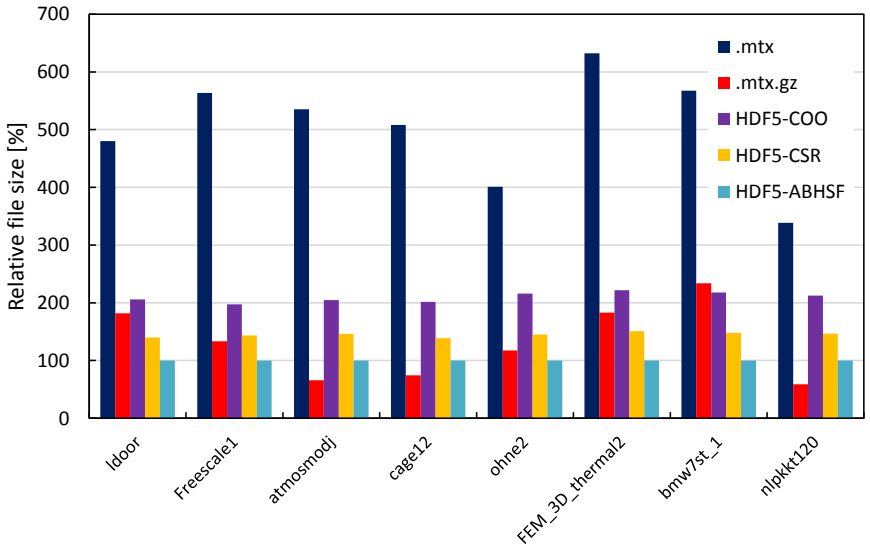

Fig. 2: File sizes in percents relative to HDF5-ABHSF for benchmark matrices and different file/storage formats.

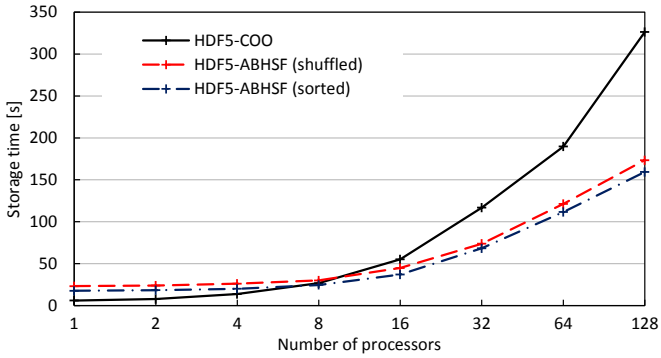

Fig. 3: Storage times for cases when COO was used as IMSF.

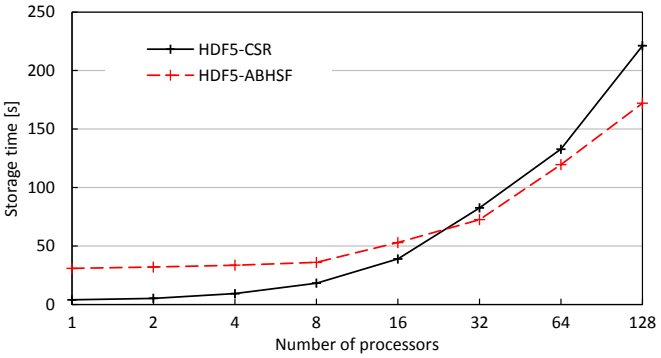

Fig. 4: Storage times for cases when CSR was used as IMSF.

We measured the storage times of steps 2 and 3 for different numbers of processors. Results for the case of using COO and CSR as IMSF are in Figure 3 and Figure 4, respectively. All measurements were performed 3 times and the average values are presented. Since the conversion algorithm from COO to ABHSF contains sorting of elements, we kept nonzero elements in memory in COO in two different orderings to evaluate the influence of the sorting algorithm. In the first case the elements were randomly *shuffled* and in the second case they were *sorted* by their (row index, column index) keys.

The obtained results clearly correspond to our assumption introduced in Section I. In case of ABHSF, there was some constant computational overhead imposed by the conversion algorithms (note that this overhead was considerably higher for the conversion from CSR, which was caused by the higher complexity of the conversion algorithm compared with the

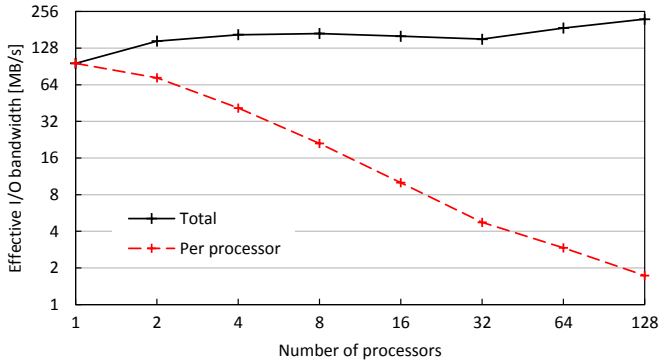

Fig. 5: Measured I/O bandwidth of the file system used for experiments.

COO case). For smaller numbers of processors, this overhead dominated the overall storage time ($t_{\text{saved}} < t_{\text{overhead}}$) and therefore it was faster to store matrices to a file system in their original IMSFs. However, **as the matrix size increased** (proportionally to P), **the amount of saved data** ($S_{\text{IMSF}} - S_{\text{SESF}}$) **increased as well, and from some point, it paid off to store matrices in ABHSF.**

From the measured storage times, we have also computed the *total I/O bandwidth* of the used file system. Provided that this total bandwidth is shared by all processors evenly, we can also express the *I/O bandwidth per processor*. These values are shown in Figure 5.

C. Generalization of Results

If we assume that the total I/O file system bandwidth is shared evenly among processors, we may rewrite (2) as

$$t_{\text{saved}} \approx \frac{L_{\text{IMSF}} - L_{\text{SESF}}}{\text{file system I/O bandwidth per processor}}.$$

This implies that **the amount of saved time generally grows inversely proportionally to the file system I/O bandwidth per processor**.

Within our experiments, we utilized a small parallel computer system with the GPFS-based storage subsystem [9]. The total I/O bandwidth of this file system varied, according to Figure 5, approximately from 100 to 200 MB/s. On this system, the point where ABHSF started to provide faster storage of matrices emerged around 16–32 processors, which corresponded to the I/O bandwidth of 4–8 MB/s per processor.

On todays biggest MPCSs, the per-processor I/O bandwidth would be typically much lower for large-scale computations. For instance, the Hopper/NERSC MPCS consists of over 153 thousands processors (CPU cores) and the listed maximum I/O bandwidth of its fastest file system is 35 GB/s. Therefore, we cannot get the I/O bandwidth per processor higher than 0.23 MB/s when utilizing the whole system. In general, for such low I/O rates, we may expect that the ABHSF storage format would be much more superior to the original IMSF when storing matrices to a file systems.

V. Conclusions

The contribution of this paper are new conversion algorithms for sparse matrices from the COO and CSR to the ABHSF storage formats and the evaluation of suitability of storing sparse matrices into file systems in ABHSF using these algorithms, with the focus on the HPC application domain. We showed that as the size of a computational problem grows, and so does the number of processors, there is some point from which it pays off to store matrices to a file system in ABHSF instead of their original IMSF.

Unfortunately, we cannot simply predict this point, since it depends on many factors, such as the I/O bandwidth of the file system, the actual workload of the file system, the clock rate of processors, the bandwidth of memory units, the available amount of physical memory per processor, the quality of the compiler, the quality of the program code, structural properties of the matrix, etc. However, provided that we use a particular MPCS and a particular HPC application that generates matrices with similar properties, many of these factors becomes fixed. Moreover, computational power and compiler capabilities that influence the overhead imposed by the conversion algorithms generally do not differ much across contemporary MPCSs. Then, the suitability of storing matrices to a file system in ABHSF (generally in any SESF) would be determined primarily by the I/O bandwidth of the file system per processor.

***Abstract*—For decades, Domain Decomposition (DD) techniques have been used for the numerical solution of boundary value problems. In recent years, the Algebraic Multigrid (AMG) method has also seen significant rise in popularity as well as rapid evolution. In this article, a Domain Decomposition method is presented, based on the Schur complement system and an AMG solver, using generic approximate banded inverses based on incomplete LU factorization. Finally, the applicability and effectiveness of the proposed method on characteristic two dimensional boundary value problems is demonstrated and numerical results on the convergence behavior are given.**

I. Introduction

DOMAIN decomposition includes a significant range of computing techniques for the numerical solution of Partial Differential Equations (PDEs). Domain decomposition techniques are based on splitting the computational domain into smaller subdomains, with or without overlap. The problems in the subdomains are independent, thus rendering domain decomposition methods suitable for parallelization. Domain decomposition techniques can themselves be used as stationary iterative schemes, as well as preconditioners in order to accelerate the convergence of other iterative methods, specifically Krylov subspace methods [14].

Domain decomposition methods can be split into two categories: overlapping and non-overlapping methods. In overlapping DD methods, often referred to as Schwarz methods due to Schwarz's work in 1870 [22], the subdomains overlap by more than the interface. The overlapping methods have a simple algorithmic structure, since there is no need to solve special interface problems between neighbouring subdomains. This feature differentiates overlapping from non-overlapping DD methods [5],[23]. Overlapping methods operate by an iterative procedure, where the PDE is repeatedly solved within every subdomain. For each subdomain, the artificial internal boundary condition is provided by its neighbouring subdomains. The convergence of the solution on these internal boundaries ensures the convergence of the solution in the entire solution domain.

In non-overlapping DD methods, also referred to as iterative substructuring methods, the subdomains intersect only on their interface. Non-overlapping methods can furthermore be distinguished in primal and dual methods. Primal methods, such as BDDC [7], enforce the continuity of the solution across the subdomain interface by representing the value of the solution on all neighbouring subdomains by the same unknown. In dual methods, such as FETI [10], the continuity is further enforced by the use of Lagrange multipliers. Hybrid methods, such as FETI-DP [8],[9],[16], have also been introduced.

In the past decades, the development of multigrid methods has also been critical for the numerical solution of PDEs. An essential component of the multigrid method is the relaxation scheme, which efficiently reduces high frequency components of the error, however is inefficient at reducing the lower frequency ones [2]. Transferring the problem to a coarser grid, those low frequency errors become more oscillatory and can be effectively damped by a stationary iterative method. Recursive application of this process produces the multigrid methods [18].

The algebraic multigrid algorithm (AMG) was first introduced over twenty years ago [1],[20]. Unlike geometric multigrid, the algebraic multigrid method does not require knowledge of the geometry of the problem to define its components. This is the reason AMG is perfectly suited for unstructured grids, both in two and three dimensions, and complicated domains. Specifically, by considering a linear system Au=f, the AMG method requires only the coefficient matrix A and the right-hand side vector f. As a result, AMG solvers can easily be integrated into existing problem solving environments as standard solvers or preconditioners [18].

Consider a linear system Au=f, where $A=\left(a_{i,j}\right), i,j\in[1,n]$ is an (n×n) coefficient matrix. A "grid" is a set of indices of the variables, thus the first grid is $\Omega=\{1,2,\ldots,n\}$. Since AMG is independent of the geometry of the problem, the coarser grids, where the successive corrections to the solu-

978-83-60810-53-8/$25.00

tion will be obtained, have to be constructed by the coarsening process, which is an essential component of the AMG algorithm.

The components needed for AMG, where superscripts indicate the level with 1 being the finest level [4],[27], are the following:

- Grids $\Omega^1 \supset \Omega^2 \supset \ldots \supset \Omega^N$ ($\Omega^1=\Omega$) containing the following two disjoint subsets:
  Coarse points set (C-points): $C^k, \mathrm{k}=1,\ldots,\mathrm{N}-1$.
  Fine points set (f-points): $F^k, \mathrm{k}=1,\ldots,\mathrm{N}-1$.
- Grid operators: $A^1, \mathrm{A}^2, \ldots, \mathrm{A}^N$, where $A^1 = A$.
- Interpolation and restriction operators:
  $I_{k+1}^k, \mathrm{k}=1,\ldots,\mathrm{N}-1$; $I_k^{k+1}, \mathrm{k}=1,\ldots,\mathrm{N}-1$.
- A smoother (relaxation scheme) for each level.

AMG consists of two main phases: the setup phase, where the above components are created, and the solution phase that utilizes the components in the recursively defined multigrid cycle.

In this article, a domain decomposition method is presented, based on the Schur complement system. An Algebraic Multigrid method is used to solve the resulting linear systems for each domain, based on the use of generic approximate banded inverses, derived from the ILU(0) factorization [13],[18]. In section II, the Schur complement method is showcased, while in section III, the AMG method is presented.

Finally in section IV, the applicability of the new proposed scheme on two dimensional boundary value problems is demonstrated and numerical results on the convergence behavior and performance are given.

II. The Schur Complement Method

In this section, the Schur complement domain decomposition method is presented.

The Schur complement method is the earliest version of non-overlapping DD methods. Methods such as Dirichlet-Neumann and Neumann-Neumann are essentially the Schur complement method with the use of particular preconditioners.

Let us consider the Poisson equation on a region Ω, with zero Dirichlet data given on $\partial\Omega$, the boundary of Ω. Let us also suppose that Ω is partitioned into two non-overlapping subdomains Ω_i:

$$\overline{\Omega} = \overline{\Omega_1 \cup \Omega_2}, \Omega_1 \cap \Omega_2 = \emptyset, \Gamma = \partial\Omega_1 \cap \partial\Omega_2$$

as shown in Fig. 1 [25].

Assuming the boundaries of the subdomains are Lipschitz continuous, we consider the problem:

$$-\Delta \mathrm{u}(\mathrm{x},\mathrm{y}) = f \quad (\mathrm{x},\mathrm{y}) \in \Omega \tag{1}$$

$$u(\mathrm{x},\mathrm{y}) = 0 \quad (\mathrm{x},\mathrm{y}) \in \partial\Omega \tag{1.a}$$

Considering a triangulation of the domain Ω and a finite element approximation of the problem (1), assuming that subdomains consist of unions of elements, leads to a linear system

$$\mathrm{Au}=\mathrm{f} \tag{2}$$

with a symmetric, positive definite matrix A. Partitioning the degrees of freedom to those internal to Ω_1, Ω_2 and those interior of Γ, the matrix A and vectors u, f can be expressed as:

$$A = \begin{bmatrix} A_{\mathrm{II}}^{(1)} & 0 & A_{\mathrm{I\Gamma}}^{(1)} \\ 0 & A_{\mathrm{II}}^{(2)} & A_{\mathrm{I\Gamma}}^{(2)} \\ A_{\Gamma\mathrm{I}}^{(1)} & A_{\Gamma\mathrm{I}}^{(2)} & A_{\Gamma\Gamma} \end{bmatrix}, \mathrm{u} = \begin{bmatrix} u_I^{(1)} \\ u_I^{(2)} \\ u_\Gamma \end{bmatrix}, \mathrm{f} = \begin{bmatrix} f_I^{(1)} \\ f_I^{(2)} \\ f_\Gamma \end{bmatrix} \tag{3}$$

The first step of many iterative domain decompositions methods eliminates the unknowns in the interior of the subdomains $u_I^{(i)}$. This leads to a block factorization of the matrix A (3) [25]:

$$A = \mathrm{LR} = \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ A_{\Gamma\mathrm{I}}^{(1)} A_{\mathrm{II}}^{(1)^{-1}} & A_{\Gamma\mathrm{I}}^{(2)} A_{\mathrm{II}}^{(2)^{-1}} & I \end{bmatrix} \begin{bmatrix} A_{\mathrm{II}}^{(1)} & 0 & A_{\mathrm{I\Gamma}}^{(1)} \\ 0 & A_{\mathrm{II}}^{(2)} & A_{\mathrm{I\Gamma}}^{(2)} \\ 0 & 0 & S \end{bmatrix} \tag{4}$$

and the resulting linear system:

$$\begin{bmatrix} A_{\mathrm{II}}^{(1)} & 0 & A_{\mathrm{I\Gamma}}^{(1)} \\ 0 & A_{\mathrm{II}}^{(2)} & A_{\mathrm{I\Gamma}}^{(2)} \\ 0 & 0 & S \end{bmatrix} u = \begin{bmatrix} f_I^{(1)} \\ f_I^{(2)} \\ g_\Gamma \end{bmatrix} \tag{5}$$

where I is the identity matrix and $S = A_{\Gamma\Gamma} - A_{\Gamma\mathrm{I}}^{(1)} A_{\mathrm{II}}^{(1)^{-1}} A_{\mathrm{I\Gamma}}^{(1)} - A_{\Gamma\mathrm{I}}^{(2)} A_{\mathrm{II}}^{(2)^{-1}} A_{\mathrm{I\Gamma}}^{(2)}$ is the Schur complement matrix relative to the unknowns on Γ.

Defining the local Schur complements by

$$S^{(i)} := A_{\Gamma\Gamma}^{(i)} - \sum_{i=1}^{2} A_{\Gamma\mathrm{I}}^{(i)} A_{\mathrm{II}}^{(i)^{-1}} A_{\mathrm{I\Gamma}}^{(i)} \tag{6}$$

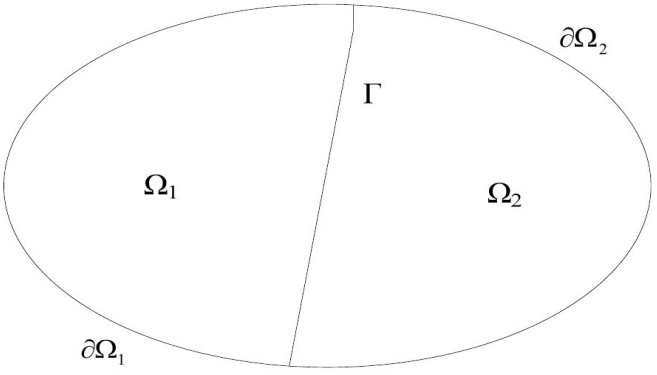

Fig. 1 Ω partitioned into two non-overlapping subdomains.

we find the Schur complement system for u_Γ to be [25]:

$$\mathrm{Su}_\Gamma = g_\Gamma \tag{7}$$

with

$$S = S^{(1)} + S^{(2)} \tag{8}$$

$$\begin{aligned} g_\Gamma := g_\Gamma^{(1)} + g_\Gamma^{(2)} = & \left(f_\Gamma^{(1)} - A_{\Gamma\mathrm{I}}^{(1)} A_{\mathrm{II}}^{(1)^{-1}} f_I^{(1)} \right) \\ & + \left(f_\Gamma^{(2)} - A_{\Gamma\mathrm{I}}^{(2)} A_{\mathrm{II}}^{(2)^{-1}} f_I^{(2)} \right) \end{aligned} \tag{9}$$

Once u_Γ is found by solving (7), the internal components can be found by using (5):

$$u_I^{(i)} = A_{\mathrm{II}}^{(i)^{-1}} \left(f_I^{(1)} - A_{\mathrm{I}\Gamma}^{(i)} u_\Gamma \right) \tag{10}$$

Equations (8) and (9) can be extended to a generic case, where there are more than two domains.

In the method presented in this paper, equation (7) is solved by using a typical direct solver, such as Gaussian Elimination. An AMG solver, based on the Generic Approximate Banded Inverse (GenAbI) algorithm [13], is used in order to solve the equations (10) for each domain.

III. The AMG Solver

In this section, we present the AMG method [13],[18] used for the solution of the systems that arise from the Schur complement method described in the previous section.

The key part of AMG's setup phase is the coarse-grid selection, which is the process of creating the degrees of freedom of a coarse-level problem. The goal of coarse-grid selection is to determine the sets C and F of coarse-grid and fine-grid points respectively, as well as a small set $C_i \subset C$ of interpolating points for each fine-grid point [20],[24]. This is called a C/F splitting, where C-points are variables that exist on both the fine and coarse levels and F-points are variables only on the fine level. Interpolation can then be defined as follows:

$$\left(I_{k+1}^k u^{k+1} \right)_i = \begin{cases} u_i^{k+1}, & i \in C \\ \sum_{j \in C_i} w_{ij} u_j^{k+1}, & i \in F \end{cases} \tag{11}$$

An important concept in the coarse grid selection is that of strong influence and strong dependence. It is highly likely that not all matrix coefficients are equally important to the selection of the coarse grids and thus only those that are "large enough" should be considered [18],[27].

It should be stated that point i depends on point j if a_{ij} is sufficiently large, denoting that in order to satisfy the i-th equation of the system, the node u_i is affected more from node u_j than other neighbouring nodes. We can then define the set of dependencies for point i as:

$$S_i = \left\{ j \neq i, -a_{ij} \geq \theta \max_{k \neq i} \left(-a_{ik} \right) \right\} \tag{12}$$

where θ is called strength threshold and is important for its influence on stencil size and convergence [27]. A typical value for θ is 0.25. The set of influences for point i can be defined as the transpose of the dependencies set.

The concept of strong influence/dependence in conjunction with the following two heuristics is vital to creating a valid coarse grid [4],[20],[27]:

- ***H1***: For each point j that strongly influences a fine-grid point i, j is either a coarse-grid point or strongly depends on a coarse-grid point that also strongly influences i.
- ***H2***: C is a maximal set with the property that no C-point influences another C-point.

Condition H1 ensures the quality of the interpolation and condition H2 restricts the size of coarser grids.

The coarsening schemes of early AMG methods are based on the Ruge-Stüben (RS) coarsening method [20]. The Ruge-Stüben coarsening is the classical coarse-grid selection algorithm, based on enforcing heuristic H1, while implicitly using heuristic H2 as a guideline. It is a two-pass process, where the first pass selects a maximal independent set guaranteeing that every fine-grid point strongly depends on at least one coarse-grid point. Further details on the two-pass RS coarsening are given in [20].

Since RS coarsening selects only a single C-point in each iteration, its main drawback is its sequential nature. However, RS exhibits optimal scalability and convergence behavior for a variety of problems.

In recent years, there has been significant progress in the development of parallel coarse grid selection schemes, most of which are based on their sequential predecessors, such as CLJP [4] and PMIS [6]. An overview of such coarsening schemes and their performance is presented in [27].

The interpolation formula used for the purposes of this article is direct interpolation, in which the weights w_{ij} are defined as follows:

$$w_{ij} = -\left(\frac{\sum_{k \in N_i} a_{ik}}{\sum_{l \in C_i} a_{il}} \right) \frac{a_{ij}}{a_{ii}} \tag{13}$$

This formula is easy to implement and only requires immediate neighbours of i, however, it generally leads to worse convergence rates compared to interpolation formulas that use extended neighbourhoods [27]. The interpolation operator can now be computed according to (11).

The restriction operator is defined as the transpose of the interpolation operator through the Galerkin condition [19]. Thus the next coarser level matrix is defined as the triple matrix product of the restriction operator, the finer grid matrix and the interpolation operator. When the current grid is considered "coarse enough", then the setup phase terminates and AMG proceeds to the solution phase.

The cycle strategy is an essential component of any multigrid algorithm and refers to the sequence in which the various grids are visited and the respective coarse grid corrections are obtained. The common cycle strategy is the V–cycle algorithm and is shown in Fig. 2 [18].

The solution can be achieved by successive applications of the cycle according to arbitrary termination criterion. The proposed multigrid scheme descends to the coarsest level and then, the multigrid method ascends to the finer levels and corrects the respective solution [18].

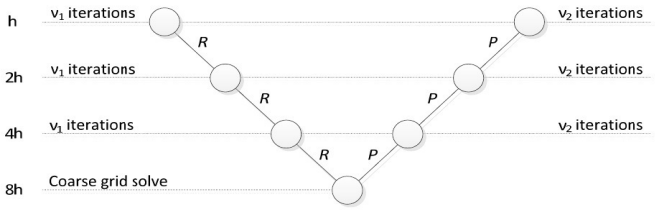

Fig. 2 The V–Cycle with finest grid Ω^h, coarsest grid Ω^{8h}, and ν_1,ν_2 pre–smoothing and post–smoothing steps, respectively.

An important component in multigrid methodology is the stationary iterative solver, namely smoother, that can be described by the following recurrence relation [13],[18]:

$$x_{(i+1)}^{k}=x_{(i)}^{k}+M^{k}r^{k},\mathrm{r}^{k}=f^{k}-A^{k}x_{(i)}^{k} \qquad (14)$$

where f^k,A^k are the right-hand side and coefficient matrix (at the k-th coarse level) and $x_{(i)}^{k}$ is the solution vector at the i-th iterative step. Equation (14) describes a family of stationary iterative methods, according to the choice of the M^k matrix.

Generic approximate banded inverses in conjunction with the general iterative method (14) can be used as smoothers for multigrid schemes, by choosing $M^{k}=\left(M^{k}\right)^{\delta \mathrm{l}}$, where $\left(M^{k}\right)^{\delta \mathrm{l}}$ is a class of approximate inverses. The class of smoothing methods proposed can be described as follows:

$$x_{(i+1)}^{k}=x_{(i)}^{k}+\omega\left(M^{k}\right)_{r}^{\delta \mathrm{l}}\left(f^{k}-A^{k}x_{(i)}^{k}\right) \qquad (15)$$

where ω is the damping parameter with $0<\omega\leq 1$ [13].

Let us assume the incomplete LU factorization, such that

$$A\approx \mathrm{LU}+R \qquad (16)$$

where L and U are upper and lower matrices of the same nonzero structure as the lower and upper parts of coefficient matrix A respectively and R is some error matrix. This is the so-called incomplete LU factorization with zero fill-in, or more commonly ILU(0) factorization [21].

Let $M^{\delta \mathrm{l}}=\left(\mu_{\mathrm{i,j}}\right),\mathrm{i}\in[1,\mathrm{n}],\mathrm{j}\in[1-\delta \mathrm{l}+1,\mathrm{i}+\delta \mathrm{l}-1]$ be the generic approximate banded inverse of the coefficient matrix A. The elements of a class of banded forms of the generic approximate inverse, by retaining δl and δl-1 elements in the lower and upper parts, can be computed by solving recursively the following systems [11],[13],[17]:

$$M^{\delta \mathrm{l}}L=U^{-1} \text{ and } \mathrm{UM}^{\delta \mathrm{l}}=L^{-1} \qquad (17)$$

Then, the elements of the approximate inverse are computed by the Generic Approximate Banded Inverse (GenAbI) algorithm [13].

Specific information on the smoothing and approximation property for the GenAbI algorithm, as well as the use of the DOUR scheme [15] in order to dynamically compute the relaxation parameter ω for the smoothing scheme can be found in [12],[13],[18].

IV. Numerical Results

In this section we examine the effectiveness of the new proposed scheme, namely Domain Decomposition-Algebraic Multigrid method in conjunction with the Generic Approximate Banded Inverse matrix.

The convergence factor depends on the required number of iterations for convergence [2],[3],[26]. The convergence factor with respect to the 2-norm is defined as:

$$q=\sqrt[m]{\|r_m\|_2/\|r_0\|_2} \qquad (18)$$

where r_m is the residual vector at the m-th iteration. The termination criterion for the AMG solver is $\|r_m\|_2<10^{-10}\|r_0\|_2$ and the numbering of the grid is lexicographical. The maximum number of iterations was set to 200 iterations.

The strength threshold θ was set to 0.25 for the AMG solver. The values for the pre-smoothing and post-smoothing steps were set to ν_1, ν_2=2. The coarsest level, with its maximum amount of variables allowed set to 15, was solved using the BiCGSTAB method.

The coarsening scheme used in the first problem was the CLJP algorithm, while for the second problem the PMIS coarsening technique was utilized. It should also be mentioned that for the second problem, the AMG solver was modified to use the V-cycle as a preconditioner for the BiCGSTAB method in order to accelerate convergence.

Model Problem I: The model problem to be solved with the proposed scheme is the Poisson equation:

$$-\Delta \mathrm{u}(\mathrm{x},\mathrm{y})=f \qquad (19)$$

$$u(\mathrm{x},\mathrm{y})=0 \quad (\mathrm{x},\mathrm{y})\in\partial\Omega \qquad (19.a)$$

discretized with the finite element method, where f(x,y)=1, Ω is $[0,1]\times[0,2]$ and $\partial\Omega$ denotes the boundary of Ω. The domain Ω was split into 8 subdomains, as shown in Fig. 3.

In Table I, the convergence factors and convergence behavior are presented for various values of the order of the linear system n and "retention" parameter δl of the generic approximate banded inverse. Additionally, the convergence factors and convergence behavior for the same values of n and δl using AMG as a standalone solver without domain decomposition techniques are given. In Table II, the performance, in seconds, of both the DD/AMG and standalone AMG methods is showcased for various values of the order of the linear system n and "retention" parameter δl of the generic approximate banded inverse.

Model Problem II: Let us consider the following elliptic PDE:

$$-\Delta \mathrm{u}(\mathrm{x},\mathrm{y})+\alpha(\mathrm{x},\mathrm{y})u(\mathrm{x},\mathrm{y})=f(\mathrm{x},\mathrm{y}) \qquad (20)$$

$$u(\mathrm{x},\mathrm{y})=0 \quad (\mathrm{x},\mathrm{y})\in\partial\Omega \qquad (20.a)$$

discretized with the finite element method, where α(x,y)=-40x+70y, f(x,y)=19x-44y^2, Ω is the unit square and $\partial\Omega$ denotes the boundary of Ω. The domain Ω was split into 16 subdomains, as shown in Fig. 4.

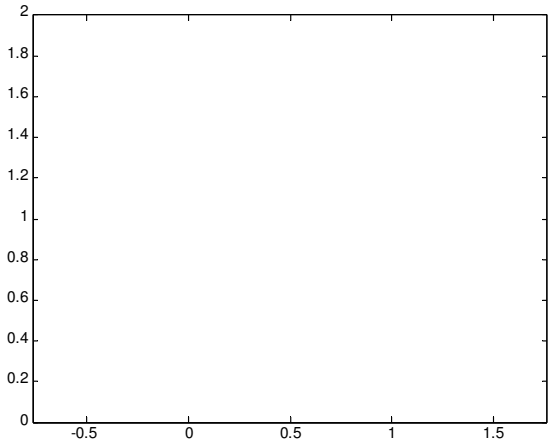

Fig. 3 Domain Ω split into 8 subdomains for model problem I.

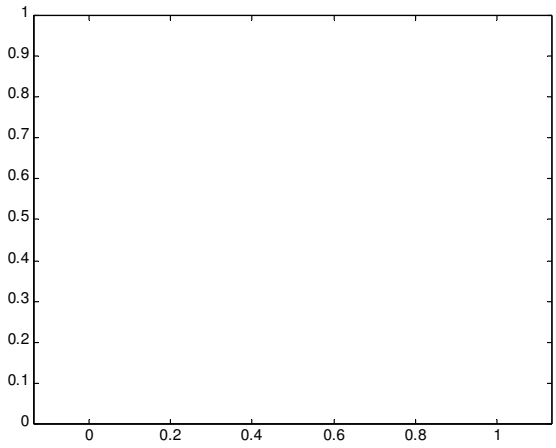

Fig. 4 Domain Ω split into 16 subdomains for model problem II.

In Table III, convergence behavior for various values of the order of the linear system n and "retention" parameter δl of the generic approximate banded inverse is presented. Additionally, convergence behavior for the same values of n and δl using AMG-BiCGSTAB as a standalone solver without domain decomposition techniques is given. In Table IV, the performance, in seconds, of both the DD/AMG-BiCGSTAB and standalone AMG-BiCGSTAB methods is showcased for various values of the order of the linear system n and "retention" parameter δl of the generic approximate banded inverse.

It should be noted that, for both problems, the convergence and performance results for the DD/AMG method are the average of the results taken from all domains, since the domains were not identical.

As already expected considering past results [18], increasing the value of the "retention" parameter δl leads to improved convergence behavior. Additionally, we notice that solving the linear systems arising from the subdomains is significantly more efficient, both in performance and convergence.

One of the drawbacks of AMG methods is the computational work added by the setup phase in addition to the solution phase. The resulting smaller linear systems from the domain decomposition method significantly reduce the workload for both phases. Considering that these systems can be solved in parallel since domain decomposition methods are well suited for parallel computing, the combination of domain decomposition with AMG can be very efficient.

Finally, it should be stated that the effectiveness and applicability of the new proposed method will be shown when applied to more general problems, such as quasilinear boundary-value problems or convection-diffusion problems.

V. Conclusions

A Schur complement domain decomposition method, utilizing an AMG solver, based on generic approximate banded inverse matrices, for solving the resulting subdomain systems was presented. The use of domain decomposition techniques was proven to be effective by improving the performance and convergence behavior of Algebraic Multigrid method. Since domain decomposition methods lead to smaller linear systems, arising from each subdomain, the load for both the setup and solution phase of the AMG solver is significantly reduced.

***Abstract*—Non-Local Means (NLM) algorithm is widely considered as a state-of-the-art denoising filter in many research fields. High computational complexity led to implementations on Graphic Processor Unit (GPU) architectures, which achieve reasonable running times by filtering, slice-by-slice, 3D datasets with a 2D NLM approach. Here we present a fully 3D NLM implementation on a multi-GPU architecture and suggest its high scalability. The performance results we discuss encourage the coding of further filter improvements and the investigation of a large spectrum of applicative scenarios.**

I. Introduction

IMAGE denoising represents one of the most common tasks of image processing. Several techniques have been developed in the last decades to face the problem of removing noise from images, still preserving the small structures from an excessive blurring [2]. All those schemes share the belief that an improved value of a given image point can be expressed as a function of the image itself; each of them diverges in how the function is defined.

One of the most performing and robust denoising approaches is the non-local means (NLM) filter, introduced in [1]. Since its first appearance, the family of NLM algorithm and implementation variants has enormously grown (just to mention some of the most relevant improvements, see [5], [6], [7], [14], [10], [4], [11]); nevertheless, all of them assume that the restoring function for a given point is a mean of all the image values, largely weighted according to the radiometric similarity between values and only weakly tied to a spatial proximity criterion.

The result is a general-purpose denoising scheme, whose performances are widely accepted to be better with respect to the previous state-of-the-art algorithms, such as the total variation, the wavelet thresholding or the anisotropic filtering [13]. In particular, it has been shown that NLM filter guarantees the homogeneity of flat zones, preserves edges and fine structures, and transforms white noise into white noise, thus avoid the introduction of artifacts and spurious correlated signal [2].

Unsurprisingly, the NLM algorithm is computationally very heavy, and even some fast versions of the scheme are quite demanding on 2D images and almost daunting on 3D datasets. The huge amount of computational demand has been recently addressed by using accelerated hardware, the Graphic Processor Units (GPUs) in particular.

In 3D datasets, *e.g.* in the context of the Magnetic Resonance Imaging (MRI), the use of fully 3D filters is more appropriate than a 2D-based slice-by-slice filtering approach to exploit all the information contained in the image.

To the best of our knowledge, although there are several 2D GPU-based NLM versions ([9], [3], [8]), the 3D version of NLM filter has been poorly investigated in terms of both implementation and performance on GPUs.

In this paper, we present GPU and Multi-GPU versions of the 3D NLM filter based on Compute Unified Device Architecture (CUDA) [12]. We report the performance of the implementation for different 3D synthetic and real datasets. The parallelization of the filter via GPUs gives clinically-feasible MRI denoising execution times.

The plan of the paper is as follows. In §II we briefly describe the NLM algorithm. To follow, in §III we provide the implementation details. In §IV we present and discuss the results. Finally, in §V we draw conclusions and future works.

II. Theory

A. General description

An N-D image X can be considered as a real function $X : \mathbb{R}^N \to \mathbb{R}$ with a bounded support $\Omega \subset \mathbb{R}^N$. The NLM filter [1] is a class of endomorphisms of the image space, identified by 2 parameters (a and h), that acts as follows:

$$[\mathrm{NLM}_{a,h}(X)](\vec{x}) = Y(\vec{x}) = \frac{\int_\Omega \exp\left[-\frac{d_a^2(\vec{x},\vec{y})}{h^2}\right] X(\vec{y}) d\vec{y}}{\int_\Omega \exp\left[-\frac{d_a^2(\vec{x},\vec{y})}{h^2}\right] d\vec{y}}\,, \quad (1)$$

where

$$d_a^2(\vec{x},\vec{y}) \equiv \int_{\mathbb{R}^N} \left|X(\vec{x}+\vec{t}) - X(\vec{y}+\vec{t})\right|^2 \cdot \frac{\exp -\frac{\|\vec{t}\|^2}{2a^2}}{(2\pi)^{n/2}\cdot a} d\vec{t}. \quad (2)$$

The intensity of a given point of the new image is a mean of the intensities of the original image, according to a weight function that disregards any explicit criterion of spatial proximity and only considers a measure (ruled by h) of self-similarity between windows of radius a centered on each point (radiometric proximity).

If the image is defined on a discrete, regular grid $\left\{\vec{x}_i \,\middle|\, 1 \le i \le \prod_{l=1}^N L_l\right\}$,

$$X(\vec{x}) = \sum_i X_i \delta(\vec{x} - \vec{x}_i)\,, \quad (3)$$

978-83-60810-53-8/$25.00

from Eqns. 1–2 it follows that the filtered dataset is given by

$$Y_i = \frac{\sum_j \exp\left[-\frac{d_a^2(\vec{x}_i,\vec{x}_j)}{h^2}\right] X_j}{\sum_j \exp\left[-\frac{d_a^2(\vec{x}_i,\vec{x}_j)}{h^2}\right]}, \tag{4}$$

$$d_a^2(\vec{x}_i,\vec{x}_j) = \sum_k \left| X(\vec{x}_i+\vec{\Delta}_k) - X(\vec{x}_j+\vec{\Delta}_k)\right|^2 \cdot \frac{\exp -\frac{\|\vec{\Delta}_k\|^2}{2a^2}}{(2\pi)^{n/2}\cdot a}. \tag{5}$$

Moreover, from Eqns. 4–5 it follows that the complexity of the filter is $O\left(\prod_{l=1}^{N} L_l^3\right)$.

B. Actual algorithm

Both computational issues and the convenience to introduce a geometric proximity criterion in addition to the pure radiometric distance measure led to a change in the original version of the NLM filter [7].

Therefore, given a search radius M, for each voxel i located at $\vec{x}_i$ we define a search box V_i as

$$V_i \equiv \left\{ \vec{x}_j \in \Omega \,|\, \|\vec{x}_j - \vec{x_i}\|_\infty < M \right\}. \tag{6}$$

The search box associated with the i-th voxel defines the ensemble of voxels whose intensities will be available in the following for restoring (denoising) of the intensity $X(\vec{x}_i)$, thus reducing the search freedom of Eqn. 4 (in that case, $V_i \equiv \Omega$). The authors of ([7], [10]) suggest that a good choice for M should guarantee the cardinality of the search box, $|V_i|$, to be of the order of 10^3.

Analogously, given a similarity radius d, for each voxel $\vec{x}_j$ within a given search box V_i, we can define a similarity box

$${}_jB_i \equiv \left\{ \vec{x}_k \in \Omega \,|\, \|\vec{x}_k - \vec{x_j}\|_\infty < d \right\}. \tag{7}$$

In this case, d plays the role of a in Eqn. 4, provided that the original smooth Gaussian kernel is replaced by a binary cut-off; a good choice for d should guarantee $|{}_jB_i| \sim 30$ ([7], [10]).

Finally, the denoised image is

$$Y_i = \frac{\sum_{\vec{x}_j \in V_i} \exp\left[-\frac{\|{}_jB_i - {}_iB_i\|_2^2}{h^2}\right] X_j}{\sum_{\vec{x}_j \in V_i} \exp\left[-\frac{\|{}_jB_i - {}_iB_i\|_2^2}{h^2}\right]}, \tag{8}$$

whence it results that the algorithm complexity is $O\left(|V_i|\cdot|{}_jB_i|\cdot\prod_{l=1}^{N} L_l\right)$.

The filter strength, which is determined by h, can be automatically tuned to obtain an optimized denoising, independently from the search radius M and the standard deviation of noise σ:

$$h^2 = 2\beta\sigma^2 |V_i| \tag{9}$$

($\beta \sim 1$ is an adimensional constant to be manually tuned).

III. Implementation

General Purpose computation on Graphics Processing Units (GPGPU) is the use of GPUs to perform highly parallelizable computations that would normally be handled by CPU devices. Programming with GPUs requires both a deep understanding of the underlying computing architecture and a massive rethinking of existing CPU based algorithms.

A. Architecture

We implement the 3D NLM filter on the NVIDIA parallel computing architecture, which consists in a set of cores, or Scalar Processors (SPs), performing simple mathematical operations.

In the NVIDIA Fermi architecture, each SM has scheduler and dispatch units, execution units and a configurable memory of 64KB, which consists of a register file, an internal shared memory and an L1 cache. This memory is configurable in 16KB (or 48KB) for shared memory and 48KB (or 16KB) for L1 cache.

B. Mapping the algoritm on GPU

The Algorithm 1 is the pseudo-code of the NLM filter.

Algorithm 1 Pseudo-code of the NLM algorithm

```
1: for each voxel (i1, i2, i3) of the 3D image to be filtered do
2:     Initialize the cumulative sum of weights and the restored value to 0;
3:     for each voxel (j1, j2, j3) of the search window V_(i1,i2,i3) do
4:         for each voxel (k1, k2, k3) of the similarity window
           (j1,j2,j3)B_(i1,i2,i3) do
5:             Cumulate squared Euclidean distance;
6:         end for
7:         Calculate and cumulate the weight of the voxel in search window;
8:         Cumulate the restored value;
9:     end for
10:    Normalize restored value to the sum of the weights;
11: end for
```

In details, the statement at line 1 represents a nested iteration structure. In our GPU version, the loops on line 1 and line 3 in the Algorithm 1 are logically mapped onto the grid of thread blocks defined by means of the CUDA framework.

A first implementation in CUDA is presented in the Algorithm 2. Moreover, in order to make this algorithm compatible

Algorithm 2 CUDA code of NLM algorithm

```
1: int const i_1 = threadIdx.x +
     blockDim.x*blockIdx.x;
2: int const i_2 = threadIdx.y +
     blockDim.y*blockIdx.y;
3:   /* local statements */
4:   if ((i_1 ≥ 0) && (i_1 < X_Dim) &&     (i_2 ≥ 0)
   && (i_2 < Y_Dim)) {
5:     for(i_3=0; i_3 < Dim_Z; i_3++) {
6:       /* do something on img[i_1 +
           i_2*X_Dim + i_3*X_Dim*Y_Dim] */ }}
```

with multi-GPU architectures, we introduce some improvements. The number of GPU devices is returned by means of a CUDA library function and stored in the variable `n_gpus`. Then, the third dimension of the image is "splitted" between the available GPUs, setting the first (`start_k`) and the last (`end_k`) slices that each GPU has to manage. We report a sketch of the GPU implementation in the Algorithm 3.

In order to explore different types of data access, we test several configurations, both mono- and bi-dimensional, for the thread block size in which each slice is divided. Each thread processes sequentially the voxels along the third dimension. The workload is divided along the third dimension for multi-GPU configurations. Inside each GPU the workload

Algorithm 3 CUDA MULTI-GPU code of NLM algorithm

```
1: int const i_1 = threadIdx.x +
     blockDim.x*blockIdx.x;
2: int const i_2 = threadIdx.y +
     blockDim.y*blockIdx.y;
3:   /* split the image ``img'' between the
   ``n_gpus'' GPUs: each GPU works on the section
   of the image ``my_img'' */
4:   /* local statements */
5:   for(i_3 = 0; i_3 < Z_Dim/n_gpus;     i_3++) {
6:       /* do something on my_img[i_1 + i_2*X_Dim +
   i_3*X_Dim*Y_Dim/n_gpus] */
7:     } }
```

is divided along the first and second dimensions, in strips (mono-dimensional configurations) and tiles (bi-dimensional configurations) of threads. Strip or tile is allowed to cover entirely or only partially the slice grid.

We test also the impact of L1-cache on performance, using the binary L1-prefer setting, which allows to choose between two possible configurations: 48KB of shared memory and 16KB of L1-cache (no L1-prefer), or 16KB of shared memory and 48KB of L1-cache (L1-prefer).

The computing system is equipped with 2 Intel Xeon CPU E5620 (2.4 GHz) and an NVIDIA TESLA S2050 card. This device consists of 4 GPGPU units, each of which with 3GB of RAM memory and 448 cores at 1.15 GHz. The numerical code is implemented by using the single precision arithmetic. The CPU system is equipped with an Intel core i5-2500S (2.7-3.7 GHz).

IV. Results and Discussions

A. Consistency

As we aim to produce a strictly equivalent GPU implementation of the sequential NLM algorithm, we check the implementation consistency by comparing voxel-by-voxel the images obtained by one-core-CPU and GPU denoising. In Fig. 1 we show the 3D NLM filtering result on a real 3D knee MRI dataset. The difference between the GPU and CPU restored images falls within machine precision order of magnitude which are likely to be due to the arithmetic logic unit precision.

B. Performance

In order to investigate cache size impact on the execution time, we perform several test runs varying L1-prefer switch. Results are shown in Table I. L1-prefer choice gives a benefit on lager dataset, with a performance improvement ranging from fraction of percent in the smallest dataset to some 5% in the largest ones. These results suggest that the L1 miss rate, is low enough to have high performance processing even with old generation cards having small amount of cache.

The strip or tile thread division influences the performance of the filter in terms of computing time due to the different type of data access. Experimental results prove that optimal configuration is given by the strip subdivision. In Table I we report running times of (128,1,1) configuration on 2-GPU.

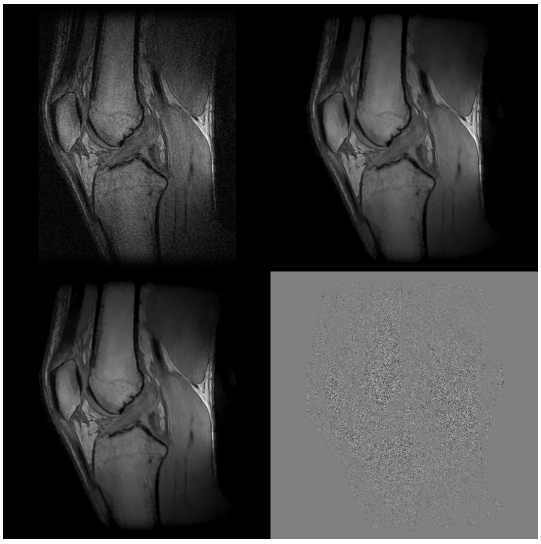

Fig. 1. From left to right and from top to bottom, the frames show a central slice of the original dataset, the GPU restored image, the CPU restored image and the difference between CPU and GPU filtered images (enhanced by a scaling factor of 10^6), respectively.

TABLE I
L1-prefer switch influence on execution times for (128,1,1) block size configuration and 3D random datasets.

	Cache configuration	
	L1-prefer	no L1-prefer
64x64x64	8.04	8.55
128x128x64	9.43	9.42
128x128x128	11.2	11.2
256x256x128	19.9	20.2
256x256x256	28.3	29.0
512x512x128	39.5	40.4
512x512x256	71.7	75.0
512x512x512	138	148

In Table II we report a comparison between running times of CPU, single GPU and multi-GPU implementation of 3D NLM filter with various thread block size. Reported running times include the overall data transfer between CPU and GPU and viceversa, which even for the biggest datasets appears negligible. Speed-up values suggest that the bigger the dataset to be filtered, the better the scalability of the implementation, which, for datasets size typical of MRI clinical practice, is close to be ideal. Moreover, the optimal thread size seems to be strips of thread between 128 and 256 elements. This result is consistent with NVIDIA guidelines [12]. Finally, on large datasets strip configuration should be prefered to tile configuration of the same size because more sequential memory access of the former. In Table III, we investigate the behavior of running times against the search ($|V_i|$) and similarity ($|_j B_i|$) window cardinalities. We note an high and almost constant speed-up among the various experiments, which makes feasible large window filter testing in a reasonable time.

Finally, in Figure 2 we outline the CPU, single GPU and multi-GPU GFlops for variable dataset sizes. It should be remarked that we are able to exploit up to 43.5% of single precision floating point peak performance of the GPU.

V. CONCLUSIONS

NLM filter is a state-of-the-art denoising algorithm. However, the huge amount of computational load prevents the large-scale diffusion of its most common implementations.

To the best of our knowledge, in this paper we presented the first multi-GPU implementation of a fully 3D NLM filter. We analyzed several configurations of thread block organization and data access, thus identifying a set of optimal settings that guarantee high performance results for a wide spectrum of application scenarios. The reduction of running times shows that scalability is close to ideal one for most common dataset sizes, *e.g.* those typical of MRI clinical pratice. Speed-up high values encourage the exploration of more sophisticated algorithm variants, and reduce the gap between the previous execution times and acceptable performance for real-time scenarios.

***Abstract*—Expander graphs are highly connected sparse finite graphs. The property of being an expander seems significant in many of these mathematical, computational and physical contexts. Even more, expanders are surprizingly applicably applicable in other computational aspects: in the theory of error corecting codes and the theory of pseudorandomness, which are used in probabilistic algorithms. In this article we present a method to obtain a new examples of families of expanders graphs and some examples of Ramanujan graphs which are the best expanders. We describe properties of obtained graphs in comparison to previously known results. Numerical computations of eigenvalues presented in this paper have been computed with MATLAB.**

I. Introduction

THERE are many different algorithms in everyday life where graphs are used. The development of information technology has allowed various representations of graphs in the memory of a computer. Graph based algorithms are used, in particular, in cryptography, coding theory, car navigation systems, sociology, mobile robotics and even in computer games. Graphs used for different purposes often must have some special properties.

One of the most interesting features of the new graphs is their expansion property. Expander graphs are highly connected sparse finite graphs. This property seems to be very significant. From a practical viewpoint, these graphs resolve an extremal problem in communication network theory. Second, they fuse diverse branches of pure mathematics: number theory, representation theory and algebraic geometry.

Expander graphs are used to efficient error reduction in probabilistic algorithms. A randomized algorithm uses a source of pseudorandom bits. During execution, it takes random choices depending on those random data. However, to collect a reasonable collection of random bits is not an easy task. Algorithms that use the random input to reduce the expected running time or memory usage have a chance of producing an incorrect result. Using expander walks allows to achieve the same error probability, with much fewer random bits. The exact form of the exponential decay in error using expander walks and its dependence on the spectral gap was found by Gillman [6].

Constructions of the best expander graphs with a given regularity and order is not easy and in many cases, it is an open problem. In this article we present a method to obtain a new examples of families of expanders graphs and some examples of Ramanujan graphs which are the best expanders. We describe properties of obtained graphs in comparison to previously known results.

Throughout this paper, only undirected simple graphs without loops or multiple edges are considered. A distance between vertices v_1 and v_2 in the graph is the length of minimal path from v_1 to v_2. A graph is connected if for arbitrary pair of vertices v_1, v_2 there is a path from v_1 to v_2. The length g of the shortest cycle in a graph is called a *girth*, [3]. Bipartite graph is a graph whose vertices set V can be divided into two disjoint subsets V_1 and V_2 such that every edge connects a vertex in V_1 to one in V_2. We refer to bipartite graph $\Gamma(V_1 \cup V_2, E)$ as biregular one if the number of neighbors for vertices from each partition sets are constants s and t (bidegrees). We call a graph regular in the case $s = t$.

By the theorem of Alon and Boppana, large enough members of an infinite family of d-regular graphs with constant d satisfy the inequality $\lambda \geq 2\sqrt{d-1} - o(1)$, where λ is the second largest eigenvalue in absolute value. Ramanujan graphs are d-regular graphs for which the inequality $\lambda \leq 2\sqrt{d-1}$ holds.

We say that a family of regular graphs of bounded degree q of increasing order n *has an expansion constant* c, $c > 0$ if for each subset A of the vertex set X, $|X| = n$ with $|A| \leq n/2$ the inequality $|\partial A| \geq c|A|$ holds. The expansion constant of the family of q-regular graphs can be estimated via upper limit $q - \lambda_n$, $n \to \infty$, where λ_n is the second largest eigenvalue of family representative of order n. It is clear that a family of Ramanujan graphs of bounded degree q has the best expansion constant.

The first explicit expander graph family was constructed by Gregory Margulis in the 1970's via studies of Cayley graphs of large girth [13].

A family of graphs G_n is a family of graphs of increasing girth if $g(G_n)$ goes to infinity with the growth of n.

The *family of graphs of large girth* is an infinite family of

978-83-60810-53-8/$25.00

simple regular graphs Γ_i of degree k_i and order v_i such that

$$g(\Gamma_i) \geq \gamma \log_{k_i} v_i, \tag{1}$$

where c is an independent of i constant (see [1], [2]).

A sparse graph has a small number of edges in comparison to the number of vertices. A simple relationship describing the density of the graph $\Gamma(V, E)$ is

$$D = \frac{2|E|}{|V|(|V|-1)}, \tag{2}$$

where $|E|$ is the number of edges of graph Γ and $|V|$ is the number of vertices. The maximal density is $D = 1$ when a graph is complete and the minimal density is 0 (Coleman & Moré 1983).

One of the very important classes of small world bipartite graphs with additional geometric properties important in this context, is a class of regular generalized m-gon, i.e. regular tactical configurations of diameter m and girth $2m$. For each parameter m, a regular generalized m-gon has degree $q+1$ and order $2(1+q+...+q^{m-1})$, [15].

According to the famous Feit-Higman theorem the regular thick (i.e. degree ≥ 3) generalized m-gons exist only for $m = 3, 4$ and 6, [5]. Thus Generalized Pentagon does not exist, in particular. We have the following properties of generalized polygons:

- the incidence graph of a projective plane $PG(2, q)$ has $|V| = \nu(q+1, 6) = 2(1+q+q^2)$ and $g = 6$,
- the incidence graph of a generalized quadrangle $GQ(q, q)$ has $|V| = \nu(q+1, 8) = 2(1+q+q^2+q^3)$ and $g = 8$,
- the incidence graph of a generalized hexagon $GH(q, q)$ has $|V| = \nu(q+1, 10) = 2(1+q+q^2+q^3+q^4+q^5)$ and $g = 12$.

II. Construction of the families

Described below families of graphs $D(n, \mathbb{F}_q)$ and $W(n, \mathbb{F}_q)$ can be used to obtain the new construction of expander graphs or even Ramanujan graphs.

Let F_q, where q is prime power, be a finite field. $CD(n, q)$ (connected components of $D(n, \mathbb{F}_q)$) and $W(n, \mathbb{F}_q)$ are connected, regular, bipartite families of graphs.

Traditionally in graph theory one subset of vertices in bipartite graphs is denoted by $V_1 = P$ and called a set of points and another one $V_2 = L$ is called a set of lines. Let P and L be two copies of Cartesian power ${\mathbb{F}_q}^n$, where $n \geq 2$ is an integer. Brackets and parenthesis will allow the reader to distinguish points and lines. In this note we concentrate on finite bipartite graphs on the vertex set $P \cup L$, where P and L are two copies of ${\mathbb{F}_q}^n$. If $z \in \mathbb{F}_q^n$, then $(z) \in P$ and $[z] \in L$.

First, we introduce the bipartite graph $D(\mathbb{F}_q)$, [9], with the following points and lines, which are infinite dimensional vectors over $\mathbb{F}_q$ written in the following way

$$(p) =$$

$$(p_{0,1}, p_{1,1}, p_{1,2}, p_{2,1}, p_{2,2}, p'_{2,2}, p_{2,3}, ..., p_{i,i}, p'_{i,i}, p_{i,i+1}, p_{i+1,1}...),$$

$$[l] = [l_{1,0}, l_{1,1}, l_{1,2}, l_{2,1}, l_{2,2}, l'_{2,2}, l_{2,3}, ..., l_{i,i}, l'_{i,i}, l_{i,i+1}, l_{i+1,1}...].$$

The point (p) is incident with the line $[l]$, which is written by the formula: $(p)I[l]$, if the following relations between their coordinates hold:

$$\begin{cases} l_{1,1} - p_{1,1} = l_{1,0}p_{0,1} \\ l_{1,2} - p_{1,2} = l_{1,1}p_{0,1} \\ l_{2,1} - p_{2,1} = l_{0,1}p_{1,1} \\ l_{i,i} - p_{i,i} = l_{0,1}p_{i-1,i} \\ l'_{i,i} - p'_{i,i} = l_{i,i-1}p_{0,1} \\ l_{i,i+1} - p_{i,i+1} = l_{i,i}p_{0,1} \\ l_{i+1,i} - p_{i+1,i} = l_{0,1}p'_{i,i} \end{cases} \tag{3}$$

where $i \geq 2$. The set of vertices of the graph $D(\mathbb{F}_q)$ of this infinite structure is $V = P \cup L$ and the set of edges consisting of all pairs $\{(p), [l]\}$ for which $(p)I[l]$.

For each positive integer $n > 2$ we obtain a finite incidence structure $(P_n, L_n, I_n)_D$ as follows. Firstly, P_n and L_n are obtained from P and L, respectively, by projecting each vector onto its n initial coordinates with respect to the natural order. The incidence I_n is then defined by imposing the first $n-1$ incidence equations and ignoring all others. The graph corresponding to the finite incidence structure (P_n, L_n, I_n) is denoted by $D(n, \mathbb{F}_q)$. $D(n, \mathbb{F}_q)$ becomes disconnected for $n \geq 6$. Graphs $D(n, \mathbb{F}_q)$ are edge transitive. It means that their connected components are isomorphic. A connected component of $D(n, \mathbb{F}_q)$ is denoted by $CD(n, \mathbb{F}_q)$. Notice that all connected components of infinite graph $D(\mathbb{F}_q)$ are q-regular trees.

The family of graphs $D(n, \mathbb{F}_q)$ is a family of q-regular, bipartite graphs of large girth (1). Graphs $D(n, \mathbb{F}_q)$, $n \geq 2$ of fixed degree q form a family of expanders with the second largest eigenvalue bounded from above by $2\sqrt{q}$, [9]. So, family $D(n, \mathbb{F}_q)$ consist of "almost Ramanujan graphs". A graph $D(n, \mathbb{F}_q)$ has practical application in the construction of error correcting codes. Firstly LDPC codes based on graphs $CD(n, \mathbb{F}_q)$ were described in [7]. They are still in practical use.

Let us consider an alternative way of presentation of q-regular infinite graph via equations over finite field F_q We consider an infinite graph $W(\mathbb{F}_q)$ with the points and lines:

$$(p) = (p_{0,1}, p_{1,1}, p_{1,2}, p_{1,3}, p_{1,4}, ..., p_{1,i}, ...),$$

$$[l] = [l_{1,0}, l_{1,1}, l_{1,2}, l_{1,3}, l_{1,4}, ..., l_{1,i}, ...].$$

$W(\mathbb{F}_q)$ is a graph of infinite incidence structure $(P, L, I)_W$ such that a point (p) is incident with the line $[l]$ ($(p)I[l]$), if the following relations between their coordinates hold:

$$l_{1,i} - p_{1,i} = l_{1,i-1}p_{0,1} \tag{4}$$

Like in the case of $D(\mathbb{F}_q)$ for each positive integer $n > 2$ we obtain an finite incidence structure $(P_n, L_n, I_n)_W$ where P_n and L_n are obtained from P and L, respectively, by projecting each vector onto its n initial coordinates with respect to the natural order. The incidence I_n is then defined by imposing the first $n-1$ incidence equations and ignoring all others.

The graph corresponding to the finite incidence structure (P_n, L_n, I_n) is denoted by $W(n, \mathbb{F}_q)$.

The family $W(n, \mathbb{F}_q)$ is a family of q-regular, bipartite graphs with $g = 8$, given by a nonlinear system of equations.

By theorem 4.2 in [14] Wenger graph $W(n, \mathbb{F}_q)$ graph is an edge transitive one.

In fact, $W(n, \mathbb{F}_q)$ form a family of small world graphs. There is a conjecture that $CD(n, \mathbb{F}_q)$ is another family of small world graphs.

Firstly, let us consider an ordinary $n+1$-gon as a bipartite graph with vertex set $V = \{(1), (2), \ldots, (n+1)\} \cup \{[1,2], [2,3], \ldots, [n, n+1], [n+1, 1]\}$. We can write the incidence relation I in $n+1$-gon as follows:

$$(A)I[a,b] \Longleftrightarrow A = a \vee A = b.$$

A line is incident with point if this point belong to this line.

Graphs $G(n+1, \Gamma(n, \mathbb{F}_q))$ correspond to incidence structure with the point set P, the line set L and symmetric incidence relation I_G. Γ is a q-regular bipartite family of graphs defined by systems of equations. Then the number of vertices in graph G is $|V| = 2(1 + q + q^2 + \ldots + q^n)$. The graph is bipartite $V = P \cup L$ and a set V consists of:

2 elements of type t_0–$((1), \emptyset)$ and $[[1,2], \emptyset]$,

$2q$ elements of type t_1–$((2), *)$ and $[[1,2], *]$,

$2q^2$ elements of type t_2–$((n+1), *, *)$ and $[[2,3], *, *]$,

$\vdots$

$2q^n$ elements of type t_n–$((\lceil \frac{n+3}{2} \rceil), \underbrace{*, \ldots, *}_{n})$ and

$[[\lfloor \frac{n+3}{2} \rfloor, \lfloor \frac{n+5}{2} \rfloor], \underbrace{*, \ldots, *}_{n}]$.

Each $*$ represents an arbitrary element from $\mathbb{F}_q$. Brackets and parenthesis will allow the reader to distinguish points $(\cdot)$ and lines $[\cdot]$. The set of edges consisting of all pairs $\{(p), [l]\}$ for which $(p)I_G[l]$.

The incidence relation I_G in graphs $G(n+1, \Gamma(n, \mathbb{F}_q))$ is described as follows. A point of type t_0– $((1), \emptyset)$ is connected by an edge with a line of type t_0– $[[1,2], \emptyset]$ and lines of type t_1. A line of type t_0– $[[1,2], \emptyset]$ is connected by an edge with a point of type t_0– $((1), \emptyset)$ and points of type t_1. For $n \geq x, y \geq 1$, the point $(p) = ((A), \alpha_1, \alpha_2, \ldots, \alpha_x)$ of type t_x is incident $(p)I_G[l]$ with the line $[l] = [[a,b], \beta_1\beta_2, \ldots, \beta_y$ of type t_y if $A = a \vee A = b$ and the following hold:

$$\begin{cases} \alpha_1 = \beta_1, \alpha_2 = \beta_2, \ldots, \alpha_x = \beta_{y-1}, \text{ for } x+1 = y \\ \alpha_1 = \beta_1, \alpha_2 = \beta_2, \ldots, \alpha_{x-1} = \beta_y, \text{ for } x = y+1 \\ (\alpha_1, \alpha_2, \ldots, \alpha_n)I[\beta_1, \beta_2, \ldots, \beta_n] \text{ in } \Gamma, \text{ for } x = y = n \end{cases} \tag{5}$$

If we rewrite incidence relation for a graph $D(n, \mathbb{F}_q)$ with the notation for points as lines as for graph $W(n, \mathbb{F}_q)$:

$$(p) = (p_{0,1}, p_{1,1}, p_{1,2}, p_{1,3}, p_{1,4}, ..., p_{1,i}, ...),$$

$$[l] = [l_{1,0}, l_{1,1}, l_{1,2}, l_{1,3}, l_{1,4}, ..., l_{1,i}, ...],$$

($p_{2,1} = p_{1,3}$, $p_{2,2} = p_{1,4}$, $p'_{2,2} = p_{1,5}$ and $l_{2,1} = l_{1,3}$, $l_{2,2} = l_{1,4}$, $l'_{2,2} = l_{1,5}$) then the first 5 equations describing incidence relations for graph $D(n, \mathbb{F}_q)$ can be written as follows:

$$\begin{cases} l_{1,1} - p_{1,1} = l_{1,0}p_{0,1} \\ l_{1,2} - p_{1,2} = l_{1,1}p_{0,1} \\ l_{1,3} - p_{1,3} = l_{0,1}p_{1,1} \\ l_{1,4} - p_{1,4} = l_{0,1}p_{1,2} \\ l_{1,5} - p_{1,5} = l_{1,3}p_{0,1} \end{cases} \tag{6}$$

and tables II, III,IV, V describe incidence relations I_G for "small" representatives of the family.

TABLE I
REGULARITY AND ORDER FOR SOME REPRESENTATIVES OF THE FAMILY

Construction	Regularity	|V|
$G(3, D(2, \mathbb{F}_q))$ $\cong G(3, W(2, \mathbb{F}_q))$	$q+1$	$2(1+q+q^2)$
$G(4, D(3, \mathbb{F}_q))$ $\cong G(4, W(3, \mathbb{F}_q))$	$q+1$	$2(1+q+q^2+q^3)$
$G(5, D(4, \mathbb{F}_q))$	$q+1$	$2(1+q+q^2+q^3+q^4)$
$G(5, W(4, \mathbb{F}_q))$	$q+1$	$2(1+q+q^2+q^3+q^4)$
$G(6, W(5, \mathbb{F}_q))$	$q+1$	$2(1+q+q^2+q^3+q^4+q^5)$
$G(6, D(5, \mathbb{F}_q))$	$q+1$	$2(1+q+q^2+q^3+q^4+q^5)$

III. COMPARISON WITH PREVIOUSLY KNOWN RESULTS

The graphs $G(n+1, \Gamma(n, \mathbb{F}_q))$ have a structure which is some aspects similar to generalized polygons. They are $q+1$ regular graphs and have the same number of vertices for fixed $n+1 = 3, 4, 6$ as generalized polygons. According to the famous Feit-Higman theorem regular thick polygons exist only for $n+1 = 3, 4, 6$ (see [5]). For $n+1 = 2$ the described construction yields classical projective plane which is a generalized 3-gon and has the second eigenvalue $\lambda_1 = \sqrt{q}$. To show that the constructed graphs for $n+1 = 4, 6$ are not isomorphic to generalized quadrangles and hexagons we prove the following theorem.

Theorem 1. *Family of graphs $G(n+1, D(n, \mathbb{F}_q))$ and $G(n+1, W(n, \mathbb{F}_q))$ are families of graphs of girth 6.*

Proof. Graphs $G(n+1, D(n, \mathbb{F}_q))$ and $G(n+1, W(n, \mathbb{F}_q))$ are bipartite so there is no cycle C_3 and C_5. Because of the structure of this families there are two possibilities of appearence C_4:

1) There is a cycle C_4 consisting of two points of type t_n and two lines of type t_n. But it means that $D(n, \mathbb{F}_q)$ or $W(n, \mathbb{F}_q)$ have cycles of length 4. and we know from [14], [9] that $g(D(n, \mathbb{F}_q)) \geq 6$ and $g(W(n, \mathbb{F}_q)) \geq 6$.
2) There exists two vertices v_1 and v_2 of type t_n in the same branch which are separated by a path of length 2 ($[l_1]I(p_2)I[l_2]$), where p_2 is of type t_{n-1} and have a common neighbor of type t_n.

   Suppose that the graph has C_4. v_1 and v_2 are from the same branch so they have equal coordinates except the last one. Assume without loss of generality that these are lines and denote them as follows:
   $[l_1] = [[\lfloor \frac{n+3}{2} \rfloor, \lfloor \frac{n+5}{2} \rfloor], *_1, *_2, \ldots, *_{n-1}, Y_1]$,

$[[3,4], l_{1,0}, \ldots, l_{1,3}]$	$-$	$-$	$-$	$+ : p_{0,1} = l_{1,0}$, $p_{1,1} = l_{1,1}$ $p_{1,2} = l_{1,2}$	$-$	$+ : p_{0,1} = l_{1,0}$, $p_{1,1} = l_{1,1}$ $p_{1,2} = l_{1,2}$ $p_{1,3} = l_{1,3}$
$[[4,5], l_{1,0}, \ldots, l_{1,4}]$	$-$	$-$	$-$	$-$	$+ : p_{0,1} = l_{1,0}$, $p_{1,1} = l_{1,1}$ $p_{1,2} = l_{1,2}$ $p_{1,3} = l_{1,3}$	$+ : l_{1,1} - p_{1,1} = l_{1,0}p_{0,1}$, $l_{1,2} - p_{1,2} = l_{1,1}p_{0,1}$ $l_{1,3} - p_{1,3} = l_{1,2}p_{0,1}$ $l_{1,4} - p_{1,4} = l_{1,3}p_{0,1}$

$[l_2] = [[\lfloor \frac{n+3}{2} \rfloor, \lfloor \frac{n+5}{2} \rfloor], *_1, *_2, \ldots, *_{n-1}, Y_2]$.
Denote their neighbor of type t_n as:
$(p_1) = ((\lceil \frac{n+3}{2} \rceil), \alpha_1, \alpha_2, \ldots, \alpha_n)$
and their neighbor (p_2) of type t_{n-1} from the same branch as:
$(p_2) = ((\lfloor \frac{n+3}{2} \rfloor), *_1, *_2, \ldots, *_{n-1})$. If in the graph $G(n+1, W(n, \mathbb{F}_q))$: $(p_1)I[l_1]$ and $(p_1)I[l_2]$ accordingly to (4) the following relations hold:

$$\begin{array}{cc} *_2 - \alpha_2 = *_1\alpha_1 & *_2 - \alpha_2 = *_1\alpha_1 \\ *_3 - \alpha_3 = *_2\alpha_1 & *_3 - \alpha_3 = *_2\alpha_1 \\ *_4 - \alpha_4 = *_3\alpha_1 & *_4 - \alpha_4 = *_3\alpha_1 \\ \vdots & \vdots \\ *_{n-1} - \alpha_{n-1} = *_{n-2}\alpha_1 & *_{n-1} - \alpha_{n-1} = *_{n-2}\alpha_1 \\ Y_1 - \alpha_n = *_{n-1}\alpha_1 & Y_2 - \alpha_n = *_{n-1}\alpha_1 \end{array}$$

From the above equality one can see that Y_1 and Y_2 are uniquely determined by the remaining coordinates and $Y_1 = Y_2$. So we got a contradiction.

Analogous procedure can be performed for the graph $G(n+1, D(n, \mathbb{F}_q))$. Any graph $G(n+1, D(n, \mathbb{F}_q))$ and $G(n+1, W(n, \mathbb{F}_q))$ without vertices of type t_n is a tree and does not have any cycle.

For an arbitrary $n \geq 2$ in $G(n+1, D(n, \mathbb{F}_q))$ and $G(n+1, W(n, \mathbb{F}_q))$ there is a cycle of length 6:

$$[[\lfloor \tfrac{n+3}{2} \rfloor, \lfloor \tfrac{n+5}{2} \rfloor], \underbrace{0, 0, \ldots, 0}_{n}] I((\lfloor \tfrac{n+3}{2} \rfloor), \underbrace{0, 0, \ldots, 0}_{n-1}) \; I$$
$$[[\lfloor \tfrac{n+3}{2} \rfloor, \lfloor \tfrac{n+5}{2} \rfloor], \underbrace{0, 0, \ldots, 0}_{n-1}, 1] I((\lceil \tfrac{n+3}{2} \rceil), \underbrace{0, 0, \ldots, 0}_{n-1}, 1) \; I$$
$$[[\lceil \tfrac{n+3}{2} \rceil, \lceil \tfrac{n+5}{2} \rceil], \underbrace{0, 0, \ldots, 0}_{n-1}] I((\lceil \tfrac{n+3}{2} \rceil), \underbrace{0, 0, \ldots, 0}_{n}) \; I$$
$$[[\lfloor \tfrac{n+3}{2} \rfloor, \lfloor \tfrac{n+5}{2} \rfloor], \underbrace{0, 0, \ldots, 0}_{n}].$$

□

The above theorem leads to the following conclusion.

Corollary 2. *For $n \geq 3$ graphs $G(n+1, D(n, \mathbb{F}_q))$ and $G(n+1, W(n, \mathbb{F}_q))$ are not isomorphic to generalized polygons.*

IV. Expanding and other properties

The families $G(n+1, \Gamma(n, \mathbb{F}_q))$ consist of bipartite graphs with $|V| = 2(1 + q + q^2 + \ldots + q^n)$ vertices and $(q+1)(1 + q + q^2 + \ldots + q^n)$ edges. $G(n+1, D(n, \mathbb{F}_q))$ and $G(n+1, W(n, \mathbb{F}_q))$ are $q+1$-regular sparse graphs and the density according to (2) is

$$\frac{q+1}{2(q + \ldots + q^n) + 1}.$$

Fig. 1. shows the graph $G(3, \Gamma(2, \mathbb{F}_2))$ with 14 vertices $V = \{((1), \emptyset), ((2), 0), ((2), 1), ((3), 0, 0), ((3), 0, 1), ((3), 1, 0), ((3), 1, 1)\} \cup \{[[1, 2], \emptyset], [[1, 3], 0], [[1, 3], 1], [[2, 3], 0, 0], [[2, 3], 0, 1], [[2, 3], 1, 0], [[2, 3], 1, 1]\}$ and density $\frac{3}{13}$. The red vertices correspond to points and the blue vertices correspond to lines.

Each of the representatives of the presented family is $q+1$-regular graph so the first eigenvalue of the adjacency matrix, corresponding to this graph, is $\lambda_0 = q + 1$. Let us denote the second eigenvalue by $\lambda_1 = \max_{\lambda_i \neq q+1} |\lambda_i|$. On the basis of numerical calculations included in tables (VI), (VII), (IX), (X), (XI) we state the following conclusions:

- For $q = 2, 3, 4, 5, 7, 9, 11, 13, 17, 19, 23$ the constructed graphs $G(4, D(3, \mathbb{F}_q))$=$G(4, W(3, \mathbb{F}_q))$ are Ramanujan graphs. The spectral gap increases with the value of q. Basing on on this observation we have included Conjecture 1.
- For $q = 2, 3, 4, 5, 7, 11$ the constructed graphs $G(5, D(4, \mathbb{F}_q))$ and $G(5, W(4, \mathbb{F}_q))$ are Ramanujan graphs. The spectral gap $|\lambda_0 - \lambda_1| = |q + 1 - 2\sqrt{q}|$ increases with the value of q and basing on this observation we have included Conjecture 2.
- For $q = 2, 3, 4, 5, 7$ the constructed graphs $G(6, D(5, \mathbb{F}_q))$ and $G(6, W(5, \mathbb{F}_q))$ are expander graphs. The spectral gap for graph $G(6, W(5, \mathbb{F}_q))$ increases with the value of q and for graph $G(6, D(5, \mathbb{F}_p))$ increases with the value of p. This observation allows us to formulate Conjecture 3.

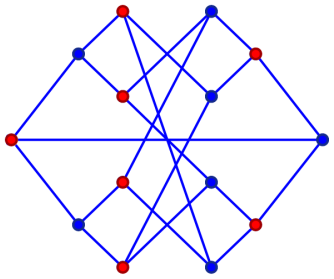

Fig. 1. $G(3, \Gamma(2, \mathbb{F}_2))$ with $|V| = 2(1 + 2 + 2^2) = 14$.

TABLE VI
Expanding properties of $G(4, D(3, \mathbb{F}_q))$=$G(4, W(3, \mathbb{F}_q))$

Number field	regularity $q+1$ first eigenvalue	second eigenvalue	$2\sqrt{q}$	$\lvert V \rvert$
$\mathbb{F}_2$	3	2.2882	2.8284	30
$\mathbb{F}_3$	4	2.8025	3.4641	80
$\mathbb{F}_4$	5	3.2361	4	170
$\mathbb{F}_5$	6	3.6180	4.4721	312
$\mathbb{F}_7$	8	4.2809	5.2915	800
$\mathbb{F}_{11}$	12	5.3664	6.6332	2928
$\mathbb{F}_{13}$	14	5.8339	7.2111	4760
$\mathbb{F}_{17}$	18	6.6713	8.2462	10440
$\mathbb{F}_{19}$	20	7.0528	8.7178	14480
$\mathbb{F}_{23}$	24	7.7598	9.5917	25440

We can use a finite ring $\mathbb{Z}_s$ and modulo operation instead of $\mathbb{F}_q$. The incidence relation for graph $G(n+1, \Gamma(n, \mathbb{Z}_s))$ can be described the same as for graph $G(n+1, D(n, \mathbb{F}_q))$. When we choose $s = 2r$ then the graphs $G(4, D(3, \mathbb{Z}_{2r}))$=$G(4, W(3, \mathbb{Z}_{2r}))$ have interesting constant value of spectral gap: $|\lambda_0 - \lambda_1| = 1$, for $2 \leq r \leq 13$. The

results of such calculations (Tab. VII) allow us to formulate Conjecture 4. When we choose $s = 3r$, where $r = 3, 5, 7, 9$, then the graphs $G(4, D(3, \mathbb{Z}_{3r}))$=$G(4, W(3, \mathbb{Z}_{3r}))$ have an interesting value of the second largest eigenvalue

$$\lambda_1 = 2\sqrt{3r\left\lfloor \frac{r}{2} \right\rfloor + \frac{3r}{2}}$$

and the spectral gap increases with the value of q (Tab. VIII). Basing on on this observation we can not say whether for arbitrarily large s above formula is true. If yes, there is a question about r: if it should be a prime power ($\neq 2^l$) or an odd number? To answer this question we must calculate λ_1 for $r = 15$ but this case can not be investigated with MATLAB in computer with 8GB RAM. The adjacency matrix in this case has 186392×186392 elements.

$\mathbb{F}_7$	8	5.9228	5.2915	39216

Conjecture 3. *The graphs $G(6, D(5, \mathbb{F}_p))$ and $G(6, W(5, \mathbb{F}_q))$ for arbitrary large q (primr power) and p (prime number) are expanders.*

Conjecture 4. *The graphs $G(4, D(3, \mathbb{Z}_{2r}))$ and $G(4, W(3, \mathbb{Z}_{2r}))$ for arbitrary large r are $2r+1$-regular expander graphs with constant spectral gap $|2r+1-\lambda_1| = 1$.*

The graphs $G(n+1, \Gamma(n, \mathbb{F}_q))$ for arbitrary n, q and any bipartite graph Γ are connected even if Γ is disconnected. What more we have conjecture that the family $G(n+1, \Gamma(n, \mathbb{F}_q))$ is $q+1$-connected, namely highly connected. A graph is said to be k-connected when there does not exist a set of $k-1$ vertices whose removal disconnects the graph.

The connectivity of graphs is important property used in many practical and theoretical aspects.

***Abstract*—The newest GPU Kepler architecture offers a reconfigurable L1 cache per Streaming Multiprocessor with different cache size and cache associativity. Both these cache parameters affect the overall performance of cache intensive algorithms, i.e. the algorithms which intensively reuse the data. In this paper, we analyze the impact of different configurations of L1 cache on execution of matrix multiplication algorithm for different problem sizes. The basis of our research is the existing theoretical analysis of performance drawbacks which appear for matrix multiplication while executed on multicore CPU. We perform series of experiments to analyze the matrix multiplication execution behavior on GPU and its set associative L1 and L2 cache memory with three different configurations: cache size of 16KB, 32KB and 48KB with appropriate set associativity of 4 and 6, respectively. The results show that only L2 cache impacts the algorithm's overall performance, particularly the L2 capacity and set associativity. However, the configuration of the L1 cache with 48KB and 6-way set associativity slightly reduces these performance drawbacks, compared to other configurations of L1 with 32KB and 16KB using 4-way cache set associativity, due to greater set associativity.**

***Index Terms*—Cache Memory, Set Associativity, GPGPU.**

I. Introduction

CACHE memory is a very important part of memory hierarchy since it reduces the performance gap between the main memory and the CPU [1]. The algorithm performance with a certain problem size depends on several cache parameters: cache size, cache replacement policy, cache levels, cache-line size, cache inclusivity, cache associativity, etc.

Today's GPU (Graphics Processing Unit) devices are more appropriate for applications with regular data access patterns [2]. They have multilevel set associative cache memory expressed with L1 and L2 level. The former is private per SM (Streaming Processor), while the latter is shared among all SMs on a single GPU device. The NVIDIA's Fermi architecture introduced size configuration (and automatically the appropriate cache set associativity) of L1 cache memory, while the newest Kepler architecture allows the programmer even further configuration.

In this paper, we configure the GPU device with three different cache sizes and two different set associativity sizes in order to determine how this new feature impacts the most common cache intensive algorithm, i.e. dense matrix multiplication (DMM). Our intention is neither to speedup the algorithm execution using the power of many core GPU, nor to speedup the algorithm using some existing transformations, but to use the DMM algorithm as a benchmark and evaluate the impact of cache sizes and associativity on the overall performance. We use only one processing unit of only one SM and realize a micro-benchmark to avoid the impact of many cores and potential additionally generated cache misses.

Since the cache set associativity can provide huge performance drawbacks for cache intensive algorithms, such as DMM, we perform additional analysis on the performance of those matrix sizes where the drawbacks are expected due to L1 and L2 cache set associativity. A performance drawback is a phenomenon where the performance does not follow the existing trend and has smaller value than the performance obtained in the neighboring points. Usually this is reflected as a negative performance peak, i.e. the performance in analyzed point x is lower than the performance in the points left or right of x, which follow a trend in performance behavior.

The goal in this research is to determine which configuration of L1 cache memory provides the best cost - performance ratio.

The rest of the paper is organized as follows. In Section II, we give an overview of related work in the area of the research problem. Analysis of possible performance drawbacks and a description of methodology used in the experiments is presented in Section III. The results of the experiments are elaborated in Section IV. Finally, we conclude our work followed by our plans for future work in Section V.

II. Related work

The latest GPUs have two level cache hierarchy organized with set cache associativity. The impact of cache associativity on GPU performance was analyzed by several authors. Performance drawbacks are likely expected for DMM execution on GPU for particular matrix sizes, due to the usage of only small subset of the cache due to the matrix storage pattern, similar to the effect on multicore architectures reported by Gusev and Ristov [3]. An example of huge performance drawbacks of DGEMM (Double precision General Matrix Multiply) for matrix size that are multiples of 1024 are reported by Matsumoto et. al [4] without deeper explanation. This problem was also analyzed by Batson and Vijakumar [5]. They propose reactive mechanisms (selective displacement and feedback) as a solution. Calder et al. propose that way prediction [6] can improve set-associative cache access times.

8192	**/**	/	4	8192	**/**	/	4	8192	**/**	/	6	**8192**	**1**	8192	16

Greater set associativity will reduce the cache misses, but will still not improve the performance since this will increase the cache hit access time. Padding the first element of the second matrix will amortize the performance drawback due to cache associativity [7]. Hongil [8] dynamically selects an optimized replacement policy for each cache set via workload speculation mechanism to improve the cache performance. Ding et al. [9] designed a software runtime library to include intelligence in the cache allowing the programmers to manage and optimize last level cache usage by allocating proper cache space for different data sets of different threads.

Gusev and Ristov [3] proved both theoretically and experimentally that CPU cache memory storage pattern can significantly reduce the performance of DMM execution by increasing the generation of last level cache misses due to the usage of set associative cache. By using their theorems one can determine the matrix sizes where maximum cache performance drawback in the matrix multiplication algorithm will appear due to matrix storage pattern in a n-way associative memory. Our recent research proved those theoretical results for GPU's L2 set associativity cache [10]. In this paper, we set a research problem to check validity of theoretical results and experimentally test if they hold for different configurations of L1 set associative cache in GPU architectures.

Two problems are exposed with usage of the caches, cache capacity problem refers to the lack of the resources, while the cache associativity problem refers to inefficient usage of the cache. In this paper, we are focused on performance analysis of the cache associativity problem.

III. TESTING METHODOLOGY

We use the classical DMM algorithm, where the operations are performed column-wise in order to exploit the effect of cache reuse, assuming that the matrix elements are stored in row-major order, usually used in C programming language.

This research is focused on GPUs analyzing both the cache capacity and cache associativity problems defined for multicore architectures by Gusev and Ristov [3].

Table I presents the cache parameters of the GPU model GeForce GTX 680 for each configuration of L1 cache and for L2 cache, using the theoretical analysis described in [3]. According to this analysis, we expect the performance drawbacks for bold values of d ($n < N/d$), as presented in Table I. Further on we calculate that maximum N for which the performance drawback will appear is determined as:

- $N = 1024$ for L1 cache configured with 16KB cache and 4 way set associative;
- $N = 2048$ for L1 cache configured with 32KB (4 way set) or 48KB (6 way set); and
- $N = 8192$ for 512KB L2 cache 16 way set associative.

This paper aims to confirm these theoretical results for GPUs by experimental research.

The Ubuntu 12.04 LTS operating system runs on Intel i7-3770 CPU@3.40GHz, 32GB of Kingston RAM @ 1.60GHz and NVIDIA GeForce GTX 680 GPU. The implementations of all of the experiments are compiled with the Nvidia's nvcc compiler from the CUDA 5.0 toolkit.

We conducted experiments for three different configurations of 16/32/48KB of L1 cache memory. Since the cache-line size (cbs) does not influence the equations in our theoretical analysis, there isn't any particular reason to choose a value of cbs. In our case we have chosen 128B. We also assume that the cache memories are set-associative.

Six experiments of the sequential matrix multiplication algorithm were performed in the regions around the critical matrix sizes: $N = 64, 128, 256, 512, 1024$ and 2048. The sequential implementation of the DMM runs one thread per only one active SM [11], thus the whole L1 cache is dedicated to the thread. Each experiment consists of twenty test cases for problems in the area around the critical points.

Average execution time is measured from 10 iterations, excluding the first iteration.

IV. RESULTS OF THE EXPERIMENTS

The obtained results of the experiments on the GPU to analyze the impact of different L1 cache size and set associativity configuration are presented in this section. Our focus is to observe the areas around the problem size for the points where maximum drawbacks are expected from the theoretical analysis performed in Section III. All 6 experiments are performed for three different configurations of L1 cache size, i.e., 16KB, 32KB or 48KB.

The results on performance around the area of $N = 64$ (**Experiment 1**) are depicted in the left part of Figure 1. For this example, both matrices can be stored completely in the L1 cache.

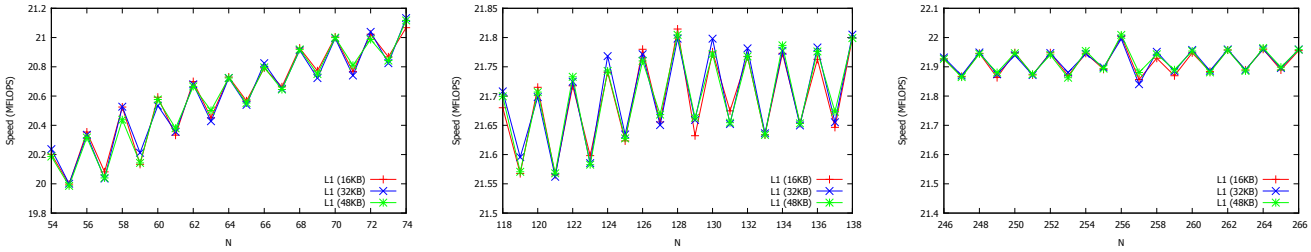

Fig. 1. Speed in the area around $N = 64$ (left), $N = 128$ (middle) and 256 (right)

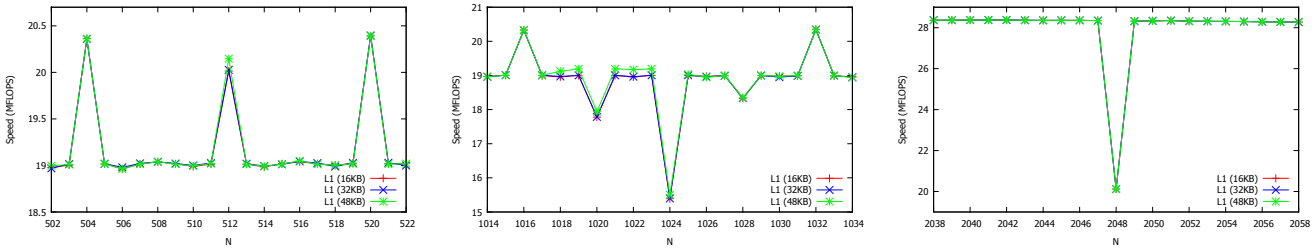

Fig. 2. Speed in the area around $N = 512$ (left), $N = 1024$ (middle) and 2048 (right)

This experiment proves our theoretical analysis since the performance drawbacks do not appear in this region. The elements of a matrix B column can be stored in a particular set and no cache misses will be generated. All three L1 cache size configuration comply with the theoretical analysis.

We observe a very strange speed curve, which increases for even matrix size N and decreases for odd matrix size N. This phenomenon appears due to the average load time for a matrix element, which is smaller for an even matrix size N. Therefore, the matrix elements fulfill the cache line more efficiently within a given cache line.

The speed in this region has a positive increasing trend due to increased amount of data reuse without repeated generation of cache misses.

Experiment 2 covers the area around matrix size $N = 128$. The middle part of Figure 1 depicts the results. The second matrix cannot be stored completely in the L1 cache for these matrix sizes and therefore drawbacks appear due to insufficient L1 cache. However, comparing it with the previous experiment, we can conclude that despite the increased number of generated L1 cache misses, the speed in the Experiment 2 is greater than the speed achieved in Experiment 1.

The results show that performance drawbacks due to L1 cache set associativity are seemingly small due to the unsatisfied condition for L2 cache set associativity, as presented in Table I. We observe a slight speed discrepancy for different L1 cache configurations using the same matrix size. Similar to the Experiment 1, performance discrepancy is observed for even and odd matrix sizes. The speed holds the positive trend as in the Experiment 1, but with smaller intensity.

The **Experiment 3** covers the area of $N = 256$. The second matrix cannot be stored completely in the L1 cache as in the Experiment 2. The speed in this region has even lighter positive trend than experiments 1 and 2, as depicted in the right part of Figure 1.

Similar to the previous case, performance drawbacks are not observed in this region, due to the smaller impact of L1 cache associativity in comparison to L2, where the set associativity problem does not appear in this region. Additionally, we observe that the performance for $N = 256$ is even greater than the values near N in that region, for each L1 cache size configuration. We explain this observation with the fact that despite the L1 cache associativity problem, the whole matrix row can be stored in the exact number of cache blocks and no L2 cache misses are generated neither due to L2 capacity nor L2 associativity problem. Therefore, the average access time is smaller for a matrix element stored in a particular cache block for $N = 256$. We observe a slightly higher speed while L1 cache is configured with 48KB.

Similar performance discrepancy is observed for even and odd matrix sizes, as in previous experiments.

The **Experiment 4** covers the area around matrix size $N = 512$ and the results of the experiment are depicted in Figure 2 (left). Matrix B cannot be stored completely neither in L1 nor L2 cache, and thus the drawback exists mainly due to their size and associativity.

Although one might think the results are strange in this region, there is an explanation. The speed for matrix size $N = 512$ is much greater than the other problem sizes in the region, except for $N = 504$ and $N = 520$. We have also tested the other close positioned points $N \in \{488, 496, 528, 536\}$ and achieved the same positive peaks. The conclusion is that the execution for $N = 512$ has performance drawback compared to these points. The observation consists of two parts: greater speed and performance drawbacks. The former appears for the same reason as explained for $N = 256$. The latter appears

compared due to cache associativity and condition of Table I, compared to points $N = 504$ and $N = 520$ (and for the other points that we measured additionally).

We also observe a slightly better speed while L1 cache is configured with 48KB for $N = 512$.

Experiment 5 analyzes the area around $N = 1024$. Matrix B cannot be stored completely in L2 cache and drawbacks appear due to L2 cache size and associativity. The speed drawbacks are clearly detected and they are depicted in Figure 2 (middle).

Significant performance drawback appears as stated in Table I, but also smaller performance drawbacks appeared in points $N - 4$ and $N + 4$ (as well as for $N + 12$ and $N - 12$).

The same positive peaks are observed in the points $N + 8$ and $N - 8$ as in the region around $N = 512$.

We also observe a slightly better speed while L1 cache is configured with 48KB in the point $N = 1024$, similar to the result for $N = 512$.

Experiment 6 analyzes the area around the matrix size $N = 2048$ where matrix B also cannot be stored completely in the L2 cache. Performance drawback is clearly observed for $N = 2048$ as depicted in Figure 2 (right).

Neither additional positive nor negative peaks are observed in this area since the number of generated L2 cache misses is huge. The impact of L2 cache capacity problem is greater than the positive impact of cache memory to data locality in this region, i.e., loading the elements of the whole cache line while reading one element of that cache line.

V. Conclusion and Future Work

The performance of GPU general purpose application can be seriously degraded by the set associative L1/L2 caches. In this paper, we present the performance drawbacks for specific problem sizes of the DMM algorithm for different L1 cache configurations and fixed L2 cache size. We have performed series of experiments in the areas of critical problem sizes, which prove the analysis.

It is shown that the side effects of the associative cache on the CPU, as discussed in our earlier paper are also present in the GPU environment. However, this paper shows also some other interesting conclusions, due to a specific organization of caches in GPU, which is quite different from CPU (very small 1st level cache and no third level cache in comparison to CPU).

A total of six experiments were evaluated in points where theoretical results expect negative performance peaks with analysis of speed diagrams. The results show that the configuration of L1 cache size does not influence significantly on performance drawbacks, which appear for $N = 1024$ and 2048 due to L2 cache set associativity. Because L2 cache set size is enough to fit the cache storage requirements for problem sizes $N = 64, 128$ and 256, performance drawbacks are not observed, i.e., the algorithm performance depends mostly on L2 cache size, rather than L1's. The performance for $N = 256$ is even greater than the matrix size values near N in that region for all L1 cache size configuration.

An interesting phenomenon appears in the region around $N = 512$. The speed for $N = 512$ is greater than the other problem sizes in the region, except for $N = 504$ and $N = 520$. Although higher values are obtained than the neighboring points, still there is a performance drawback compared to analyzed points $N = 504$ and $N = 520$. More interestingly, we have found smaller negative peaks in the region around $N = 1024$ in points $N + 4$ and $N - 4$, as well as positive peaks in the points $N + 8$ and $N - 8$.

Another phenomenon was observed in the regions around $N = 64, 128$ and 256, i.e., the speed increases for even matrix size N and decreases for odd matrix size N. This happens due to the effect of loading the elements of the whole cache line while reading one element of the same cache line.

Probably the most important result is to report the platform impact of reconfigurable cache, i.e. what the user can choose for configuration of the L1 cache to achieve maximum processing speed and avoid associativity problems.

Future work will cover further research on these phenomenons, as well as analysis of correlation of power consumption with the L1/L2 capacity and associativity, since the results show that L1 cache size does not impact the algorithm performance, but different cache associativity configuration due to different cache size configuration can reduce the power consumption.

Also, we plan to measure the number of generated L1 and L2 cache misses to determine the performance drawbacks and performance discrepancies more precisely.

Abstract—**In order to make a proper selection for the given matrix-matrix multiplication operation and to decide which is the best suitable algorithm that generates a high throughput with a minimum time, a comparison analysis and a performance evaluation for some algorithms is carried out using the identical performance parameters**

Keywords- parallel algorithms for matrix multiplication, systolic array, linear transformation, nonlinear transformation, performance measures, number of processor elements Introduction.

I. INTRODUCTION

Most of the parallel algorithms for matrix multiplication use matrix decomposition that is based on the number of processors available. This includes the systolic algorithm [1], Cannon's algorithm [2], Fox's and Otto's Algorithm [3], PUMMA (Parallel Universal Matrix Multiplication) [4], SUMMA (Scalable Universal Matrix Multiplication) [5] and DIMMA (Distribution Independent Matrix Multiplication) [6]. The standard method for multiplying $n \times n$ matrices requires $O(n^3)$ multiplications. Most existing parallel algorithms are parallelization of the standard method. All implementations of the standard method have a cost, i.e., time-processor product of at least $O(n^3)$. Therefore, it is interesting to develop highly parallel and processor efficient algorithms that have less than $O(n^3)$ cost.

II. WHY SYSTOLIC ARRAY?

The MPI technique needs two kinds of time to complete the multiplication process, t_c and t_f, where t_c represents the time it takes to communicate one data between processors and t_f is the time needed to multiply or add elements of two matrices. It is assumed that matrices are of type $n \times n$. The other assumption is that the number of processors is p. Each processor holds n^2/p elements and it was assumed that n^2/p is set to a new variable m^2.

The number of arithmetic operations units will be denoted by f. The number of communication units will be denoted by c. The quotient $q = f/c$ will represent the average number of flops per communication access. The speedup is $S = q \cdot (t_f / t_c)$. We assume that the number of processors is $p = 4$. The dimension of the matrix is $n = 600$. The last assumption is that $t_f / t_c = 0.1$. Also we need to use the Efficiency formula $E = S/p$. In the table 1 we record the results that we obtain for all algorithms, under the assumptions that we made. [2, 3, 4, 7, 8, 9, 10, 11].

III. DEFINITION OF SOME PERFORMANCE MEASURES FOR SYSTOLIC ARRAYS

Definition 1: The array size (Ω) is the number of PEs in the array.

Definition 2: The computation time (T) is the sum of the time for the date input in the array-T_{in}, the time for the algorithm executing-T_{exe} and the time necessary for dates leaving the array-T_{out}, i.e.

$$T = T_{in} + T_{exe} + T_{out} \tag{1}$$

Definition 3: The execution time, T_{exe}, is defined as:

$$T_{exe} = 1 + \max_{(t,x,y) \in P_{ind}} t - \min_{(t,x,y) \in P_{ind}} t_{out} \tag{2}$$

Theorem 1: [12] The execution time is given by the relation:

$$T_{exe} = 1 + \sum_{j=1}^{3} (N_j - 1) \cdot \left| \min_t t_{ij} \right| \tag{3}$$

Definition 4: The Pipelining period (α)**:** The time interval between two successive computations in a PE. If λ is a scheduling vector and u is a projection direction, then the pipelining period is given by the relation:

$$\alpha = \lambda^T u \tag{4}$$

978-83-60810-53-8/$25.00

Definition 5: The geometric area (g_a) of a two-dimensional systolic array is the area of the smallest convex polygon which bounds the PEs in the (x, y)-plane. The geometric area is given by the formula:

$$g_a = (N_1-1)(N_2-1)|T_{13}| + (N_1-1)(N_3-1)|T_{12}| + (N_2-1)(N_3-1)|T_{11}| \quad (5)$$

Definition 6: The Speedup (S) of a systolic array is the ratio of the processing time in the SA to the processing time in a single processor (T_1), i.e.

$$S = \frac{T_1}{T} \quad (6)$$

Definition 7: The Efficiency (E) is defined as the ratio of the speedup to the number of PEs in the array i.e.

$$E = \frac{S}{\Omega} = \frac{T_1}{T x \Omega} \quad (7)$$

Theorem 2: [12, 13] The number of processors on SHSA array is (the array where we have no using the linear transformation):

$$\Omega = 3N^2 - 3N + 1 \quad (8)$$

Theorem 3: [14] The number of processing elements in 2-dimensional systolic array for the algorithm of matrix-matrix multiplication for which is used the projection direction $u = [1 \ \ 1 \ \ 1]^T$, could be reduced and given with $\Omega = N^2$.

Theorem 4: [15] The number of PEs for the systolic array which is constructed by using the nonlinear transformation the number of PEs is given by the relation:

$$\Omega = n \cdot \left\lfloor \frac{3n-1}{2} \right\rfloor \quad (9)$$

Definition 8: The transformation matrix T maps the index point $(i, j, k) \in P_{ind}$ into the point $(t, x, y) \in T \cdot P_{ind}$, where P_{ind} is the set of index points and

$$Tt = T_1 [i \ \ j \ \ k]^T = i + j + k \quad (10)$$

IV. THE ADVANTAGE OF USING THE LINEAR TRANSFORMATION IN DESIGNING THE SYSTOLIC ARRAY FOR MATRIX MULTIPLICATION

From theorem 2, For N=4 then $\Omega = 37$ (which can be seen from fig.2 too). Because of theorem 3, the number of processors (which can be seen from fig. 1) is $\Omega = 4^2 = 16$. So, we can conclude how the number of processors on the array can be reduced using the linear transformation. For N=4 is 16 vis-à-vis 37 without using the transformation. On the table 3 we give the comparison for number of PE for different values of N. This information is taken from [13].

TABLE 3: COMPARISON FOR NUMBER OF PE

N	Without using L	By using L
5	61	25
10	271	100
50	7351	2500
100	29701	10000

For the pipeline period, in the case of the array in fig. 2, using relation (4) we get

$$\alpha = \lambda^T u = 3 \quad (11)$$

If this formula is used for the systolic array which is constructed by using the linear transformation matrix (the array in fig.1), we get $\alpha = 1$. This means that in the case of fig. 1 the PEs perform in every step.

If k is an index point, then of course, $\max k = (N_1, N_2, N_3)$ and $\min k = (1,1,1)$. Using the relation (10) we have that:

$$\max_{(t,x,y)\in P_{ind}} t \ \ t = N_1 + N_2 + N_3; \ \min_{(t,x,y)\in P_{ind}} t = 1+1+1 = 3 \quad (12)$$

From relations (2) and (12) the execution time may is:

$$T_{exe} = 1 + N_1 + N_2 + N_3 - 3 = N_1 + N_2 + N_3 - 2 \quad (13)$$

If one uses the fact that if $N_1 = N_2 = N_3$, then $T_{exe} = 3N - 2$. On the other hand $T_{in} = T_{out} = N - 1$, so the computation time is:

$$T = 5N - 4 \quad (14)$$

In the case of the array in fig.1 the execution time will be ordered by using the theorem 1:

$$T_{exe} = 1 + (N_1 - 1) \cdot 0 + (N_2 - 1) \cdot 1 + (N_3 - 1) \cdot 1 = N_2 + N_3 - 1 \quad (15)$$

If $N_2 = N_3$ then $T_{exe} = 2N - 1$. In this case $T_{in} = N - 1$ and $T_{out} = 0$, therefore the computational time is

$$T = 3N - 2 \quad (16)$$

In the case of the array which was constructed by using the nonlinear transformation, we have that $T_{exe} = 3N - 1$, $T_{in} = N - 1$ and $T_{out} = 0$. Therefore the computation time is

$$T = 4N - 2 \quad (17)$$

For the geometric area in the case of the array in fig.2, if one takes $N_1 = N_2 = N_3 = N$ then

$$g_a = 3N^2 - 6N + 3 = 3(N-1) \tag{18}$$

For the second case (the array in fig. 1) the geometric area If one takes $N_1 = N_2 = N_3 = N$ will be calculated as

$$g_a = (N-1)^2 \tag{19}$$

In the case of the array with nonlinear transformation, one can calculate the geometric area in a similar way as above

$$g_a = 2(N-1)^2 \tag{20}$$

Since the duration of matrix multiplication on a system with only one processor is $T_1 = N^3$, the speedup and efficiency in the case of the array in fig.2, using relations (6) and (7), will be respectively:

$$S = \frac{N^3}{5N-4} \tag{21}$$

$$E = \frac{N^3}{(5N-4)(3N^2-3N+1)} \left(\lim_{N\to\infty} E = \frac{1}{15} = 6.7\% \right) \tag{22}$$

The same parameters in the case of using linear transformation matrix are:

$$S = \frac{N^3}{3N-2} \tag{23}$$

$$E = \frac{N}{(3N-2)} \left(\lim_{N\to\infty} E = \frac{1}{3} = 33.3\% \right) \tag{24}$$

And finally these parameters for the array where nonlinear transformation has been used are:

$$S = \frac{N^3}{4N-2} \tag{25}$$

$$E = \frac{N^2}{(4N-2)\cdot\left\lfloor \frac{3n-1}{2} \right\rfloor} \left(\lim_{N\to\infty} E = \frac{1}{6} = 16.7\% \right) \tag{26}$$

Using the results obtained by the relations (14-26), as well as theorems 1, 2, and 3, one can construct the corresponding table, where all the results can be compared. In table 2 it is given a comparison of performance characteristics for some values of N.

V. CONCLUSION

In this paper are analyzed some performance measures for parallel matrix multiplication. We emphasized the systolic approach as most efficient. We can conclude that using the identical performance parameters, for each parameter, the array which is constructed using linear transformation matrix has better performances. Especially for the efficiency when N tends to the infinity we have that it is approximately five times better than the array without using the linear transformation. From the table 2 we can deduce the advantage of using the linear transformation.

***Abstract*—The aim of the paper is to show how to design and implement fast parallel algorithms for Linear Congruential, Lagged Fibonacci and Wichmann-Hill pseudorandom number generators. The new algorithms employ the *divide-and-conquer* approach for solving linear recurrence systems. They are implemented on multi GPU-accelerated systems using CUDA. Numerical experiments performed on a computer system with two Fermi GPU cards show that our software achieve good performance in comparison to the widely used NVIDIA CURAND Library.**

I. Introduction

PSEUDORANDOM numbers are very important in practice and pseudorandom number generators are often central parts of scientific applications such as simulations of physical systems. They are used by Monte Carlo methods, especially in case of multidimensional numerical integration [1], [4], [9]. In [8] we showed the general techniques for implementing recursion-based generators of pseudorandom numbers on GPU-accelerated systems which are much more efficient than their sequential counterparts.

NVIDIA CURAND Library [5] provides routines for simple and efficient generation of high-quality random numbers. It comprises two types of generators:

- XORWOW, MRG32K3A and MTGP32 are *pseudorandom number generators* which means that a sequence of random numbers which they produce satisfy most of desired statistical properties of a truly random sequence and they work on 32-bit numbers,
- SOBOL32, SCRAMBLED_SOBOL32, SOBOL64, SCRAMBLED_SOBOL64 are *quasirandom number generators*, n-dimensional points obtained from these fill n-dimensional space evenly, SOBOL32, SCRAMBLED_SOBOL32 use 32-bit arithmetic and SOBOL64, SCRAMBLED_SOBOL64 use 64-bit arithmetic.

Unfortunately, these generators utilize only a single GPU device, thus if we want to perform computations using multiple GPUs, we should apply some parametrization techniques for parallel generation of pseudorandom numbers [3] what can lead to possible unwanted correlations between numbers resulting in their poor statistical properties [6]. It should be noticed that only one generator from CURAND produces fully 64-bit results.

In this paper we show how to design fast parallel algorithms for Linear Congruential, Lagged Fibonacci [3] and Wichmann-Hill [10] pseudorandom number generators which employ the *divide-and-conquer* approach for solving linear recurrence systems [7] and can be easily used in computations on multi-GPU systems. Our generators have exactly the same statistical properties as their sequential counterparts.

Numerical experiments performed on a computer system with two Fermi GPU cards show that they achieve good speedup in comparison to the standard CPU-based sequential algorithms [8] and implementations provided by NVIDIA CURAND Library. Our implementation is freely available as the C++ template library which requires only CUDA Toolkit. It can be downloaded from `http://dominisz.umcs.lublin.pl/gpu-rand`.

II. Parallel Pseudorandom Number Generators

We consider the following three pseudorandom number generators:

1) **Linear Congruential Generator (LCG)**: $x_{i+1} \equiv (ax_i + c)(\mod m)$, where x_i is a sequence of pseudorandom values, $m > 0$ is the *modulus*, a, $0 < a < m$ is the *multiplier*, c, $0 \leq c < m$ is the *increment*, x_0, $0 \leq x_0 < m$ is the *seed* or *start value*,
2) **Lagged Fibonacci Generator (LFG)**: $x_i \equiv (x_{i-p_1} + x_{i-p_2})(\mod m)$, where $0 < p_1 < p_2$,
3) **Wichmann-Hill Generator (WHG, [10])**:

$$\begin{aligned} x_i &\equiv 11600x_{i-1}(\mod 2147483579) \\ y_i &\equiv 47003y_{i-1}(\mod 2147483543) \\ z_i &\equiv 23000z_{i-1}(\mod 2147483423) \\ t_i &\equiv 33000t_{i-1}(\mod 2147483123) \\ W &\equiv x_i/2147483579.0 + y_i/2147483543.0 \\ &\quad + z_i/2147483423.0 + t_i/2147483123.0 \\ W_i &\equiv W - \lfloor W \rfloor. \end{aligned} \tag{1}$$

It should be noted that, in fact, WHG combines four LCG generators, each with the increment 0 (such generator is also called Multiplicative Congruential Generator, MCG). This generator has much better statistical properties than LCG. Its period is about 2^{121}. It passes Big Crush test from TestU01 Library [2].

978-83-60810-53-8/$25.00

In case of LCG and LFG, $m = 2^M$, where $M = 32$ or $M = 64$, thus these generators produce numbers from $\mathbb{Z}_m = \{0, 1, \ldots, m-1\}$. It allows the modulus operation to be computed by merely truncating all but the rightmost 32 or 64 bits, respectively. Thus, when we use `unsigned int` or `unsigned long int` data types, we can neglect "$(\mod m)$". In case of WHG, we have moduli given explicitly. Note that the integers x_k are between 0 and $m-1$. They can be converted to real values $r_k \in [0, 1)$ by $r_k = x_k/m$.

It is clear that LCG, LFG, WHG generators can be considered as special cases of linear recurrence systems [7]. Indeed, LCG can be defined as

$$\begin{cases} x_0 = d \\ x_{i+1} = ax_i + c, \quad i = 0, \ldots, n-2, \end{cases} \tag{2}$$

and similarly for LFG we have

$$\begin{cases} x_i = d_i & i = 0, \ldots, p_2 - 1 \\ x_i = x_{i-p_1} + x_{i-p_2}, & i = p_2, \ldots, n-1. \end{cases} \tag{3}$$

The details of our single-GPU implementations of LCG and LFG generators can be found in [8]. Here we only recall the most important formulas. The parallel version LCG can be expressed as follows

$$\begin{cases} \mathbf{x}_0 = A^{-1}\mathbf{f}_0 \\ \mathbf{x}_i = \mathbf{t} + x_{is-1}\mathbf{y}, \quad i = 1, \ldots, r-1, \end{cases} \tag{4}$$

where $\mathbf{x}_i = (x_{is}, \ldots, x_{(i+1)s-1})^T \in \mathbb{Z}_m^s$, $\mathbf{f}_0 = (d, c, \ldots, c)^T \in \mathbb{Z}_m^s$, $\mathbf{f} = (c, \ldots, c)^T \in \mathbb{Z}_m^s$, and

$$A = \begin{bmatrix} 1 & & & \\ -a & 1 & & \\ & \ddots & \ddots & \\ & & -a & 1 \end{bmatrix} \in \mathbb{Z}_m^{s \times s}.$$

Moreover $\mathbf{t} = A^{-1}\mathbf{f}$ and $\mathbf{y} = A^{-1}(a\mathbf{e}_0)$, where $\mathbf{e}_0 = (1, 0, \ldots, 0)^T \in \mathbb{Z}_m^s$.

Similarly, for LFG we have

$$\begin{cases} \mathbf{x}_0 = A_0^{-1}\mathbf{f} \\ \mathbf{x}_i = \sum_{k=0}^{p_2-1} x_{is-p_2+k}\mathbf{y}_k + \sum_{k=0}^{p_1-1} x_{is-p_1+k}\mathbf{y}_k, \\ \qquad\qquad\qquad\qquad i = 1, \ldots, r-1, \end{cases} \tag{5}$$

where matrix A_0 and vectors $\mathbf{f}$, $\mathbf{y}_k$ are defined analogously as for LCG case (see [8] for details). Note that (5) is the generalization of (4).

III. Multi-GPU implementation

To implement the parallel algorithms efficiently on GPU, we will form the following matrix

$$Z = [\mathbf{x}_0, \ldots, \mathbf{x}_{r-1}] \in \mathbb{Z}_m^{s \times r}, \tag{6}$$

where all vectors $\mathbf{x}_i$ are defined by (4) or (5). This allows to use fast coalesced memory access and makes possible the use of shared memory.

The equation (4) has a lot of potential parallelism. The algorithm comprises the following steps. First (Step 1) we have to find $\mathbf{y}$, $\mathbf{t}$. Then (Step 2) we find the last entry of each vector $\mathbf{x}_i$, $i = 1, \ldots, r-1$. Finally (Step 3), we find $s-1$ entries of the vectors $\mathbf{x}_1, \ldots, \mathbf{x}_{r-1}$ in parallel. In case of multi-GPU implementation vectors $\mathbf{y}$, $\mathbf{t}$ are computed by CPU and then sent to all GPU devices. The generator seed required to compute Step 2 is received from the previous GPU device and sent to the next one after Step 2 is completed locally (Figure 1). Then all GPUs perform Step 3 independently.

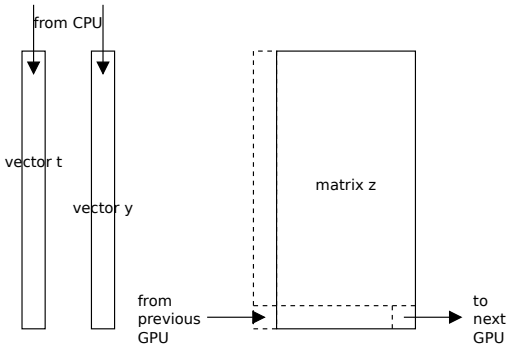

Fig. 1. LCG: data structures on a GPU device and communication scheme

We can develop a similar parallel algorithm for LFG. During the first step we have to find vector $\mathbf{y}_0$. This vector is computed by CPU and sent to all GPUs. It is easy to verify that

$$\mathbf{y}_k = (\underbrace{0, \ldots, 0}_{k}, 1, y_1, \ldots, y_{s-1-k})^T.$$

Then (Step 2) using (5) we find p_2 last entries of $\mathbf{x}_1, \ldots, \mathbf{x}_{r-1}$. Finally (Step 3) we use (5) to find $s - p_2$ first entries of these vectors in parallel. Note that Step 2 requires communication (sending and receiving the seed consisting of p_2 numbers) between GPU devices (Figure 2).

The parallel algorithm for WHG is a simple extensions of the parallel LCG. Instead of vectors $\mathbf{t}$ and $\mathbf{y}$, we have four instances of $\mathbf{y}$, each for one MCG. We also have four separate "last rows" of matrix Z, corresponding to appropriate MCG, which are required during Step 2 (Figure 3).

IV. Results of experiments

The considered algorithms have been tested on a computer with Intel Xeon X5650 (2.67 GHz, 48GB RAM) and NVIDIA Tesla M2050 (448 cores, 3GB GDDR5 RAM with ECC off), running under Linux with `gcc` and NVIDIA `nvcc` compilers and CURAND Library ver. 5.0 provided by the vendor. The results of experiments are presented in Figures 4-6. We can conclude the following:

- Parallel LCG is the fastest among the considered generators. It produces $\approx 32 \cdot 10^6$ `unsigned int` pseudorandom numbers per second, while the fastest CURAND pseudorandom generator achieves the speed of $\approx 12 \cdot 10^6$.

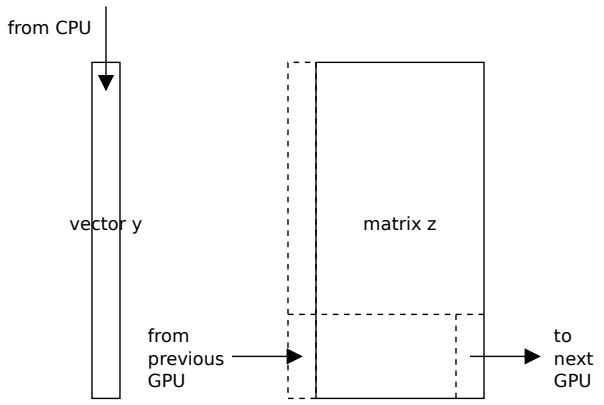

Fig. 2. LFG: data structures on a GPU device and communication scheme

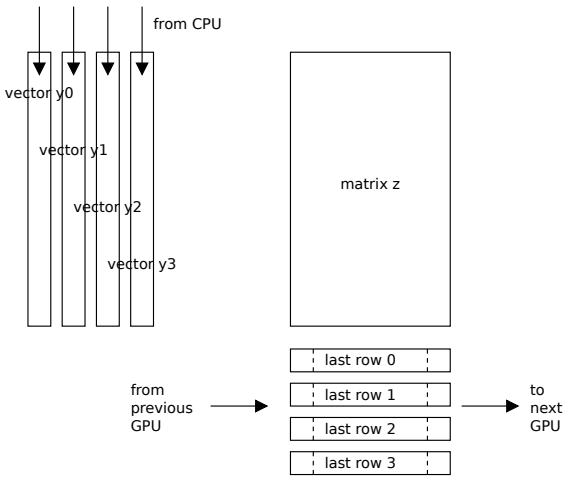

Fig. 3. WHG: data structures on a GPU device and communication scheme

- Parallel WHG is about 6 times slower than LCG. However it uses more computations and communications in comparison to LCG. It also has better statistical properties, so it should be use instead of LCG, when the performance is not so important.
- The performance of parallel LFG depends on the values of p_1 and p_2.
- Our template library provides both 32-bit and 64-bit versions of all generators. CURAND does not support 32-bit or 64-bit arithmetic in all cases (hence missing bars in Figure 4).
- The use of two GPUs accelerates the overall time of computations (Figure 6). In case of LCG we obtain almost linear speedup. The scalability of WHG is worse because of longer lasting Step 2. Unfortunately, the scalability of LFG is poor for large values of p_1, p_2.

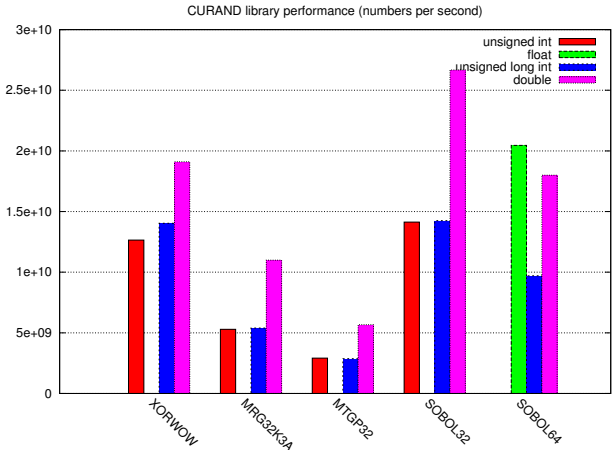

Fig. 4. CURAND Library performance: generation of random number using various generators

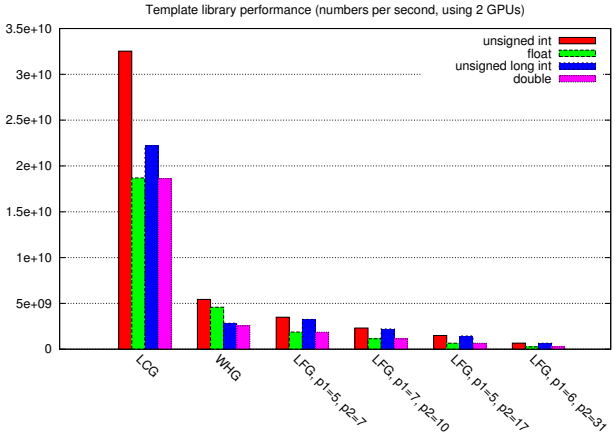

Fig. 5. Our template library performance: generation of random number using various generators

V. Using template library

Let us consider the use our template library in case of LCG. The following class template should be used (we only show `public:` part of it).

```
template <class T>
class LcgGpu {
  public:
    LcgGpu(T multiplier, T increment,
           T seed, size_t count);
    void generate();
    void generateFloat();
    void generateDouble();
    T* getNumbersFromDevice(int device);
    size_t getCountFromDevice(int device);
    int getDeviceCount();
    ...
}//class LcgGpu
```

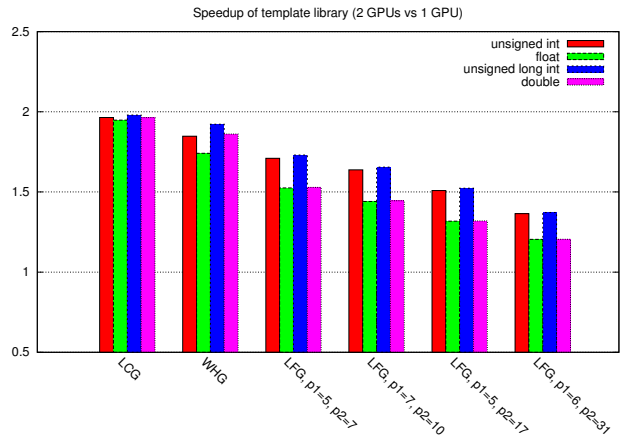

Fig. 6. Our template library: speedup 2 GPUs vs 1 GPU

In order to use the generator we should create an object providing desired parameters (multiplier, increment, seed of the generator and the number of pseudorandom numbers to generate).

```
unsigned int multiplier=1664525;
unsigned int increment=1013904223;
unsigned int seed=31;
size_t count=100000000;

LcgGpu<unsigned int> lcg
  =new LcgGpu<unsigned int>(multiplier,
                            increment,
                            seed, count);
```

Then we generate random numbers (e.g. uniformly distributed real numbers from interval $[0, 1)$).

```
lcg->generateFloat();
```

Generated numbers are stored in global memories of all GPU devices. We use the following routines to obtain the number of GPU devices, which produce numbers, the number of pseudorandom numbers generated by a given device and the address of memory block containing the numbers:

```
int getDeviceCount();
size_t getCountFromDevice(int device);
T* getNumbersFromDevice(int device);
```

Generated numbers can be used directly by each GPU or can be transferred to CPU memory using loop for accessing all devices.

```
for (i=0; i<lcg->getCountFromDevice(); i++) {
        cudaMemcpy(cpuNumbers+offset,
          lcg->getNumbersFromDevice(i),
          lcg->getCountFromDevice(i)
            *sizeof(unsigned int),
          cudaMemcpyDeviceToHost);
    offset=offset
      +lcg->getCountFromDevice(i);
}//for
```

Generation of numbers can be repeated as many times as desired to obtain very long sequence of pseudorandom numbers. Finally we can delete the object.

```
delete lcg;
```

Using LFG generator is quite similar. The only difference is when the object is created. For example, we can use the following code.

```
unsigned int p1=24;
unsigned int p2=55;
unsigned int seed[]={...}; //array of
                           //length p2
size_t count=100000000;

LfgGpu<unsigned int> lfg=
  new LfgGpu<unsigned int>(p1, p2
                           seed, count);
```

Analogously for WHG we use the following.

```
unsigned int seedX=389933028;
unsigned int seedY=148667295;
unsigned int seedZ=146045161;
unsigned int seedT=767880647;

WhgGpu<unsigned int> whg=
  new WhgGpu<unsigned int>(seedX, seedY,
                           seedZ, seedT,
                           count);
```

When we parametrize template with `unsigned int` type then we can use the following routines to generate 32-bit pseudorandom numbers (integer or real numbers).

```
void generate();
void generateFloat();
```

When we need 64-bit precision we use `unsigned long int` type to parametrize template and the following routines.

```
void generate();
void generateDouble();
```

VI. Conclusions

We have showed how to implement fast parallel LCG, LFG and WHG pseudorandom number generators using the *divide-and-conquer* approach on contemporary multi-GPU systems. Numerical experiments performed on a computer system with modern Fermi GPU cards showed that our routines achieve good performance in comparison to the widely used NVIDIA CURAND Library. Our template library is easy to use and it is freely available for the community.

International Symposium on Multimedia Applications and Processing

ORGANIZED BY

Software Engineering Department, Faculty of Automation, Computers and Electronics, University of Craiova, Romania "Multimedia Applications Development" Research Centre

Background and Goals

Multimedia information has become ubiquitous on the web, creating new challenges for indexing, access, search and retrieval. Recent advances in pervasive computers, networks, telecommunications, and information technology, along with the proliferation of multimedia mobile devices - such as laptops, iPods, personal digital assistants (PDA), and cellular telephones - have stimulated the development of intelligent pervasive multimedia applications. These key technologies are creating a multimedia revolution that will have significant impact across a wide spectrum of consumer, business, healthcare, educational and governmental domains. Yet many challenges remain, especially when it comes to efficiently indexing, mining, querying, searching, retrieving, displaying and interacting with multimedia data.

The Multimedia - Processing and Applications 2013 (MMAP 2013) Symposium addresses several themes related to theory and practice within multimedia domain. The enormous interest in multimedia from many activity areas (medicine, entertainment, education) led researchers and industry to make a continuous effort to create new, innovative multimedia algorithms and applications.

As a result the conference goal is to bring together researchers, engineers, developers and practitioners in order to communicate their newest and original contributions. The key objective of the MMAP conference is to gather results from academia and industry partners working in all subfields of multimedia: content design, development, authoring and evaluation, systems/tools oriented research and development. We are also interested in looking at service architectures, protocols, and standards for multimedia communications - including middleware - along with the related security issues, such as secure multimedia information sharing. Finally, we encourage submissions describing work on novel applications that exploit the unique set of advantages offered by multimedia computing techniques, including home-networked entertainment and games. However, innovative contributions that don't exactly fit into these areas will also be considered because they might be of benefit to conference attendees.

Call for Papers

MMAP 2013 is a major forum for researchers and practitioners from academia, industry, and government to present, discuss, and exchange ideas that address real-world problems with real-world solutions.

The MMAP 2013 Symposium welcomes submissions of original papers concerning all aspects of multimedia domain ranging from concepts and theoretical developments to advanced technologies and innovative applications. MMAP 2013 invites original previously unpublished contributions that are not submitted concurrently to a journal or another conference.

Papers acceptance and publication will be judged based on their relevance to the symposium theme, clarity of presentation, originality and accuracy of results and proposed solutions.

Topics

Topics of interest are related to Multimedia Processing and Applications including, but are not limited to the following areas:

- Audio, Image and Video Processing
- Animation, Virtual Reality, 3D and Stereo Imaging
- Multimedia File Systems and Databases: Indexing, Recognition and Retrieval
- Machine Learning, Data Mining, Information Retrieval in Multimedia Applications
- Multimedia in Internet and Web Based Systems:
  - E-Learning, E-Commerce and E-Society Applications
- Human Computer Interaction and Interfaces in Multimedia Applications
- Multimedia in Medical Applications
- Entertainment and games
- Security in Multimedia Applications: Authentication and Watermarking
- Distributed Multimedia Systems
- Network and Operating System Support for Multimedia
- Mobile Network Architecture
- Intelligent Multimedia Network Applications

Design of Digital Watermarking System Robust to the Number of Removal Attacks

Sergey Anfinogenov
State University of Telecommunications,
St. Petersburg, Russia
Email: serganff@gmail.com

***Abstract*—In this paper it is proved that in fact the zero-bit digital watermarking system based on local maxima embedding in frequency area heuristically proposed recently is resistant to a number of removal attacks. It is shown how the watermark can survive after such conversions as shift cropping rescaling rotation and jpeg transform. The theoretical base of each transformation is given. Also it is shown how the image Fourier amplitude spectrum is affected by the image distortions and how the watermark can overcome those distortions and stay untouched.**

I. Introduction

THE MAIN idea of the watermarking method offered in [1] is an embedding of a zero-bit watermark (identification key) into the positions of maxima of the local areas, which are selected in the amplitude spectrum of the two dimensional discrete Fourier transform (DFT), calculated from the original image.

Now let us remember how this algorithm works step-by-step. First we generate a binary key K, which can be represented as the two dimensional matrix $K(n,m)$ where the number of columns N and rows M is equal to the width and height of the image respectively. Then we calculate the DFT of the image and get the amplitude spectrum. Next we change the amplitude spectrum according to the rule: If $K(n,m)=1$ we build the local area $(n-a..n+a, m-a..m+a)$ with the size (2a+1)x(2a+1) around this point, where a is a constant value which determines local area size. Then maximum of each local area is calculated. This maximum is multiplied by β value ($\beta > 1$) and placed in the point $K(n,m)$. Later we combine this new amplitude spectrum with a phase untouched before and perform the inverse DFT to get the watermarked image.

During the extraction process we calculate the amplitude again and using previously saved key K build the same local areas and verify if the maximum of each area is situated in the point $K(n,m)$. Next we count all positive answers and divide this value by the total number of local areas. Percepts of watermark are recognised if this value exceeds some threshold. If the watermarked image was untouched there would be no errors and all key points would be recognised. If some attack is applied to the watermark image, then some maxima can be lost, but the watermark will still be detectable sometimes.

The current method of zero-bit WM embedding and extraction seems to be robust against such transforms of an image as cyclic shifting, rotation, removal of rows and columns, noise addition, JPEG transform and cropping, but these conclusions have been based on simulation. In the next section we are going to present the proof of this claim based on the properties of DFT.

II. The proof of robustness of the proposed zero-bit WM system to different attacks

Now let us concentrate on the robustness of the algorithm and answer two main questions. After what image distortions a watermark can survive and why? The direct and inverse Fourier transforms for 2D signal $h(n,m)$(Image in our case) with N columns and M rows are as usually given by:

$$F(h) = \widehat{h}(k,l) = \sum_{n=0}^{N-1}\sum_{m=0}^{M-1} e^{-i(\omega_k n+\omega_l m)} h(n,m) \quad (1)$$

$$h(F) = \frac{1}{NM}\sum_{k=0}^{N-1}\sum_{l=0}^{M-1} e^{-i(\omega_k n+\omega_l m)} \widehat{h}(k,l) \quad (2)$$

Often it is convenient to express frequency in vector notation with $\vec{k} = (k,l)^t$, $\vec{n} = (n,m)^t$, $\vec{\omega}_{kl} = (\omega_k, \omega_l)^t$ and $\vec{\omega}^t\vec{n} = \omega_k n + \omega_l m$. The vector form will help us when we talk about DFT properties. In this section we will show

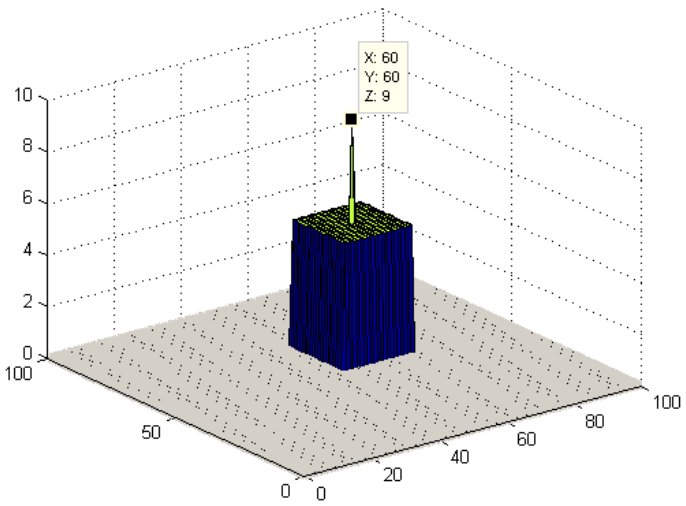

Fig. 1. Test amplitude spectrum

978-83-60810-53-8/$25.00

how the proposed watermarking algorithm can stand against different transformations. The set of transformations that are usually performed to remove a watermark are described in [5] and [4]. Now let us discuss each transformation one by one. To show an effect of each transformation we generate a test amplitude spectrum Fig. 1 where we have only one local area with maximum in the center. Such model differs from the real situation where there are many local maxima, but this simplified model helps us to show how each transformation affects on the behaviour of local maxima positions in each local area.

A. Translation

Using the shift property of the Fourier transform

$$F[f(\vec{x}-\vec{x}_0)] = \exp(-i)\vec{\omega}^t\vec{x}_0)\widehat{f}(\vec{\omega}) \tag{3}$$

it is easy to see that only phase of the DFT is affected by the translation of the image. The amplitude spectrum where the watermark is embedded remains untouched. So that transformation has no impact on a watermark detection.

B. Rotation

According to FFT property a rotation of the image causes the rotation of the FFT amplitude.

$$F(x,y) \rightarrow F(x\cos\theta + y\sin\theta, x\sin\theta + y\cos\theta) \tag{4}$$

To overcome a rotation problem if the watermark is not found initially the detection process is repeated after rotation of the image on a small angle. Another solution can be used with a normalisation algorithm described in [3] where the image is converted to the domain invariant to rotation. In fact, the image rotation on more than 10 degrees can be distinguished from the original. So it is possible to reduce number of calculations and image rotations. The last way to deal with rotation is to extend the size of local areas and detect maxima not in one certain point but in several points around the embedded maxima. That will help especially in case of small rotation angles.

C. Noise Addition

Let us define a set of n points $x_1, x_2, x_3, ...x_n$ with constant amplitude A and a point $x0$ with amplitude $\beta A(\beta > 1)$. At all points we add zero mean i.i.d Gaussian noise. The probability that the maximum stay in the previous position after the addition of noise is the following:

$$P = Pr(\tilde{x_0} \geq x_1, \tilde{x_0} \geq x_2 ... \tilde{x_0} \geq x_n) = ? \tag{5}$$

where

$\tilde{x_0} = \beta A + n_0, \tilde{x_i} = A + n_i$

$i = 1, 2..n..n_i \in i.i.dN(0, \sigma^2)$

It is easy to see that:

$$P = \int_{-\infty}^{+\infty} \omega_0(y) \prod_{i=1}^{n} (P_\tau(x_i) \leq y)dy \tag{6}$$

where

$$Pr\{\tilde{x} \leq y\} = \frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{y} e^{-\frac{t-A^2}{2\sigma^2}} dt, \tag{7}$$

$$\omega_0(y) = \frac{1}{\sqrt{2\pi, \sigma^2}} e^{-\frac{(y-\beta A)^2}{2\sigma^2}} \tag{8}$$

Substituting (7) and (8) in (6) we get:

$$P = \frac{1}{\sqrt{2\pi, \sigma^2}} \int_{-\infty}^{+\infty} e^{-\frac{(y-\beta y)^2}{2\sigma^2}} \cdot (\int_{-\infty}^{y} e^{-\frac{(t-A)^2}{2\sigma^2}})^n dy, \tag{9}$$

It is easy to find the lower bound of that probability using the equation:

$$P \geq \prod_{i=1}^{n} P_\tau\{\tilde{x_0} \geq \tilde{x_i}\} = (P_\tau\{\tilde{x_0} \geq \tilde{x_i}\})^n \tag{10}$$

where $(P_\tau\{\tilde{x_0} \geq \tilde{x_i}\})^n = (P_\tau\{\tilde{x_0} - \tilde{x_i}\} \geq 0)^n$

$$(P_\tau\{\tilde{x_0} - \tilde{x_i}\} \geq 0)^n = (\frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{+\infty} e^{-\frac{t-A(\beta-1)}{2\sigma^2}} dt)^n \tag{11}$$

But unfortunately it is the most interesting for us to find the upper bound of that probability, because we want to know when the local maximum changes its position. Taking into account that a calculation by (9) is very tedious procedure, we can try to solve it by simulation. Fig. 2 shows the effect of noise addition and Table I demonstrates the results of correct maxima recognition for $A = 100$, $\beta = 1.5$, $\sigma = 0.097927$.In the similar manner we can calculate the results for other embedding parameters.

We can see from Table I that maxima are recognised whenever signal-to-noise ratio $\frac{\beta^2}{\sigma^2}$ is greater than 0.49808 ($\sigma < 2.1254$).

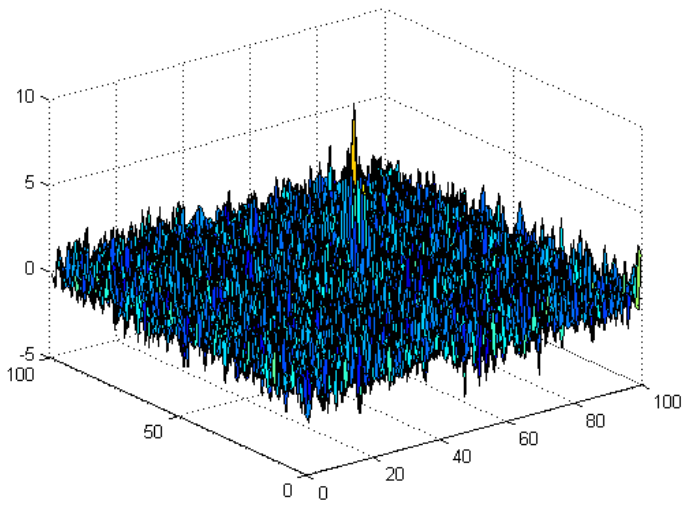

Fig. 2. Amplitude spectrum after noise addition for $A = 100$, $\beta = 1.5$, $\sigma = 0.097927$

D. Cropping

During the cropping process some parts of the image are removed, and as the result some frequency components can be changed. Let's analyse this process in more details.

We can present cropping of the image as a multiplication of window by raster image. That is represented in one dimensional form (for the simulation) as one local area of the image amplitude Fig. 4 where cropping is given by the rectangular window function. According to the convolution theorem of the Fourier transform [2] the Fourier transform of the product of the two functions is equal to the convolution of their individual transforms.

So we get:

$$f(n,m)h(n,m) \rightarrow F\left(n',k'\right) * *H\left(n',k'\right) \tag{12}$$

where $f(n,m)$ - raster image,
$h(n,m)$ - the window of cropping. So now we can look on those functions separately.

In the frequency domain window function (in the 1-D case) is defined as follows:

$$h(t) = \frac{\sin\frac{\omega t}{2}}{\frac{\omega t}{2}} \tag{13}$$

The frequency ω is defined by the size of the window. Let's calculate the convolution between $h(t)$ and the test function with one local area (rectangular impulse with the maxima in the center) as follows:

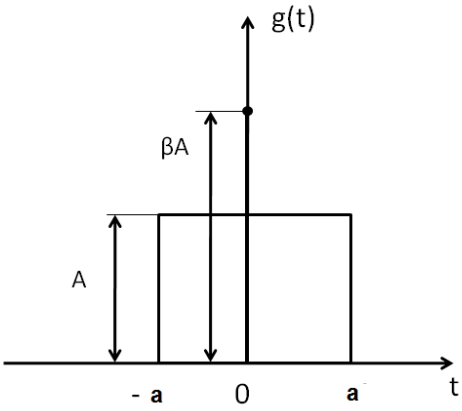

Fig. 3. Local area of the amplitude spectrum

$$y(t) = g(t) * h(t) \tag{14}$$

$$y(t) = FT[I_w(x,y)Rect(c_x(x-x_0), c_y(y-y_0))] \tag{15}$$

where c_x, c_y, x_0, y_0 - cropping parameters.

$$y(t) = \frac{1}{c_x c_y} I'_w(u,v) * e^{-i2\pi(c_x x_0 + c_y y_0)} e^{-i\pi(\frac{u}{c_x}+\frac{v}{c_y})} \times sinc\frac{\pi u}{c_x} sinc\frac{\pi v}{c_y} \tag{16}$$

where $sinc(x) = \frac{sin(x)}{x}$ if $x \neq 0$, $sinc(x) = 1$ if $x = 0$.

Now we can represent $I'_w(u,v)$ as the sum of amplitude of the original image and key $K(u,v)$ multiplied by β', where β' is the max value of local area multiplied by a constant β.

$$y(t) = [K(u,v)\beta' + I(u,v)] * * \frac{e^{-i2\pi(c_x x_0 + c_y y_0)}}{c_x c_y} e^{-i\pi(\frac{u}{c_x}+\frac{v}{c_y})} sinc\frac{\pi u}{c_x} sinc\frac{\pi v}{c_y} \tag{17}$$

To make the equation more simple we will denote the expression $\frac{e^{-i2\pi(c_x x_0 + c_y y_0)}}{c_x c_y} e^{-i\pi(\frac{u}{c_x}+\frac{v}{c_y})} sinc\frac{\pi u}{c_x} sinc\frac{\pi v}{c_y}$ as E and use the distributivity property.

$$y(t) = [K(u,v)\beta'] * E + [I(u,v)] * E \tag{18}$$

The key $K(u,v)$ can have only two values 0 and 1.

If $K(u,v) = 0$ then $y(t) = I(u,v) * E$

else $y(t) = \beta' * E + I(u,v) * E$

If we want the maxima to survive the value of the amplitude in where $K(u,v) = 1$ should be greater than the other points.

$$\beta' * E + [I(u,v)] * E > [I(u,v)] * E \tag{19}$$

$$\beta' * \frac{e^{-i2\pi(c_x x_0 + c_y y_0)}}{c_x c_y} e^{-i\pi(\frac{u}{c_x}+\frac{v}{c_y})} sinc\frac{\pi u}{c_x} sinc\frac{\pi v}{c_y} > 0 \tag{20}$$

Let us substitute the cropping parameters and see when the maximum would be recognised. Table II shows the results of calculation for the different size of the window function. We

29	71	29	71	N
30	70	30	70	N

gradually reduce the size of the window Fig. 4 and check how the detection process is performed. We can see that the maxima can be still detected after removing a half of an image.

E. Resize

Resizing the image results in inverse resizing of an amplitude spectrum. Resize can be represented as a multiplication of the coordinates on a corresponding constant value. If we look on the similarity theorem:

$$f(an, bm) \rightarrow \frac{1}{|ab|} F\left(\frac{n'}{a}, \frac{m'}{b}\right) \tag{21}$$

we can see that the resize in spatial domain causes frequency shift in the spectra. In combination with the resize maxima remains on the same distance from the center. So the maxima in the amplitude spectra will not change their positions.

F. Jpeg transform

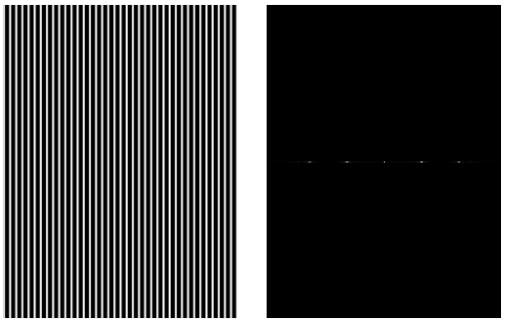

Fig. 5. Image after JPEG transform and the amplitude spectrum

Converting an image using JPEG algorithm produce specific kind of distortions. Many watermarking algorithms can not stand against such transform. The proposed algorithm can survive after JPEG transform performed with up to 30 present quality factor. This value may vary from image to image depending on image type and especially image size. Looking on the amplitude of the image after such transform we can see that some extra maxima appeared Fig. 5 right image. But all the values of those additional maxims are as the result much smaller than original ones. As long as we are searching for the max values those additional maxima give small effect on the extraction. We can see it only when additional maxima appear in the neighbour local areas with the smaller main maxima. Another effect of the JPEG transform is a removal of the high frequencies. After such transform most of the high frequencies are erased including the embedded maxima. The total number of maxima in the real system is about 350 for 100x100 pixel image. But the number of survived maxima is enough to detect the watermark.

The results of the experiments presented in Table III show that the probability of false detection appears equal to 0. The probability of successful detection of a WM is equal or close to 1 also after the cyclic shift on 50% on a vertical and a horizontal, and removal of 10% of the rows and columns.

In the Table III the recognised maxima number ratio to their total number of embedded maxima are presented. Total number of the embedded and extracted maxima is a mean value of the number of maxima, calculated as a result of 100

TABLE III
EXPERIMENTAL RESULTS

Characteristic	(1)	With embedding of a WM				
		(2)	(3)	(4)	(5)	(6)
Detected maxima number	25	295	209	252	240	231
Detected maxima %	8	100	72	85	81	78
Probability of successful WM extraction	0	1	1	0.92	0.93	0.97

(1): No embedding
(2): Without distortions
(3): Cyclic shift of 50% on a vertical and a horizontal axis
(4): Noise adding 5%
(5): Removal of 10% of rows and columns
(6): Cropping 20% of the image

images testing. For all experiments the parameters $a = 2$, $\beta = 1.5$ have been selected.

The probability of successful data extraction is sometimes less than 1, but it remains still acceptable, for the thing after adding a noise (5% of the image brightness range). However, the commercial value of the images after such strong conversions is low, and it is very unlikely to be applied to the images by pirates.

III. CONCLUSION

So in this paper we tried to explain why the watermarking system can survive after image distortions. We showed that in spite of the fact, that image distortions affect on the amplitude spectra the most part of local maxima survives and therefore zero-bit watermark can be recognised with great probability.

ACKNOWLEDGMENT

The author would like to thank Dr. Valery Korzhik for help and support.

***Abstract*—Cattle identification receives a great research attention as an important way to maintain the livestock. The identification accuracy and the processing time are two key challenges of any cattle identification methodology. This paper presents a robust and fast cattle identification scheme from muzzle print images using local invariant features. The presented scheme compensates some weakness of ear tag and electrical-based traditional identification techniques in terms of accuracy and processing time. The proposed scheme uses Scale Invariant Feature Transform (SIFT) for detecting the interesting points for image matching. For a robust identification scheme, a Random Sample Consensus (RANSAC) algorithm has been coupled with the SIFT output to remove the outlier points and achieve more robustness. The experimental evaluations prove the superiority of the presented scheme as it achieves 93.3% identification accuracy in reasonable processing time compared to 90% identification accuracy achieved by some traditional identification approaches.**

I. Introduction

RECENTLY, governments pay a great attention to the livestock by providing vaccination against the most of diseases. They seek to overcome some food problems and keep the livestock as huge as possible. Cattle identification plays an important role in controlling the disease outbreak, vaccination management, production management, cattle traceability, and cattle ownership assignment [1]. Traditional cattle identification methods such as ear notching, tattooing, branding, or even some electrical identification methods such as Radio Frequency Identification (RFID) [2] are not able to provide enough reliability to the cattle identification due to theft, fraudulent, and duplication. Therefore, the need to a robust cattle identification scheme is a vital requirement.

Human biometrics is a key fundamental security mechanism that assigns unique identity to an individual according to some physiological or behavioral features [3], [4]. These features are sometimes called as biometrics modalities, identifiers, traits, or characteristics. Human biometrics identifiers must fulfill some operational and behavioral characteristics such as uniqueness, universality, acceptability, circumvention, and accuracy [5].

Adopting human biometric traits into animals is a promising technology for cattle identification domain. It has many applications such as cattle classification, cattle tracking from birth to the end of food chain, and understanding animal diseases trajectory and population. On the other side, using animal biometrics in computerized systems faces great challenges with respect to accuracy and robustness as the animal movement can not be easily controlled. Driven from this perspective, adopting human biometrics to cattle identification can overcome plenty of the current cattle identification weaknesses.

Muzzle print, or nose print, was investigated as distinguished pattern for animals since 1921 [6]. It is considered as a unique animal identifer that is similar to human fingerprints. Paper-based or inked muzzle print collection is inconvenient and time inefficient process. It needs special skill to control the animal and get the pattern on a paper. Furthermore, the inked muzzle print images do not have sufficient quality, and hence, it is difficult be used in a computerized manner [7]. Therefore, there is a lack of a standard muzzle print benchmark. Driven from this need, the first contribution of this research is to collect a database of live captured muzzle print images that works as a benchmark for evaluating the proposed cattle identification scheme.

A local feature of an image is usually related to a change of an image property such as texture, color, and pixel intensity [8]. The advantage of local features is that they are computed at multiple points in the image, and hence, they are invariant to image scale and rotation. In addition, they do not need further image pre-processing or segmentation [9]. Scale Invariant Feature Transform (SIFT) [10] is one of the popular methods for image matching and object recognition. SIFT features have been used by some researchers in human biometrics with applications on fingerprints [11], [12] and palmprints [13]. SIFT efficiently extracts robust and unique features, therefore it has been used to overcome different image degradation factors such as noise, partiality, scale, and rotation.

The identification accuracy is the foremost important fac-

Fig. 1. The process of building a single SIFT keypoint descriptor: (a) A Single SIFT keypoint extracted from muzzle print image, (b) A 16 × 16 pixel orientations, (c) A single 4 × 4 cells descriptor with 8 pixel orientations. The default length of a single SIFT keypoint descriptor is 4 × 4 × 8 = 128 element.

tor for measuring the performance of any automatic cattle identification approach. This paper presents a robust cattle identification scheme that uses SIFT features for calculating the similarity score between the input muzzle print image and the template one. The superiority of the proposed scheme is the assured cattle identification robustness provided by combining the robust SIFT features with a RANdom SAmple Consensus (RANSAC) algorithm for robust SIFT features matching [14].

The reminder part of this paper is organized as follows: Section II covers some preliminaries topics. Section III explains the design and the implementation of the proposed scheme. Section IV shows the evaluation phase of the proposed scheme. Conclusions and future work are written in Section V.

II. Preliminaries

A. SIFT Features

The SIFT feature extraction works through sequential steps of operations. These steps can be summarized as scale space extrema detection, keypoints localization, keypoint orientation assignment, and building the keypoints descriptor [15]. The Difference-of-Gaussian (DOG) is used to detect the keypoints as the local extrema of DOG function. The pixel is compared against 26 neighboring pixels (8 in the same scale, 9 in the above scale, and 9 in the below scale) to detect the local pixel extrema and minima. Following on, the detected keypoint is localized by determining its neighborhoods, and examine them for contrast and edge parameters. The keypoints with low contrast and weak edge responses are rejected. The keypoint neighborhoods region is used to build the histogram of the local gradient directions, and the keypoint orientation is calculated as the peak of the gradient histogram [10], [15], [16]. The default SIFT feature extraction produces keypoint associated with a descriptor of 128 element length. The descriptor is constructed from (4 × 4 cells) × 8 orientations [17]. The cascaded operations of building a single SIFT keypoint descriptor from muzzle print image are shown in Fig. 1.

Applying SIFT feature extraction translates the muzzle print image into a set of keypoints according to the local maxima. The extracted keypoint is associated with a descriptor related to the orientations of the surrounded pixels. In this paper, a standard SIFT extraction has been used for keypoint detection and building the associated descriptor. SIFT features have been extracted and matched using the VLFeat library [18]. The output of matching process is a similarity score between the input image and the template that is enrolled in the database.

B. Identification Accuracy

In order to measure the accuracy of the presented cattle identification scheme, The identification *Error Rate* (*ER*) is considered. The ER is defined as "the rate that the identified animal, the animal who corresponds to the template image, is different from the animal of the input image". We also consider the standard verification error rates as FAR, FRR, and ERR [19]. The *False Acceptance Rate* (*FAR*) is the rate that the similarity between the images of different animals is greater than a threshold. Whereas the *False Rejection Rate* (*FRR*) is calculated as the rate that the similarity between two images of the same animal is less than a threshold. Thus, the FAR and FRR depend on the similarity threshold. The *Equal Error Rate* (*EER*) is the value of FRR and FAR at the point of the threshold where the two error rates are identical [20].

III. Proposed Identification Scheme

Analogy to the human fingerprints, cattle muzzle prints have some discriminative features according to the grooves, or valleys, and beads structures. These uneven features are distributed over the skin surface in the cattle nose area. These features are defined by the white skin grooves, or by the black convexes surrounded by the grooves [7], see Fig. 3 for consulting the convexes and the grooves in muzzle print images taken from two different animals.

Minagawa et al. [7] used the joint pixels on the skin grooves as a key feature for muzzle print matching. Some long preprocessing steps were conducted to extract the joint pixels. This approach achieved maximum and minimum matching scores as 60% and 12%, respectively. It achieved unsatisfactory identification performance (accuracy) that was around 30% measured over a database of 43 animals.

Noviyanto and Arymurthy [21] applied Speeded-Up Robust Features (SURF) on muzzle print images for enhancing the identification accuracy. A U-SURF method was applied on 8

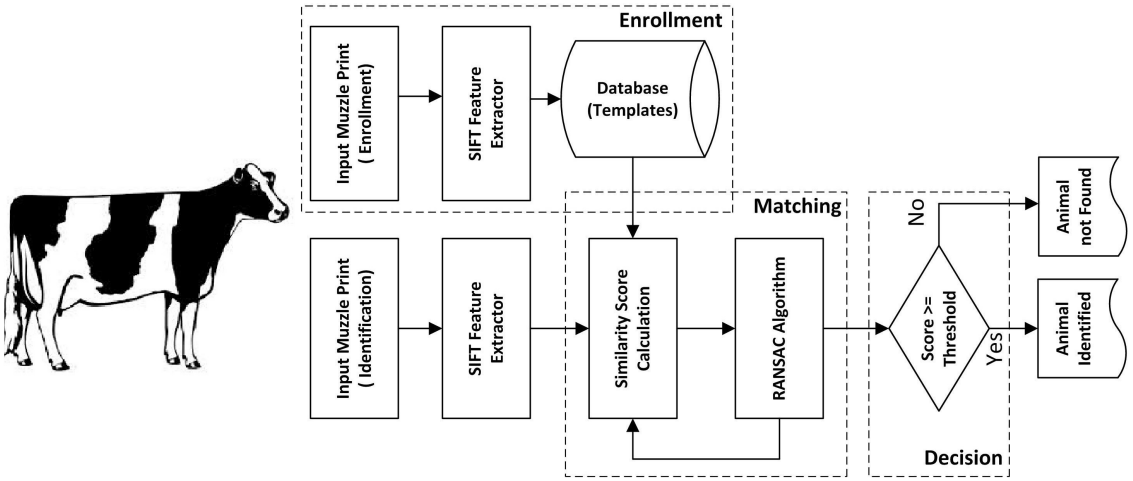

Fig. 2. A block diagram of a complete cattle identification system using muzzle print images. The components of the enrollment phase and the identification phase are emphasized in the block diagram. The proposed identification scheme is represented as a combination between SIFT features and RANSAC algorithm.

animals with 15 images each. The experimental scenario used 10 muzzle print images in the training phase, and the other 5 images were used as input samples. The maximum achieved identification accuracy under rotation condition was 90%.

The presented scheme in this research is robust from two perspectives. First, it invests the robustness of the SIFT features to image scale, shift, and rotation. Second, it uses the RANSAC algorithm as a robust inliers estimator for enhancing the matching results of SIFT features, and ensure the robustness of the matching process. The proposed scheme includes SIFT feature extraction, SIFT feature matching, and RANSAC algorithm. Fig. 2 shows a generic and complete muzzle print based cattle identification system, and highlights the cascaded components of the presented scheme.

RANSAC algorithm has been developed by Fischler and Bolles [14] especially for computer vision, and it works as robust estimator for features matching. In many images matching cases, RANSAC is an effective robust estimator, which can handle around 50% mismatch contamination levels of the input samples. The integration of the extracted local invariant features and RANSAC is valuable for optimizing the images similarity score measurement using SIFT features [22].

Admittedly, the generic animal identification system, shown in Fig. 2, works the same way of the human identification one. It has two phases; enrollment phase and identification phase. In the enrollment phase, a muzzle print image is presented and the SIFT feature vector is constructed. Then, the extracted feature vector is stored as a template in the database. The identification phase includes the same enrollment procedure plus matching and decision sub-phases. For calculating the similarity score, the SIFT features of the input image is matched against the templates stored in the database as (1:N) matching procedure. The muzzle print image corresponding to the feature vector that has a shortest distance to the input feature vector is considered as the most similar one, and it is given the highest similarity score. RANSAC homography algorithm comes at the end of the matching process to remove the matching outliers, mismatched SIFT keypoints, data and ensure the robustness of the similarity score. The animal identity is then assigned according to the highest estimated similarity score between the input image and the template one.

IV. Performance Evaluation

The experiments in this paper have been conducted using a PC with Intel® Core™ i3-2120 running at 3.30 GHz, and 8 GB of RAM. The PC is empowered by Matlab® and Windows® 64-bit. The VLFeat library [18] has been used for extracting, processing, and matching the SIFT features. VLFeat has been installed and optimized for the mentioned experimental environment.

A. Database

The lack of a standard muzzle print images database was a challenge for conducting this research. Therefore, collecting a muzzle print images database was a crucial decision. The database has been collected from 15 cattle animals with 7 live captured muzzle print images each. A sample of muzzle print images captured from two individual animals is shown in Fig. 3. A special care has been given to the quality of the collected images. The collected images cover different quality levels and degradation factors such as image rotation and image partiality for simulating some real time identification conditions.

The identification scenario works as follows: 7 images of each animal have been swaped between the enrollment phase an identification phase, and the similarity scores between all of them are calculated. Therefore, similarity score matrix with dimension of 105 $\times$ 105 have been created. The animal is correctly identified if the similarity score between the input sample and the template samples is greater than or equal a specific threshold. The template of a single animal has been constructed from 6 images which were marked as $T_1, T_2, T_3, ..., T_6$. The remaining 1 image has been used as

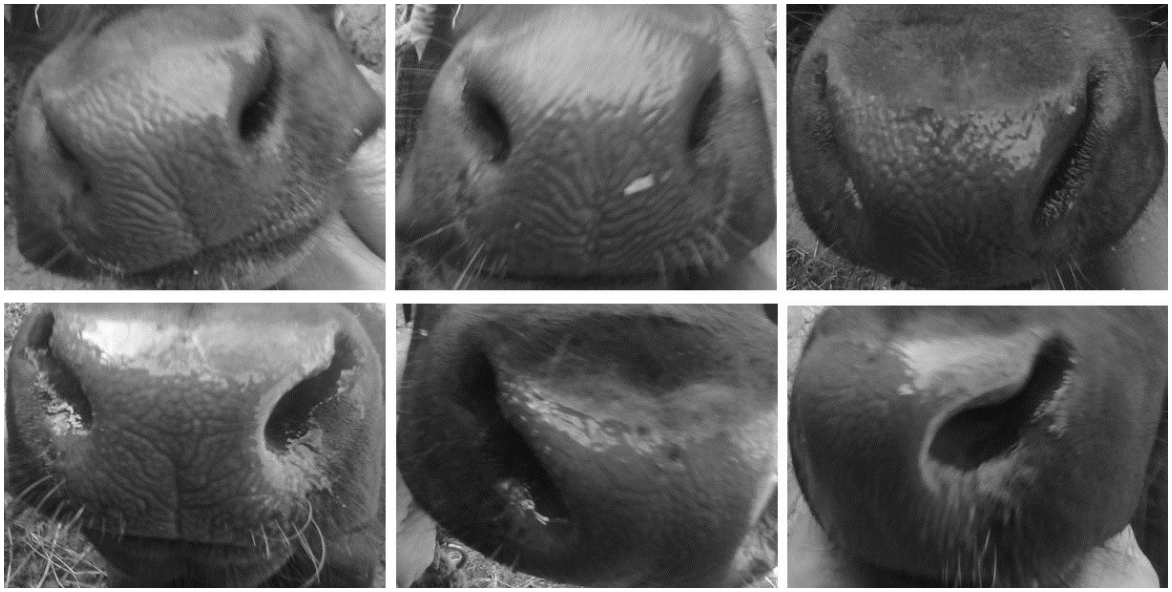

Fig. 3. A sample of the collected muzzle print images database from live animals. The represented muzzle print images have been taken from two different animals. The muzzle print images show different deteriorating factors include orientated images, blurred images, low resolution images, and partial images.

input, and was marked as I_1, S was a similarity function, and H was a similarity score. A correctly identified animal should strictly following the next equation as:

$$S(I_1, T_1) \parallel S(I_1, T_2), ..., \parallel S(I_1, T_6) \geq H \qquad (1)$$

The FAR, FRR, and ERR have been calculated according to the criteria mentioned in Section II-B.

B. Evaluation Results

Preceding to any experimental work, the database images have been processed in terms of image enhancement, image segmentation, and image normalization. The first experimental scenario is directed toward setting the best SIFT parameters that compromise the number of extracted features (keypoints) with the consumed processing time. The preparatory experiments showed that the most effective parameter is the peak threshold (`PeakThresh`) [15], [18], thus the objective of this scenario is to optimize the peak threshold. The results of the conducted experiments is shown in Fig. 4. The reported results are the average of value of 105 feature extraction processes and 5565 matching operations. The maximum number of features is achieved with (`PeakThresh = 0.0`), however with (`PeakThresh = 0.001`), the extracted features are reduced by 30, and the extraction time is reduced by 5 ms. The other `PeakThresh` values achieve unacceptable number of features regardless of the time factor. The optimum `PeakThresh` value is selected as 0.0 seeking for more SIFT features, and hence, more robustness in feature matching. Following on, the SIFT peak threshold is set to that optimum value, whereas the other parameters were kept as defaults.

In real time identification, 6 images of each individual animal have been processed and enrolled in the database, the

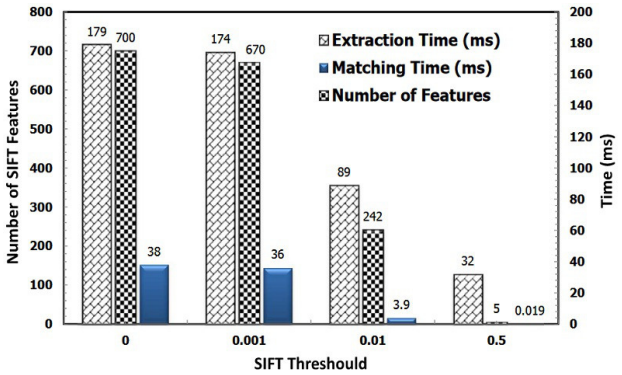

Fig. 4. The behavior of SIFT feature extraction with different peak threshold (`PeakThresh`) values with respect to the number of features, the extraction time, and the matching time. The optimum value is `PeakThresh = 0.0`.

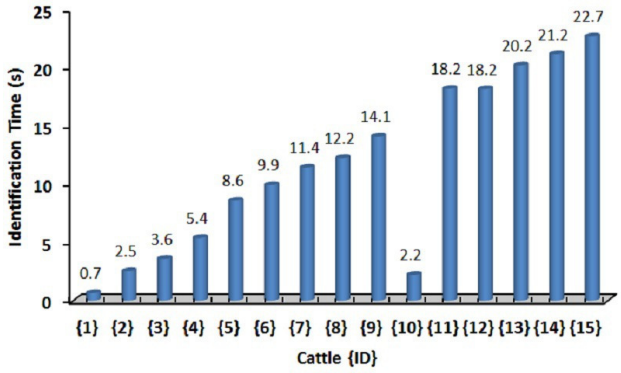

Fig. 5. The identification time for each input animal. Due to the linear search approach, the identification time linearly increases as the order of the template inside the database increases. The cattle with ID $\{10\}$ is wrongly identified.

TABLE I
THE INPUT IMAGES, THE MATCHED IMAGES, THE MATCHING SCORES, AND THE IDENTIFICATION STATUS FOR THE IDENTIFICATION SCENARIO.

Input Image	Matched Image	Matching Score	Identification Status
101_5	101_3	71.56	Correct
102_5	102_4	45.45	∼
103_5	103_1	73.33	∼
104_5	104_1	42.00	∼
105_5	105_7	45.00	∼
106_5	106_3	51.85	∼
107_5	107_3	87.77	∼
108_5	108_1	48.00	∼
109_5	109_3	95.37	∼
110_5	**102_3**	**45.76**	**False**
111_5	111_7	39.00	Correct
112_5	112_1	70.37	∼
113_5	113_3	89.59	∼
114_5	114_1	57.14	∼
115_5	115_1	50.00	∼

total images in the database were ($6 \times 15 = 90$), and 1 image has been used as input to simulate the identification operation. According to equation 1, 14 animals out of 15 have been correctly identified which achieves equivalent identification accuracy value as 93.3%. It is worth notice that the average consumed feature extraction time is 179 ms and the average individual matching time is 38 ms including RANSAC optimization, which are consistent with Fig. 4. However, both times are considered very short for single feature extraction and matching operation, the total identification time still long, around ≈ 23 s at maximum, because a linear database research method has been used, and the identification time is based on the location of the template inside the database. The identification time of each input animal is shown in Fig. 5.

Table I summarises outcomes of the conducted real time identification phase in terms of the input image, the matched template image, the matching score, and the status (correctness) of the identification operation. The image naming scheme works as $1XX\_Y$, whereas XX is the cattle ID (1 to 15), and Y is the image order (1 to 7). The Table shows that the cattle with ID $\{10\}$ is wrongly identified because the similarity score with a template image from cattle ID $\{2\}$ is greater than the defined threshold. The reported results in the Table are consistent with Fig. 5 as the wrongly identified animal consumes very short identification time, and violates the linearity of the incremental identification time with the increased cattle ID.

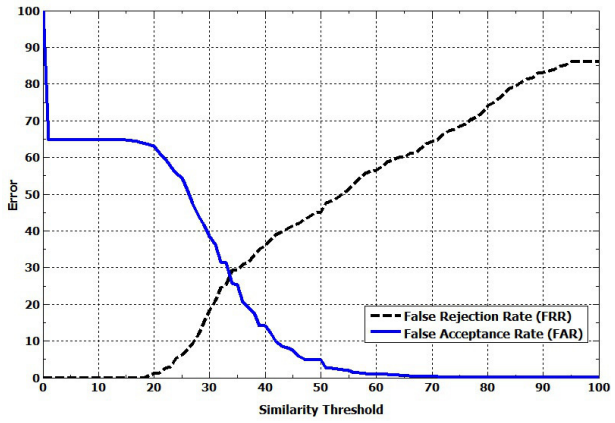

Fig. 6. False Acceptance Rate (FAR) and False Rejection Rate (FRR) plotted versus the similarity threshold. The Equal Error Rate (ERR) is shown as the cross point between FAR and FRR. ERR is ≈ 27.4 with threshold is ≈ 34.0.

The wrongly identified animal is considered as false matched or false accepted input because the match occurred with a template that does not correspond to the input sample. The FAR in this case is 6.67%, and it is equal to the identification ER. The relations between FAR, FRR, and ERR are determined according to the similarity threshold. Fig. 6 shows FAR versus FRR related to the similarity threshold. In order to achieve FAR equal to 6.67%, the similarity threshold should be selected around 45. However, the conducted experiments showed that FAR equals to 6.67% has been achieved with a threshold equals to 39, and with FRR equals to 0. We do believe that this is because of combining multiple images from the same animal in one database template.

V. CONCLUSIONS AND FUTURE WORK

This paper has presented a robust cattle identification scheme that uses muzzle print images as input to SIFT feature extraction and matching. Due to the lack of standard muzzle print database, we have collected 105 images from 15 animals to work as a benchmark for the presented scheme. In order to evaluate the robustness of the scheme, the collected images cover different deteriorating factors such as rotated images, blurred images, partial images, and low resolution images. The achieved identification accuracy is 93.3% compared to 90% reported in the literature. The superiority of the presented scheme comes from the coupling of local invariant features with RANSAC homography as a robust outliers removal algorithm. Muzzle print images database extension and standardization for international benchmark of muzzle print related algorithms is one of the future work. Additionally, the reduction of the identification time in a large database is an interesting challenge that will also be tackled in the future.

***Abstract*—Content inappropriate for children on Internet television is a serious problem in today's multimedia world. There are numerous methods which are used to control the content of the transmitted television programmes. However, these well-known methods do not solve the above mentioned problem completely. The paper presents a more effective method for automatic identification of the provider's logo based on an original image sequence analysis. The automatic identification of the provider's logo can be used to block access to video programmes of the selected providers. The method has been tested on some chosen video transmissions on-line, achieving over 98% of correct identification.**

I. Introduction

THE problem of underage persons' easy access to the multimedia video with inappropriate content and its consequences is well known [3,14]. One of the sources enabling the access to such video programmes is the widely available Internet TV. There are numerous methods which are used to control the content of the television programmes transmitted via the Internet. These include, among others, blocking video materials at certain hours [19,20] or filtering chosen IP addresses and keywords on web pages [18]. There are also parental control modules, which can be embedded in the anti-virus software, web browsers and operation systems. All these well-known methods do not, however, solve the above mentioned problem completely. Thus, in the case of a temporary access block on Internet TV, parents must be involved in the process of programme assessment and selection. With regard to IP address filtering, the problem concerns a rapidly growing number of keywords, which the filter should block, as well as easily made changes of the IP addresses by Internet providers.

Another solution is to do an analysis of the provider's logo transmitted together with the video stream. In a video production, logos are used to convey information about the provider's programme content, which can be used in the selection of age-appropriate programmes while broadcasting video. There are related applications which try to identify brand logotypes in video data [5, 6, 11, 15] by using the static character of the logo. In order to identify the logo, some logo detection algorithms use neural network and image analysis procedures [1,7,8,10,16,17]. However, the selection of an adequate neural network's models, their over-fitting capacity and the high computational cost of the methods limit their applications in practice.

The logo identification in the programme categorisation is presented by Cozar et al. 2007 [4]. This method performs a temporal and spatial segmentation by calculating the minimal luminance variance region of the set of frames and the non-linear diffusion filtering. However, 95% of correct identification has been achieved only when the analysis is conducted on-line. A different solution is presented by Ozay, Sankur [13]. This time, an algorithm performs a detection of the logo by morphological operations. Nevertheless, online tests for detection and recognition on running videos have achieved lower than 96% average accuracy. In [2] logo detection techniques have been used to differentiate advertisements from TV programmes. This approach assumes that a logo exists if a region with stable contours can be found in the image. No temporal information is used and the method has not been tested on video material in a real time transmission, which has resulted in many false detection cases.

Contrasting the aforementioned methods, the paper presents a more effective method for automatic identification of the provider's logo based on an original image of sequence analysis. The automatic identification of the provider's logo allows to block access to video programmes of the selected providers. It takes place regardless of the transmission time, IP address or the keywords used to find a required website.

The method has been tested on some transmitted video, achieving over 98,7% of correct identification.

The article consists of several parts. Section 2 contains a description of the logo detection algorithms based on spatial segmentation. It additionally presents the logo identification and its comparison with logo patterns. Section 3 concentrates on testing the presented method on chosen video streams and illustrating the results of its application. The article ends with Section 4, which includes main conclusions and presents plans for the further development of the above method.

II. Algorithm Description

The video streaming Internet TV programme is a set of ordered frames through time. These frames can include one or several superimposed logos. Usually, a logo is defined as

978-83-60810-53-8/$25.00

a small graphic or picture that appears behind the anchor person on the screen. Logo image areas show luminance variance values in narrower interval than other image areas, depending on the logo transparency. An important feature of a logo image is that the logo contours are stable, while the background varies during video broadcasting. Besides, during video broadcasting a logo can be present or absent, for instance during an interruption of the programme transmission. Logotypes are usually placed at any of the four corners of a frame. Therefore, four image corners should be considered as the regions of interest (ROIs). Moreover, their size is limited, since logos should not perturb video viewing (see Fig. 1). Furthermore, logo areas do not significantly change from frame to frame.

Fig. 1 Example of the frames from broadcasting TV

A logo is a characteristic feature of any programme provider as well as its contents. Logo identification enables verification of various programmes providers, which makes it a tool of parental control, enabling blocking unsuitable programmes for underage viewers. A child's parent or guardian chooses logo patterns from a providers' base which are regarded as inappropriate for children. When a programme transmission takes place, its logo is identified and compared with the ones selected as unwelcome by the parent or guardian. Depending on the received information, the video signal is either blocked or allowed to flow.

When the logo of the transmitted on-line programme is not included in the data base, the system can add this new candidate logo to the logo patterns base. The new candidate undergoes a process of segmentation, yet it is not included in the currently transmitted logo identification process. Automatic logo adding to the logo data base can take place after it has been projected and recognised several times.

Let a mathematical model of a logo image be a matrix, $I = I(i, j), i = 1..m, j = 1..n$, where m and n define the size of the logo image.

Initially, the digital image I of the analyzed logo region is converted to the monochrome image $\mathbf{I}'$. This operation includes the calculation of the brightness $I'(i, j)$, $0 \le I'(i, j) \le 255$, for each pixel of the RGB colour components $I'(i, j)$.

To extract contours of the logo regions of the monochromatic image $\mathbf{I}'$, the Sobel operator [9] is applied. Due to this operation an image of the logo contours is created $\mathbf{I}^*$. However, the extracted contours of the logo regions are often not salient because the result of the extraction depends considerably on the time variable background where logos appear. In order to achieve better quality of the contours, the adopted method averages the sequence of the logo contours $\mathbf{I}^*$:

$$\bar{I} = \frac{1}{K} \sum_{k=1}^{K} I_k^*, \qquad (1)$$

where I_k^* is the logo contours image and K – is the number of frames, $\bar{\mathbf{I}}$ -the average image of the logo's contours.

It seems clear that in the sequence (see eq. 1) the number of the processed frames K depends mostly on the characteristics of the video stream.

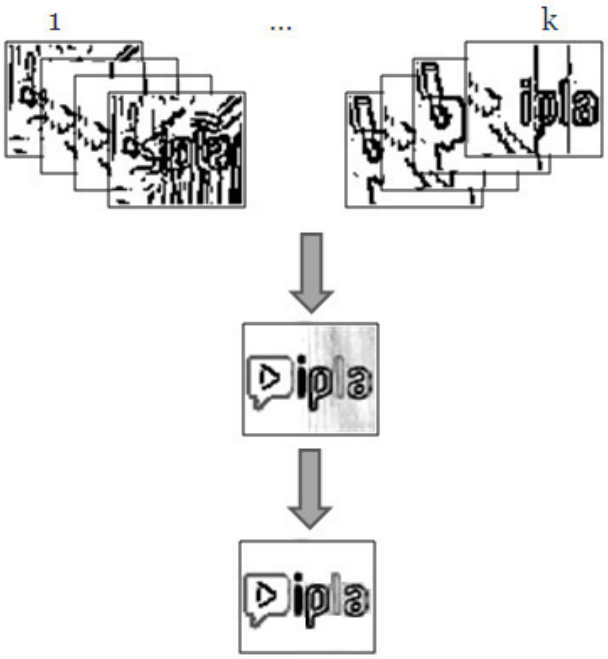

Fig. 2 Images obtained in each stage of the algorithm for a real sequence through time: logo contour image , average logo contour image and binary logo image

Thus, a video with a dynamic sequence of frames needs fewer frames to generate stable logo contours than the one with a static sequence. Therefore, K value should be chosen experimentally. It seems plausible that a large value K can guarantee better detection for logos which are static for a long period of time. However, a wrong logo contour image is obtained if logo changes occur within the K frames. In this case, the number of frames K used for the logo extraction must be decreased.

In the next stage, a spatial segmentation of logo contours is conducted binarizing of $\mathbf{I}^*$:

$$\mathbf{B} = B(i,j) = \begin{cases} 0, for & \bar{I}(i,j) \geq p_1 \\ 1, for & \bar{I}(i,j) < p_1 \end{cases}, \; i = 1..m, \; j = 1..n \tag{2}$$

where **B** is the binary image of the logo contours and the threshold level p_1 which are arbitrarily determined from a histogram. An appropriate choice of the threshold level p_1 is the basis of a proper process of identifying the logo contours from the image. In order to calculate the required level, average histograms of the logo contours are determined $\bar{\mathbf{I}}$, which, due to different backgrounds, vary considerably (see fig. 3).

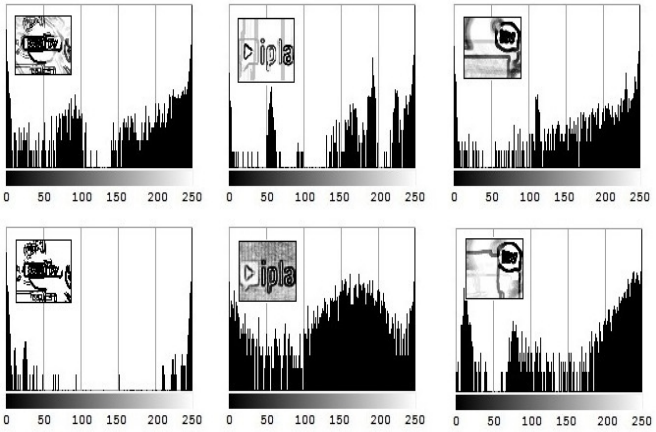

Fig. 3 Images of averaged logo contours $\bar{\mathbf{I}}$ and their respective histograms

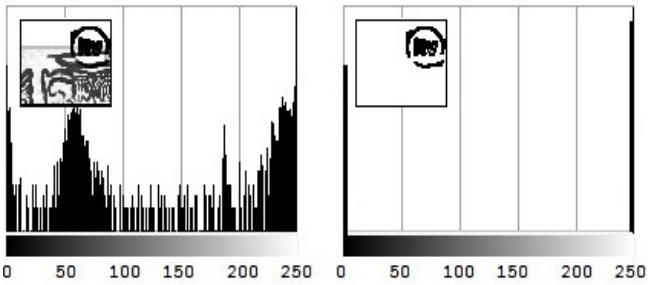
The optimum level p_1 is calculated by means of the Otsu [13] method according to formula 3.

$$p_1 = \arg\max_{p} \left(\omega_0 \omega_1 (\mu_1 - \mu_0)^2 \right) \tag{3}$$

where ω_0 - constitutes a standardised quantity of the logo contours (a quotient of the number of points belonging to the contours and the number of the image points), ω_1 is the standardised number of the background quality, μ_0 and μ_1 are the averaged qualities of the points brightness for the contours and background respectively, $0 \leq p \leq 255$.

Fig.4 presents example of an image and histogram before and after the application of the Otsu method.

Generally, there are cases when the analysed video stream does not comprise any logo, for instance, during commercial breaks. To recognise such a case the following procedure of logo histogram analysis is proposed. Examples of images without logo $\bar{I}$ and their respective histograms are presented in Fig. 5.



a) b)

Fig. 4 An image and its histogram before (a) and after the application of the Otsu binarisation method (b).

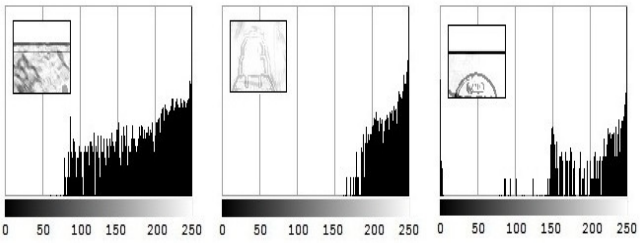


Fig. 5 Some images without logo $\bar{I}$ and their respective histograms.

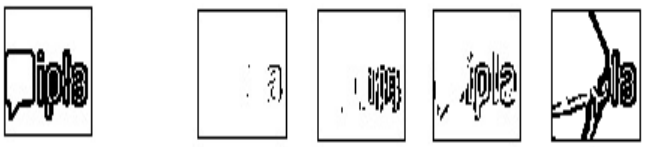
The next step includes calculating sums S_1 and S_2 how often grey scale values $h(p)$ larger than $0.5h_{max}$ appear into the two ranges <0... p_1 > and (p_1 ...255> respectively, where h_{max} indicates the maximum of a histogram. If $S_1 \leq S_2$, it may be inferred that the logo is not included in the image.

When images undergo the analysis process, two kinds of errors may take place. The first one concerns a situation when the logo is present but has not been identified by our algorithm. This happens when algorithm reads incomplete logo contours, i.e. when it identifies light contours in a light background. The case is illustrated by figure 6.



a) b)

Fig. 6. Examples of binary image contours of the logo B presenting the logo of IPLA provider in real time sequences: full logo contours (a), and incomplete logo contours (b)

The other error connected with the logo identification may take place when the logo is not present and algorithm identifies static contours of an object as the logo, and subsequently adds the identified contours to the data base as a new pattern. Some examples concerning such situations are presented in figure 7.

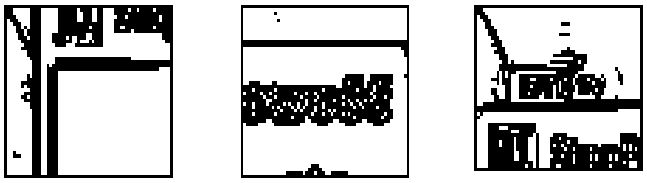


Fig. 7. Examples of binary logo B contours identified inappropriately as potential candidates for new logos.

The above situations may take place due to the nature of the discussed problem. Proper recognition of such cases by our algorithm is, however, difficult.

To identify the logo, it is first of all necessary to define the logotype database as a set of the logo patterns representing different broadcast providers of the Internet TV programmes. Let $\left\{B_r^z\right\}$, $r=1..R$, be the reference set of the R logo patterns. Each pattern B_r^z is obtained by the same procedure as the one described above, when the background is stable.

A good descriptor of the binary image **B** of the logo contours is the shape itself, but a long feature vector would be created. An important reduction of the feature vector size, without a great loss of accuracy, can be achieved if the x-axis and y-axis shape projections are used.

Let $w_i=\sum_{j=1}^{n} B(i,j)$, $i=1..m$, and $k_j=\sum_{i=1}^{m} B(i,j)$, $j=1..n$ mean x-axis and y-axis shape projections of a binary image **B** of the logo contours.

Then, a good metric to compare the feature vectors [**w**, **k**] and [**w**^{z}, **k**^{z}] of **B** and B_r^z respectively is the distance given by the following expression:

$$\min_r \left(\sum_{i=1}^{n} |w_i^I - w_{r,i}^z| + \sum_{j=1}^{m} |k_i^I - k_{r,i}^z| \right), \quad r=1..R \qquad (6)$$

Algorithm enables an automatic supplementation of the pattern data base. A candidate analysis of a new pattern is conduced according to of the rank of correlative factors τ Kendala [10] between the analysed image and patterns. The method enables qualifying if the logo included in the transmitted programme exists in the data base or whether it should be added as a potential candidate.

III. Method Verification

„*StopPlay*", a novel application shown in Figure 3, has been written in the C# language. The our application analyses a video stream of the selected Internet television programmes in on-line regime. In order to verify the correctness of the algorithm in the process of the logo recognition, a set of six patterns of the logo $\left\{B_r^z\right\}$, $r=1..6$ (see Fig. 8) of popular Internet televisions was defined. The Internet addresses of Internet television programmes used in the tests include Inter Alia: http://www.itv.net.pl, http://www.ipla.pl.

The logo images of dimensions 60x50 pixels are automatically extracted from each frame in the video stream during the transmission of Internet television programme. The number of binary images needed to create an average contour image was set at K=40.

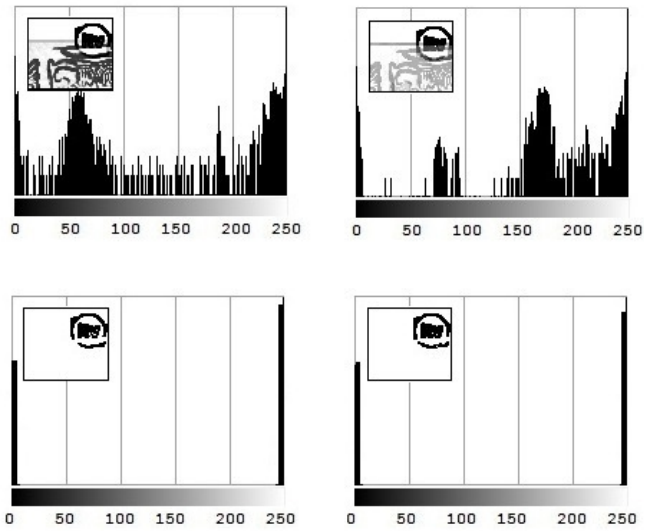
Fig. 8 An exemplary set of chosen logotypes and main application window

As it is argued in Section 2, in order to rid the programme of disturbances and get clear contours of the logo in its background, qualities p_1 cannot be taken arbitrarily. Fig. 9 presents examples of averaged contours of the logo and their respective binary images and histograms. The threshold levels p_1 are chosen according to the Otsu method and depend on the levels of grey shades in the image.

The use of such values allows to achieve approximately 99% of correct identification in the logo detection procedure.

The only activity left for the user is to choose the names of the provider (providers), whose logo should be recognised from a particular set of programmes. Fig. 10 presents an analysis of the tested logos of the television programmes. The tests were conducted on an average of 20 000 video frames during approximately three hours' time on the three available TV sites: ITV, EZO, IPLA. The algorithm was tested during the TV programme transmission as well as during commercial breaks. The obtained results show that the presented algorithm detects the logo with an accuracy of over 99%.

The lack of proper recognition of the logo is due to cases when the logo and the background are in the same colours, i.e. without visible logo's contours, as well as cases when some permanent objects are present in the logo. When recording consecutive frames of video sequences these additional objects become regions identified in the algorithm as a logo.



a) b)

Fig. 9. Averaged images of the logo contours and their respective binary images with appropriate quality levels $p_1 = 35$ (a), $p_2 = 100$ (b) presented according to the Otsu method and their histograms.

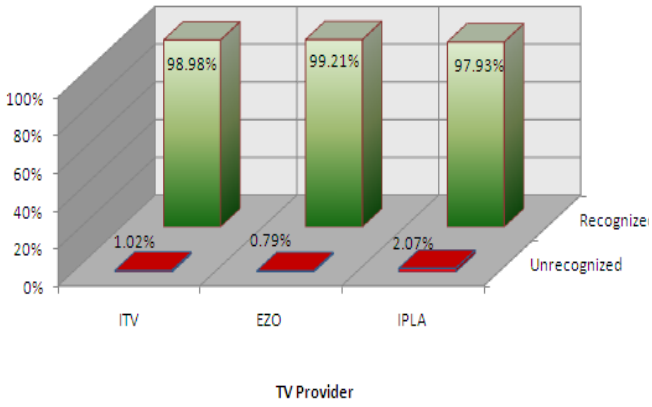


Fig. 10 Percentage chart for positive recognised logos in the selected broadcasting Internet video

IV. Conclusions

This article presents our logotype recognition algorithm and its application in the television programme providers in the on-line regime.

The suggested method takes advantage of a multi-step segmentation of temporal and spacious logo, which enables detecting the image contours and eliminating the background objects from the on-line video images. A comparison of the achieved images of the logo with the patterns allows an automatic identification of the transmitted programme. The identification process takes into account situations when the logo is not present due to, for instance, an interruption of the transmission process.

It has been proved that the implemented algorithm is capable of detecting images of the logo with an accuracy of over 98,7%. The cases which are problematic are due to situations when the logo and background images are in the same colours and when permanent objects appear in the logo region. Under such circumstances the algorithm identifies the entire regions as logos. However, in contrast to many other object recognition algorithms, the proposed algorithm does not require preparation of any learning set or application of any advanced methods for image processing. This allows for its practical and easy use in the application of automatic identification of television programmes and minimises the potential negative effects of Internet television on children.

The future works will be focused on development of the proposed algorithm for cases when known logo is slightly modified by TV providers in mourning days.

Semantic Multi-layered Design of Interactive 3D Presentations

Jakub Flotyński, Krzysztof Walczak
Poznań University of Economics, Poland
email: {flotynski, walczak}@kti.ue.poznan.pl

***Abstract*—Dependencies between interactive 3D content elements are typically more complex than dependencies between standard web pages as they may relate to different aspects of the content—spatial, temporal, structural, logical and behavioural. The Semantic Web approach helps in making data understandable and processable for both humans and computers by providing common concepts for describing web resources. However, semantic concepts may be also used to improve the process of designing content. In this paper, a new approach to semantic multi-layered design of interactive 3D content is presented. The proposed solution provides a semantic representation of 3D content in multiple layers reflecting diverse aspects of 3D content. The presented solution conforms to well-established 3D content and semantic description standards and—therefore—may facilitate creation, dissemination and reuse of 3D content in a variety of application domains on the web.**

***Index Terms*—3D web, 3D content, semantic modelling, ontology, RDF, OWL, RDFS**

I. Introduction

WIDESPREAD use of interactive 3D technologies has been recently enabled by increasing hardware performance, rapid growth in the network bandwidth as well as availability of cheap 3D accelerators and input-output devices. However, the potential of 3D technologies in everyday use may be fully exploited only if accompanied by easy-to-use methods of creating, searching and combining distributed interactive three-dimensional content.

Creating, searching and combining distributed interactive 3D content are much more complex and challenging tasks than in the case of typical web pages. Relationships between components of an interactive three-dimensional virtual scene may include, in addition to its basic meaning and presentation form, also spatial, temporal, structural, logical, and behavioural aspects. The Semantic Web approach makes the described data understandable for both humans and computers achieving a new quality in building web applications that can ”understand” the meaning of particular components of content and services as well as their relationships.

Semantic Web standards may be applied to 3D content, leading to much better methods of creating, searching, reasoning, combining and presenting content. 3D content models based on commonly used semantic concepts may be independent of particular description methods and languages. The use of common concepts facilitates dissemination and reuse of individual components of the content that may be semantically assembled to create particular VR/AR presentations depending on the user location, preferences, device used, etc. Moreover, extending geometrical, structural, spatial, logical, and behavioural components with their semantic descriptions permits reasoning on complex semantically described 3D scenes that include these components.

Although a number of methods and languages for programming 3D presentations, and several solutions for creating semantic descriptions of 3D content have been proposed, they do not support layered design of interactive 3D presentations and do not enable semantic representation of components of 3D objects and scenes.

Layered design of 3D presentations provides a separation of concerns between particular semantic layers corresponding to different aspects of the presentation. It reduces the complexity and the number of connections between particular components of the content, facilitating their implementation and exchange, and simplifying the creation of the desirable final presentation.

The main contribution of this paper is an approach to semantic multi-layered representation of interactive 3D presentations. The proposed solution provides a complex representation of 3D content in multiple layers reflecting various aspects of the content—geometry, structure, appearance, scene, logic, and behaviour. The solution conforms to well-established 3D content and semantic description standards.

The remainder of this paper is structured as follows. Sections II and III provide an overview of the current state of the art in the domains of 3D content presentation and semantic description of web resources. Section IV introduces a novel semantic multi-layered model of 3D content. Section V discusses an implementation of the proposed approach. An example of the semantic design of 3D content is explained in Section VI. Finally, Section VII concludes the paper and indicates the possible directions of future research.

II. Interactive 3D Presentations

A number of technologies (including languages, libraries, frameworks, and game engines) have been devised for creating interactive 3D content presentations, in particular built into web applications.

The Virtual Reality Modeling Language (VRML) [1] is an open, textual language devised by the Web3D Consortium for describing static and animated 3D content in a declarative way. A VRML scene is represented as a graph with nodes reflecting different aspects of the described 3D content—geometry, structure, appearance, space, logic, and behaviour.

978-83-60810-53-8/$25.00

VRML also supports linking external multimedia resources—images, audio and video. In addition to the use of specific behavioural VRML nodes, the logic and behaviour of the presented 3D objects may be described by embedded imperative ECMAScript code. Several implementations of VRML browsers are available, e.g., ParallelGraphics Cortona3D [2], Bitmanagament BS Contact [3], FreeWRL [4], and InstantReality [5].

The Extensible 3D (X3D) [6] is a successor to VRML, also designed by the Web3D Consortium. X3D introduces several functional extensions to VRML, such as Humanoid Animation, NURBS and CAD geometry. Furthermore, it supports additional XML-based and binary encoding formats as well as basic means for metadata description. Depending on the set of implemented features, different X3D profiles may be selected for the presentation of particular 3D content. Currently, X3D is implemented by a few browsers, e.g., BS Contact, FreeWRL and InstantReality. VRML and X3D enable standardized presentation of 3D content on the web, accessible with additional browser plug-ins. To enable seamless integration of X3D content with web pages, X3DOM [7] has been designed. It is an open source framework intended as a potential extension to HTML5. The content encoded with X3DOM can be presented without additional plug-ins by the majority of modern web browsers.

PDF3D [8] is another approach to 3D content presentation. It utilizes the U3D [9] file format for model representation and a proprietary JavaScript API for programming its behaviour. A PDF document with 3D content may be directly embedded in a web page, and presented with the Abobe Reader plug-in.

A number of libraries have been developed for creating 3D content presentations. Such libraries usually permit programming of the logic and behaviour of the content, while 3D objects in the scene are represented by external resources, which are encoded in, e.g., JSON, COLLADA, AWD, Wavefront OBJ or 3DS. Several libraries have been implemented on the basis of JavaScript and OpenGL to enable 3D presentations built into web pages—WebGL [10], GLGE [11], JebGL [12], Oak3D, [13], and O3D [14]. Other libraries (Papervision3D [15], Alternativa3D [16], Away3D [17] or Sandy 3D [18]) have been developed for the ActionScript—an object-oriented dialect of ECMAScript that is used for web applications compatible with the Adobe Flash Player. Web presentations of 3D content can also be built using Java applets implemented with JOGL [19] or Java3D [20] libraries.

Another group of solutions incorporates game engines, which allow for the development of complex 3D web applications enriched with additional aspects, such as physics, collision detection, artificial intelligence and networking. For instance, Unity [21] and Unreal [22] permit 3D presentations accessible with the Unity Web Player and the Adobe Flash Player.

III. Semantic Descriptions of 3D Content

In this section, the state of the art in the area of semantic description of web content is presented. In particular, basic techniques for describing the semantics of web resources, metadata and ontologies for 3D multimedia content as well as methods of semantic creation of 3D content are considered.

A. Foundations for the Semantic Web

The primary technique for describing data semantics on the web is the Resource Description Framework (RDF) [23]—a standard devised by the W3C. RDF introduces general rules for making statements about resources. Each statement is comprised of three elements: *a subject* (a resource described by the statement), *a predicate* (a property of the subject) and *an object* (the value of the property).

RDF introduces classes (as types of resources), containers and lists to provide basic concepts for semantic descriptions. However, these notions are often insufficient for describing the semantics of complex resources. The RDF Schema (RDFS) [24] and the Web Ontology Language (OWL) [25] are W3C standards based on RDF providing higher expressiveness for semantic descriptions of web resources, e.g., hierarchies of classes and properties, constraints, property restrictions as well as operations on sets. OWL defines a set of profiles, which differ in complexity and decidability. Semantic Web Rule Language (SWRL) [26] is an extension to OWL devised for describing semantic Horn-like rules. While RDF and RDF-based techniques permit the creation of ontologies and knowledge bases, SPARQL [27] is a language for querying RDF data sources.

RDF and RDF-based technologies have been intended as the basis of the Semantic Web. Hence, they are applicable to any type of web resources, but they do not address specific aspects of particular content types (especially 3D). That is why application-specific ontologies are required to describe content of various types on the web.

B. Metadata and Ontologies for 3D Content

To provide a common space for the classes and properties of resources on the web, several vocabularies, metadata schemas and ontologies have been proposed for various application domains and types of resources, in particular for 3D multimedia content. The Multimedia Content Description Interface (MPEG-7) [28] is an extensive standard that defines a set of tools for creating metadata—Descriptors, Description Schemes, the Description Definition Language and Coding Schemes. There is a wide range of target media types that may be described with MPEG-7—images, audio, video and 3D objects, including multimedia content in VR applications [29].

A few ontologies have been proposed for multimedia content. The Ontology for Media Resources [30] has been devised by the W3C on the basis of RDF, RDFS and OWL, as a common solution for describing multimedia published on the web. It provides an interoperable core vocabulary that is mapped to a set of metadata formats for media content (e.g., MPEG-7). The Core Ontology for Multimedia (COMM) [31], [32] is another solution designed for describing media content such as images, audio, video and 3D objects. COMM is based on MPEG-7, but it represents knowledge with open Semantic Web

solutions avoiding some interoperability problems that occur in MPEG-7, e.g., with semantically equivalent descriptors that are processed in different manners [32].

C. Semantic Creation of 3D Scenes

Several works have been devoted to the semantic creation of 3D content. In [33], an approach to creating interoperable RDF-based Semantic Virtual Environments, with system-independent and machine-readable abstract descriptions has been presented. In [34][35][36], a rule-based framework based on MPEG-7 has been proposed for the adaptation of 3D content, e.g., geometry and texture degradation or filtering of objects. The content can be described with different encoding formats (in particular X3D), and it is annotated with an indexing model. In [37], an integration of X3D and OWL using scene-independent ontologies and the concept of semantic zones are proposed to enable querying 3D scenes at different levels of semantic detail and they have been used to implement a tour through the Venetian Palace.

In [38], a method of structured design of VR content has been proposed. In [39][40][41], an approach to generating virtual words upon mappings of domain ontologies to particular 3D representation languages (e.g., X3D) has been considered. The following three content generation stages are distinguished: specification of a domain ontology, mapping of the domain ontology to a 3D description language, and generation of the final presentation. The solution stresses spatial relations (position and orientation) between objects in the scene.

Several works have been conducted on the modelling of behaviour of VR objects. In [42], the Beh-VR approach and the VR-BML language have been proposed for the dynamic creation of behaviour-rich interactive 3D content. The proposed solution aims at simplification of behaviour programming for non-professionals. Another method facilitating the modelling of content behaviour [43][44][45] provides a means for expressing primitive and complex behaviours as well as a set of temporal operators. Finally, a rule-based ontology framework for feature modelling, consistency check and feature modelling, has been explained in [46].

IV. Semantic Model of Interactive 3D Content

Although several approaches have been devised for semantic modelling of 3D content, they lack solutions for semantic representation of 3D content. Layered design of 3D presentations provides a separation of concerns between particular layers corresponding to different aspects of the designed presentation, which are described in individual, specific manners. It reduces the complexity and the number of connections between components, which are incorporated in different layers, facilitating their implementation and exchange, and simplifying the creation of the desirable content. In addition, possible implementation profiles of a structured solution may cover only layers reflecting the required aspects of the context—geometry, structure, appearance, space, logic, or behaviour.

In this section, a novel approach to the semantic design of interactive 3D presentations is proposed. The presented solution is based on a multi-layered semantic representation of 3D content. The model complies with the Semantic Web approach, and it has several important advantages in comparison to the available solutions for modelling of 3D content. First, the components of semantically described content may be searched, explored and reused by applying well-established Semantic Web standards. Second, it allows for reasoning on the content, which further enables discovering knowledge that has not been explicitly encoded. Third, 3D content described by commonly used concepts is platform- and standard-independent, and it may be transformed to final presentations encoded in different languages, depending on particular requirements, e.g., the context of interaction, client device used, user preferences.

The proposed semantic model of 3D presentations is depicted in Fig. 1. It includes six layers corresponding to distinct aspects of 3D content and different stages of the development of 3D presentations—*Geometry Layer*, *Structure Layer*, *Appearance Layer*, *Scene Layer*, *Logic Layer*, and *Behaviour Layer*. The subsequent layers are partly dependent—every layer uses only its own concepts and the concepts specified in the lower layers (gray arrows), i.e. a 3D presentation may fully utilize the components of a particular layer without referring to its higher layers. Like in OWL, the concepts defined are classes as well as data properties and object properties describing respectively the attributes and relations between class instances. The specification of the relations between class instances in the class definitions indicates optional and obligatory dependencies between components, which are specified during the modelling process while creating instances of these classes.

In the proposed approach, a 3D presentation may be created at an arbitrary layer and the development process includes the creation of components which are defined in the selected layer and its lower layers. For instance, design of a complex 3D scene with behaviour covers all of the layers of the presented model. However, presentations that consist only of lower layers are also possible, e.g., reusable structural 3D objects without appearance that are to be injected into different complex presentations can be created at layer 2.

Two types of classes are distinguished—*abstract* and *concrete*. With the presented solution, a developer designs a presentation by creating instances of the selected concrete classes. The properties in the presented model are specified as optional or obligatory with a given cardinality. A component in the resulting scene is assigned the properties of its class and the superclasses. Created objects may be described with desirable data properties and linked one to another with object properties.

The proposed semantic model has been designed with regards to concepts commonly used in well-established 3D content representation languages and libraries, such as X3D, Unity, etc. In the diagram presented in Fig. 1, several data properties which are typical for different 3D content representation standards as well as exact data types and ranges of

properties have been omitted as they are not crucial for the proposed idea. The presented model contains key concepts used in designing 3D presentations, but it may be extended with new classes and properties depending on the particular use.

The proposed model is semantically complete—no classes or properties are created or removed during the content presentation, only the values of properties may change. For instance, a moving object may be stopped by turning off its motion animation, but not by removing it.

The following sections describe the semantic design of 3D presentations with regards to the particular layers of the proposed model. The design starts with the description of basic shapes included in the created presentation (the *Geometry Layer*). Second, the basic objects are assigned spatial properties to be combined into arbitrary complex structural objects—complex shapes with spatial dependencies (the *Structure Layer*). Third, appearance properties are added to the complex structural objects to create visual components, which may be illuminated and enriched with environmental effects (the *Appearance Layer*). Next, the components with appearance are included in a scene with a viewpoint and navigation modes (the *Scene Layer*). Finally, logic and behaviour may be added to the scene and all its components (the *Logic* and *Behaviour* layers).

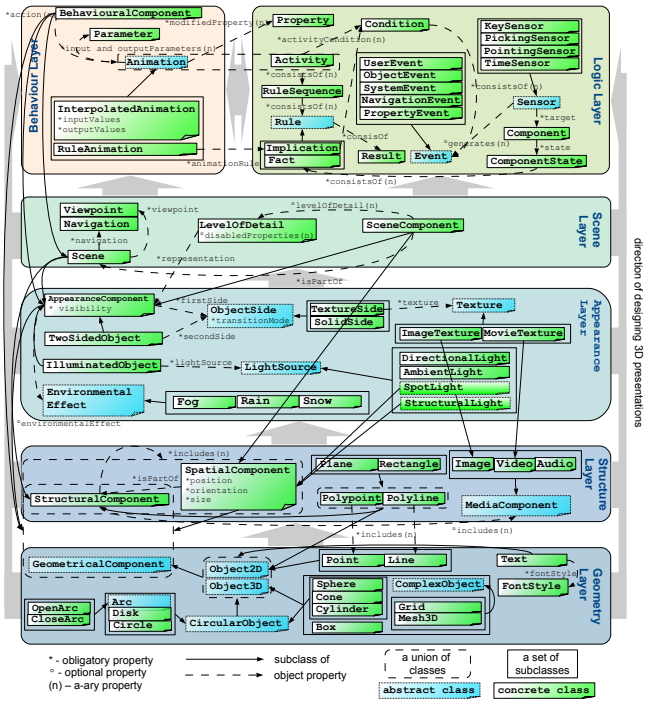

Fig. 1. The semantic model of interactive 3D content

A. Geometry Layer

The *Geometry Layer* is the base layer of the proposed semantic model and it includes concepts of basic 2D and 3D geometry shapes, which physically form the presentation. In the proposed model, this layer is aimed at the low-level manipulation of the geometry of scene components. The primary `GeometricalComponent` class is abstract, thus all shapes created are instances of its descendants. The classes of the *Geometry Layer* are relatively simple, in comparison to the classes defined in the other layers, as they are mainly determined by using data properties specific to 2D and 3D content. Since the components of this layer have no common point of spatial reference, their spatial properties (exact size, position and orientation) cannot be given. As this layer does not specify other aspects of 3D content (space, appearance, logic and behaviour), it allows only for modelling simple separated objects that do not combine into complex models and scenes. Hence, this is not sufficient for building practical 3D presentations. `GeometricalComponents` have limited expressiveness in 3D presentations, as they can only represent isolated integral objects, e.g., 3D models of sculptures or shapes of buildings.

B. Structure Layer

The *Structure Layer* is the second layer of the model and it depends only on the *Geometry Layer*. While the `GeometricalComponents` describe basic shapes included in a scene, `StructuralComponents` enable creating logical and spatial combinations of them into complex objects. `StructuralComponents` may recursively include other `StructuralComponents` as well as `Media` (`Images`, `Audio` and `Video`) and `Spatial` components. `SpatialComponents` are `Geometrical` and `Structural` components with spatial properties (`position`, `orientation` and `size`) set relatively to the parent `StructuralComponent`.

Thanks to the specific meaning of the `include` inverse functional property, `StructuralComponents` may be considered as a whole while assigning some properties (sub-properties of the `structurallyTransitive` property) in higher layers, e.g., appearance or spatial properties are automatically set for all the subcomponents of a complex `StructuralComponent` when the property is set to it.

Although the components of this layer have no appearance and thereby they are not sufficient for practical 3D presentations, they describe its structure and are managed from within higher layers, e.g., when determining logic and behaviour.

C. Appearance Layer

The *Appearance Layer* is aimed at adding appearance to `Geometrical` and `Structural` components that are defined in the previous layers. The primary `AppearanceComponent` may be either a single- or a two-sided object. Each side can be covered with textures (images or movies), or described by typical appearance properties (`colour`, `transparency`, etc.). The same appearance properties may be set for a whole `StructuralComponent` with all its subcomponents by specifying `transitionMode`—to ignore or respect the individual settings of subcomponents. In addition, `AppearanceComponents` may be illuminated

by LightSources of several types and enriched with EnvironmentalEffects. At this layer, a 3D presentation consists of a set of logically structured components with appearance that have no logic and behaviour, e.g., static museum artefacts, furniture, buildings, etc.

D. Scene Layer

The primary class of the *Scene Layer* is the Scene that is an AppearanceComponent or a StructuralComponent. It has assigned a list of Viewpoints and a list of Navigation modes. A background and EnvironmentalEffects of the Scene may be specified at the lower *Appearance Layer*. The subcomponents of Scene are SceneComponents inheriting from either Spatial or Appearance components. Complex SpatialComponents may be presented with different LevelsOfDetail depending on the current distance between the object and the observer. Each LevelOfDetail indicates a set of AppearanceComponents that are the ingredients of a particular target object, to be visible, and a set of appearance properties to be disabled. At this layer, designing complex navigable 3D presentations (without logic and behaviour) is feasible, e.g., static virtual museum exhibitions, models of cities, etc.

E. Logic Layer

The *Logic Layer* is intended as a framework providing concepts for describing the logic of components that are defined in other layers. This layer does not introduce apparent effects to 3D presentations, as opposed to the previous layers. As the logic may be related to different aspects of the created 3D content, the *Logic Layer* links all of the previous layers. This layer has been designed according to the rule-based approach that enables both complex declarative descriptions and reasoning on the created 3D presentations. The primary entity of logic description is a Rule that may be either a Fact or an Implication (if a Condition—a conjunction—is satisfied then a Result is also satisfied). While Facts describe the ComponentStates of any object defined in any layer of the presented semantic model, Implications are mainly used for describing complex RuleSequences. In a RuleSequence, the result of an Implication is the Condition of its following Implication. Such a chain permits an ordered performance of consecutive steps, like in typical imperative programming. In turn, several independent sequences may create an Activity that is initiated when a common required alternative of Conditions is satisfied. A Condition may refer to Events (generated either by a user interaction, an object, the navigation, the system, or a change of a property value). Events are generated by Sensors (e.g., KeySensor or PointingSensor for user interactions, PickingSensor for object interactions, TimeSensor for system interactions). Events and Sensors, as well as the relations between them defined in the model are similar to the corresponding concepts widely-used in other technologies for describing 3D, thus they are not described in detail in Fig. 1.

F. Behaviour Layer

The *Behaviour Layer* provides concepts that introduce apparent behavioural effects to 3D presentations built upon the previous layers. Like the *Logic Layer*, the *Behaviour Layer* leverages all the lower layers, as the behaviour of a component may concern different aspects of 3D content. In particular, selected classes of the *Logic Layer* are especially important for defining behaviour. The primary BehaviouralComponent class extends the Geometrical, Structural, Appearance components, or Scenes with an arbitrary number of actions—Activities or Animations. Activities, which are conditionally dependent on Events, enable programming interactions. While Activities are entirely defined in the *Logic Layer*, Animations are behavioural objects with sets of input and output Parameters used to control modifiedProperties. Two types of Animations may be distinguished. RuleAnimations utilize Implications to bind input and output Parameters in a functional manner. InterpolatedAnimations specify sets of values of input and output Parameters. The changes of classification attributes are gradual. For numeric attributes with continuous domains, intermediate input and output values that are not specified explicitly, are calculated from their neighbouring values. At this layer, the created presentations may be dynamic 3D scenes with components including all the aspects of 3D content. The presentation may change in time due to interactions between objects in the scene, user interactions, system interactions, etc.

V. Implementation of the Proposed Semantic Model

The proposed semantic model of interactive 3D content has been implemented as an ontology with well-established Semantic Web standards (RDF, RDFS, OWL, SWRL and SPARQL), using the Protege editor [47]. The implementation rules of the model are explained below.

A. Class Definitions

The classes of the model are described by the owl:Class type. Inheritance between classes is described by the rdfs:subClassOf property. In some cases, the subclasses of a class union have been defined, e.g., BehaviouralComponents may inherit either from Geometrical, Appearance, StructuralComponents, or Scenes; behavioural Actions may be either Activities or Animations.

B. Disjointness of Classes

In the presented model, the subclasses of a common superclass (surrounded by solid rectangles in the diagram) are mutually disjoint classes described with the owl:disjointWith property, e.g., 2D and 3D objects, media components, events.

C. Property Definitions

Data and object properties are reflected by the owl:DatatypeProperty and the owl:ObjectProperty, respectively. In some cases,

properties defined for a superclass need to be implemented individually for different subclasses, e.g., the `size` specifies two values (two dimensions) for 2D components, and three values (three dimensions) for 3D objects. Such dependencies have been encoded as hierarchies of properties using the `rdfs:subPropertyOf`.

D. Optionality and Cardinality of Properties

Some classes of the model may allow or require their instances to have selected properties specified with a particular cardinality, e.g., a `SpatialComponent` included in a `StructuralComponent` must be assigned a single `position`, a single `orientation` and a single `size`. Classes with such requirements have been indicated as subclasses or equivalent classes (`owl:equivalentClass`) of restricted superclasses (the `owl:Restriction` property). Optional unary, optional n-ary, obligatory unary, and obligatory n-ary properties of components are described, respectively, by the `owl:maxQualifiedCardinality`, `owl:someValuesFrom`, `owl:qualifiedCardinality`, and `owl:minQualifiedCardinality` properties set to 1. However, to check if the exact and maximal cardinality are satisfied, the closed world assumption should be made. This requirement can be met for 3D presentations designed strictly for the particular use, whose components come from limited or well-known sources.

E. Domains and Ranges of Properties

To unambiguously connect properties to the corresponding classes, domains and ranges have been determined for properties. In the vast majority of cases, domains and ranges enclose single classes, e.g., the sides of an `AppearanceObject`, the `Viewpoint` of a `Scene`. However, a few domains and ranges are unions of classes, e.g., a `consistOf` property may be indicated for an `Activity`, a `RuleSequence` or a `Rule`; an `includes` property can indicate a `Geometrical` or a `StructuralComponent`.

F. Structurally Transitive Properties

Structurally transitive properties influence not only the component they are specified for, but also the subcomponents it `includes`. Structurally transitive properties have been defined with SPARQL rules (Listing 1)—if a component has a property (line 2) that is a structurally transitive property (3), and the component has a subcomponent (4), then this subcomponent is also assigned the property with the same value (1).

In the presented semantic model, structurally transitive properties are related to appearance and spatial aspects of the content, e.g., colour, transparency, light sources (the parts of an illuminated object are also illuminated).

Listing 1. A SPARQL rule spreading structurally transitive properties

```
1 construct {?subcomponent prop ?value.}
2 where { ?component ?prop ?value.
3         ?prop rdfs:subPropertyOf STproperty.
4         ?component includes ?subcomponent. }
```

G. Logic Definitions

To enable complex descriptions of logic and reasoning on the content, components of the *Logic Layer* are implemented in SWRL. An `Implication` with a `Condition` and a `Result` is encoded as a `ruleml:imp` element containing a body (`ruleml:_body`) and a head (`ruleml:_head`). A `RuleSequence` is mapped to a list of `ruleml:imp` elements, in which the head of an implication is the body of the next one. Several independent sequences which are attainable by a common `Condition` (their initial rules have the same body) form an `Activity`.

VI. Example Layered Design of a 3D Artefact Model

In this section, an example of the use of the implemented semantic model is presented in the context of designing a 3D presentation of a virtual museum artefact, e.g., in development of educational games, creating commercial presentations, etc. The artefact is a complex static reusable 3D component that represents a bronze statue with a hat. The example focuses on modelling activities performed by a developer in the consecutive layers of the proposed model.

The design process is illustrated and based on an instance of the model (a knowledge base indicated by the `museum` prefix, Listing 2), which is compliant with the implemented model ontology (the `sm` prefix) and includes descriptions of the created objects, their properties and logic rules. The knowledge base is manually transformed to a concrete 3D scene. However, a tool for automatic transformation could be developed. In the presented example, the resulting 3D content description is encoded in X3D (Listing 3), however, other formats could be used as well.

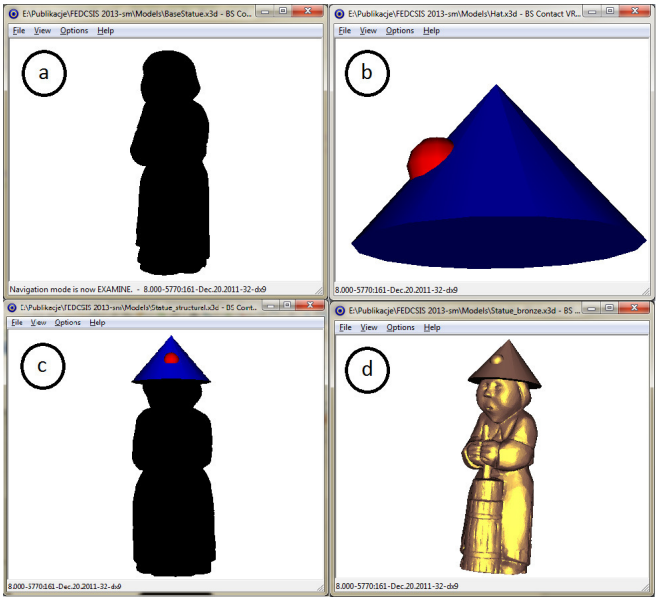

Fig. 2. The results of the consecutive stages of the example layered design of the 3D artefact: the geometry of the artefact (a), the hat element (b), the artefact as a structural component (c), the artefact as a component with appearance (d)

Fig. 2 depicts particular steps of the design process. During the first stage of the process, a `Mesh3D` geometrical object (Listing 2, line 17) is created by a scanner or a modelling tool (e.g., Blender or 3ds Max) to describe the shape of the body of the statue—its coordinates and coordinate indexes (2/20-21). The generated X3D code (3/18-19) leads to the view depicted in 2a. This is not a full 3D presentation due to the lack of properties describing the appearance—the created geometrical object is theoretically invisible.

In the second stage, a desirable `Hat` is found in another existing knowledge base and retrieved—e.g., by a SPARQL query with given conditions (Fig. 2b). In contrast to the body of the statue, the `Hat` is not limited only to geometry, but it has also structure, appearance, and spatial properties applied to its subcomponents (a brim and a decoration, Listing 2, lines 4,5). In the resulting X3D document the `Hat` is represented by a `Transformation` element with nested `Shape` elements (3/7-16).

Listing 2. An example of a semantically designed virtual 3D artefact

```
1  museum:Hat rdf:type owl:NamedIndividual ;
2    rdf:type sm:SpatialComponent ,
3    sm:SceneComponent ;
4    sm:includes museum:HatBrim ;
5    sm:includes museum:HatDecoration ;
6    sm:size "50 50 50" ;

11   sm:Scene .
12   sm:includes museum:BronzeStatueBody ;
13   sm:includes museum:Hat ;
14   sm:firstSide museum:BronzeStatueSide ;
15   sm:viewpoint museum:Viewpoint;
16   sm:navigation museum:Navigation .
17 museum:BronzeStatueBody rdf:type sm:Mesh3D ,
18   owl:NamedIndividual , sm:SpatialComponent ,
19   sm:SceneComponent ;
20   sm:coordinateIndex "..." ;
21   sm:coordinates "..." ;
22   sm:size "35 30 150" ;
23   sm:orientation "0 0 0" ;
24   sm:position "−5 100 0" .
25 museum:BronzeStatueSide rdf:type sm:SolidSide ,
26   owl:NamedIndividual ;
27   sm:color "0.65 0.45 0.4" ;
28   sm:transitionMode "override" .
29 museum:Viewpoint rdf:type sm:Viewpoint ,
30   owl:NamedIndividual ;
31   sm:position "−11.5858 −6.00235 1038.03" ;
32   sm:orientation "1.0 0.0 0.0 0.0" .
33 museum:Navigation rdf:type sm:Viewpoint ,
34   owl:NamedIndividual ;
35   sm:mode "examine" ;
36   sm:transitionType "linear" .
```

At the third stage, a structure is added to the designed model to represent its complexity. A new `StructuralComponent BronzeStatue` is created, and it includes both the `Hat` and the `BronzeStatueBody` (2/9-13). Since the `Hat` and the `Body` are parts of the `Statue` their `positions`, `orientations` and `sizes` need to be specified relatively to the parent `BronzeStatue` component (2/6-8,22-24). Then the subcomponents are inferred to be `SpatialComponents` (2/2,18), as they are defined as parts of a `StructuralComponent`. This structuralization leads to the X3D code (3/7-20), excluding an instruction describing the appearance of the statue body (3/17). At this stage of the design, the complex `BronzeStatue` may be illustrated as a complex component with spatial relations between its subcomponents (Fig. 2c).

At the next stage, appearance is specified for the whole `BronzeStatue` (2/14). The `BronzeStatueSide` (2/25-28) is a `SolidSide` component that defines a colour (2/27) used for the entire complex `BronzeStatue` overriding colours set for its subcomponents (2/28). The corresponding X3D `diffuseColor` attribute is set appropriately for both the `StatueBody` and the parts of the `Hat` (3/10,14,17). Since the appearance is specified for the whole statue (and not only for its `Hat`), it is inferred to be an `AppearanceComponent` (2/10), as it is a `StructuralComponent` with an `ObjectSide` assigned. The resulting X3D scene is depicted in Fig. 2d and Listing 3, lines 7-20—it is a reusable complex component with the appearance and the spatial relations between its subcomponents.

The last stage encloses activities performed in the *Scene Layer* and it extends the previous `AppearanceComponent` statue with a `Viewpoint` (2/29-32) and a descriptor of `Navigation` (2/33-36). With a `Viewpoint` and a `Navigation` mode specified, the `BronzeStatue` starts to be classified as a `Scene` (2/11), and its subcomponents—the `Hat` and the `Body`—as `SceneComponents` (2/3,19). The corresponding X3D description contains all the instructions in Listing 3, including lines 5,6.

Listing 3. The final representation of the virtual 3D artefact in X3D

</Shape></Transform></Scene></X3D>                                              20
```

VII. Conclusions and Future Works

In this paper, a novel approach to the semantic multi-layered design of interactive 3D presentations has been proposed. The presented division of the structure of 3D content into several distinct semantic layers facilitates the content creation process at the level of 3D model representation. However, the considered model does not address 3D content creation at an arbitrary high level of semantic abstraction, in particular by the use of domain concepts and ontologies. In addition, the presentations created with the model require explicit specification of all the components and relationships between them, which need to be presented in the resulting scene. Methods of semantic modelling and composition of 3D content at an arbitrarily

high level of abstraction may be proposed to permit implicit conditional query-based assembly of complex 3D scenes.

Other possible directions of future research incorporate several facets. First, although the presented approach is independent of any modelling tools, the use of semantic editors (e.g., Protege [47]) is highly recommended as it significantly facilitates working with the utilized Semantic Web standards. A specific development environment may be devised to support designing 3D presentations with regard to the consecutive layers of the presented model. Second, the implementation of the model should be evaluated and compared to other platforms in terms of the simplicity of 3D content creation. Furthermore, translators for selected target languages and technologies might be implemented, e.g., Java3D or Unity. To permit semantic exploration of 3D content in real-time, a persistent mapping between the primary semantic representations and the generated final scenes encoded in particular 3D content representation languages should be elaborated. Finally, the context of user–system interaction (e.g., user location, preferences, client device, etc.) can be semantically modelled to enable multi-platform 3D content presentations.

Microformat and Microdata Schemas for Interactive 3D Web Content

Jakub Flotyński, Krzysztof Walczak
Poznań University of Economics, Poland
email: {flotynski, walczak}@kti.ue.poznan.pl

***Abstract*—The paper presents new Microformat and Microdata schemas for creating descriptions of interactive 3D web content. Microformats and Microdata are increasingly popular solutions for creating lightweight attribute-based built-in semantic metadata of web content. However, although Microformats and Microdata enable basic description of media objects, they have not been intended for 3D content. Describing 3D components is more complex than describing standard web pages as the descriptions may relate to different aspects of the 3D content—spatial, temporal, structural, logical and behavioural. The main contribution of this paper are new Microformat and Microdata schemas for describing 3D web components and 3D scenes with metadata and semantic properties. The proposed schemas may be combined with X3D, a well-established 3D content description standard. Thanks to the use of the standardized solutions, the presented approach facilitates widespread dissemination of 3D content for use in a variety of multimedia applications on the web.**

***Index Terms*—3D content, semantic metadata, Microformats, Microdata, X3D**

I. Introduction

INTERACTIVE 3D technologies have enabled significant progress in the quality and functionality of human-computer interfaces. Widespread use of interactive 3D technologies, including virtual reality (VR) and augmented reality (AR), has been recently enabled by increasing hardware performance, availability of versatile input-output devices, as well as rapid growth in the available network bandwidth. However, the potential of 3D/VR/AR technologies in everyday applications can be fully exploited only if accompanied by the development of efficient and easy-to-use methods of creation, publication and sharing of interactive 3D multimedia content.

Building, searching and combining distributed three-dimensional interactive content are much more complex and challenging tasks than in the case of typical web pages. The relationships between components of an interactive three-dimensional virtual scene may include, in addition to its basic meaning and presentation form, also spatial, temporal, structural, logical, and behavioural aspects.

The aforementioned problems may be alleviated by describing 3D content with appropriate metadata and semantic properties. Research on the Semantic Web was initiated by T. Berners-Lee and the W3C (World-Wide Web Consortium) in 2001. This research aims at evolutionary development of the current web towards a distributed semantic database linking structured content and documents. Semantic description of web content makes it understandable for both humans and computers achieving a new quality in building web applications that can ”understand” the meaning of particular components of content and services as well as their relationships, leading to much better methods of searching, reasoning, combining and presenting web content.

On the basis of Semantic Web recommendations such as the Resource Description Framework (RDF) [1], the RDF Schema [2] and the Web Ontology Language (OWL) [3], a number of vocabularies, schemas and ontologies have been devised for a variety of application domains, in particular for multimedia systems, e.g., the Multimedia Content Description Interface [4], the Ontology for Media Resources [5] and the Core Ontology for Multimedia [6]. Available approaches to creating semantic descriptions of media content introduce a number of common attributes convenient for the general type of web resources, e.g., identifier, title, description, contributor, etc. In addition, they provide specific classes and properties intended for images, audio and video, but not for complex 3D web components, which may be described by multiple specific properties such as interactivity, animations, illumination, levels of detail, etc. Such metadata properties may be useful for exploration and analysis of 3D content, in particular for multimedia retrieval and optimization of queries for 3D content by providing values of attributes that are relatively constant and whose calculation is time-consuming.

Microformats [7] and Microdata [8] are increasingly used approaches to creating built-in semantic descriptions of web content with schemas defined in common repositories on the web. Embedding metadata directly in web content has a few important advantages in comparison to approaches that decouple resources from their descriptions. First, with embedded metadata, resources are unambiguously and inextricably linked with their descriptions. Second, it enables more concise descriptions and faster and less complicated authoring and analysis of semantically described content. Furthermore, it facilitates combining the semantic descriptions of resources with descriptions of web pages that embed the resources. Finally, it permits storage of content in structurally simpler databases. However, although existing Microformats and Microdata enable basic semantic descriptions of several types of multimedia objects, such as images, audio and video, they do not provide support for describing 3D content.

The main contribution of this paper are new Microformat and Microdata schemas for creating semantic metadata of interactive 3D web components and 3D scenes. The proposed

978-83-60810-53-8/$25.00

schemas facilitate indexing and retrieval of 3D content that meets specific criteria. The schemas include a number of specific properties that may be useful for contextual 3D content presentation dependent on, e.g., hardware/software platform, user–system interaction paradigms, user preferences, etc. The schemas may be combined with Extensible 3D (X3D) [9]—a well-established 3D content description standard, but they are not limited to this language. Thanks to the use of standardized solutions, the proposed approach enables flexible description and widespread dissemination of 3D content for use in a variety of multimedia web systems, e.g., in cultural heritage, education, simulations, geospatial visualisations, etc.

The remainder of this paper is structured as follows. Section II provides an overview of the state of the art in the domain of semantic and metadata descriptions of web resources, in particular 3D web content. In Section III, new Microformat and Microdata schemas are proposed for creating built-in semantic metadata of interactive 3D web content. Section IV describes a possible application of the proposed schemas in a system for searching 3D models by their metadata properties. Finally, Section V concludes the paper and indicates the possible directions of future research.

II. Semantic Descriptions of Multimedia Web Content

In this section, the state of the art in the field of semantic and metadata descriptions of multimedia web content is presented. In particular, metadata and ontologies as well as Microformats and Microdata for describing multimedia content are discussed. Next, methods of creating attribute-based embedded semantic and metadata descriptions of interactive 3D web content are considered.

A. Metadata and Ontologies for Multimedia Content

Several vocabularies, metadata schemas and ontologies have been proposed for describing multimedia content. DIG35 [10] defines metadata schemas for digital images. CableLabs [11] introduces vocabularies for both images and videos. The QuickTime File Format Specification [12] provides a schema for describing movie files. The Multimedia Content Description Interface (MPEG-7) [4] is a standard that defines a set of sophisticated tools for creating metadata—Descriptors, Description Schemes, the Description Definition Language and Coding Schemes. There is a wide range of target multimedia content that may be described with MPEG-7, including images, audio, video and 3D objects [13][14], however the standard is strongly focused on audio-visual data. The standards mentioned above typically include a number of generic properties (e.g., resource identifier, title, description, contributor, etc.), and a number of specific properties for describing images, audio and video, but not for complex interactive 3D web content.

A few ontologies have been proposed for multimedia content. The Ontology for Media Resources [5] has been devised by the W3C on the basis of the Resource Description Framework (RDF) [1], the RDF Schema [2] and the Web Ontology Language (OWL) [3] as a common solution for describing multimedia published on the web. It provides an interoperable core vocabulary that is mapped to a set of metadata formats for media content (e.g., DIG35, CableLabs and MPEG-7). A number of concepts defined in this ontology are common for web content of different types. There is a limited set of attributes typical for multimedia content, e.g., frameSize, compression, duration and samplingRate. This ontology lacks classes and properties typical for interactive 3D content, such as illumination, animations, navigation, levels of detail, etc.

The Core Ontology for Multimedia (COMM) [6][15] is another solution designed for describing media content. COMM is based on MPEG-7, but it represents knowledge with open Semantic Web solutions avoiding some interoperability problems that occur in MPEG-7, e.g., with semantically equivalent descriptors that are processed in different manners [15]. This ontology is convenient for describing images, audio and video, but it contains only a limited set of concepts suitable for interactive 3D web content.

Some other works are devoted to metadata for describing interactivity of 3D objects [16] and their interfaces [17]. Such descriptions may be used for finding 3D components by their properties [18]. In [19], metadata schemas for media objects have been proposed in the context of teaching architecture. The Metadata 3D Initiative [20] is a project in which a number of companies and research centres collaborate on the standardization of schemas for 3D (stereoscopic) content to make interoperable lenses, cameras, rigs, stereoscopic image processors, etc. In [21], the Multimedia Web Ontology Language, an extension to OWL, designed for creating ontologies and models for probabilistic reasoning in multimedia processing is presented.

B. Microformat and Microdata Schemas for Multimedia Content

Microformats [7] and Microdata [8] are solutions that are currently increasingly used for encoding semantic metadata of web content. In contrast to RDF-based approaches, which enable semantic descriptions with ontologies distributed across the web, Microformats and Microdata permit rapid creation of lightweight built-in semantic descriptions of content with schemas defined in common repositories on the web [7][22]. Such descriptions may be understandable for widely-used web search engines, such as Google, Yahoo and Bing. Currently, both Microformats and Microdata provide a variety of schemas for describing different types of web resources, in particular for multimedia content including images, audio and video.

The `hMedia` Microformat [23] is used for describing images, audio and video with a common set of properties. This schema is convenient for creation of general semantic descriptions that do not go into specific details with regard to individual media types. The `hAudio` [24] has been designed for describing audio content. There are no specific Microformats for describing images, video and 3D content.

In comparison to Microformats, Microdata provides a few more compound schemas, which form a hierarchical structure

with inheritance of properties. The root of this hierarchy is the `MediaObject` [25] schema, which defines a set of properties common for different types of media objects (like the `hMedia` Microformat)—images, audio and video. In addition, more extensive semantic and metadata descriptions of the particular media types may be created with descendant schemas of the `MediaObject`—`ImageObject` [26], `AudioObject` [27] and `VideoObject` [28]. Like the approaches mentioned above, Microdata does not provide schemas and properties sufficient for creating metadata and semantic descriptions of interactive 3D web content.

C. Attribute-based Embedded Metadata for 3D Web Content

In [29][30], a method of creating lightweight attribute-based semantic descriptions built into interactive 3D web content has been presented. The method enables metadata and semantic descriptions of both real objects and their virtual 3D counterparts by putting metadata into individual X3D metadata nodes. The resulting metadata and semantic descriptions of 3D web content are equivalent to Microformat and Microdata descriptions of typical web pages in terms of expressiveness. Moreover, such descriptions may use the same schemas, thus the method permits bidirectional transformation between descriptions that are built into web pages and descriptions embedded in 3D web content. Due to the use of the standard syntax and structure of X3D documents, the compatibility of the proposed approach with available X3D browsers is preserved.

The proposed approach is depicted in Fig. 1. The primary entity of the semantic description of 3D content is an X3D `MetadataSet` node. Since the method enables semantic descriptions of both real objects and their virtual 3D counterparts, both types of resources are referenced in the same manner—by their URIs. If a particular 3D component is to be described, it has to be assigned a URI in the X3D `DEF` attribute. The `name` attribute of the `MetadataSet` indicates a list of types of the described item, each of which may determine a set of semantic metadata properties. New item properties may be added to a `MetadataSet` independently of the schemas used. The optional `value` attribute specifies the URI (navigable or non-navigable) of the described object. The `reference` attribute of the `MetadataSet` contains a list of references to attributes that have been specified in other semantic descriptions and need to be shared with the primary one.

In addition to specifying the type and the URI of an item, the `MetadataSet` serves also as a container for item properties and relationships with other resources, which are reflected by nested typed metadata nodes (integer, float, double, string). The name and value of a property/relationship are given by the `name` and `value` attributes, respectively. The `reference` attribute is used to distinguish a property from a relationship. Metadata describing a property (e.g., data type) or a relationship may be contained in an additional metadata node of a desirable type, which is nested in the property/relationship typed element.

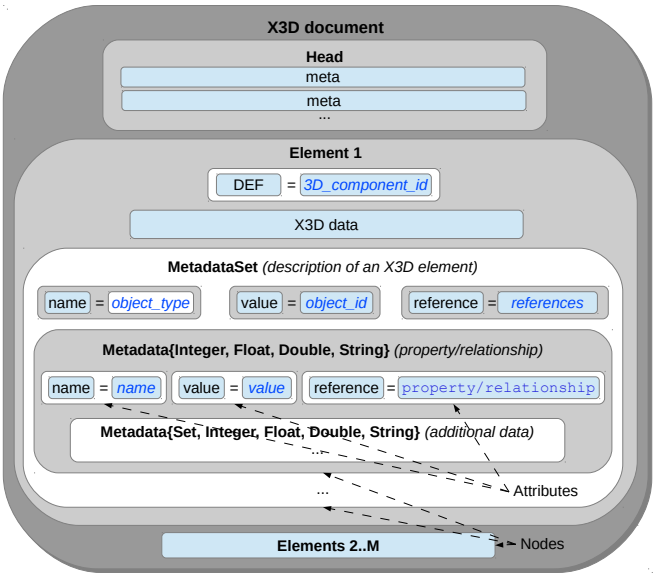

Fig. 1. Attribute-based embedded semantic descriptions of 3D content

In [31], a novel method of harvesting embedded attribute-based semantic metadata descriptions from distributed X3D web content has been proposed. The presented solution is an XSLT-based equivalent to the GRDDL [32] approach (originally intended for typical web pages), which has been designed for selection and processing of semantic descriptions of complex 3D/VR/AR scenes and components distributed across the web. The selection is based on the actual format, type and structure of the components, which are determined by their syntax. Filtering of the metadata to be extracted is necessary for reducing large semantic descriptions of complex 3D/VR/AR content to excerpts relevant to a particular application. The harvesting of metadata is a preliminary stage of the semantic analysis of the content, and it may precede the following activities, such as loading the generated semantic descriptions into a database and querying the system for semantically described 3D components.

III. Metadata Schemas for 3D Content

The aforementioned approaches address different aspects of creating metadata and semantic descriptions of web content, but they do not provide metadata schemas convenient for describing interactive 3D web content. To enable semantic descriptions of interactive 3D web components and complex 3D scenes, new metadata schemas are proposed in this section. They are intended to facilitate indexing, exploration and analysis of 3D content, and searching for 3D components and scenes described with embedded metadata attributes. Furthermore, the schemas include a number of specific properties that may be useful for contextual 3D content presentation dependent on, e.g., hardware/software client platform, user–system interaction paradigms, user preferences.

First, a classification of semantic metadata properties of interactive 3D web content is introduced. Then, new Micro-

format and Microdata schemas are proposed for describing 3D content with metadata and semantics.

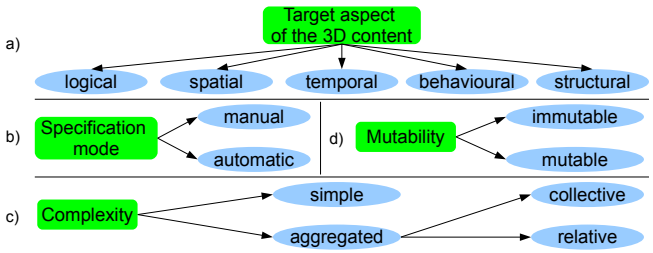

Fig. 2. The classification of metadata properties of interactive 3D web content in terms of the target aspect of the described 3D content (a), the specification mode of the property (b), the complexity of the property (c), and the mutability of the property (d)

A. Classification of Metadata Properties of Interactive 3D Web Content

The classification of metadata properties of interactive 3D web content is depicted in Fig. 2. The proposed classification is discussed in the four following aspects.

1) Target aspect of the 3D content: The metadata properties may be divided into different groups in terms of the described target aspect of the 3D content—*logical* (e.g., content description, presented object), *spatial* (e.g., dimensions, levels of detail), *temporal* (e.g., duration of an animation), *behavioural* (e.g., interactivity, animations) or *structural* (e.g., 3D sub-components).

2) Specification mode: The metadata properties may be distinguished in terms of the mode of specification, which may be *manual* or *automatic*. The first group incorporates properties that cannot be derived from the described 3D content and must be specified manually, in particular, by the author of the 3D content, e.g., the URI of the prototype of the described 3D component, the description of the component, and the semantic roles of its sub-components. The second group includes properties that can be automatically derived from the described 3D content, e.g., dimensions, animations, interactions.

3) Complexity: *Simple* and *aggregated* properties may be distinguished. *Simple* properties may be automatically retrieved from the described 3D component without appealing to its sub-components, e.g., the background of the scene or navigation modes. The main advantage of extracting *simple* properties is a possibility to reference them in queries that are built with a query language.

In contrast to *simple* properties, *aggregated* metadata properties are set with regard to the sub-components of the described 3D content, as opposed to other media types that do not incorporate a complex hierarchy of nested objects. *Aggregated* properties are determined by recursive processing and analysis of the content, which may be difficult and time-consuming, e.g., determining the number of levels of detail, animation types, light sources for the described content and all its sub-components. The main advantage of using *aggregated* metadata properties is that the calculation of them is performed once, before the described 3D content is loaded into a system. The presented approach may be preferred for 3D content that is rarely modified, for which the calculated properties are valid for a relatively long time. In such cases, the presented approach accelerates queries sent to the system, which do not need to initiate time-consuming processing of the content.

Two types of *aggregated* automatically determined metadata properties may be distinguished—*collective* and *relative* properties. *Collective* properties are specified by the analysis of sub-components of the described 3D component and determining a single aggregated value or a list of aggregated values. The results are related to the described 3D content as a whole, e.g., the dimensions, mass or volume of the described component are calculated as the sums of the dimensions, masses and volumes of its particular sub-components.

Like *collective* properties, *relative* properties are determined with regard to the sub-components of the described component, but the value of a *relative* property always describes either a relationship between the described component and its particular sub-components, or a relationship between particular sub-components of the described component. Such properties are convenient for expressing relative physical quantities, e.g., collision detection, velocity, acceleration, angular velocity, angular acceleration that are determined only by relationships between particular objects. In contrast to *collective* properties, *relative* properties are not aggregated.

4) Mutability: Metadata properties may be categorized in terms of the mutability into *immutable* and *mutable* properties. The first group comprises properties that do not change during the content presentation, e.g., the URI of the object presented by the described component or the names of additional packages required for correct content presentation. The second group contains properties that potentially can (but do not have to) change, e.g., dimensions, mass, illumination may change because of disappearing of some sub-components, switching off some light sources, etc. In the presented approach, it is not assumed that *mutable* properties are up to date for the whole period of the 3D content presentation. Instead, an author of the described 3D content may arbitrarily select a condition or a point in time for which the property is specified. It is recommended to select a specific condition/point in time, e.g., the start or the end of an animation that modifies the described property, and to indicate the selected point by the metadata of this property.

B. Metadata Properties of the Proposed Schemas

The list of metadata properties of the proposed `Microformat3D` and `Microdata3D` schemas are presented in Table 1. In the table, the aspect of 3D content (logical, spatial, temporal, behavioural and structural), the name and data types are provided together with the complexity, mutability and description for each property. In the *Type* column, the first data type is specified according to the proposed Microformat, the second one—to the proposed Microdata schema.

Target aspect of the 3D content	Property	Type	Complexity	Mutability	Description
logical	presentedObject	string	simple	immutable	A uniform identifier of the object (prototype) that is presented by the described 3D content. The presented object may be either real or virtual with a URI specified, e.g., as an HTTP address.
	packages	string[]	collective	immutable	The list of the names or URIs of additional packages necessary for the presentation of the whole described 3D content including all its sub-components. It is specific to the particular 3D content description standard used. For instance, X3D content may require such additional packages as Geospatial, NURBS, Human Animation, Distributed Interactive Simulation or CAD.
spatial	dimensions	double[] / float[]	collective	mutable	The width, height and length of the described 3D component including all its sub-components.
	mass	double / float	collective	mutable	The mass of the described 3D component including all its sub-components.
	volume	double / float	collective	mutable	The volume of the described 3D component including all its sub-components.
	fog	double / float	collective	mutable	The minimal visibility range for the described 3D scene and all its sub-components.
	background	string	simple	mutable	The name/value of the color or a URI of the image that is used as the background of the described 3D scene.
	illumination	(string, long)[]	collective	mutable	The list of types and numbers of light sources of the particular type, which are used in the scene and its sub-components. The light types may be, e.g., `point`, `spot`, `directional`, `area`, `model`, `ambient`.
	levelsOfDetail	(long, double/float)[]	collective	mutable	The list of the levels of detail used for the described 3D scene. Each level is specified by the number of polygons and a range. If multiple sub-components are combined within the described complex 3D scene, this parameter should be a combination of the levels of detail with regard to these sub-components.
	collisions	string[][]	relative	mutable	The list of the sets of URIs of 3D sub-components of the described 3D scene, for which collision detection is enabled.
temporal and behavioural	interactivity	string[]	collective	mutable	The list of user interactions allowed for the described 3D component and its sub-components, e.g., `selection`, `manipulation`, `navigation`, `system control`, `symbolic input`, etc.
	navigation	string[]	simple	mutable	The list of navigation modes allowed for the described 3D scene, e.g., `any`, `fly`, `walk`, `examine`, `lookat`, `slide`, `rotate`, `pan`, `game`, `jump`, `none`.
	animations	string[]	collective	mutable	The list of animation types used in the described 3D scene and its sub-components, e.g., `position`, `orientation`, `scale`, `structure`, `shape`, `appearance`, etc. For complex 3D scenes, the list should include animations in relationships between particular sub-components of the scene as well as between the scene and its sub-components, e.g., `position` animation.
structural	imageComponents	(string, string)[]	collective	immutable	The list of image components (textures) that are linked to the described component and its sub-components, with their URIs and semantic roles in the described 3D content, e.g., a texture of a dish, a sculpture, an exhibit, etc.
	audioComponents	(string, string)[]	collective	immutable	The list of audio components that are linked to the described component and its sub-components, with their URIs and semantic roles in the described 3D content, e.g., a background sound, a piano sound, etc.
	videoComponents	(string, string)[]	collective	immutable	The list of video components that are linked to the described component and its sub-components, with their URIs and semantic roles in the described 3D content, e.g., a projection, a movie, etc.
	3DComponents	(string, string)[]	collective with relative properties	immutable	The list of 3D sub-components with their URIs and semantic roles in the described 3D component, e.g., artefact, exhibition stand, wall, floor, furniture, etc.

Table 1. Semantic metadata properties of the proposed Microformat3D and Microdata3D schemas

The proposed Microformat and Microdata schemas are partially based on metadata properties devised in previous research works, e.g., the ARCO (Augmented Representation of Cultural Objects) 3D virtual museum system [33][34]. The presented list focuses only on properties specific for interactive 3D web content, and it is common for the new proposed Microformat and Microdata schemas. The schemas make use of the aforementioned Microformats and Microdata for media resources (`hMedia`, `hAudio`, `MediaObject`, `ImageObject`, `AudioObject`, and `VideoObject`) extending them with new metadata properties for 3D content. Attributes common for different media types have been omitted in the list, as they are inherited from the parent schemas. The inherited properties (not listed in Table 1) are mainly immutable and manually specified (e.g., `title`, `contributor`, `description`) or they are simple attributes, determined automatically without processing of their sub-components (e.g., `encodingFormat`, `uploadDate`). In Table 1, only the `presentedObject` must be specified manually, e.g., by a content creator. Other properties may be automatically determined—usually as aggregations of values from sub-components.

Microformats and Microdata introduce several equivalent metadata schemas, e.g., the `hAudio` and `hMedia` Microformats have as counterparts the `AudioObject` and the `MediaObject` in Microdata. Although these schemas usually contain common sets of properties, their numbers and types of attributes are frequently different, e.g., the `contributor` attribute indicates a `hcard` in Microformats and a `Person` or an `Organization` in Microdata. Hence, although the new proposed `Microformat3D` and `Microdata3D` schemas have the same properties specific for describing 3D content, they differ in the numbers and

types of properties that are inherited from their parent standard-specific schemas.

The proposed schemas do not impose the use of any particular units for individual metadata properties, but it is recommended to conform to the quantities and units specified in the described 3D content, e.g., metres and kilograms may be used for specifying the `dimensions` and the `mass` of the described object. Like any metadata describing a particular semantic property, unit descriptions may be nested into the descriptions of the relevant properties.

Although, overall, it is recommended to embed descriptions directly in the described 3D content, this is not required. The proposed `Microformat3D` and `Microdata3D` schemas are intended to be used directly within 3D content descriptions (in particular in X3D documents), but they may be also used in other types of documents, e.g., web pages embedding the 3D content. Hence, the name of the new Microformat does not start with a letter indicating a particular standard of the parent document—as opposed to the `hMedia` and `hAudio` Microformats that have been originally designed for HTML web pages.

IV. Searching 3D Content by Semantic Metadata Properties

This section explains the architecture of a planned system enabling 3D content retrieval using attribute-based built-in descriptions. The system leverages the proposed `Microformat3D` and `Microdata3D` schemas. First, the client–system interaction is discussed, second, an illustrative example is considered.

A. Client–system Interaction

The interaction between a client (a web browser) and the system is discussed in the two following aspects—loading 3D content into the system and querying the system for 3D content.

1) Loading 3D content into the system: Loading of 3D content into the system (Fig. 3a) is performed by the *Web Client*. Any browser can be used as the client, not imposing any specific and difficult to meet software requirements for the client side. A user sends 3D content with a built-in semantic description to the *3D Loader* web service via a web page with a file input component. The *3D Loader* sends the 3D content with its embedded metadata to the *GRDDL Agent* that extracts the metadata and creates a separate RDF document according to the rules presented in [31]. The document contains a semantic description equivalent to the built-in description. No changes are introduced to the primary X3D document. Finally, both the X3D document with built-in metadata and the generated RDF document are stored in the *Database*.

2) Querying the system for 3D content: Fig. 3b presents the consecutive steps performed every time 3D content is requested the system. First, a user utilizes a *Web Client* to build a query that specifies desirable metadata properties of the content. The query is embedded in an HTTP request and sent to the *Query Handler* web service. The *Proxy* is a Java application that mediates in the communication and extends the request with a context description of the client–system interaction that may specify, e.g., the client device and the software platform, user preferences and location, interaction paradigm, etc. Next, the *Query Handler* web service translates the extended query into a SPARQL [35] statement which is delivered to a *SPARQL Query Engine*. The engine retrieves desirable 3D components from the *Database*. The components are sent back to the *Query Handler* that invokes a *Web Page Builder* to create a representative web page. Finally, the web page is delivered to the *Web Client*.

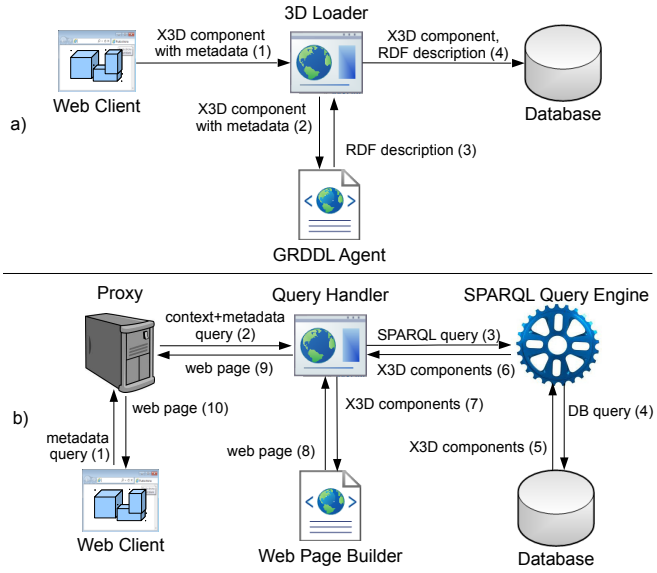

Fig. 3. Loading 3D content into the system (a) and querying the system for 3D content (b)

Listing 1. X3D content described with the proposed `Microformat3D`

```
<Shape DEF='Sculpture'>                                                          1
 <Appearance>...</Appearance><IndexedFaceSet>...</IndexedFaceSet>                2

  <MetadataSet name='3DComponents' reference='property'>                         15
   <MetadataSet name='http://www.kti.ue.poznan.pl/StringTuple'>                  16
    <MetadataString name='URI' value='http://.../dish.x3d' reference='property' />  17
    <MetadataString name='role' value='dish' reference='property' />             18
  </MetadataSet></MetadataSet>                                                   19
 </MetadataSet>                                                                  20
</Shape>                                                                         21
```

B. Illustrative Example

Below, two examples of the client–system interaction are presented with regard to the steps described in the previous subsection. In the examples below, 3D content is described

with the proposed Microformat, but an equivalent description could be created as well using the Microdata schema.

1) Loading 3D content into the system: Example X3D content that presents a 3D model of a sculpture is presented in Listing 1. The X3D `head` and several other elements reflecting the geometry and appearance have been omitted as they are not crucial for this example. The method of embedding semantic descriptions into 3D content has been explained in detail in [29][30]. In the presented example, the metadata properties have been specified manually while creating 3D components. However, it is desirable to develop an additional tool automatically calculating and embedding the properties into 3D content.

The 3D content is described with the `Microformat3D` (line 3) with multiple properties inherited from the `hMedia` (`fn`-4, `enclosure`-5, `description`-6), logical (`presentedObject`-7), spatial (`dimensions`-8, `collisions`-11, `illumination`-12), temporal and behavioural (`interactivity`-13, `navigation`-14) as well as structural (`3DComponents` 15-19). Next, the 3D content is sent to the *3D Loader* web service and stored in the *Database*, which is implemented using Oracle XML DB [36].

Listing 2. Example conditions sent to the system by a user (a), and the SPARQL query including contextual requirements inserted by the *Proxy* (b)

```
a) ?component description ?description
     FILTER regex(?description, "artefact").
   ?component material ?material
     FILTER regex(?material, "wood").
   ?component illumination "point".
   ?component animations "position".

b) select ?URI where {
                ?component enclosure ?URI.
                ?component interaction "manipulation".
                ?component navigation "walk".
                ?component levelsOfDetail ?lod.
                ?lod numOfPolygons ?polygons.
                FILTER (?polygons >= 100 000).
                { select count(?lod) as ?n where
                            { ?component levelsOfDetail ?lod. }}.
                FILTER (?n >= 3). }
```

2) Querying the system for 3D content: Querying the system for 3D content starts with specifying conditions using the *Web Client* (e.g., a web page). The *Web Client* builds a SPARQL query, which is encoded with the SPARQL Protocol for RDF [37], built into HTTP address and sent to the *Query Handler* web service. In the presented example, a user specifies semantic properties of the desirable objects by requiring 3D models of artefacts made of wood. In addition, the following metadata properties of the 3D objects are specified—the artefacts should be illuminated by `point` light sources and their `positions` should be animated (Listing 2a). The *Proxy* inserts additional contextual requirements into the request that specify 3D components suitable for desktop devices equipped with a keyboard and a high-resolution screen—with the `manipulation` interaction, the `walk` navigation mode enabled, having at least 100k `polygons` and at least 3 `levelsOfDetail` (Listing 2b). The *Query Handler* conveys the extended query to the *SPARQL Query Engine* (implemented with Apache Jena [38]). Next, 3D components that satisfy the given conditions are retrieved from the *Database* and provided to the *Query Handler*. Finally, the *Web Page Builder* creates a web page (Fig. 4), inserting the found 3D components into a web page template. The resulting document is delivered to the *Web Client*.

Fig. 4. An example web page with the requested 3D components

V. Conclusions and Future Works

In this paper, Microformat3D and Microdata3D schemas have been proposed for describing interactive 3D web content. Although a number of schemas and ontologies have been designed for describing the metadata and semantics of multimedia content on the web, they have been intended mostly for images, audio and video and not for interactive 3D content. The lack of commonly accepted schemas for describing the metadata and semantics of 3D resources is one of the important obstacles to widespread creation, dissemination and reuse of interactive 3D web content.

The proposed Microformat3D and Microdata3D schemas allow for metadata and semantic descriptions of interactive 3D web components and 3D scenes. The proposed schemas make use of the available Microformats and Microdata schemas for flexible semantic descriptions, and they may be combined with X3D, which is the leading standard for describing 3D content on the web. The compatibility with well-established web approaches enables the use of the presented schemas for describing, retrieving and exploring (finding, classifying, clustering, cataloguing, etc.) interactive 3D content in a variety of multimedia web systems, using a number of available tools (editors, validators, parsers, transformers, etc.), with minimal additional effort. The presented approach may be used for query optimization in applications with context-based user–system interaction.

The proposed approach stresses the compatibility of the created descriptions with the current syntax and structure of X3D documents and available X3D browsers. To provide the conformance of the presented solution to popular web search engines, the proposed schemas need to be encoded using the original Microformat and Microdata syntax, which has been intended for web pages and which is not compatible with 3D content standards. Therefore, the metadata should be inserted into web pages embedding the described 3D content.

We plan implementation of the proposed approach as an extension to the ARCO virtual museum system. Such extension

will allow for creating built-in metadata and semantic descriptions of virtual museum exhibitions, and will enable evaluation of the schemas in terms of the achieved optimization of queries to digital repositories of 3D exhibits.

Possible directions of future research incorporate several facets. First, the paper describes only an initial set of properties that may be used for describing 3D content. Based on practical experiences from implementation of systems using this kind of descriptions, the presented schemas may be further extended to include more specific properties describing 3D content. Also, possible values of the properties together with the preferred syntax should be specified. Second, the presented metadata model may be implemented using powerful RDF and RDF-based technologies such as OWL and RDFS. This will permit sophisticated exploration of semantically described content, including querying data sources and reasoning. Third, a tool for automatic computation of the proposed metadata properties should be developed and used for new 3D components loaded into the system. Next, the contextual rules managed by the *Proxy* might be described with Semantic Web standards to be accessible and processable with widely-used semantic tools. Finally, an evaluation of the system should be performed to assess the benefits from the query optimization provided by the proposed metadata schemas.

Abstract—This paper explores inexperienced user performance through a usability testing of three alternative prototypes of a mobile tablet application. One key factor in inexperienced users adopting mobile technology is the ease of use of mobile devices. The interface layout one of the three prototypes was built on the basis of previous research conducted in collaboration with users. More specifically, our study involves five navigation tasks which novice users were required to complete with each of the three prototypes. Our results showed that participants displayed better task performance with the prototype F1, which was created in collaboration with participants, in contrast to prototypes F2 and F3, which both caused navigation problems.

I. Introduction

THE rapid growth of mobile tablet technologies has lead to exponential growth in numbers of novice users, that is, in ordinary people who lack skills in computer science and who are drawn from a wide range of backgrounds. According to Hassenzahl [1], there is no guarantee that users will actually perceive and appreciate the product in the way designers desire it to be perceived and appreciated. For example, a product with a specific screen layout intended to be clear and simple will not necessarily be perceived as such. Despite the best efforts on the part of designers, new technologies often fail to meet basic human needs and desires [2]. The difficulties concerned in designing an interface that will deal effectively with individual preferences and experience, while minimizing frustration on the part of the user, transfer errors and learning effort, is widely recognized as a persistent problem of Human Computer Interaction [3]. Making things more usable and accessible is part of the larger discipline of user-centered design (UCD), which includes a number of methods and techniques [4]. Usability testing is a method used to evaluate a product by testing it on representative users. Greenberg and Buxton point out that *"Usability evaluation is valuable for many situations, as it often helps validate both research ideas and products at varying stages in its lifecycle"* [5].

Prototyping is an essential part of usability testing, as it confirms whether users can effectively complete tasks by means of the prototypes that are being tested and allows us to deal with various types of problems. Furthermore, prototypes can also be useful in dealing with the more subjective aspects of an interface. A previous study by the present authors has shown that inexperienced users structure content information in a mobile tablet application differently from experienced users, when the former interact with mobile devices [6]. Carroll argues that an effective way of dealing with system complexity for the novice user is to provide a functionally simple system [7]. In order to create more affordable mobile interactive artifacts for inexperienced users, we have focused on the interface design of a mobile tablet application and tested it on real users. The goal of this study is to investigate the effect of different interfaces in usability testing with regard to inexperienced user performance and the perceived usability of a tablet mobile application. To present the results of our study, we start our paper with a review of the literature, which establishes the theoretical background for our study. We then describe the research methodology employed. We analyse the data and give our results, which we discuss, before offering some conclusions.

II. Background

A. Prototyping

Prototyping is an essential procedure that structures design innovation. The translation of user needs into a system specification was facilitated in our study by iteratively refined prototypes validated by users. Beaudouin-Lafon and Mackay define any prototype as a concrete representation of part or all of an interactive system [8]. A prototype is, in their view, a tangible artifact, rather than an abstract description that requires interpretation. In Moggridge's, view a prototype is a representation of a design made before the final solution exists [9]. By offering different prototypes of a mobile application to users and requesting feedback, we can be sure that we are designing for those who will actually use our designs. Prototyping serves various purposes in a human-centered design process. With a view to improving this process, we developed, as a continuation of two previous studies of card sorting and creative session , three interactive prototypes in order to explore more intuitive navigation methods for inexperienced users who are to interact with

978-83-60810-53-8/$25.00

mobile tablet devices. Our decision to construct three, rather than one prototype, rests on work by Tohidi et al. and Dow et al., who argue that multiple prototypes are more helpful than merely one in aiding users to formulate negative or positive comments [10],[11]. Moreover, we were able to verify whether or not the prototype that we created on the basis of user requirements has responded effectively to these. Houde & Hill classify the ways in which the prototypes can be of value to designers [12]. Prototypes, in their view, include any representational design idea, regardless of the medium involved. Their model defines three types of issues that a prototype may affect, namely, the role of a product in the context in which it is used, the look and feel of the product and its technical implementation. Floyd, in an earlier laboratory prototyping of complex software systems, describes two primary objectives of prototypes, namely, 1) to act as a vehicle for learning and 2) to enhance communication between designers and users, as developer introspection of user needs often leads to inadequate products [13]. Buchenou & Suri note that the prototypes perform an additional function. They strengthen empathy, *"an original experience every kind of representation, in any medium, that is designed to understand, to explore or communicate what you could work with the product, space or system design"*[14]. Lim et al., stress the role of prototypes as a vehicle for learning, "*prototypes are the means by which designers organically and evolutionary learn, discover, generate, and refine designs*" [15].

B. Usability testing

The term *"usability"* is frequently employed in the field of human-computer interaction (HCI). Nielsen describes usability as an issue related to the broader issue of acceptability [16]. In his view, *"Usability is a quality attribute that assesses how easy user interfaces are to use"*. Usability is a significant part of the user experience and therefore of user satisfaction. A formal definition of usability is given in the ISO standard 9241–11 : *"...the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction, in a specified context of use"*. Effectiveness is defined as the accuracy and completeness with which users achieve specified goals and efficiency as the resources expended in relation to the accuracy and completeness with which users achieve goals. Satisfaction is defined as the freedom from discomfort, and positive attitude to the use of the product, whilst the context of use is defined as users, tasks, equipment and the physical and social environments in which a product is used [17].

Usability testing is a method employed in user-centered design to evaluate product design by testing it on representative users. Such users thus yield quantitative and qualitative data in that they are real users performing real tasks. Usability testing requires an artifact that is fairly complete and rationally designed, which means that the appropriate place for usability testing is at a stage quite late in the design cycle [18].

Dumas & Redish argue that usability testing is a *"a systematic way of observing actual users trying out a product and collecting information about the specific ways in which the product is easy or difficult for them"* [19]. They also recommend that usability test possess the following five features:

1. The primary goal is to improve the usability of a product. For each test, you also have more specific goals and concerns that you articulate when planning the test.
2. The participants represent real users.
3. The participants do real tasks.
4. You observe and record what participants do and say.
5. You analyze the data, diagnose the real problems, and recommend changes to fix those problems.

III. Research Methodology

To examine how novice users conceptualize a mobile tablet application, we created a user test involving three prototypes of a mobile tablet application themed around the topic of 'first aid' (Fig.1).

Fig. 1 Participant during the usability testing.

All three interfaces had the same look and feel, in order to standardize the visual appeal and the emotional impact made by the various alternative versions employed in the test. These versions vary in terms of conceptual models and menu navigation, one of them F1 having been created on the basis of the participant collaboration in previous studies by the present authors [6], [20].

A. Participants

The literature gives no clear optimum number of participants to be employed in usability testing.

Nielsen [21] argues that five participants will discover 80% of the problems in a system. In any case, a small amount of users, that is, generally fewer than 10 subjects, is sufficient for any formative evaluation of usability [22]. On the other hand, Spool and Schroeder [23] state that five

users identified only about 35% of the problems in a website. The research by Turner et al. implies that a group size of seven may be optimal, even when the study is fairly complex [24].

According to Sauro & Lewis *"the most important thing in user research, whether the data are qualitative or quantitative, is that the sample of users you measure represents the population about which you intend to make statements"* [25]. Our session was designed specifically to include a pool representative of potential users of the mobile application being tested. Twelve participants (N=12) ranged from 18 to 79 (mean age = 41,6, SD = 20.9, years), seven of whom were men and five women, all of whom had participated in one or more previous studies. All participants were novices in terms of computing. They had no visual or cognitive impairment and their education was of at least high school level. Given the evidence from our previous studies, the number of people in this experiment was sufficient to provide satisfactory evidence and depth for us to study. The age and gender of the participants is shown in Table I.

TABLE I.
AGE, GENDER AND NUMBER OF PARTICIPANTS.

ID	**P1**	**P2**	**P3**	**P4**	**P5**	**P6**
Age	50	38	26	27	57	79
Gender	M	F	M	F	M	M
ID	**P7**	**P8**	**P9**	**P10**	**P11**	**P12**
Age	52	31	18	45	65	67
gender	M	M	F	F	F	M

B. Material

Usability testing was performed on a Dell Inspiron Duo, 10.1tablet computer with a touch screen. A Panasonic HDC-SD40 digital camera was used to create a complete record of all user interactions with the interface. Furthermore, Camtasia Studio software was used to record a video of the movements made by the user on the interface during the test. Camtasia studio software captures the action and the sound from any part of the desktop. Digital tape recorder was also used.

C. The three prototypes

To reproduce a realistic software environment, for a period of three months, three prototypes were developed in Adobe Flash and we used them as a tool for recording user behavior during interaction. Prototypes help designers to balance and resolve problems that occur in different dimensions of design. Each prototype allowed the user to interact with mobile application and to carry out some tasks.

Interface F1

The first screen of the interface consists of icons that offer easy accessibility to the topic. We settled on this layout after a participatory session with users involved in our previous study [6]. There we concluded that users preferred icons for main menu selection, rather than a representation of options in words arranged hierarchically.

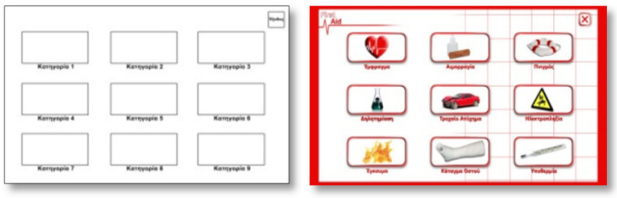

Fig. 2 The Interface F1

Interface F2

The colors remain the same in prototype F2, but the main menu has been moved to the left of the screen and now employs words, instead of icons. The options are the same in number as in the prototype F1. The subcategories are now placed in the middle of the screen. The aim of this layout was to explore whether a larger amount of text helps or hinders the inexperienced user to interact with a mobile application.

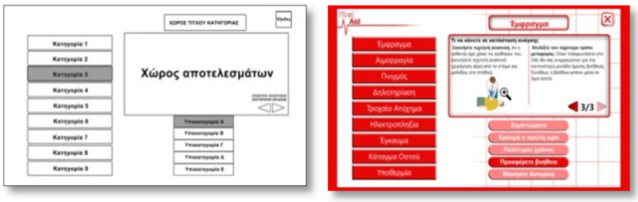

Fig. 3 The Interface F2

Interface F3

Prototype F3 is identical in basic design to prototype F2, except for a horizontal bar at the top of the screen, which enables the user to select subcategories. This layout resembles that of a website. The aim of this arrangement, which simulates the web environment, was to test the familiarity of users with little experience of surfing.

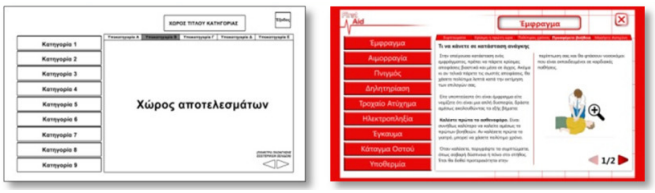

Fig. 4 The Interface F3

D. User Tasks

For the usability test, the participants were required to complete the five tasks given in Table II. The tasks were chosen as being representative and covered as many as possible of the features of the application.

TABLE II
PARTICIPANTS TASKS

Task 1	Turn on the mobile tablet device and select the icon "first aid".
Task 2	Find the information on Cardiopulmonary resuscitation (CPR.)
Task 3	Enlarge the image in order to see details.
Task 4	Select information on heart attacks.
Task 5	Find the information on symptoms of broken bones. Turn off the mobile device

E. User Performance

User performance was recorded in terms of the effectiveness, efficiency and ease of use of prototypes. In order to evaluate task effectiveness, we measured the percentage of tasks successfully completed within the set time limit. Task completion time refers to the time needed to accomplish the task. To evaluate efficiency, we recorded the time needed to process a task. To measure user satisfaction, we asked users to complete a post-test questionnaire.

F. Post -test Questionnaire

The main aim of administering written questionnaire after the test (post-test questionnaire) is to record participants' preference, in order to identify potential problems with the product. Information collected usually includes opinions and feelings regarding any difficulties encountered in using the product. Our questionnaire was based on System Usability Scale (SUS) developed by Brooke [26], since this is the most precise type of questionnaire for a small number of participants, as is shown by Tullis and Stetson's study [27]. SUS employs a "quick and dirty" approach in evaluating the overall subjective usability of a system (Appendix A). While SUS was originally intended to be used for measuring perceived usability, i.e. measuring a single dimension, recent research shows that this provides an overall measure of satisfaction of the system [27],[28],[29]. In addition to these advantages over other systems, the SUS is a powerful and multifunctional instrument [30].

G. Test protocol

Participation in the study lasted approximately one hour and 20 minutes and was conducted in an isolated room in our department. It consisted of the series of tasks that we mention above. All participants were tested individually.

After being welcomed by the experimenter, participants were told that they were to take part in a usability test and were to work with a prototype of a mobile tablet application. All participants gave their permission to be recorded on video. Subsequently participants completed the five tasks. The process of user testing is illustrated in Fig. 5. To minimize the potential for learning bias, the presentation order of the prototypes was counterbalanced.

IV. Results And Discussion

The main factors to be examined when testing usability are effectiveness, efficiency and user satisfaction. Effectiveness refers to how "well" a system does what it supposed to do. In order to evaluate task effectiveness, we measured the percentage of steps successfully solved within the time limit (7min). Efficiency refers to how quickly a system supports the user in what he wants to do. To evaluate efficiency, we recorded the time needed to process the task. Satisfaction refers to the subjective view of the system on the part of the user [4]. Qualitative and quantitative data were collected from each participant. Qualitative data included the participants' verbal protocol as recorded in videotapes.

Problems of usability were identified and categorized. We also collected comments on the prototypes and preference

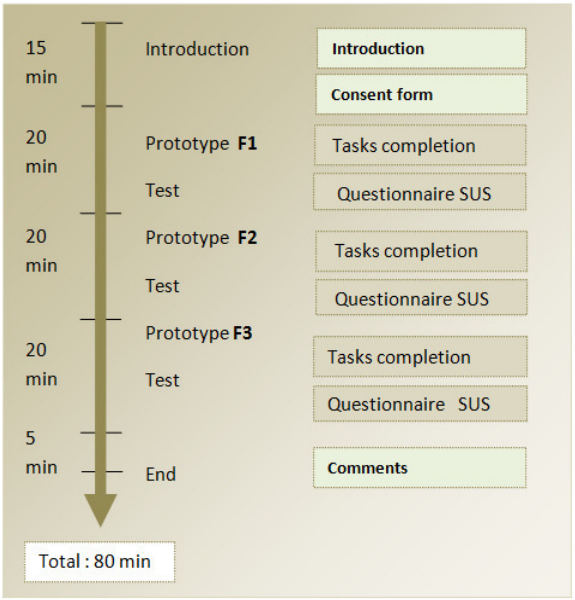

Fig. 5 User test process.

data and evaluations in the form of the SUS data questionnaire completed by the users after the test. Any user action that did not lead to the successful completion of a task we defined as error.

A. Effectiveness.

The percentage of users that manage to complete a task successfully thus becomes a measure of the effectiveness of the design. The number of errors made on the way to completing a task is an example of a performance measure [4]. An interaction effect is noticeable in the results, suggesting that the approach employed in the interface F1 may well have a marked impact on reducing the number of errors made. Tables III, IV show the user tasks and the error rate.

TABLE III
TASKS COMPLETION RATES

	Prototype F1	Prototype F2	Prototype F3
Task1	12/12	11/12	12/12
	100%	**91%**	**100%**
Task2	11/12	9/12	6/12
	91%	**75%**	**50%**
Task3	9/12	8/12	7/12
	75%	**66%**	**58%**
Task4	9/12	7/12	4/12
	75%	**58%**	**33%**
Task5	11/12	7/12	6/12
	91%	**58%**	**33%**

Errors were classified into two main categories, navigation errors and comprehension errors. Navigation errors occurred when partcipants didn't move as expected. Comprehension errors occured when participants didn't understand the design of the interface.

B. .Efficiency - Task Completion Time

We recorded the total amount of time required to complete each task in prototypes F1,F2 and F3, starting from turning

TABLE IV
TYPES OF ERRORS BY PROTOTYPE

Type of error	Prototype F1	Prototype F1	Prototype F1
Navigation	3	7	12
Comprehension	3	6	6
Total	6	13	18

the device on to turning it off. The mean amount of time required by participants in each age group is shown in Fig.7. Participants P6, P11, P12 failed to complete their tasks in prototype F2 within the time set (7min). In prototype F3, participants P2, P6, P11, P10, P12 failed to complete their tasks . Table V shows the results of the mean completion time and standard deviation for the participants for prototypes F1,F2 and F3. Data regarding time taken by each participant for each task is given in Appendix B.

Participant	Age	F1	F2	F3
P1	50	0:02:41	0:03:52	0:05:43
P2	38	0:02:49	0:03:35	
P3	26	0:02:10	0:04:11	0:04:26
P4	27	0:02:53	0:03:28	0:04:42
P5	57	0:02:15	0:02:40	0:05:07
P6	79	0:05:47		
P7	52	0:02:55	0:04:22	0:06:06
P8	31	0:02:45	0:03:33	0:04:30
P9	18	0:02:10	0:03:02	0:04:11
P10	45	0:02:23	0:04:53	
P11	65	0:03:58		
P12	67	0:04:26		

Fig.6 The tasks completion mean time (seconds).

For users testing the prototype F1, the time needed to complete tasks ranged between 2:10 min and 2:53 min up to the age of 57. For participants aged 57 years or older, task completion time increased. This affected mean task completion time and standard deviation. For prototype F2 tasks, completion times were clearly higher. Participants older than 57 failed to complete their tasks within the specified time. The mean completion time of those who did finish their tasks was 20.43% greater than the corresponding figure in prototype F1. For prototype F3, the mean completion time for those who succeeded in finishing was 33.04% greater than the corresponding figure in prototype F1.

Elderly users were thus not able to complete all the tasks in prototype F2 and F3 and specifically in prototype F3, where the layout of the prototype was slightly different, in that it resembled a web site. They had more information to process located on the left and at the top of the screen. These users found the interaction difficult to understand and to activate. On the whole, all users were more comfortable when interacting with prototype F1.

TABLE V
TASKS COMPLETION TIME (MEAN, SD)

	Prototype F1	Prototype F2	Prototype F3
Task completion time (mean)	03:06	03:44	04:58
Standard Deviation (SD)	01:06	00:41	00:43

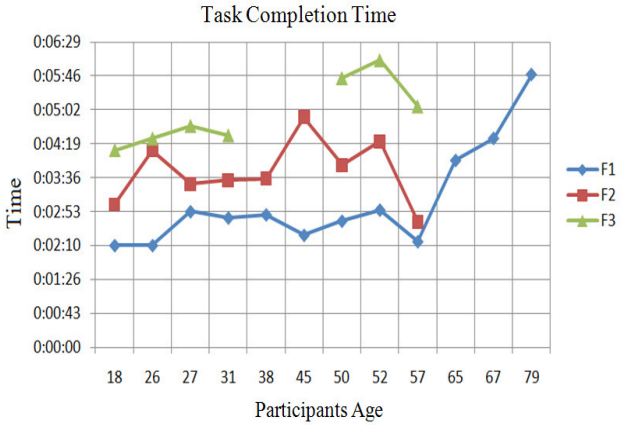

Fig.7 Task completion time per interface type.

C. Post test Questionnaire

We realised that time-on-task measures can be useful for collecting data on the efficiency of a system. On the other hand, such data does not give any information on overall satisfaction on the part of the user. User satisfaction may be an important factor in motivating people to use a product and may affect user performance. So, as a final point we decided participants were to complete an SUS questionnaire, so as to explore their experiences when interacting with the prototypes. A crucial feature of the SUS lies in the fact that asks the user to evaluate the system as a whole, rather than specific aspects.

All 10 questionnaire statements having been processed, the overall SUS score for each prototype turned out to be that given in Table VI. To calculate the SUS score, first we summed the score contributions of the items 1, 3, 5, 7 and 9 (Appendix A). The score contribution of these items are their scale position minus one. We then summed the score contributions of the other items: five minus their scale position. Finally, we multiplied the sum of the scores by 2.5, to obtain the overall score with a range between 0 to 100.

The survey results showed the overall satisfaction. Sauro [31] reports that a mean value over 74 is level B, value above 80.3 is level A. An average value of below 51 is level F (fail). The prototype F1 with an average value of 80.6 passes the threshold of 80.3 and are to be placed on level A, F2, with an average value of 63.3, belong to level B and F3, with a value of 48.1, is to be placed at Level F, which is regarded as failure.

However, with respect to F1, nearly all participants preferred the interface with the icons over the other two interfaces (F2, F3), in which there was a large amount of text. Some of the participants simply misunderstood the graphics keys that depicted a lens and whose purpose was to increase the photographs on the screen and the arrows that represented the act of selecting the next screen. If perhaps users had understood the graphics more fully, the error rate for prototype F1 may perhaps have been as low as zero.

TABLE VI
OVERALL SUS SCORE

Participants	F1	F2	F3
P1	80.0	70.0	70.0
P2	82.5	70.0	25.0
P3	90.0	82.5	60.0
P4	95.0	82.5	72.5
P5	87.5	80.0	72.5
P6	65.0	25.0	25.0
P7	77.5	70.0	27.5
P8	75.0	75.0	75.0
P9	92.5	82.5	75.0
P10	82.5	72.5	25.0
P11	70.0	25.0	25.0
P12	70.0	25.0	25.0
Mean	**80.6**	**63.3**	**48.1**

Overall users liked the process and regarded their interaction with the prototypes positively. Nevertheless, in some cases, the participants were apprehensive. Uncertain in their selections, they demanded greater confirmation and reassurance about the actions they were to take. In such cases, it is important for the researcher to motivate participants, encouraging them discreetly to investigate alternative directions, while simultaneously recording any mistakes made. As for individual prototypes, participants prefered the design of the first interface, which contained icons (F1). This was to be expected and users commented positively on its simplicity, ease of use and intuitiveness.

V. CONCLUSION

The aim of our study was to examine whether an interface design approach could improve performance of tasks by inexperienced users during interaction. To do this, we employed three different prototypes of the same application. We tested our empirical methodology on twelve individuals, all of them novices in terms of computer use.

One of the most remarkable discoveries we made is the large degree of difference in performance among the three different prototypes with regard to user effectiveness and the number of errors. The effectiveness and efficiency of the F1 prototype is evident in the fact that users made fewer errors and took less time to complete their tasks. Participants reported that the icon menu of the F1 prototype facilitated the execution of their tasks, as did the absence of text in menu selections. This confirms what emerged from a previous study by the present authors. Our findings imply that the users did not understand the basic conceptual models informing prototypes F2 and F3 [2].

The usability test performed on each of the prototypes showed that most users considered the prototype easy to use and intuitive. When evaluated by SUS, the same prototype received an overall score which placed it on level A. The test also helped in locating various issues regarding the other two prototypes F2 and F3 and, in particular, regarding what is to be corrected, so as to improve its usability for the elderly. However, we believe that our paper, which focuses more on the users and their cognitive abilities, offers a new insight into how inexperienced users perform tasks on mobile tablets.

Universal approach for sequential audio pattern search

Róbert Gubka, Michal Kuba, Roman Jarina
Faculty of Electrical Engineering, University of Žilina
Univerzitná 1, 010 01 Žilina, Slovak Republic
Email: robert.gubka@fel.uniza.sk

***Abstract*—This article deals with universal sequential audio pattern search and sound recognition method. Inspired by classical phoneme-based speech recognition and word spotting systems, where longer speech patterns are formed by sequences of basic speech units, we propose a methodology for creating a finite database of elementary sound models. These models can be arbitrary concatenated into sequences, thus forming a model of the required acoustical pattern or sound event.**

I. Introduction

AUTOMATIC speech recognition and word spotting systems are nowadays getting to the forefront in daily use. Intelligent human-computer communication interfaces allow us to take up the control over electronic equipment using our voice, making their usage more native and comfortable. All this is possible thanks to rigorous research in the field of human speech production and recognition. However, voice operated devices can only work with human speech and react only to specific spoken keywords or phrases in certain language, mostly English.

Universal intelligent system should be versatile, easily expandable for new commands in different languages, have ability to learn and operate also with non-speech sounds and acoustical events, e.g. for better evaluation of content and context of a situation. Such system can be adopted in different application areas. Audio is useful especially in situations when other sensors fails to reliably detect an event. For example in the context of surveillance systems, in weakly illuminated places, public transport areas, public halls or streets where it is not possible to evaluate video, or visual information alone is unreliable, the audio events spotting system can be very useful as burglar or violence alarm by detecting sound events, like glass brake, shout, footsteps, or any other significant sound defined by user [1], [2].

Another topic in the field of audio processing is information retrieval over multimedia content. Currently, huge amount of multimedia data such as music recordings, broadcast news, dialogs and conversations, etc., are available in large audio databases. However, most of these data are unstructured and have limited or no tag information about the content, hence, it is not easy for user to locate desired audio samples or segments.

Most of the existing applications perform the content-based analysis by segmentation of the audio data and subsequently classification of audio sequences into one of the specified sound classes, represented mostly by a statistical model [3]–[5]. Disadvantage of this approach is, that a sufficient amount of representative data is needed for each sound class to be created and user has only limited possibility to adding new queries into search. Moreover, with growing number of sound classes or queries in search also the computation and memory demands grow.

”Query-By-Example” (QBE) paradigm is an alternative approach to multimedia information retrieval. In the context of audio information, the user provides a short sound clip as a query and the system returns audio samples that are similar to the query. For example, the user provides a short utterance spoken by a particular person and expects that the system returns all the samples from the audio (video) database that contain the voice of the same person. Or the user gives a sample of an applause sound and the system should return all clips from the audio/video content that contain applause.QBE approach is also very popular in music information retrieval [6], [7]. The challenge of the QBE approach is that only very limited amount of training/reference data are available in advance and sound classes are apriori not known, thus conventional statistical model-based approaches and learning algorithms cannot be straightforward adopted.

Among various approaches to example-based audio event detection and retrieval, the most popular ones are based on similarity measure in audio feature vector space [8], [9] or hidden Markov models (HMM) [10], [11]. The approach in [11] was based on feature-based segmentation of audio using a dynamic Bayesian network. The inherent similarity or difference between sounds was determined by the corresponding similarity or difference between the audio features trajectory represented by HMM that approximates a general trend in query time behaviour.

In this paper we adopt different strategy to HMM modeling of an audio pattern. We propose the HMM approach that is inspired by methods very well explored in automatic speech recognition (ASR) and ASR-based spoken term retrieval. Every spoken word or sentence of speech of given language can be formed as a combination of basic acoustical-linguistic units, which are called phonemes. In every languages, there is a finite number of phonemes, e.g. there are approximately 44 phonemes in English language (may differ with particular dialect). In ASR-based keyword spotting systems, the search space is created only by statistical models of phonemes and

978-83-60810-53-8/$25.00

keywords or speech patterns are added into search as logical sequences of these models.

Our effort was to adopt the concept of elementary units for general sound and language independent speech recognition task. This approach requires to define a basic unit of sound (hereinafter called the elementary sound) and create a finite, but sufficiently large database of these units. For this purpose, we have adopted methods of unsupervised cluster analysis applied over huge amount of various audio data to create a database of elementary sound models. Major contribution of our proposal is that the elementary sound models can be treated as analogy to phoneme-based models in speech processing. Thus, statistical methods for speech recognition can be applied for general audio. As it is known to the authors, no similar method has been proposed in literature.

II. Concept of Elementary Sound Units

A. Elementary sounds

The idea of elementary sound units is based on the assumption that, in general, any acoustical pattern can be synthesized as a concatenation of short-time sound elements, stored in finite (but sufficiently large) sound inventory. This idea is derived from speech recognition and keyword spotting systems based on concatenation of sub-word phoneme units from finite database, to represent the sentences of speech. These units are predominantly represented by their parametric statistical models, created and estimated according to corresponding acoustical training examples.

Of course there are many challenges to successfully implement such approach. The biggest problem is the fact that unlike speech, which can be easily modeled since its physical production is known, general sounds are produced by unlimited number of ways and thus can be of infinite variance in temporal-spectral behavior. Unlike the phonemes, we can not practically create a database of the acoustical examples for general sound basic units. Instead, we have performed a cluster analysis over statistical models and created a database of the elementary sound models. The process of the creation is described below.

B. Parametric modeling

First step to create the database of the elementary sound models is to select a suitable method for statistical modeling and model parameters. For this purpose, we choose modeling via hidden Markov models (HMM), which is suitable for statistical description of time series of observations and therefore is commonly used in speech and general sound recognition tasks. A continuous-density HMM with N states consists of a set of parameters that generally comprises the matrix of transition probabilities, the initial state distribution, and the parameters of the state output density function, which is mainly approximated by a mixture of Gaussian components that can be expressed as follows:

$$P(\boldsymbol{x}|S) = \sum_k w_k \mathcal{N}_k(\boldsymbol{x}, \boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k) \quad (1)$$

where $\mathcal{N}_k$ is the Gaussian component with mean vector $\boldsymbol{\mu}_k$ and covariance matrix $\boldsymbol{\Sigma}_k$, and w_k is the weighting coefficient of this component in the state of the model. However, as the number of states in the search space grows, the system becomes more computationally and memory demanding. For this reason, we adopt a semi-continuous-density models, where all states share the same Gaussian components. Output density function of particular state is then determined only by the weighting vector $\boldsymbol{w}$.

Furthermore, assuming that only one of the components has major contribution to the resulting likelihood of the state, the summation operation in (1) can be replaced by the selection of maximal value. This modification reduce the processing time with minimal impact on resulting likelihood (mean difference less than 5%).

Similar to phoneme models, we choose a 3-state left-to-right model structure with equal transition probabilities, which can therefore be omitted.

C. Unsupervised clustering

One of the problems of statistical modeling is the determination of optimal number of Gaussian mixture components for output density function, which is usually determined by experiments [3], [4]. More sophisticated approach is based on Bayesian or Akaike Information Criterion [12], [13], Kullback-Leibler divergence [13], and unsupervised clustering methods [14], [15]. In [15], unsupervised *K-Variable K-means* clustering algorithm was proposed. This algorithm was adopted in our work to determine the optimal number of mixture components and also for derivation of the elementary sound models. The clustering algorithm is described below.

Algorithm 1 K-Variable K-means

1: Compute m and s as the mean and standard deviation of the distances between any pair of frames.
2: Set threshold distances: $T_1 = m - C.s$; $T_2 = m + C.s$ where $C \in < 0.5; 1.5 >$
3: Create 1st centroid as $\boldsymbol{c}_1 = \arg\max_i(\|\boldsymbol{x}_i\|)$
4: **for** $\forall \boldsymbol{x}_i$ **do**
5: $d_i = \min_j(d_{ij}(\boldsymbol{x}_i, \boldsymbol{c}_j))$; Find the distance to the closest centroid.
6: **if** $d_i < T_1$, Make $\boldsymbol{x}_i$ member of cluster j;
7: **if** $d_i > T_2$, Make $\boldsymbol{x}_i$ the center of a new cluster;
8: **end for**
9: Make all the remaining unclassified vectors members of their closest cluster.

D. Database of the Elementary Sound Models

The most important part of our system for general audio pattern searching is the database of the elementary sound models. Due to the gargantuan number of different sounds that may generally occur, it is impossible to create a finite database of acoustical training examples for elementary sound models. Therefore we have adopted the cluster analysis do derive and group sounds with similar statistical characteristics.

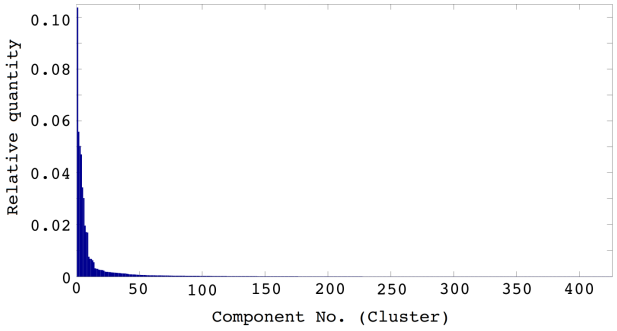

Fig. 1. Distribution of acoustical observations among clusters.

First, a sound database was collected, that consist of more than 30 hours of various short audio clips. This database involve different types of environmental and machinery sounds and noises, animal sound, human produced sounds and speech of different languages, music of different genres, etc.

The database was processed and the audio features described in section III were extracted. To obtain the Gaussian mixture components, all feature vectors were divided into clusters. Before the actual clustering, confusing data vectors were eliminated. The centroid of the whole data set was computed and the mean m and standard deviation s of distances of data vectors from this centroid were computed. Vectors with distance $d > m + 3.s$ were discarded.

Remaining data vectors were clustered using the unsupervised clustering and the means $\boldsymbol{\mu}_k$ and diagonal covariance matrices $\boldsymbol{\Sigma}_k$ occurred in (1) were computed for each cluster respectively. Clusters with less than 30 observations were discarded. As the result of clustering, state output density function consist of 426 Gaussian mixture components. Fig. 1 shows the distribution of acoustical observations among clusters.

Next, audio stream from all sound clips was formed and divided into 1 second long segments with 0.5 second overlap. From each segment a 3-state model was estimated. Because the models are defined by their weighting coefficient vector in each state, estimated models were clustered by unsupervised clustering. A histogram of distribution of the models within the clusters was computed. The clusters were assorted from the biggest to the smallest according to the number of members within the cluster. The elementary sound models were then derived as the means of the clusters. The clustering results in more than 10^4 clusters, although most of them comprise only one member. Therefore, only first 500 models were adopted for experiments.

Each of these models describe the audio segment in that the acoustical observations are statistically very similar. Conversely, acoustical observations of different elementary sounds differ in their characteristics.

III. Audio Features Selection

In order to achieve the best performance for classification, we have selected features that can capture the temporal and spectral characteristics of audio. Following work in [16], in which the features were selected by optimization algorithm, we have selected the following features:

1) *Line spectral frequencies/pairs (LSF/LSP)* - used as an alternative to linear prediction coefficients. The LSF are obtained by decomposing the LP filter transfer function A(z) into pair of auxiliary polynomials:

$$\begin{aligned} P(z) &= A(z) + z^{-p+1}A(z^{-1}) \\ Q(z) &= A(z) - z^{-p+1}A(z^{-1}) \end{aligned} \tag{2}$$

where $P(z)$ is symmetrical and $Q(z)$ asymmetrical p+1-order polynomial, where the zeros of $A(z)$ are mapped onto the unit circle in the z–plane.

2) *Spectral flux (SFX)* - measures changes in the shape of magnitude spectrum by calculating the difference between magnitude spectra of successive frames. The spectral flux is computed for frame at discrete time t as follows:

$$SFX(t) = \frac{\sum_k [a_k(t) - a_k(t-1)]^2}{\sqrt{\sum_k a_k(t)^2}\sqrt{\sum_k a_k(t-1)^2}} \tag{3}$$

where a_k is the k-th element of magnitude spectrum of given frame. Spectral flux describes the temporal changes of magnitude spectrum, thus represents the dynamic coefficients of spectrum.

3) *Zero crossing rate (ZCR)* - the number of time-domain zero-crossings within a frame, computed as a number of sample sign changes.

These features were extracted using the Yaafe [17] extraction tool. The resulting feature vector consists of 10 LSF's, one SFX, and one ZCR coefficient.

IV. Audio Pattern Searching

The theoretical background for sequential audio pattern searching was taken from [18] where a decoder for keyword spotting was proposed. Its function is based on Viterbi algorithm with propagation of accumulated score through the

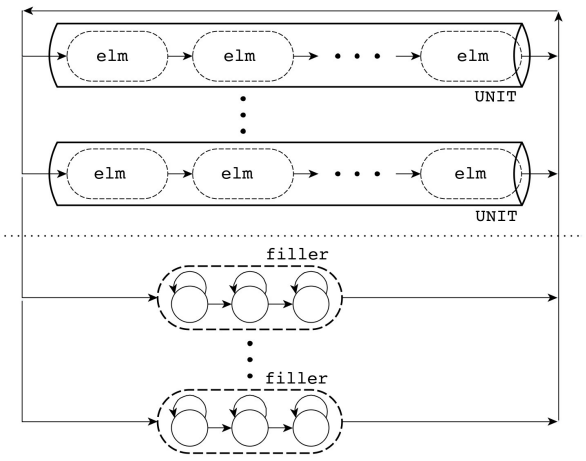

Fig. 2. Looped network of units and fillers.

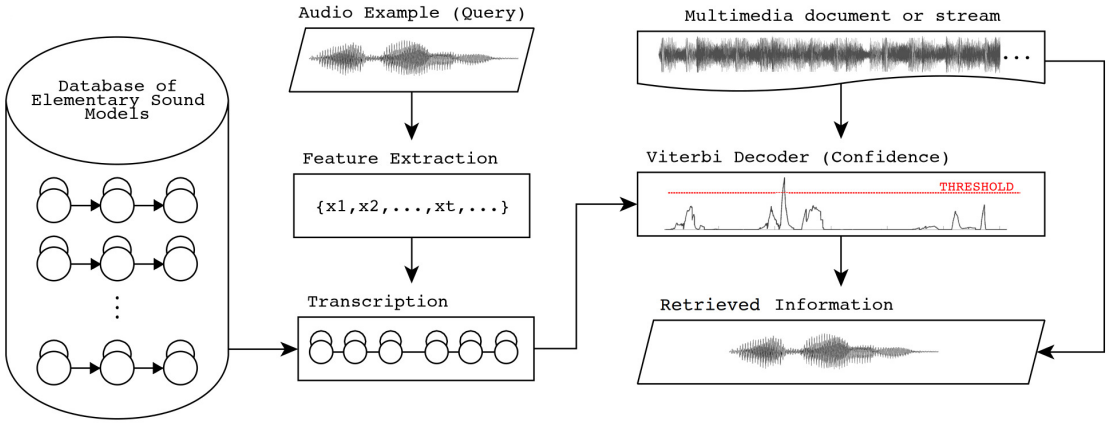

Fig. 3. Query-by-Example search.

looped network of units that represents searched keywords, and fillers.

In our implementation, the basic unit of the decoder is the elementary sound. In process of creating the model of demanded audio pattern, a representative audio sample is passed into decoder and transcribed into sequence of the elementary sound models. This transcription is found as the path through the elementary sound models with the highest score achieved for the training example. This logical sequence of elementary sounds is then added into search space as a unit, representing the searched audio pattern. Example of model network with units and fillers is shown in Fig.2.

In the process of decoding, each acoustical observation must be assigned to one of the states in model network. The acoustical observations between segments that correspond with searched patterns are assigned to the filler models, that represents any sound that may occur in background. This definition of filler offers us the possibility of using the proposed database of elementary sound models itself.

Another benefit of using the elementary sounds as fillers is that we can compute the confidence of particular unit as proposed in [18]. The confidence $C(u,t)$ of unit u at discrete time t is defined as normalized acoustic score as follows:

$$C(u,t) = S(u,t)/S(f_c,t) \tag{4}$$

where $S(u,t)$ it the acoustic score achieved for segment of audio by unit u, and $S(fc,t)$ is the acoustic score achieved by the best concatenation of fillers (in our case the elementary sound models) for the same segment. It follows that the confidence reaches the maximum value of 1 only when the score of the unit and the score of fillers concatenation are equal. In this case, the audio segment precisely correspond with the unit training example. In other cases when $C(u,t) < 1$ the probability of correct detection decreases and proper threshold must be set for experimental data. Fig. 3 shows the principal functions of the complex system for query-by-example general audio pattern recognition.

V. Experimental Results

A. Experiment setup

The experiments on the proposed database of the elementary sound models were performed in task of audio pattern search in recordings, which include acoustical patterns of five different sound types: *applause, crying, laughing, gunshot and speech (10 Slovak keywords)*. Ten artificial audio tracks were created by random concatenation of 20 audio examples from each sound class and various types of environmental background noises respectively. For each audio track, the examples were chosen randomly from the sound database.

Accuracy of the search was evaluated on the level of acoustical observations against the human annotation of records with common precision (P), recall (R), and F_1-measure (F_1) metrics defined as follows:

$$P = \frac{n_{correct}}{n_{total}}; R = \frac{n_{correct}}{n_{target}}; F_1 = \frac{2.P.R}{P+R}; \tag{5}$$

where $n_{correct}$ stands for correct positive detections, n_{total} for total positive detections and n_{target} for target positive detections.

B. Audio event detection

For each searched sound example, the unit was created, as described in Section IV. Each of these units was used as query for searching. Units were able to find corresponding training examples with practically 100 % accuracy and confidence close to 1. Although using simple correlation will be much more efficient in this case, this experiment proved our prior assumption that specific audio pattern can be modeled as a sequence of the elementary sound models.

In the next experiment, only one representative example for each class was used as query for search. By changing the confidence threshold, the balance between precision and recall was set, to obtain highest possible F-measure score. The decoder was able to find also other audio segments similar to the queries. Overall average precision and recall reaches 62.5 % and 58.5 % respectively.

TABLE I
EXPERIMENTAL RESULTS ON VARIOUS ACOUSTIC PATTERNS

Pattern (Class)	*	**Number of examples in query**		
		1	***2***	***3***
Applause	P	73.40 %	81.55 %	89.33 %
	R	76.78 %	97.81 %	96.75 %
	F_1	75.60 %	88.95 %	92.89 %
Crying	P	55.69 %	85.98 %	81.52 %
	R	55.50 %	52.49 %	57.71 %
	F_1	55.60 %	65.18 %	67.58 %
Laughing	P	52.88 %	98.73 %	83.76 %
	R	41.21 %	52.07 %	80.08 %
	F_1	46.32 %	68.18 %	81.88 %
Gunshot	P	87.18 %	84.35 %	91.00 %
	R	80.68 %	79.25 %	88.62 %
	F_1	78.07 %	81.72 %	89.80 %
Keywords	P	43.17 %	75.41 %	80.78 %
	R	48.38 %	63.17 %	70.22 %
	F_1	45.63 %	68.75%	75.13 %

In the next search run, one additional representative example of each class was added into the search space, so that two examples were in the query. By setting the confidence threshold for each example of representative pair, the overall average precision and recall increased to 85.2 % and 69.0 % respectively. Lastly, three representative examples were selected as queries and put into search. The confidence threshold was set for each examples of three. The average precision and recall again increased to 85.3 % and 78.7 % respectively.

The advantage of our system is that if a user has only one example of demanded audio pattern (query-by-example), new examples can be added into search as selected audio segments found in previous run. Thus, the system has ability to "learn" from users feedback after the search. Table I shows the average results achieved using 1, 2, and 3 examples in query for each sound class.

VI. CONCLUSION

The system for universal sequential audio pattern search has been proposed. Statistical model specifications were introduced and the database of elementary sound models was created, using the unsupervised clustering method. Experimental results show that it is possible to adopt the concept of elementary sound units for general audio pattern modeling and recognition. However, a proper confidence threshold must be set experimentally for each unit to obtain the best possible result. Experiments also show that adding more examples of particular audio pattern can significantly improve searching results. If these examples are selected by a user from previous search run results, the system is also able to learn according to user feedback.

In our future work, we aim to include expectation–maximization algorithm in the clustering and adopt Viterbi alignment and discriminative training for better discrimination of elementary sound models. We also plan to compare the performance of the system on larger set of audio features extracted from audio data.

***Abstract*—We have checked if it is possible to increase effectiveness of standard tracking library (Kinect Software Development Kit) by fusion of body joints gathered from different sensors positioned around the user. The proposed calibration procedure enables integration of skeleton data from set of tracking devices into one skeleton. That procedure eliminates many segmentation and tracking errors. The test set for our methodology was 700 recordings of seven various Okinawa Shorin-ryu Karate techniques performed by black belt instructor. In case when side Kinects were rotated in $\frac{\pi}{2}$ and -$\frac{\pi}{2}$ around vertical axis relatively to central one number of all not classified Karate techniques dropped by 48% while excessive misclassification error remained in the same level.**

I. Introduction

THE COMMON approach in gesture recognition is partitioning the movement sequence into sections that are represented by key frames. Those frames are than classified by different recognition techniques. For example in [1] authors propose an automatic learning method for gesture recognition. First, they apply the Self-Organizing Map to divide the sample data into phases and construct a state machine. Next, they apply the Support Vector Machine to learn the transition conditions between nodes. Nowadays multimedia devices that enable real-time tracking of observed users (like Microsoft Kinect controller) can be bought relatively cheaply. Because of that more and more researches apply them to record human body data (called body joints) that are automatically segmented from depth camera video data by dedicated software (like one implemented in Kinect SDK - Software Development Kit) like in [2], where a comparison of human gesture recognition using data mining classification methods in video streaming is proposed. The recognized gesture patterns of the study are stand, sit down, and lie down. Classification methods chosen for comparison study are back propagation neural network, support vector machine, decision tree, and naive Bayes. It has been proved that data acquired by Kinect device can be use not only to classify typical common - live gestures like waving or sitting but also to recognize high-speed gestures of martial arts sportsmen. In [3] authors aim at automatically recognizing sequences of complex Karate movements and giving a measure of the quality of the movements performed. The proposed system is constituted by four different modules: skeleton representation, pose classification, temporal alignment, and scoring. The proposed system is tested on a set of different punch, kick and defense Karate moves executed starting from the simplest case, i.e. fixed static stances up to sequences in which the starting stances is different from the ending one. All previously described methods uses many body features as an input for classification algorithm. However, in [4] the authors showed, that the majority of the information regarding the human motion resides in a lower dimensional space than one that can be obtained from all available features. These considerations further support the argument that human motion can be classified using a representation which considers a relatively low number of dimensions [5].

Knowing all of this we have proposed our new semantic classifier [6] called Gesture Description Language (GDL). The idea of GDL approach is to code the gesture sequences as the series of static key frames that appears in defined order. Those sequences are coded with context-free grammar called GDL script. GDL script consists of set of rules that creates together knowledge database similar to one an expert system has. The preliminary description of GDL architecture has been presented elsewhere [6], [7]. The basic assumption of GDL is:

- It is capable of classifying human body movements in real time.
- It can classify not only simple, real life gestures but also complicated movements like Karate techniques.
- It does not require large training dataset. Gestures are defined by user in GDL script. User can utilize as many body features as he or she needs in each rule definition.
- Gestures are split into key frames that appears in some order under given time restriction.
- The input data for classifier is set of body joints that arrive from tracking software in real - time (approximately with

978-83-60810-53-8/$25.00

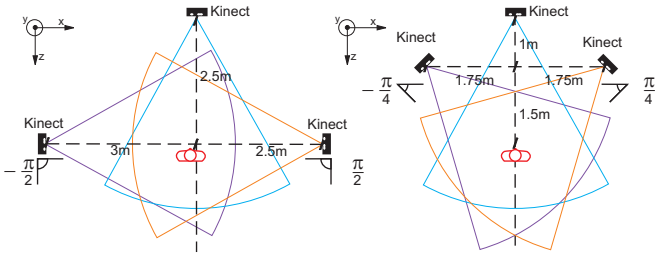

Fig. 1. Two tested multi-kinect environment configuration. Length of Kinect's view cone is 4 meters.

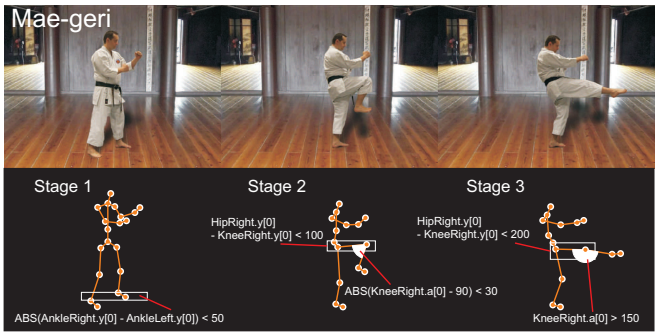

Fig. 2. Example Karate key-frames for GDL script. Movements are separated into stages, each stage is a key-frame used in semantic description. In this picture Mae-geri (front kick) begins with Moto-dachi (stance) but in our experimental recordings set it started from different, "neutral" position.

frequency 30 Hz). The set of tracked body joints is called Skelton (see Figure 2, bottom row).

- Our notation is invariant to user rotation around viewport of camera, because it can generates features regarding to angles measured between vectors defined by pairs of body joints (similarly to approach in [3]). Hovewer in opposite to [3] we can defines those angles dynamically while tailoring the GDL script description.

The idea of applying formal language to describe gestures is not new and was previously introduced for example in [8], [9]. However those papers describe only general framework of gesture description that might be potentially applicable for further recognition. The authors did not show how to use they annotations in pattern recognition tasks. They did not also validate they approach on any type of real-life data. Because of that those previous approaches were rather purely theoretical.

The novel contribution of this paper is test of GDL classifier performance on dataset that was acquired with one or three Kinect sensors that were positioned in two different configurations. We have checked if it is possible to increase effectiveness of standard tracking library (Kinect SDK) by fusion of body joints gathered from different sensors positioned around the user. The proposed calibration procedure enables integration of skeleton data from set of tracking devices into one skeleton. The test set was various Okinawa Shorin-ryu Karate techniques performed by black belt instructor. The whole solution runs in real-time and enables online and offline classification.

II. Material and Methods

In this section we will present experimental hardware setup, basis of GDL description and test dataset.

A. Multi - Kinect environment: setup and calibration

Figure 1 presents two tested multi-Kinect environment configuration. Each Kinect use its own tracking module (well know algorithm from Microsoft Kinect SDK which implementation can be used out of charges) that segments and tracks user skeleton in real time.

If front Kinect does not "see" particular body joint system checks if this joint is visible by another device. If yes our software takes coordinates measured by that second device. If more than two devices have detected same joint, coordinates are taken from camera that is closest to observed point. Each Kinect measure distance to observed point in its own right-handed Cartesian frame situated relatively to sensor orientation. Because of that same point V has different coordinates $\overline{v'} = [x', y', z', 1]$ and $\overline{v} = [x, y, z, 1]$ relatively to each pair of devices.

Our task now is to map all of those points to the same coordinate system. Let us assume that a Cartesian frame that represents orientation of each Kinect was translated and rotated around y (vertical) axis relatively to each other frame. That means there are four degrees of freedom (three for translation, one for rotation). Knowing that the linear transformation that maps coordinates of a point represented by vector $\overline{v'}$ in one coordinate system to coordinates $\overline{v}$ in another one has form of following matrix:

$$\overline{v'} \cdot \begin{bmatrix} cos(\beta) & 0 & -sin(\beta) & 0 \\ 0 & 1 & 0 & 0 \\ sin(\beta) & 0 & cos(\beta) & 0 \\ t_x & t_y & t_z & 1 \end{bmatrix} = \overline{v} \tag{1}$$

In order to find unknown matrix coefficients following linear system has to be solved:

$$\begin{bmatrix} x'_1 & z'_1 & 1 & 0 \\ z'_1 & -x'_1 & 0 & 1 \\ x'_2 & z'_2 & 1 & 0 \\ z'_2 & -x'_2 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} cos(\beta) \\ sin(\beta) \\ t_x \\ t_z \end{bmatrix} = \begin{bmatrix} x_1 \\ z_1 \\ x_2 \\ z_2 \end{bmatrix} \tag{2}$$

$$y' + t_y = y \tag{3}$$

Where $\overline{v_1} = [x_1, y_1, z_1, 1]$, $\overline{v_2} = [x_2, y_2, z_2, 1]$ are points which coordinates are known in both frames. The linear system (2) and equation (3) is product of multiplication of matrix (1) by $\overline{v_1}$ and by $\overline{v_2}$. They multiplication by $\overline{v_1}$ produces the first and second equation in matrix (2) and equation (3). The multiplication by $\overline{v_2}$ produces third and fourth equation in matrix (2).

B. Bases of GDL scripts

The preliminary description of GDL architecture has been presented elsewhere [6], [7]. Because of that we will present only one example GDL script and its graphical explanation.

As we previously mentioned movement is separated into key frames. Each key frame is repressed by a rule that has a conclusion. If rule is satisfied for actual set of body joints positions (GDL uses forward chaining rezoning schema) its conclusion is memorized. It is possible to check with GDL script if some conclusion was satisfied in given time period. With this mechanism it is possible to generate key frames chains, which together create gesture. First row of Figure 2 presents three key frames of GDL script from Appendix that describes the Mae-geri kick. Second row explains body joints dependencies that are present in GDL script description. The last rule in script (the one with *sequenceexists* function) checks if all stages of movement have appeared in defined order under 1 second time restriction.

C. Test dataset

The dataset for our research are recordings of black belt Karate instructor[1] that performs seven different techniques: four static stances (Moto-dachi, Zenkutsu-dachi, Shiko-dachi and Naihanchi-dachi), two blocks (Gedan-uke and Age-uke) and one kick (Mae-geri). The instructor has indicated essential aspects of each technique (starting and ending positions of limbs and movement trajectory). The data was recorded during two sessions: one in which cameras was positioned as it was presented in Figure 1 on left, the second one as in Figure 1 on right. Second recording was done several weeks after the first one. Each gesture was partitioned into key-frames (Figure 3) that was later verified and accepted by instructor. Also expert was present during final validation of method. The same GDL script was used for all of recordings. The frame capture frequency was 30 Hz.

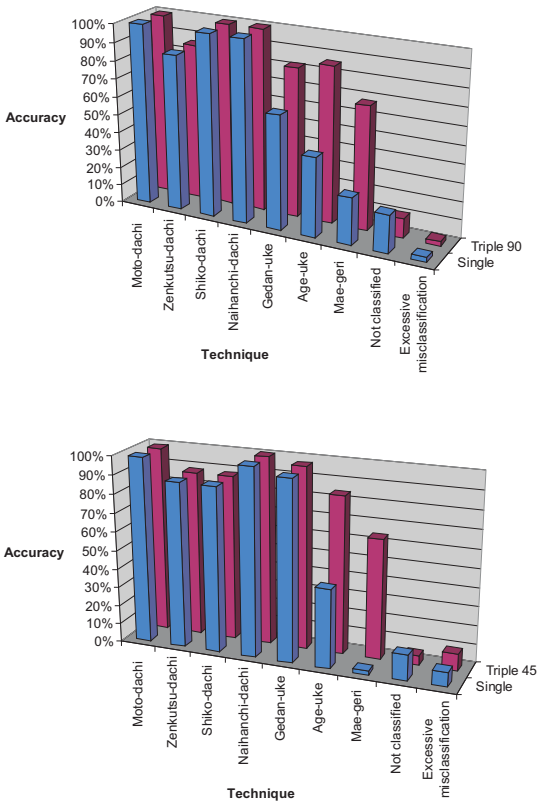

Fig. 3. Classification results from single and triple Kinect recordings. Triple 90 is left setup from Figure 1, Triple 45 is right setup from Figure 1.

III. Results

Tables 1-4 summarize the classification results of our experiment. The description in first column is the actual technique (or group of techniques) that is present in particular recording. Each technique (or group of techniques) was repeated 50 times. Symbol + means that particular recording consisted of more than one technique. Description in first row is classification results. Last but one row sums up percentage of correct classifications of particular technique. The last row sums up the percentage of correct classifications of techniques from first column. Summing up, we had 350 recordings of Karate techniques in each Kinect configuration (totally 700 recordings).

Because several Karate techniques can be present in same movement sequence we investigated if actual technique/techniques was/were classified. If yes that case was called correct classification. If technique was not classified and was not mistaken with similar one (like Moto-dachi which is similar to Zenkutsu-dachi) that case was called not classified. If technique was mistaken with similar one that case was called misclassified. Those three sums up to 100%. If technique was correctly classified but additional - actually not present - behavior was classified that case was called excessive misclassification. According to this terminology 90.4% of recordings from Table 4 was correctly classified, 5.2% was not classified and 4.4% was misclassified. Excessive misclassification was at the level of 9.0%. Figure 3 graphically presents results from Table 1-4.

IV. Discussion and conclusion

Our experiment has shown that integration of tracking data acquired by several Kinect devices with standard software increases the effectiveness of GDL classifier. This is due the fact that additional sensors that are situated at different angles than central one are capable of tracking body joints that in some situations might be covered by different body parts. This condition is especially visible in case of Mae-geri. Tracking of Karate kick is difficult task because of two factors: feet is moving with relatively high speed with large radius of path and in the last stage of Mae-geri feet is situated nearly at the same horizontal position as hip and knee. If the sportsman[2] is filmed only in front view knee and hip body joints are covered by feet and proper position of them have to be approximated by the software what, in practice,

generates serious positioning errors. Our results have showed that in both configurations of multi-Kinect environment the effectiveness of classification increases because of increasing of tracking accuracy. In case when side Kinects were rotated about $\frac{\pi}{2}$ and $-\frac{\pi}{2}$ around vertical axis relatively to central one number all not classified techniques dropped by 48% while excessive misclassification error remained on the same level. In case when Kinects were rotated about $\frac{\pi}{4}$ and $-\frac{\pi}{4}$ around vertical axis relatively to central one number all not classified techniques dropped by 61.9% while excessive misclassification error increased by 15.4%. It can be concluded that if we want to increase the correct classification factor in case when excessive misclassification error is not critical second setup of Kinects is more profitable. Otherwise, one should apply first setup, which, in our experiment did not change excessive misclassification rate.

Our future goal will be development of GDL script for recognition of complete set of most popular Karate techniques. The completed classifier will be than utilized in self-training multimedia application. We also plan to apply our classifier as a part of touchless interface in our medical data visualization module [10]. This will allow medical personnel to personally access patient data during surgical interventions while their hands are sterile. We also consider to expand GDL script terminal symbols and to test its capability in recognition of sign language gestures [11].

Abstract—Herein we describe the latent semantic algorithm method for identifying broadcast news story boundaries. The proposed system uses the pronounced forms of words to identify story boundaries based on popular noun unification. Commonly used clustering methods use latent semantic analysis (LSA) because of its excellent performance and because it is based on deep semantic rather than shallow principles. In this study, the LSA algorithm with and without unification was used to identify boundaries of Malay spoken broadcast news stories. The LSA algorithm with the noun unification approach resulted in less error and better performance than the LSA algorithm without noun unification.

Keywords: spoken document; broadcast news; story boundary identification; latent semantic analysis

I. Introduction

Because nouns bear more semantic meaning than other parts of speech and because they are the main characteristics used to identify documents stories [1], natural language processing applications often focus on nouns as essential components of the documents being processed. Names of persons, for example, are useful noun components in natural language processing, especially during automatic sentence clustering. In recent years, spoken document processing has become a popular and interesting topic within the field of natural language processing. In general, spoken document processing adapts natural language processing applications using speech input rather than text input.

Processing spoken documents is challenging because of the word errors generated by the automatic speech recognition (ASR) process [2], [3]. Determining the boundaries of broadcast news stories is another obstacle to processing spoken documents. The lack of overt punctuation and formatting contributes to this problem. In order to retrieve information, the beginning and the end of the segments or paragraphs within a document must be determined [3]-[6]. The process of determining the boundaries of the segments in the text is not an easy process [3]-[7].

Word errors generated by the ASR process can occur when recordings are made in a noisy environment or when pronunciation is unclear. The latter is especially true for vowel letters. An example from a Malay broadcast news story is as follows: The name of a professional badminton player was written four different ways in four sentences when converted from spoken news to written news by the ASR system (lee chong wei, choong wei, chong wee, and chan wee). The conversion problem was related to the vowel sound, in that the [u:] sound can be written as “oo, o, ou, ew, ue, u, and ui” and the [i:] sound can be written as “ee, ea, ei, and ie.” Silent sounds (pronounced n+ unpronounced g) also pose problems for ASR [8], [9].

Identification of story boundaries with the added problem of pronunciation errors is a complicated task. It requires human knowledge of the rules of correct pronunciation of lexical items. To address these problems, we propose a new method to improve story boundary identification in spoken documents using the popular noun unification approach.

II. Related Work

The absence of punctuation and capitalization in spoken documents makes it challenging to automatically identify story boundaries in multimedia documents. Previous attempts have concentrated on three types of cues: visual cues, such as the presence of an anchor’s face [7] or motion changes [7]; audio cues, such as significant pauses or reset of pitch; and lexical cues, such as word similarity measures within speech recognition transcripts or closed captions of video [10], [11]. Cues from completely different modalities (audio, video, and text) are often consolidated to achieve better story boundary identification [7], [12].

Hearst et al. (1997) proposed the TextTiling approach to story boundary identification [10]. It is based on the straightforward observation that different topics usually employ different sets of words and that shifts in vocabulary usage are indicative of topic changes [10]. As a result, pairwise

978-83-60810-53-8/$25.00

sentence similarities are measured across the text and a local similarity minimum implies a story boundary. Stokes et al. (2004) evaluated word cohesion using a lexical chaining approach; in this method, related words in a text are linked into chains, and a high concentration of chain starting and ending points is an indication of a story boundary [11]. These two approaches were recently used to segment speech recognition transcripts of spoken documents such as broadcast news [12], [13] and meetings [14]. Rosenberg et al. (2006) presented results from a broadcast news story boundary identification system developed for the SRI NIGHTINGALE system, which was applied to English, Arabic, and Mandarin news show to provide input for subsequent question-answering processes [12]. Xie (2008) used word and subword multiple scales for story boundary identification and showed the robustness of subwords for reducing the impact of errors and improving identification of broadcast news story boundaries [13] . Wu (2009) used decision tree and maximum entropy methods to identify the positional story boundaries locally and then used a genetic algorithm to identify the final story boundaries [15].

III. Latent Semantic Analysis

The clustering of sentences can be used to find repeated information, and the clustering process is conducted by grouping similar sentences together. Previous studies have examined a number of different methods that can be used to identify similar sentences. Some of these methods use shallow techniques to detect the similarities in sentences (e.g., word or n-gram overlap), whereas other methods use a deep approach to examining the syntactic or semantic similarities. The latent semantic analysis (LSA) technique can be used to estimate both the similarity of word matching and semantic structures. Accordingly, the problem of synonymy is avoided [16], [17].

Spoken documents are typically scanned and split into sentences throughout the preparation process, and then term-by-sentence matrices (TSMs) are ultimately created. One of the payoffs of using LSA is that it reduces dimensionality and thus results in quicker clustering. When the matrix is prepared, it is subjected to singular value decomposition (SVD) (Figure 1) [16]. The SVD formula can be stated as follows:

$$A = L_{EV} * S * R^{T}_{EV}$$

Any rectangular matrix A (i.e., a TSM matrix) with order t×s is decomposed into three matrices (L_{EV}, S, R^{T}_{EV}). The matrix L_{EV} contains the left eigenvectors of A and describes the relationship between terms (rows) and sentences (columns), or it refer to a term-to-concept similarity matrix resulting from the equation $L_{EV} = A^{T}A$. The matrix S is an m × m diagonal matrix with the entries sorted in decreasing order. The entries of the S matrix are the singular values (eigenvalue), and the S matrix describes the relative strengths of each concept. The R^{T}_{EV} matrix, which is defined by the equation $R^{T}_{EV} = A\,A^{T}$, contains the left eigenvectors of A, and this matrix refers to a sentence-to-concept similarity matrix [16].

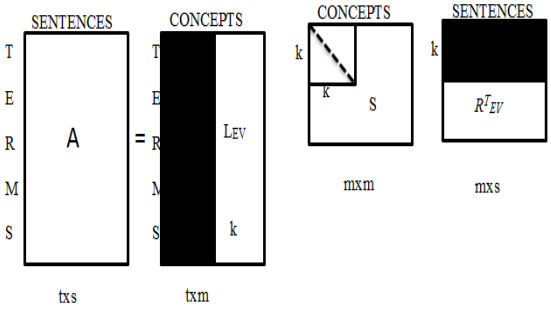

Fig. 1. Singular value decomposition (SVD)

The functionality of LSA will be explained using an example from the term similarity calculation. Consider Table I, which consists of four sentences from technical reports.

Table I. Example includes four sentences

The rank (r) of a matrix is the smaller of the number of linear independent rows and columns. SVD is used to reduce the rank and thereby the file size of the text. A reduced-rank SVD is performed on the matrix, in which the k largest singular values are retained, and the remainder is set to 0. The resulting representation is the best k-dimensional approximation of the original matrix in the least-squares sense [16]. Each sentence and term is now represented as a k-dimensional vector in the space derived by the SVD. In most applications the dimensionality k is much smaller than the number of terms in the TSM. In the above example, SVD ranks the concepts by importance for the text. By reducing the rank to 2, only the first two concepts are kept. Thus, the ranking matrices for the example are:

L'_{EV} =

0.3012 -0.2918
0.3966 -0.1282
0.3966 -0.1282
0.2443 -0.3932
0.3615 0.6315
0.3428 0.2522

S' =

4.2055 0.0000
0.0000 2.4155

R'^{T}_{EV} =

0.4652 -0.6738
0.6406 0.6401
0.5622 -0.2760
0.2391 0.2450

Basically, to compute the similarity between the sentences the ranking matrix of R'^{T}_{EV} is used as input for the cosine distance equation. The cosine distance is a very popular way to measure the similarity and to compute the distance between any two sentences. Given two vectors of attributes, A and B, the cosine similarity, θ, is represented using a dot product as:

$$\text{Similarity} = \cos(\theta) = \frac{A.B}{\|A\|\|B\|} \dots (1)$$

To calculate cosine similarities for the example, the R'^{T}_{EV} matrix was used to calculate cosine similarities for each sentence as follows:

sim(Si, Sj) = (Si• Sj) / (|Si| |Sj|)

In our example, the similarity for S1 is calculated as:

sim(S1, S2) = (S1• S2) / (|S1| |S2|)
sim(S1, S3) = (S1• S3) / (|S1| |S3|)
sim(S1, S4) = (S1• S4) / (|S1| |S4|)

$$sim(S1,S2) = \frac{\left((0.4652 * 0.6406) + (-0.6738 * 0.6401)\right)}{\sqrt{\left((0.4652)^2 + (-0.6738)^2\right)} * \sqrt{\left((0.6406)^2 + (0.6401)^2\right)}} = -0.1797$$

$$sim(S1,S3) = \frac{\left((0.4652 * 0.5622) + (-0.6738 * -0.2760)\right)}{\sqrt{\left((0.4652)^2 + (-0.6738)^2\right)} * \sqrt{\left((0.5622)^2 + (-0.2760)^2\right)}} = 0.8727$$

$$sim(S1,S4) = \frac{\left((0.4652 * 0.2391) + (-0.6738 * 0.2450)\right)}{\sqrt{\left((0.4652)^2 + (-0.6738)^2\right)} * \sqrt{\left((0.2391)^2 + (0.2450)^2\right)}} = -0.1921$$

S3 returns the highest value; pair S1 with S3. The same method then is used to compute the similarity for S2, S3, and S3, S4. Consequently, similar sentences (cosine distance > threshold) are placed together to create a new sentence cluster. Then, a new matrix is created from this cluster and from the rest of the sentences. After applying SVD, all sentences are compared in a pairwise manner. This process is repeated until the distance of the similarity between the document sentences is larger than the previously indicated threshold.

IV. Proposed System

Previously developed systems for identifying news story boundaries depend on the dictation form of words. In contrast, the proposed framework uses the pronounced form. Table III shows some examples of the differences between the dictation and pronounced forms for some popular nouns.

TABLE III. EXAMPLES OF THE DIFFERENCES BETWEEN THE DICTATION AND PRONOUNCED FORMS OF SOME POPULAR NOUNS

Dictation form	Pronounced form with syllables
Abdul Rahman Abdulrahman Abdurrahman Abdulrrahman	ab/dur/rah/ma/n abdurrahman
Yassin,Yasin Yassen, Yasen Yasain, Yassain	Yas/si/n Yassin
Mohammed Mohamed	Moham/ma/d

Mohammad Mohamad Mohamat	Mohammad
Noor, Nour Nur, Nor	No/or Noor

The pronounced forms are more difficult in writing than in reading, as can be seen in the following examples:

1. Most of the sun letters or solar letters (t, v, d, r, z, s, l, and n) can be written with or without a duplicate letter, such as "s" in Yasain or "ss" in Yassain (both are correct). Duplicate consonants in popular nouns are considered to be a common diacritic, with the first being a consonant and the second a vowel [18], [19].

2. Dummy letters have no relation to neighboring letters and no correspondence to pronunciation; in other words, they are empty letters that have no sound (e.g., /h/ in Sarah, Fatimah, John, and Johnny) [8], [9].

3. Auxiliary letters with another letter constitute a diphthong (i.e., two letters combined to represent a single phoneme). These may be further categorized as a standard single-letter representation that uses another letter, as with "oo, ou, u, o in noor, nour, nur, and nor." These are irregular in dictation form. Table IV shows some examples of diphthongs and other ambiguous sounds [8], [9].

TABLE IV. THE DIFFICULTIES IN WRITING POPULAR NOUNS

Combination sound	Example
ai, ay, ei, y	Maitham, Maytham, Meitham, Mytham
oo, ou, o, u	Noor, Nour, Nor, Nur Fong, Foong Choy, Chooy
dh,z	Nadhem, Nazem
s, z	Asman, Azman
ee, ei	Swee, Swei
(ss,s), (dd, d), (mm, m), (rr, r), (tt, t), (vv,v), (zz,z), (ll, l), (nn, n)	Yassain, Yasain Aladdin, Aladin Mohammed, Mohamed Abdurrahman, Abdulrahman Abdultawab, Abduttwab Razzaq, Razaq, Razzak, Razak Abudllah, Abdulah Alnoor, Annoor

Avoiding the problem of writing popular nouns in different ways and thus reducing their impact on story boundary identification involves writing them in generalized and unified ways. This process requires use of an edit distance algorithm (Figure 2). This algorithm controls weights for the characters added and deleted and for the sun letters and dummy letters that are written but not pronounced in popular nouns.

The new system proposed herein proceeds in six stages:

Stage 1: Decode the spoken broadcast news to text using the sphinx 3 ASR system.
Stage 2: Use the maximum a posteriori (MAP) and maximum likelihood linear regression (MLLR) algorithms to improve the ASR acoustic model.
Stage 3: Apply the part of speech tagger (POS) to tag each word with its corresponding part of speech.
Stage 4: Use the generalized noun algorithm to unify the popular nouns (see section V).
Stage 5: Apply preparation processing (see section VI).
Stage 6: Identify the story boundaries using the LSA algorithm (see section III).

V. GENERALIZED NOUN ALGORITHM

The noun unification approach depends on phonetics (i.e., on the pronunciation of popular nouns rather than on the written form). The pronounced form of a word is based on the principle that "only the pronounced sounds are written down, even if they have no corresponding letters in dictation form. Also, what is not pronounced is left unprinted, even if it has a corresponding letter in dictation form"[1][8], [9]. Accordingly, some letters are either inserted or deleted in the pronounced form. There are many reasons for un-standard popular nouns, including the following:

1. The vowel combination makes it more difficult to find one form for the same noun.
2. Sun letters may or may not be duplicated.

[1] Alabbas, pp 5

```
Procedure LevenshteinDistance(S, T)
{
        Str1 ←Char( S) // Split S to array of characters
        Str2 ←Char( T) // Split T to array of characters
        m ←ArrayLen( Str1) // m=length of Str1 array
        n←ArrayLen( Str2) // n=length of Str2 array
        D[m,n] ← 0 // set initial values to Distance matrix D

         For (i←1 to m) // iterates until all char are validated

                D[i,0] ← i

         For (j←1 to n) // iterates until all words are validated

                D[0,j] ← j

        For (i←1 to m)
                For (i←1 to m)
                {
                 if Str1[i] = Str1[j] then
                        D[i, j] := D[i-1, j-1] // no operation required
                 else
                        {
                        if ( Str1[i] and Str1[j] == vowel) then weight=0.3; // substitution vowel letter
                        else // sound that have some relation like (“z/s”, “d/t”)
                         if ( relation(Str1[i], Str1[j] )==true) then weight=0.5;
                        else
                         weight=1;
                         D[i, j] := minimum
                         (
                 D[i-1, j] + 1, // a deletion
                 D[i, j-1] + 1, // an insertion
                 D[i-1, j-1] +weight // a substitution
                 )
                        }
                 }

}
```

Fig. 2. Edit distance algorithm

3. No two phones are exactly identical; within the same language, people pronounce things differently, and between different languages, no two sounds are ever exactly identical.
4. The distinction between vowels and consonants is not always clear cut, and there is a fuzzy boundary region between them in both human pronunciation and automatic recognition.

5. Some sounds are silent (dummy sounds) and are written in dictation form but are not pronounced [3].
6. Some foreign letters can be pronounced and written down using different letters. For instance, consider “Nazem” and “Nadhem:” The letters “z” and “dh” are used to represent the same name.

Converting popular nouns in a document to the general form using the generalized noun algorithm proceeds as follows:

```
Procedure Generalized Noun (Doc)
{
W ← Split (Doc , “ ”) // splits the text on every space
For (i←0 to N) // iterates until all words are validated
{ // check is W[i] noun or not using Part-of-Speech (POS) Tagger
If POS(W[i])= Noun then
        {
                //Find vowel combination and generalized it
            Loop
                Case (Ch← W[i]) :
                        // Group A include (vowel+h letter)
                Group A: replace Ch with μ;
                 // Group B include [ei] sound
                 Group B: replace Ch with β;
                 // Group C include (sun letteers)
                 Group C: replace Ch with λ;
                 // Group D include [ai] sound
                 Group D: replace Ch with Ω;

                                ...
        }  // End case }  // End Loop }  // End if
        } }
```

Poplar Nouns (PN)	Unified (PN)	Levenshtein Distance (LD)		Remark
		Before Unified	After UniFied

TABLE V. MEASUREMENT OF THE SIMILARITY BETWEEN TWO STRINGS USING LEVENSHTEIN DISTANCE

Table V illustrates the measurement of the similarity between two strings using Levenshtein distance for several examples. The number of transformations (deletions, insertions, or substitutions) required to transform one string into another were measured before and after the generalized noun algorithm was applied.

VI. PREPROCESSING STAGE

The preprocessing module performs tagging, removal of stopping words, stemming, feature selection, and TSM creation. During the tagging process, each word is tagged with its corresponding POS. For example, the sentence "ali pergi ke sekolah" (Ali goes to school) is tagged as "ali/noun pergi/verb ke/preposition sekolah/noun." In this study we used the Qtag POS tagger. The next step is to remove stopping words, which removes all of the frequent and common words that do not carry important information. This step reduces the size of the spoken document. Such words include auxiliary verbs and prepositions (e.g., adalah/(is, are), akan/will, was/ialah, ke/to, pada/at). The removal of such words helps to improve the quality of the story boundary identification results by retaining only the words that contain significant information. This step can be performed using the stopping word list, which includes 1312 common Malay stopping words.

Stemming refers to reducing morphological variants of words to their stem, base, or root form, and it is used to improve the effectiveness of information retrieval (IR). The effect of stemming depends on the nature of the language vocabulary, and in some cases stemming may degrade retrieval performance [20]. Thus, a stemmer can improve the effectiveness of IR for some text corpora more than others [16], [17], [20]. In the system proposed here, an affixation stemmer for the Malay dataset was used. The words permakanan (diet) and makanannya (his/her food), for example, contain the base word "makan," and the common stem of the various forms of the word was weighted using the tf-idf (term frequency-inverse document frequency) weighting approach in the term-by-document matrix (TDM). The use of the stemming algorithm can increase retrieval performance by reducing morphological

variants of words and the time required for processing; at the same time, use of the roots of the words increases the similarity probability between the words in the clustering module.

After stemming is completed, feature selection is performed. One of the major challenges facing artificial intelligence applications is how to reduce the number of high dimensional data spaces. Dimensionality reduction is the process of reducing the number of random variables (words here) under consideration (for instance, retaining the significant words or the high frequency words) [16]. The efficiency of the relevant algorithms can be improved by decreasing the dimensionality of the size of the effective vocabulary and data spaces. In such cases, feature selection can be applied. Feature selection chooses an effective subset from a huge set of features. In this study, we used the open source library "weka" to select the useful features, and only the selected keywords (words) were used in the subsequent building of the TSM.

In the TSM, each row defines the terms contained in a sentence. Each cell entry contains the frequencies of occurrence of a term in a sentence. This TSM can be used to calculate the similarity between terms using story boundary identification methods. To illustrate, suppose we have the following set of five sentences:

S1 = w1 w2 w3 w4 w5 w6
S2 = w7 w2 w3 w4 w5 w6
S3 = w6 w8 w4 w5
S4 = w1 w9 w10 w4 w6
S5 = w10 w2 w2 w4 w11 w5

A data set can be represented by the TSM using the frequency weight matrix shown in Table VI.

TABLE VI. TERM-BY-SENTENCE MATRIX (TSM)

	w1	w2	w3	w4	w5	w6	w7	w8	w9	w10	w11
S1	1	1	1	1	1	1	0	0	0	0	0
S2	0	1	1	1	1	1	1	0	0	0	0
S3	0	0	0	1	1	1	0	1	0	0	0
S4	1	0	0	1	0	1	0	0	1	1	0
S5	0	2	0	1	1	0	0	0	0	1	1

VII. EXPERIMENTS AND RESULTS

To demonstrate the performance of the proposed algorithms, a transcript produced manually from spoken broadcast news was used [21] to identify the story boundaries. The databases used for this are called the mass-news corpus, and they consist of Malay broadcast news documents that were collected at Universiti Sains Malaysia as the output of the Malay ASR system [21]. The news stories used for this evaluation were collected in March 2011. The data set includes ~25 hours of transcribed speech. The ASR system was trained using a ~15 hour portion of the database, and the test sets included the remaining ~10 hours. The broadcast news stories included multiple speakers and recording in noisy environments. None of the test sets overlapped with the ASR training set. Table VII shows the Malay data source details that were used in this study.

TABLE VII. DATA SOURCE DETAILS

Size of language model	150 MB
Size of dictionary	1.74 MB
Number of news shows	18
Number of news stories in all news shows	379
Number of sentences in news database	4698
Number of words in the news	81116
Number of popular nouns in the news	39698 (49%)
Word error rate before adaptation	34.5%
Word error rate after adaptation	33.9%
Story length	Around 1 to 167
The rate of the audio signal extract	10 ms

Errors resulting from the process of story boundary identification were measured using the F-score, precision, and accuracy. To evaluate[2] the effectiveness of the story boundary identification module, we tested it using Malay spoken documents that contained ~380 stories in different domains (e.g., politics, economics, sports, local news, and international news). We evaluated two corpora. The first corpus was a gold standard file (GSF) corpus that represents the manual transcription of the Malay broadcast news. The second corpus was the ASR result (Hypothesis Result (HR)) for the Malay broadcast news. The GSF corpus was segmented into stories by human experts. In this experiment different k-dimensional clustering spaces were built where k ϵ [32, 50, 80, 100, 125, 150, 200]. This paper reports only the best results.

Table VIII shows the results of the story boundary identification for LSA with and without the noun unification process.

[2]The tools that used in this study
Java, Python, Apache Lucene package (java package) was used for compute F-measure and the other Measurement, Sphinx 3 as ASR system, WEKA package for feature selection, SPSS for Wilcoxon signed-ranks test, Qtag tool for part of speech tagger, an affixation stemmer tool, Jama package for Matrix computations.

TABLE VIII. STORY BOUNDARY IDENTIFICATION MODULE PERFORMANCE

	LSA			
	Without		With	
	GSF	HR	GSF	HR
Precision	0.759	0.680	0.895	0.814
Recall	0.617	0.559	0.914	0.769
F-Measure	0.681	0.613	0.904	0.791

The results of the story boundary identification algorithms were evaluated statistically using the Wilcoxon signed-ranks test. By applying the same statistical significance test, the results of the proposed algorithm were compared statistically with the results of the baseline algorithm (i.e., LSA without the noun unification process). The proposed system using the popular noun unification algorithm achieved an F-measure of 0.791, whereas the value was 0.613 for the baseline system when tested on the same set of Malay broadcast news stories.

VIII. CONCLUSIONS

Identifying broadcast news story boundaries plays an important role in many natural language processing applications, such as topic identification and story classification. The proposed system uses the pronounced forms to identify story boundaries based on popular noun unification. LSA is commonly used in clustering methods because of its excellent performance and because it is based on deep semantic rather than shallow principles. In this study, the LSA algorithm with popular noun unification achieved a better result than the general LSA algorithm in identifying news story boundaries for the same test set. The LSA algorithm with popular noun unification achieved an overall F-measure of 0.791 versus 0.613 for the general LSA algorithm when identifying news story boundaries for the same test set.

We predict that further work by adding ASR confidence measure to distinguish between correct and incorrect words in ASR result before any processing, e.g. story boundaries identification. In future work, we will apply this algorithm for English language.

***Abstract*—We consider the watermarking method based on a holographic transform domain image proposed by A. Bruckstein. Our testing showed that it is resistant not against all possible attacks declared by his inventor, under the condition of a very high image quality just after WM embedding. Only a small part among 120 bits embedding into the image has an acceptable error probability after extraction if some attacks hold. Therefore we propose to modify this system for fingerprinting where only fixed bits are embedded into the most reliable places of the frequency mask. Systematic linear binary codes with large minimal code distance are used in order to correct errors. Simulation showed that such system provides sufficiently reliable tracing "traitors" under the most types of attacks subjected to remove WM, while keeping a good quality of the image just after embedding.**

***Index Terms*—Watermarking, image processing, error correction codes, tracing traitors**

I. Introduction

DIGITAL watermarks effectively can be used for copyright protection of still images [1], [2], [3], [4]. However, intruders, the so-called "pirates", try to copy and spread these products illegally, and they attempt to remove the WM by performing different (sometimes very sophisticated) transforms over the watermarked products which, not impairing the product itself, should make impossible to extract them. In [3] there has been proposed an approach for watermarking insertion that is invariant to several transforms as rotation, scale and translation. But the use of the log-polar transforms results (confirmed at our experiments) to significant corruption of the cover images after WM embedding. Only a very restricted number of possible transforms are considered in [4]. A good robustness to practically all possible transforms has been obtained in [5] but unfortunately it works only for o-bit watermark. An extension of this method to multiple-bit watermark was presented in [6] but without the use of error correcting codes. Thus it can be concluded that although there were many proposals in the design of WM systems resistant to different attacks, this problem is so far not solved completely.

In [7], a WM system based on a "holographic" transform domain has been proposed, where the embedding procedure is performed in the area of the Fourier amplitude and then the message can be extracted even from cropped WM-ed image. This is why this method was called *holographic*, it is a metaphor of the physical hologram where the whole can be recovered from its small part.

The authors of [7] declare that this method allows to embed up to 120 message bits and to extract them correctly using an informed decoder even after several attacks as cropping, JPEG compression, changing of contrast and some other combinations of them. The embedding procedure is performed then as follows:

$$I^W = \mathcal{F}^{-1}\left(W_b \cdot \mathcal{F}\left(I\right)\right) \tag{1}$$

where $I = \left(I(x,y)\right)_{(x,y)}$ is a grey-level (8 bit) image in an (x,y)-pixel area, $W_b = \left(W_b(u,v)\right)_{(u,v)}$ is an embedding mask,

$$W_b(u,v) = 1 + (-1)^b \varepsilon \text{ whenever } (u,v) \in S^b_{ij}, \tag{2}$$

with $\left(S^0_{ij}\right)_{ij}$, $\left(S^1_{ij}\right)_{ij}$ being some collections of selected areas, corresponding to the chosen embedding mask in the frequency area for the (i,j)-th message bit 0 or 1, respectively, ε is a depth of embedding, $\mathcal{F}$, $\mathcal{F}^{-1}$ are, respectively, the direct and the inverse Fourier transforms, and $I^W = \left(I^W(x,y)\right)_{(x,y)}$ is the resulting watermarked image. An embedding mask can be chosen in different manners. In the paper [7] it is used the so called "equally radius" geometry shown on Fig. 1. For such mask it is possible to embed 120 message bits in the whole image. The extraction of each of the (i,j)-bits is performed by the following rule optimal in additive Gaussian noise attack channel:

$$b_{ij} = \frac{1}{2}\left[1 - \text{Sign}\left(B^1_{ij} - B^0_{ij}\right)\right] \tag{3}$$

where

$$B^b_{ij} = \sum_{(i,j)\in S^b_{ij}} \Re\left(\overline{q_{ij}}\, s_{ij}\right) \quad , \quad b \in \{0,1\},$$

$\left(s_{ij}\right)_{(i,j)} = \mathcal{F}(I)$ is the array of complex values obtained as the Fourier transform of the original image I, $\left(q_{ij}\right)_{(i,j)} = \mathcal{F}(I^W)$ is the array of complex values obtained as the Fourier transform of the watermarked image I^W, $\Re$ is the "real part" operator and the overline denotes complex conjugation.

Since the knowledge of original image $\left(I(x,y)\right)_{(x,y)}$ is necessary for the extraction procedure, this method is called

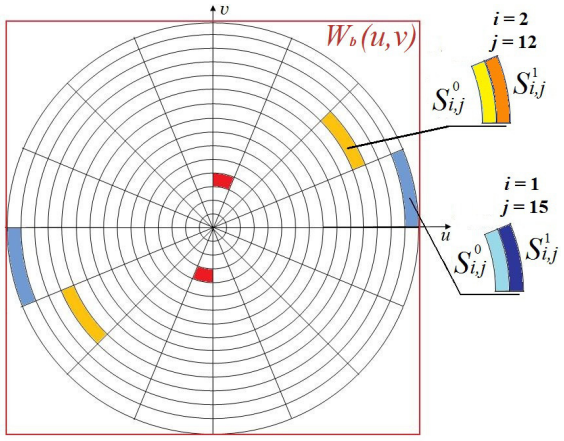

Fig. 1. Equally radius geometry embedding mask.

an *informed decoder*. Moreover, if the WM-ed image has suffered some attack, say cropping of windows or the removal of some rows and columns, it is necessary to know the changed version of the original image after such attacks. This means that the decoder should know the exact place of the window or the locations of rows and columns removed after the attack. Such problem is called the *registration problem*. Sometimes it can be solved very easily (because both attacked and original image are available for the decoder) but sometimes it requires a solution of an additional problem, known as the *registration one*. But we leave the registration problem outside our investigation.

II. Abounding on testing a commonly used method

Let us present the tests realized in accordance with the method proposed at [7].

The quality of the watermarked image is determined by the depth of embedding ε. In the Fig. 2, an original image and its watermarked images with $\varepsilon = 0.05$ and $\varepsilon = 0.2$ are presented.

We can see that the quality of the WM-ed image is still acceptable for $\varepsilon = 0.05$ but indeed unacceptable if $\varepsilon > 0.2$. (This claim has been confirmed after a testing of many typical images on computer screens.)

The results of message extraction for different images are presented at Table I, once a given image has been attacked through several transforms, while keeping good image quality after the embedding and attacks.

This testing shows that although a cropping of small "windows" gives excellent results as well as JPEG compression with quality factor $Q \geq 60\%$, further decreasing of the window's sizes and a quality of the JPEG compression results in a degradation of the WM system as well as an addition of a Gaussian noise with variance larger 25. Thus the claim [7] that such WM system satisfies the required conditions for being resistant against any attacks is only partly correct. (It is true only for some specific images). But in order to maintain a good idea proposal in [7] regarding the holographic transform domain and portioning of decision bit area into two subareas

(a)

(b)

(c)

Fig. 2. Image before and after watermarking. (a) Original image, (b) WM-ed image with $\varepsilon = 0.05$, (c) WM-ed image with $\varepsilon = 0.2$.

in line with the decoding rule (3) we suggest to modify WM system in some manner to adopt it in a modified form.

TABLE I
THE RESULTS OF ERROR PROBABILITY IN EXTRACTION PROCEDURE AFTER DIFFERENT ATTACKS.

Name of attack	PC
Cropping of window 200×200 pixels	4
Cropping of window 170×170 pixels	8
Saving in JPEG format with $Q = 60\%$	3
Saving in JPEG format with $Q = 50\%$	6
Saving in JPEG format with $Q = 20\%$	25
Saving in JPEG format with $Q = 10\%$	30
Addition of Gaussian noise with a variance $d = 25$	15

PC: Percent of corrupted bits on average of several images.

A description of the extraction procedure results, by simulation after different attacks, within this new approach and and the original method are presented in Section III and IV, respectively.

III. DESCRIPTION OF THE MODIFIED WM SYSTEM

Firstly, the results of our simulations, which show the probabilities of errors after extraction of bits on different places into the frequency mask and after different attacks, are presented in the Tables II-V.

By observing these tables, we can conclude that there are some bit locations where the probabilities of errors are unacceptable even if we would use some error correction codes, while there are some other bit locations where the probabilities of errors approach to zero. Then the following natural idea arises – let us embed message bits only in such "cells" of the mask where there appears a moderate number of errors.

We could try of course to execute a diversity concept. This means that the same bit is embedded in several cells. But experiments show that a soft decoding occurs useless in this case because the values q_{ij} in eq. (3) are falsely increased for some cells after the JPEG transforms and make worse the result of decision in a comparison with hard decision. One can use the hard (majority) decoding rule but it requires a large multiplicity of diversity and to find the gain to remove bits from "bad" cells which are providing the negligible effect. The amount of bits which have the acceptable probability of error is about 64 and they are displayed at columns 2–9 at Tables III–V. This value is not sufficient in order to embed reasonable information but it may be enough for a scenario of fingerprinting.

Let us consider a situation in which the owner of some image sales it legally to a set of M users without a permission to distribute this product further outside of this buyer set. But some members of the set did illegal redistribution of the product. Fortunately, the owner has access to the illegally redistributed copies. The owner of the product wants to recognize who was the illegal distributor (the "pirate" in other words). It is worth to note that such digital fingerprinting (FP) has very important role in enabling an early-release HD movie window for VOD [8].

In order to solve this problem, the owner can proceed in the following manner: he embeds an unique bit string in every copy sold to legal users, he extracts the embedded WM (which is called usually the *fingerprint*) from illegally redistributed copy and trace the pirate. We propose to select unique strings of the length equal to the number of practically error-moderate bits (in our case it is 64). Let us denote by R the area consisting of the columns labelled 2-9 at each of the Tables II-V (emphasized at their displays). The other bits, displayed at columns 10-15 are free of embedding.

Since there may occur errors even among the specially selected 64 bits, it is reasonable to use error-correction codes.

First of all we consider the use of BCH codes of length 63 with a hard decoding on Hamming distance [9], namely the codes $(63, 7)$, $(63, 10)$ and $(63, 16)$. But since the probabilities of bit errors, even among the columns 2-9, depend (as it can be seen from Tables II-V) on the positions of these bits, it is reasonable to use a more effective maximum likelihood decoding algorithm, namely, let:

$$\tilde{j} = \arg\max_{j} \left[\prod_{i \in I(e_{j1})} P_i \cdot \prod_{i \in I(e_{j0})} (1 - P_i) \right] \qquad (4)$$

where $\tilde{j}$ is the number of codeword after decoding, P_i is the error probability at the i-th bit, $I(e_{j1})$ is the set of components with value one at the vector e_j (the *support* of e_j), $I(e_{j0})$ is the set of components with value zero at the vector e_j (the *null set* of e_j), and $e_j = u \oplus v_j$ where u is the received binary vector after demodulation by (3), and v_j is the j-th code word at the BCH code.

In the next Section we consider the results of simulation of the proposed approach after attacks by different transforms.

IV. RESULTS OF FINGERPRINTING SYSTEM SIMULATION AFTER DIFFERENT TRANSFORMS

We use the embedding according to the relations (1), (2) into the area R, the bit extraction by the rule (3) and the decoding of the code words of the BCH codes $(63, 7)$, $(63, 10)$ and $(63, 16)$, by the minimal Hemming distance and maximum likelihood algorithm (4). As image transforms we apply the following ones:

- cropping of windows;
- removal of rows and columns;
- JPEG compression with different quality;
- addition of Gaussian noise.

We selected 1000 grey scaled images from the bank of images [10] and each of these images was tested 10 times with randomly chosen bit embedding. In reality we try BCH codes of the length 63 for more variants on the number of information bits, other than 3, but we show now only those cases in order to justify that there is no sense to take $k > 10$, because it results in poor probability of correct decoding even after the use of an optimal decoding algorithm.

In the Fig. 3 a fingerprinted image and its cover image after different transforms are presented.

3	5	4	3	9	9	11	11	14	13	22	22	28	33	25	30
4	0	3	1	4	3	10	6	13	13	16	13	22	16	29	29
5	1	2	2	1	5	11	14	10	15	14	26	21	22	28	39
6	1	4	3	7	13	8	20	14	16	24	23	23	23	28	25
7	1	0	4	7	8	11	20	20	22	22	20	24	26	35	33
8	1	0	5	3	4	10	9	7	13	21	18	23	29	23	28

In all cases we assume that the original image is known during the extraction procedure. Sometimes this condition can be provided very easily, whereas sometimes it requires to solve an additional problem for the original image registration, in this last case we refer to cropping (where it is necessary to know the window) or to row and column removal (where it is necessary to know which of them have been removed).

It is worth to note that the pirates can remove rows or columns in two different ways.

Consider the first way. A pirate selects some rows (or columns) and changes them to another ones, which can be obtained by interpolation of neighboring lines. In this case the image size and places of another rows are not changed. Hence it is the case when it is not necessary to solve a problem of original image registration.

Another case arises where the pirate deletes the lines and then he shifts the remaining lines to make invisible the removal place. In this case, the image size and places of several lines

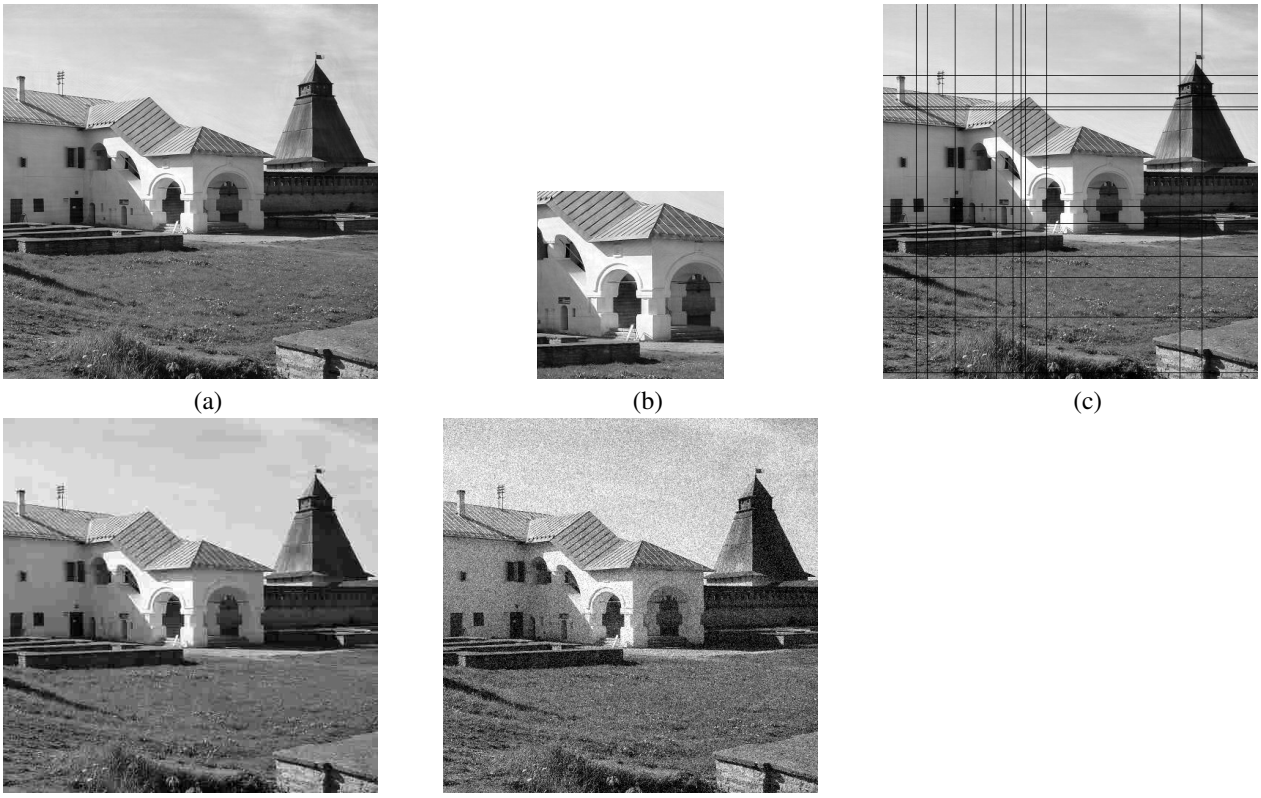

Fig. 3. Fingerprinted image (a) and the same image after different transforms: (b) cropping of window 200×200 pixels, (c) removal of rows and columns, (d) JPEG compression with factor $Q = 20$, (e) addition of Gaussian noise with $d = 25$.

are changed. Therefore for extraction procedure it is necessary to solve a registration problem.

The results of simulation (in terms of the incorrect decoding probabilities) depending on the type of code and different attack transforms are presented in Table VI.

Similar results for optimal decoding algorithm are shown in Table VII.

We note that for those attacks that can be easily recognized by a legal user (removal of rows and columns, cropping, addition of noise) the values of the symbol probabilities P_i, that are necessary for optimal decoding by the algorithm (4) can be taken from Tables IV–V, whereas it is hard to establish the quality factor Q used in the JPEG transform. The probabilities for the worst case ($Q = 20\%$) can be used because we proved that it results in the minimal probability of incorrect decoding on average.

From Tables VI–VII it can be seen that the maximum number of information bits k, that can still provide the acceptable probability of incorrect decoding after all attack transforms is 10 and the optimal decoding algorithm given by (4) is superior to the minimal Hamming distance algorithm.

V. Conclusion

Traitor tracing is a very important problem in the case of an early release of HD movie window for VOD. In the current paper we adopt a general idea to embed WM using the so called "holographic" concept [7] when the embedding procedure is performed in the Fourier domain. However we showed that such WM system is vulnerable to different image transforms which provide still a good image quality after them. Therefore we propose a modification of the WM system considered in [7] to a fingerprinting system, where it is sufficient to provide only a limited number of identification code words corresponding to different users that can be potential pirates. In a particular case we have selected 64 bits which survive after most of the transforms and we propose to execute a binary $(63, 10)$-BCH code to correct errors. We propose also to use a maximum likelihood decoding algorithm instead of the minimum Hamming distance algorithm since that is more effective

The simulation results showed that for many typical images the proposed fingerprinting scheme is resistant to such transforms as cropping, removal of rows and columns, JPEG compression and addition of Gaussian noise. Therefore we are rather sure that the proposed scheme can be recommended for practical applications to copyright protection within fingerprinting procedures.

But the problem of original image registration arises.

Sometimes it is easy to solve because the original images always are at the disposition of their owners. But sometimes it requires to know some parameters of transforms (as numbers

of the removed rows and columns and their places) executed by pirates. This is still an open problem in general. Another problem is to change the equality radius geometry embedding mask (see Fig. 1) to another one in order to try to use the area with columns 10-15 (or maybe areas structured by another manner) to embed more than 10 bits with good enough probability of correct decoding. We are going to investigate these problems in the near future.

***Abstract*—This paper presents a novel real-time hardware implementation of the ViBe (VIsual Background Extractor) background generation algorithm in reconfigurable FPGA device. This novel method combines the advantages of typical recursive and non-recursive approaches and achieves very good foreground object segmentation results. In this work the issue of porting ViBe to a FPGA hardware platform is discussed, two modification to the original approach are proposed and a detailed description of the implemented system is presented. This is the first, known to the authors, FPGA implementation of this algorithm.**

I. Introduction

DETECTION of moving objects (foreground objects) is one of the most important issues in video sequences processing and analysis. It is used in advanced, automated video surveillance systems and traffic monitoring systems, where the robust segmentation of peoples or vehicles is essential to perform reliable tracking or recognition. Intensive work on the mentioned systems can be observed in the image processing researcher community as well as in the industry.

Foreground object detection methods can be divided into three categories: simple successive frame differencing, the so-called background modelling approach followed by background subtraction and optical flow.

In this paper, a hardware implementation of a method belonging to the second of these categories is presented. An extensive review of different approaches to foreground object detection can be found in [3].

The concept of background subtraction involves object detection based on the difference between the current video frame and the background, where the background is understood as an empty scene, i.e. without objects of interest (people, cars). It is worth noting that foreground object detection is not just a simple moving object detection issue. The background may contain moving elements: flowing water, moving leaves and shrubs, which should not be detected. On the other hand, some objects (eg. a pedestrian) may remain still for a while and should be continuously detected. Another source of segmentation errors are objects that start to move (eg. a parked car). The left empty space is than usually misclassified as foreground (a so called "ghost"). That is why the background representation should be adaptive in order to compensate some normally occurring changes such as lighting or movement of certain objects (i.e. chair in an office), as well as handle difficult cases like ghosts. The process is referred to as background generation or modelling.

In the literature one can find many descriptions of FPGA implementations of background generation methods. An extensive discussion of this issue is presented in [6]. The most important and recent articles are:

- Mixture of Gaussian [4] – HD greyscale video stream processing (1920 × 1080 @ 20 fps),
- Horparsert method [9] — 1024 × 1024 @ 32.8 fps, video stream processing, the high level synthesis language Impulse-C was partially used,
- Codebook [8] — 768 × 576 @ 60 fps video stream processing,
- Clustering [6] – HD colour video stream processing.

An FPGA implementation of background generation algorithms can be used in hardware accelerators (e.g. frame-grabbers with an FPGA device, which perform some image pre-processing and analysis) or smart cameras, where all the image processing, analysis and recognition is performed in the camera and only the results are transmitted to the main processing unit of a surveillance system.

II. The ViBe Algorithm

The foreground object segmentation algorithm ViBe (VIsual Background Extractor) was proposed by O. Barnich and M. Van Droogrnbroeck and described in detail in [1], [2], [12]. It contains several innovative elements (the solution is patented) and allows to obtain very good results, which is confirmed by a high place in the object detection algorithms ranking [5].

The background model in ViBe consists of a set of observed pixel values. This is an important difference compared to the most common methods, where the background model is based on probability distribution function. The authors of ViBe justify this concept, pointing out the difficulties in selecting the appropriate probability distribution and the corresponding update mechanism.

Let $v(x)$ denotes the pixel value in a given colour space at the point x in the image, and v_i the i-th sample from the background model. Then the model for each pixel x is defined as a set of N samples:

$$M(x) = \{v_1, v_2..., v_N\} \tag{1}$$

978-83-60810-53-8/$25.00

In order to classify the pixel $v(x)$ a sphere $Sr(v(x))$ of radius R centred at the point $v(x)$ is defined. The analyzed pixel is considered as background, if at least $\#_{min}$ samples from the model $M(x)$ lie inside the sphere. The distance is defined as Euclidean, and the procedure requires, in the worst case, N distance calculations and N comparisons.

The authors proposed a method of initializing the background model using a single video frame. This results in fast initialization and re-initialization i.e. in case of a sudden lighting change or surveillance system reboot. In this approach, however, the temporal context (history of the pixel) is not available, therefore, the assumption has been made that the adjacent pixels should have similar values. The initialization procedure involves filling the buffer $M(x)$ with randomly selected samples from the pixel's spatial context (size 3×3).

The disadvantage of this approach is its susceptibility to artefacts in the form of "ghosts" — a collection of pixels classified as belonging to the foreground, but actually not related to any real object. The elimination of such interference provides the discussed below background model update mechanism.

The ViBe algorithm uses a conservative update approach — the background model is modified only in the case of classifying a pixel as part of the background. On one hand, it prevents the penetration of moving objects into the background model, but at the same time it can lead to irreparable segmentation errors (e.g. "empty" space left by a car which drove away is classified as an object).

Contrary to popular background generation algorithms that use a pixel buffer approach (average of the buffer, the median of the buffer) where the update process relays on replacing the oldest sample by a new value (FIFO scheme) in ViBe the temporal context is not considered. The sample, to be updated, is chosen at random. In conjunction with the conservative approach this results in an exponential lifespan of a given sample. To further extend the time interval, which is covered by the background model, the update is performed with a fixed probability (e.g. 1/16).

In order to counteract the negative effects of the assumed conservative approach, a mechanism of updating the adjacent background models was proposed. It can be described as follows. If the current pixel $v(x)$ is regarded as belonging to the background, two update procedures are executed: for the current and the neighbouring background models. First of all, in a random fashion, it is determined whether the update should be executed (the proposed by the authors likelihood equals 1/16). Then, in the first case the sample to be substituted is randomly selected (1 out of N). In the second, the neighbouring model (1 out of 8 assuming a 3×3 context) and the sample (1 out of N) are chosen. The selected samples are then replaced by the value $v(x)$.

It is worth noting that the ViBe method requires very few parameters. The authors of the paper [2] proposed the following values: $N = 20$ (number of samples in the model), $R = 20$ (the radius of the sphere, value for greyscale images), $\#_{min} = 2$ (the minimum number of samples, which must lie within the sphere) and the update probability (1/16) and they were used in the module.

III. Considerations About Implementing ViBe in Hardware

One of the main problems with implementing background generation algorithms in hardware is providing a quick access to the external memory resources, where the background model is stored [6]. In the case of the ViBe algorithm is necessary to ensure the following transfer rate:

$$T = N \times B \times PC \times 2 \tag{2}$$

where: N – model size (number of samples), B – number of bits per one sample (for greyscale images $B = 8$, for RGB $B = 24$, for CIE Lab $B = 23$), PC – pixel clock (for VGA resolution 640×480 PC is 25 MHz). The use of the multiplier two, results from the need to perform write and read operations. Substituting the appropriate values the following rates are obtained: $T \cong 690$ MB/s for greyscale and $T \cong 2070$ MB/s for RGB. In case of HD image processing (i.e. 1920×1080, pixel clock 148.5 MHz) the rates are respectively: $T \cong 4898$MB/s i $T \cong 12293$ MB/s.

Modern FPGA boards are usually equipped with an external DDR3 RAM module. In this study two platforms were analyzed: ML605 (Virtex 6 device) and VC707 (Virtex 7 device), both from Xilinx. The first of these is equipped with a memory with a maximum theoretical transfer rate of 6400 MB/s, and the other 12800 MB/s. Wherein, in the case of dynamic memory, it is impossible to obtain the maximum values, because of the necessity of refreshing and accessing individual banks, and columns.

Analysis of the presented numbers allows to draw the following conclusions. VGA-resolution algorithms can be implemented on both platforms. In the case of an HD video stream only the grey-scale version can be realized on the newer VC707 board. Also, there are a few possibilities to process a HD video stream without increasing the memory bandwidth: processing every n-th frame (lower FPS) or storing for example only one out of four pixels (3 from the 2×2 context are approximated).

The ViBe method can be quite easily implemented in hardware. The distance calculation between the current pixel and the samples in the model is possible to realize in parallel. Other operations, including the pseudo-random number generation are also feasible. Quite complex is only the propagation of the current pixel value to neighbouring models mechanism, which requires the generation of a very wide (more than $N \times B$ bits) context and therefore large number of delay lines - usually implemented in Block RAM memory resources.

IV. The Modifications Proposed to the Algorithm

In the first stage of the research the paper [12], in which the authors propose a series of improvements to the ViBe algorithm was examined in detail. Unfortunately, implementing most of the presented ideas in reconfigurable resources in

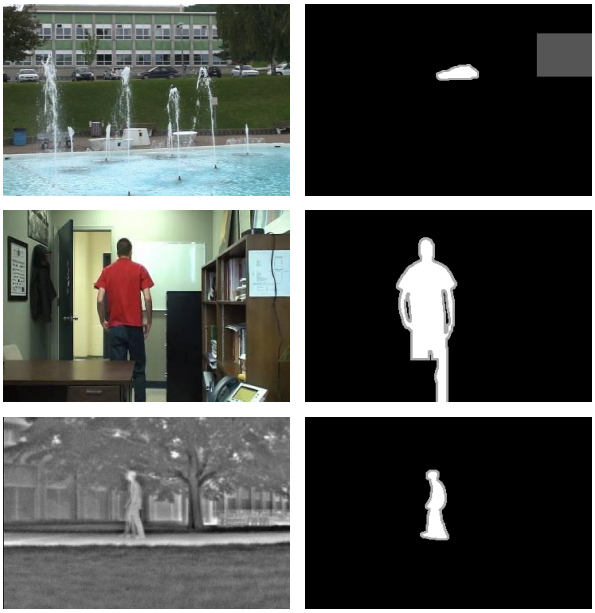

Fig. 1. Sample test images from the `changedetection.net` database. Left coloum - input images, right column - groundtruth. First row — *fountain* sequence (movement in background), second row — *office*, third row — *park* (thermal image)

a pipeline data processing scheme cause huge difficulties or seems to be impossible.

However, in order to enhance the algorithm, two ideas: changing the colour space and a false detection reduction mechanism in areas with background motion (e.g. flowing water) were examined in detail in this paper.

A software model of the algorithm was implemented in C++ using the OpenCV library [7] and examined on the IEEE Workshop on Change Detection (*changedetection.net*) [5] database to evaluate the proposed improvements. The database contains sequences divided into six categories: basic, dynamic background (e.g. flowing river), camera jitter, intermittent object motion, shadows and thermal images. In each of them 4 to 6 videos are included. It can be concluded that the database contains sequences which cover a large part of the situations occurring in surveillance system which are problematic to background generation algorithms. However, the main advantage of the database and a feature that distinguishes it from other collections (e.g. Wallflower [11]), is a large number of manually annotated reference frames with areas marked as: background, shadow, movement, slight blurring and motion (foreground objects). This allows for a reliable assessment of the algorithms performance in different situations. Furthermore, performance results for the most state of the art algorithms are avaliable online (`http://www.changedetection.net/`). Sample images are presented in Figure 1.

The methodology used in the experiments can be described as follows. The object mask computed by the algorithm was compared with the reference mask. Because the ViBe method does not contain a build-in shadow detection procedure, only the foreground and background classification were considered. The following rates were calculated:

- TP (true positive) – pixel belonging to a foreground object classified as a pixel belonging to the foreground,
- TN (true negative) — pixel belonging to the background classified as a background pixel,
- FP (false positive) — pixel belonging to the background classified as a pixel belonging to the foreground,
- FN (false negative) — pixel belonging to a foreground object classified as a background pixel.

Then, based on the calculated parameters two measures were determined: the percentage of wrong classifications:

$$PWC = \frac{FN + FP}{TP + FN + FP + TN} \times 100\% \qquad (3)$$

and precision:

$$P = \frac{TP}{TP + FP} \qquad (4)$$

In the first experiment three colour spaces were examined: greyscale, RGB and CIE Lab. In the first two cases the Manhattan (L1) distance metric was used. Additionally for RGB the Euclidean (L2) metric was calculated. In the case of CIE Lab the fo following formula was used:

$$d_{CIELab} = \alpha \cdot |L_I - L_B| + \beta \cdot (|a_I - a_B| + |b_I - b_B|) \qquad (5)$$

where: L_I, a_I, b_I – current pixel in CIE Lab colour space, L_B, a_B, b_B – background model sample in CIE Lab colour space, α, β - weights (in the experiments set to α = 1, β = 1.5). The parameter values for α and β were chosen after evaluation on several test images. The analysis of the CIE Lab colour space was performed due to good segmentation results obtained in a previous work [6]. The experimental results are summarized in Table I.

TABLE I
PERFORMANCE OF THE VIBE ALGORITHM DEPENDING ON THE USED COLOUR SPACE

Colour space	Distance	PWC [%]	P
Greyscale	L1	3.78	0.67 %
RGB	L1	2.71	0.62 %
RGB	L2	2.28	0.69 %
CIE Lab	eq. (5)	2.18	0.71 %

The presented values are the average rates for the entire dataset. The only modified algorithm parameter was the R threshold. It was set experimentally to obtain best PWC and P ratios.

The results indicate a slight advantage of the CIE Lab over the RGB (L2 metric) colour space. In addition, the hardware implementation of equation (5) is much easier than the Euclidean distance calculation (square and the square root operations require large amounts of FPGA logic resources). Therefore in the final hardware module it was decided to use the CIE Lab colour space, which is a modification to the original proposal from [2].

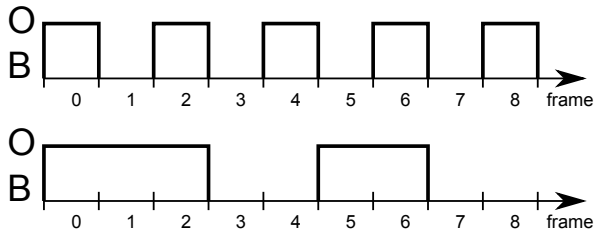

Fig. 2. Two kinds of blinking pixel. O – classification as foreground object, B – classification as background

In the paper [12] an extension to the ViBe method was proposed to detect pixels that are alternatively classified as object and background. They occur most often in cases where small background movement is present (flowing water, fountain, moving grass or leaves). The authors introduced the following mechanism to compensate these interferences. The pixels belonging to the inner boundary of the background that in the previous iteration were classified differently than in the current were detected. In this case the auxiliary variable "blink rate" was incremented by 15, otherwise decremented by 1. If the ratio exceeded the threshold value (set to 30), this pixel was removed from the object mask [1].

This paper proposes an extension to that analysis, which uses two counters: the consecutive classifications of a pixel as background and as an object. This made it possible not only to detect the pixels that change every single iteration (video frame), but also every few ones (Figure 2, bottom graph).

The proposed approach yielded slightly better results. For example, for the "`changedetection.net`" sequence "Canoe" (flowing water) the original approach obtained results: $PWC = 2.19$ and $P = 0.63$, and the proposed $PWC = 1.97$ and $P = 0.68$. It is worth noting that the modification only slightly complicates the algorithm, especially few the hardware implementation.

As post-processing the binary median filter (square window, size 7×7) was selected. It is worth noting thant adding the filter significantly improves the results obtained by the algorithm. An example is presented in Table II.

TABLE II
THE IMPACT OF THE POST PROCESSING MEDIAN FILTERING ON THE ALGORITHMS PERFORMANCE. MEAN RESULTS FOR THE WHOLE DATABASE

Post-processing	PWC [%]	P
none	2.18	0.71 %
median 7×7	1.76	0.88 %

[1] in [12] the mask has been divided into two categories (object and update) and the blinking pixel detection affected only the second. Due to the significant complexity of implementing in pipeline the filling holes operation, which was proposed as post-processing of the update mask, in the presented research this topic was omitted and only one mask was used. For the same reasons the determination of the inner boarder was omitted.

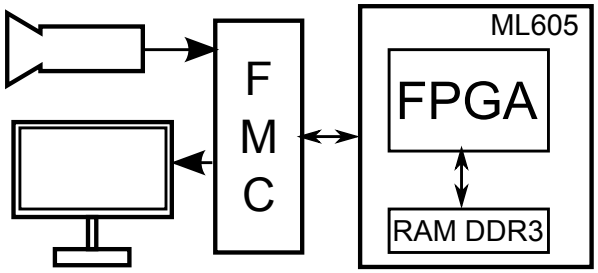

Fig. 3. Scheme of the proposed foreground object detection system

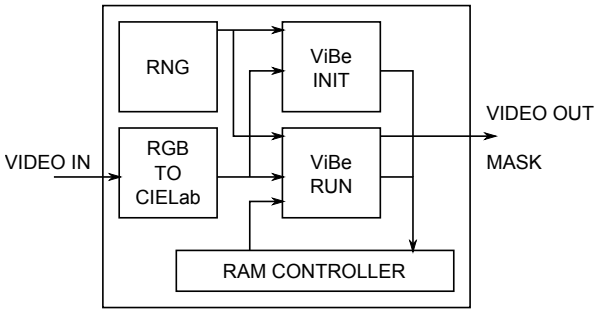

Fig. 4. Block diagram of the modules implemented in the FPGA device

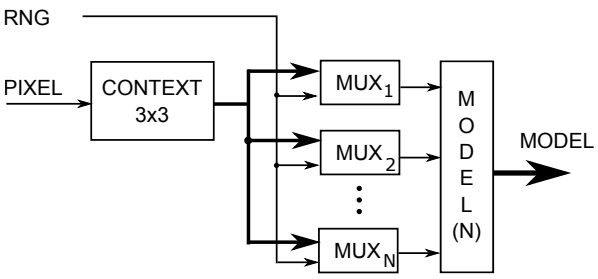

Fig. 5. Block diagram of the *ViBe INIT* module

V. HARDWARE IMPLEMENTATION

Schematically, the proposed system is presented in Figure 3. It consists of an HDMI source (camera or graphic card), HDMI display (LCD screen), Avnet FMC DVI IO module (FPGA Mezzanine Card) with HDMI input and output, and ML605 development board with Virtex 6 FPGA device (XC6VLX240T) from Xilinx. The board is also equipped with an external DDR3 RAM.

All modules were described in VHDL and Verilog hardware description languages. The block diagram of the FPGA design is shown in Figure 4. The *RGB TO CIELab* module is responsible for the colour space conversion [6]. Pseudo-random number generation (*RNG*) was carried out using the concept described in [10]. It is worth noting that the authors made the VHDL code of different RNG versions available, which easy integrates with the project. The used external RAM controller was very similar to the described in [6].

The *ViBe INIT* module is responsible for initializing the background model. The scheme is presented in Figure 5. It consists of a 3×3 context generation module, which uses

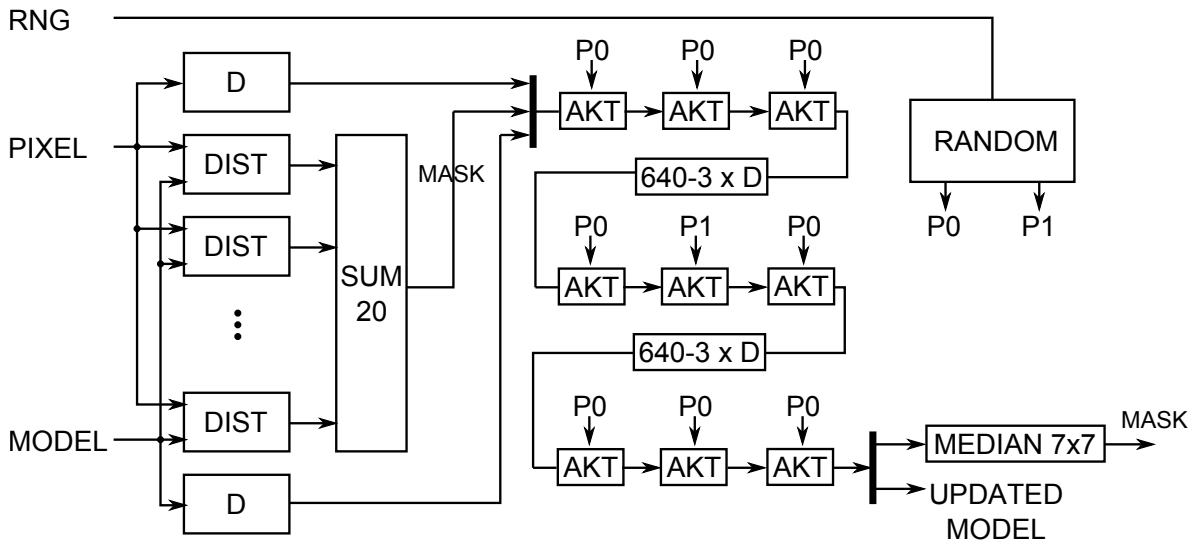

Fig. 6. Block diagram of the *ViBe RUN* module

a delay line approach and N ($N = 20$) multiplexers (*MUX*), which are responsible for the selection of the appropriate sample from the context (1 out of 9 for each *MUX*). The selected value is then stored in the background model. The multiplexers are controlled using a vector obtained from the *RNG* module, thus the model is randomly initialized.

The main module is *ViBe RUN*, which detailed diagram is presented in Figure 6. The inputs are: RNG (pseudo-random number vector), PIXEL (current pixel in the CIE Lab colour space), MODEL (background model read from the external RAM). In the first phase, the distances between the current pixel and the samples from the model are calculated and then compared with the value R (*DIST* - realization of equation (5)). Then it is checked whether the number of distances less than R exceeds the $\#_{min}$ threshold. In the next stage, the 3×3 context consisting of the following signals PIXEL, MODEL and MASK (foreground object mask) is generated. It is worth noting the significant resource usage of this solution - it requires the use of 28 block memory modules (Block RAM). The delay block *D* allows synchronizing the pipeline. The *ACT* module has both a function of a single delay and contains logic that implements the update procedure. The substitution of a background model sample with the current pixel is controlled by the variable P0 (for neighbouring pixels) or P1 (for the central pixel) and depends on the random factor (see Chapter 2) which is schematically illustrated in the form of the *RANDOM* module. The last stage of the process is the median filtering (*MEDIAN 7×7*). The updated model is stored in the DDR RAM and the foreground mask displayed. The blinking pixel detection logic is omitted for clarity reasons.

The presented system was integrated and synthesized for the Virtex 6 FPGA device using the Xilinx ISE Design Suite 14.4. The maximum operating frequency (reported after place & route) was 140 MHz, which is more than enough for processing a VGA colour stream in real-time. FPGA resource usage is summarized in Table III. It is worth noting that due to the large context used in the design and buffers required for the DDR RAM controller, the BRAM_18 (Block RAM) utilisation is quite high. The compatibility of the hardware module with the software C++ model was confirmed using the ISim simulation tool.

TABLE III
FPGA RESOURCE USAGE

Resource	Used	Available	Percentage
FF	12571	301440	3 %
LUT 6	9278	150720	6 %
DSP 48	13	768	1 %
BRAM_18	172	832	20 %

VI. CONCLUSION

This paper describes the implementation of the ViBe background generation algorithm in FPGA. Two modifications were proposed: the use of the CIE Lab colour space and improved detection of blinking pixels that have both increased the effectiveness of the method. The results show that, using an appropriate hardware platform, with a fast external RAM, allows implementing in a pipeline manner a quite complex video stream analysis algorithm in real-time. The proposed system enables processing of a colour video stream with a resolution of 640 × 480 and 60 frames per second. The module can be used in advanced, automated video surveillance systems and other application with require a reliable foreground mask and real-time image processing.

ACKNOWLEDGMENT

This work was supported by the AGH University of Science and Technology grant no 11.11.120.612. The authors would like to thank Mateusz Komorkiewicz for his support in redesigning the DDR RAM controller used in this project.

***Abstract*—One of the methods most commonly used for learning and classification is using decision trees. The greatest advantages that decision trees offer is that, unlike classical trees, they provide a support for handling uncertain data sets. The paper introduces a new algorithm for building fuzzy decision trees and also offers some comparative results, by taking into account other methods. We will present a general overview of the fuzzy decision trees and focus afterwards on the newly introduced algorithm, pointing out that it can be a very useful tool in processing fuzzy data sets by offering good comparative results.**

I. Introduction

IN TODAY'S society there is a continuous process of improvement in the wide area of knowledge acquisition, as it has a direct impact on many areas of activity. Algorithms dealing with extracting knowledge from data have as a result the decision trees and the inference procedures. The classification methods offer different results, in terms of efficiency, domains they can be applied to or ease of use.

The ID3 algorithm was initially introduced by Quinlan [14]. This algorithm offers some restrictions in terms of applicability, as it offers good results for symbolic domains, but not for numerical domains as well. [15]

Fuzzy sets have developed as an extension of the neural networks, since decisions are easier to understand when using them. They provide support for knowledge comprehensibility by offering a symbolic framework. [16] [17]

The symbolic rules together with the fuzzy logic offer complementary support for ease of understanding and modeling fine knowledge details. The fuzzy methods are today's subject in many studies, undergoing continuous improvements in order to offers good results when dealing with inexact data.

The data extraction method we propose in this paper takes into account both a fuzzy approach and a classical decision tree, being able to handle inexact data in a way that is easy to understand.

Some known studies of the fuzzy decision trees present the automatic induction of binary fuzzy trees using new discrimination quality measures. [5] The present method uses for the construction of fuzzy sets an adapted version of the ID3 algorithm. One of the methods we use as a reference is the ID3 algorithm adapted by Janikow in order to be used with fuzzy sets. [2]

II. Fuzzy Decision Trees

Decision tree structures are used to classify data by sorting it from root to leaf nodes. From the well known common tree induction algorithms we mention ID3, C4.5 or CART as they consisted reference points for our work.

In classical decision trees, nodes make a data follow down only one branch since data satisfies a branch condition, and the data finally arrives at only a leaf node.

On the other hand, fuzzy decision trees allow data to follow down simultaneously multiple branches of a node with different satisfaction degrees ranged on [0,1]. To implement these characteristics, fuzzy decision trees usually use fuzzy linguistic terms to specify branch condition of nodes. Different fuzzy decision tree construction methods have been proposed so far.[15] [14] [24]

Different papers are considering the direct fuzzy rules generation without Fuzzy Decision Tree. [26] [27] Complex techniques are used including generation of fuzzy rules from numerical data pairs, collect these fuzzy rules and the linguistic fuzzy rule base, and, finally, design a control or signal processing system based on this combined fuzzy rule base.

In [13] decision tree construction methods are incorporated into fuzzy modeling. They use the decision tree building methods to determine effective branching attributes and their splitting intervals for classification of crisp data. These intervals are then used to determine fuzzy boundaries for input variables, which will be used to form fuzzy rules. As a matter of fact, they use the decision tree construction methods for preprocessing and not for building fuzzy decision tree.

Regarding the approach in [24], the discretization of attributes is made in linguistic terms, relying on the distribution of pattern points in the feature space. Opposite to other fuzzy decision trees, this discretization to boolean form helps in reducing the computational complexity while preserving the linguistic nature of the decision in rule form. In order to minimize noise it's used pruning, resulting in a smaller

978-83-60810-53-8/$25.00

decision tree with more efficient classification. The extracted rules are mapped onto a fuzzy knowledge-based network.

The rest of the paper contains the description of the proposed algorithm for fuzzy tree induction, the set of experiments and the conclusions to the current approach.

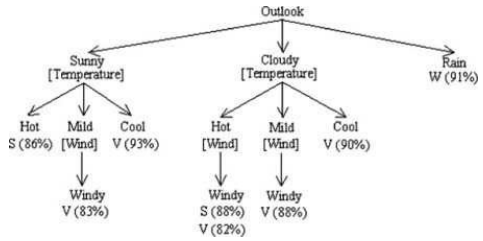

Fig. 1. Example of Generic Fuzzy Decision Tree

III. Proposed Method for Fuzzy Decision Tree Induction

A. Cluster Optimal Index Partitioning for Fuzzy Sets

A very common problem in clustering is finding the optimal set of clusters that best describe the data set. Many clustering algorithms generate a required set of clusters passed as input. In order to solve this problem, the solution would be to repetitively run the algorithm with a different set of inputs until the best schema is found.

In order to validate that, an auxiliary measure needs to be taken care of. We called this cluster optimal index.[1]

A number of cluster validity indices are described in the literature. A cluster validity index for crisp (non fuzzy) clustering is proposed by Dunn [18].

The implementation of most of these measures is very expensive computationally, especially when the number of clusters and the number of objects in the data set grow very large.

In regards to the clusters resulted by applying this mechanism, we have implemented a method of calculating the membership function of the numerical data obtained for each cluster.

The membership degree set is not a binary element from 0, 1 (as for classical decision trees), but is included in the interval [0, 1]. For each node, an attribute has a different membership degree to the current set, and this degree is calculated from the conjunctive combination of the membership degrees of the object to the fuzzy sets along the path to the node and its membership degrees to the classes, where different t-norms operators can be used for this combination.

The fuzzy decision tree induction has two major components: the procedure for fuzzy decision tree building and the generation of the fuzzy set of rules. The proposed fuzzy decision tree building procedure constructs decision tree by recursive partitioning of data set according to the values of selected attribute.

The following steps need to be implemented: attribute value space partitioning methods, branching attribute selection branching test method to determine with what degree data follows down branches of a node, and leaf node labeling methods to determine classes for which leaf nodes stand.

B. Algorithm notations and abbreviations

For better understanding of the described methodology, we have used specific notations as listed below:

- $L = \{L_1, \ldots, L_m\}$, represents the set of m classes of objects,
- $A = \{A_1, \ldots, A_n\}$, represents the set of n attributes we are taking into consideration for our analysis For each attribute we consider the following:
  - $dom(A_i)$ is the domain for the attribute A_i
  - $u^i \in dom(A_i)$, is a crisp value of attribute A_i
  - $FS_i = \{a^i_{p_1}, a^i_{p_2}, \ldots, a^i_{p_{i_k}}\}$, denotes the set of fuzzy numbers resulted after the fuzzy clustering of attribute A_i
  - we denoted FS the set of all fuzzy numbers for all attributes:
$$FS = \{FS_1, \ldots, FS_n\}.$$
- $T = \{t_1, t_2, \ldots, t_s\}$, represent the s training objects. Each element has the following format:
$$t_k = (u^1_k, \ldots, u^n_k, y^1_k, \ldots, y^m_k),$$
where:
  - $u^i_k \in dom(A_i)$ is the crisp value of attribute A_i from the training object t_k
  - a single value from y^i_k is 1, the rest of them are 0 (having 1 on the i^th position means that object t_k belongs to class L_i)
- Membership degree of value $u^i_k \in t_k$ to fuzzy number $a^l_j \in FS_l$ is denoted by $\mu_{a^l_j}(u^i_k)$. For simplicity, this matching operation is denoted by T_0 operator.
$$T_0(u^i_k, a^l_j) = \mu_{a^l_j}(u^i_k) \quad (1)$$
- $\chi = (\chi_1, \ldots, \chi_s)$ are the confidence factors of the objects from the training set ($\chi_i \in [0,1]$ represents the membership degree of object t_i from the training set T). Usually $\chi_i = 1$, $\forall i \in \{1, \ldots, s\}$.
- The Fuzzy set of the set of training objects in node N is denoted by
$$\chi^N = (\chi^N_1, \ldots, \chi^N_s), \quad (2)$$
where χ^N_i is the membership function of object t_i in node N.
- $I(\chi^N)$ represents the entropy of class distribution to set χ^N, in node N
- $I(\widehat{\chi}^N)$ represents the entropy of class distribution after the current node is split by attribute A_i
- $\chi^{N|a^i_j} = (\chi_1^{N|a^i_j}, \ldots, \chi_s^{N|a^i_j})$, denotes the membership degree of training objects from T to fuzzy numbers of attribute A_i, ($\chi_k^{N|a^i_j}$ represents the membership degree of

object t_k to fuzzy number $a_j^i \in FS_i$).
$\chi_k^{N|a_j^i}$ is calculated as follows:

$$\chi_k^{N|a_j^i} = T(T_0(u_k^i, a_j^i), \chi_k^N),$$

where:

- T_0 is defined in 1,
- T is a $T-norm$ operator that can be defined as follows: $T(a,b) = \min(a,b)$

- $Z_k^{N|a_j^i}$, represents the counter for examples in T belonging to class C_k and fuzzy number a_j^i of attribute A_i ($a_j^i \in D_i$).
$Z_k^{N|a_j^i}$ is calculated as follows:

$$Z_k^{N|a_j^i} = \sum_{l=1}^{s} T_1(\chi_l^{N|a_j^i}, y_l^k),$$

where T_1 is a $T-norm$ operator that can be used as follows:$T_1(a,b) = a \times b$.

C. Decision Tree Node Structure

We considered a custom node structure for the extended fuzzy decision tree.

Each node N from the fuzzy decision tree is described as follows:

- F is the set of restrictions on the path from N to the root node
- V is the set of splitting attributes on the path from N to the root node
- S is the set of children of node N, when splitting is done according to attribute A_i
- χ contains the membership degree to node N

D. Fuzzy Decision Tree Induction Algorithm

In what follows it's presented a recursive algorithm for fuzzy decision tree induction of the training objects associated to the dataset we used. It is supposed that the partitioning (or clustering) mechanism of the considered attribute data is already implemented and now further used.

As described above, the numeric partitioning is done using a modified version of C-Means algorithm with additional clustering logic. The algorithm is recursive, it returns the root node and it is called for each splitting phase. Basically, at each level, after attribute partitioning, a particular attribute is selected for further splitting and branching the tree.

As already mentioned, negative information gain can also result from the t-norm (min operator) that is used in the algorithm to compute the membership degrees of the samples in a node. A negative information gain, even if it hasn't a real meaning, can lead to a correct ranking of the candidate test attributes. Instead of that, if information gain ratio is used, a negative value for the information gain cannot produce a good result. answer.

  $N.S_j.F \leftarrow N.F \cup \{[A_{imax}\ is\ a_j^{imax}]\}$
  $N.S_j.V \leftarrow N.V \cup \{A_{imax}\}$
end for
return N
end function

IV. EXPERIMENTS

In order to demonstrate the applicability of the proposed framework we executed a wide set of experiments and verified the accuracy of the results. We have performed comparative results between the algorithm we developed, denoted here as *BFD* and two other well known similar approaches.

The other references we used were *C*4.5 [23], a well known decision tree learner based on neural networks and *NEFCLASS*, a fuzzy rule based classifier which combines fuzzy systems with neural networks. We analyzed precision and complexity for each of the 3 implementations.

For our tests we used four data sets from *UC Irvine Machine Learning Repository*[20]. You can see in Table I information related to the attributes used in the dataset we considered.

TABLE I
TEST DATASETS

data	size	attributes	classes	missing value
iris	150	4	3	no
glass	214	10 (incl. id)	7	no
thyroid	215	5	3	no
pima	768	8	2	no

The basic approach for testing was 10-fold cross validation. Data was broken into 10 sets of size n/10. We trained on 9 datasets and tested on 1. Performed this operation 10 times and considered the mean accuracy. For the algorithm we developed (*BFD*), we considered a threshold of 10% for the clustering mechanism, and since using Fuzzy C-Means, we also considered a maximum of 10 number of clusters as parameter.

In the Table II we present the average error rate $\bar{\varepsilon}$ after testing with each of the implementation.

TABLE II
ERROR RATE COMPARISON

model	iris	glass	thyroid	pima
BFD	5%	33%	5%	23%
C4.5	4%	30%	7%	31%
NEFCLASS	4%	35%	6%	29%

The precision analysis of the models considered, as seen in the table above, is good for the implementation we made, and certifies that the approach we had has good results and will offer similar results on other data sets, as part of our future work.

In terms of implementation, the algorithm was developed in *C#.NET*, and is part of a complex framework we continuously improve. The implementation decision was taken given the advantages and support that Microsoft offers for their products and the large community supporting, for best practices, performance and efficient problem solving.

V. CONCLUSION

This paper is aimed to introduce a new fuzzy method for handling inexact data. The approach is an extension of the classical decision trees by using fuzzy methods.

The comparative analysis we presented in this paper demonstrate that the considered approach is very solid and returned consistent results.

As observed in the above table, the precision of the proposed method is good enough and we can use it as a good reference and further integrate it in a framework we build among this approach.

The decision of considering algorithm implementation using fuzzy sets reported higher evaluation scores when focusing the training and tests on specific operational fields. We presented a novel and enhanced mechanism of image semantic annotation for segmented color images.

***Abstract*—This paper describes the architectural redesign of a distributed execution framework called State Machine Based Distributed System which uses a state machine-based representation of processes in order to reduce the applications development time while providing safety and reliability. Initially the system has been built on top of the .Net Framework employing static programming techniques and made use of a custom data storage. The new architecture is intended to take advantage of the fast growing technologies like dynamic languages and graph databases for speeding up even more the applications development and improve the dynamism of the execution model.**

I. Introduction

NOWADAYS, complex systems have become more and more demanding for online visualization and computational steering. Analyzing the outcome of a complex simulation as a post-processing phase is almost unacceptable, while interactivity is a must-have feature. Distributed computing as well as super fast networks, have come to rescue, offering a proper environment for achieving high performance simulation, online visualization and steering. Building complex systems is more a matter of integrating state of the art tools into execution platforms.

Online visualization and computational steering techniques play a very important role in speeding up simulations by allowing on-the-fly analysis and guidance of the ongoing process. Computational steering is nothing else than manual intervention against the ongoing process with the purpose of guiding it towards the space of interest. Computational steering occurs at three different levels: the program level (***program steering,***) which implies changes on the program's state (shared variables), data level (***data steering***), which allows interventions against the data space, and execution level (***dynamic steering***), which implies direct changes to the program's flow by injecting code or invoking routines.

Developing distributed simulation platforms able to provide the means for interactivity has not been easy. Many surveys have documented the task [1], [2], however only few of them get close to fulfilling production needs. It's worth mentioning few of them.

Collaborative Online Visualization and Steering framework, COVS [3] integrates tools for visualization (VTK), communication libraries (VISIT, PV3), steering tools (VISIT, ICENI, gViz).

RealityGrid [4]. [5] is a library which serves as an API which uses check-pointing techniques for steering commands.

CUMULVS (Collaborative User Migration, User Library for Visualization and Steering) [6], [7] developed at Oak Ridge National Laboratory, besides steering, it benefits of powerful recovery techniques and tasks migration.

CSE [8], [9] (Computational Steering Environment) carries out steering through a data manager which works closely with simulation processes (called satellites).

After examining all these platforms it became obvious that choosing the right tools for a distributed simulation and steering system is not an easy task. While ensuring scalability, portability, flexibility, extensibility, could be achieved with the proper tools, ensuring safety seems more like a design task. Writing safe code does not guarantee that the output of the application will be safe. Just imagine the effects of a malfunction of a medical software which assists a surgery. It is essential that at each moment in time, the application is in a consistent and expected state. When designing the application one must make sure that the application reacts accordingly no matter what. This led us to the idea of representing the tasks (processing units) as finite state machines. This way, we force the application developer to consider all states that the application may step into, prior to implementing them properly. Besides an execution model (transitioning states until a final state has been reached) finite state machines serve as packages which can be spread across a distributed environment leading our way towards load balancing and recovery algorithms.

A similar approach has been introduced in [10], and it made use of Statecharts as a conceptual model for a visual tool called Statemate. Statemate is a very powerful simulation environment for statecharts-based models. Statecharts imply a hierarchical and compositional structure increasing the complexity of the model which could lead to an increase of the risk of design errors.

Our previous researches have resulted in the implementation of a state machines-based distributed framework (SMBDS) [11] consisting of an execution engine as well as a class library. The class library reduces the development time considerably by including a set of interfaces and base classes. Developing new applications on top of the frame-

978-83-60810-53-8/$25.00

work only requires the implementation of these interfaces and classes (parameters and state machines). The execution engine loads them and runs them on the distributed environment. SMBDS has been implemented on top of the .Net Framework using C# language. In order to be able to dynamically load custom parameter/state machines classes, the .Net Reflection package has been used. However, C# still remains a static language and for this reason all nodes in the distributed system needed to have access to all code files which makes the distributed environment harder to maintain (whenever a new type of state machine is needed, all nodes need to be updated with the corresponding code file). To overcome this drawback we started considering the power of dynamic languages. There were arguments in favor and against dynamic languages, which will be discussed later in this paper. However we considered the advantages of using dynamic languages worth assuming the drawbacks. This led us to a redesign process which changed the framework almost entirely. At first, we considered only including the dynamic code as a string and simply run it. But then, as we dig into the load balancing and scheduling algorithms, we realized that the execution model is similar to a graph, so why not changing the execution engine so we can take advantage of the NoSQL graph databases. We will discuss the execution model later in this paper.

The rest of the paper is organized as follows. Section II shortly presents the technologies used for implementation pointing out the main benefits of using them. Section III shortly describes the architecture of the state machines-based distributed system (SMBDS) as it used to be prior to the redesign process and explains the reasons behind redesign. Section III presents a new execution model for the state machines-based distributed framework. Section V concludes the paper and presents our future development intentions.

II. Tools and Technologies

In this section we will argument our decisions regarding the infrastructure.

The first choice that we have had to make after deciding to use a dynamic language, was which language we should use. The most popular dynamic languages that we have considered were Python and Ruby. A 'versus' discussion between Ruby and Python is beyond the scope of this paper. After all they can both reach the scope of our framework. However we decided to go for JRuby, as it stands on top of the Java Virtual Machine which makes it possible to call java code from JRuby offering the possibility of including dynamically invoked java code in our state machines.

The second choice that we have had to make was related to the graph representation of our execution model. We have examined the most popular graph database infrastructures, namely Neo4j, Titan Server with three storage back ends (Apache Cassandra, Apache HBase, Oracle Berkley DB) together with the Tinkerpop stack [12].

Neo4j proved to be the most mature graph database. However it falls fast in distributed environments as it's storage is limited to only one machine.

Titan claims to bring a lot of performance boost. Even though it is a relatively new product and it has some limitations (for example, the most important: indexes need to be declared before first use of the key), Titan Server seems a good choice since it uses very powerful storages behind it.

Considering the CAP theorem (any practical database system can only provide two of the following three: scalability, availability and consistency), Titan can use three storage backends: Apache HBase, which provides consistency and scalability, Oracle Berkley DB which provides consistency and availability and Apache Cassandra which provides scalability and availability.

In our case HBase and Cassandra seem to be the best choices depending on the applications needs (distributed systems require scalability). There is a tradeoff between high availability (Cassandra) and consistency (HBase). Both of them are scalable therefore they are suitable for our framework's needs. Their performance and reliability have been successfully proven in production environments at Facebook or Twitter.

As HBase and Cassandra are open-source, distributed and column-oriented storages, and not really graph databases, it might feel strange to use them as graphs, however the Tinkerpop stack models successfully the graphs on top of these storages and they claim for very high performance results [13], [14], outperforming regular SQL relational databases.

The Tinkerpop stack includes a very powerful graph traversal language, Gremlin, built on top of a widely used java interface for graph databases, Blueprints. This makes Gremlin compatible with multiple existing graph engines and eventually with future engines that will implement the Blueprints interface. Being implemented on top of JVM, Gremlin can run java code, so one can actually traverse the graph with custom java code.

Putting all these pieces together we get a very powerful distributed platform for our framework.

Fig. 1 illustrates the software stack for our framework. JVM is where all tools met. On top of it runs JRuby together with all libraries that implement Blueprints. As a bridge between SMBDS and the graph database storages we are using the Tinkerpop's Gremlin language which complies to the Blueprints interface.

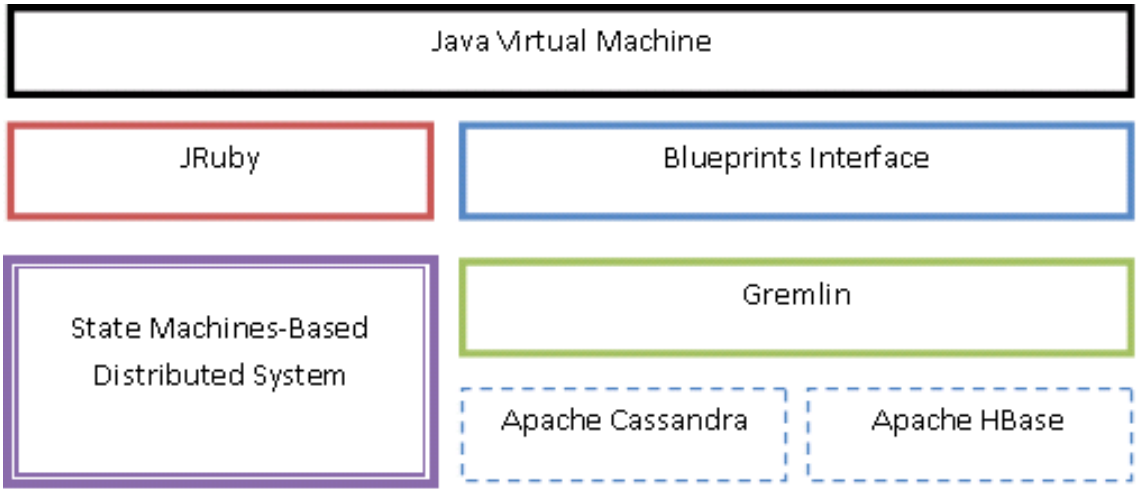

Fig. 1 Software stack

III. Framework's Architecture

This section is intended to reveal the motivation behind the redesign process. Let's examine the static architecture of the system before we proceed with the redesign process.

The challenge behind SMBDS was to offer safety and reliability while taking advantage of a distributed execution environment. SMBDS aims of ensuring safety at design time rather than code safety only, and it does that by representing all computational tasks as finite state machines. This representation forces the application developer to consider all states that the application may step into and react accordingly to each of them. This eliminates the erroneous states while offering a robust and traceable execution model.

The architecture of SMBDS is illustrated in Fig. 2.

SMBDS consists of five modules: Simulation Module (or Processing Module), Visualization Module, Control and Communication Module, Shared Memory and Client Application.

All the magic of SMBDS happens on the simulation level as this is where the simulation tasks, represented as state machines, are being executed.

Each node of the system owns a state machines manager which is the bridge between all modules, mainly because it is responsible for acquiring the state machines from the distributed environment, migrating them to other hosts when necessary, running the state machines and at the same time interacting with the client application for handling steering commands and providing visualization information.

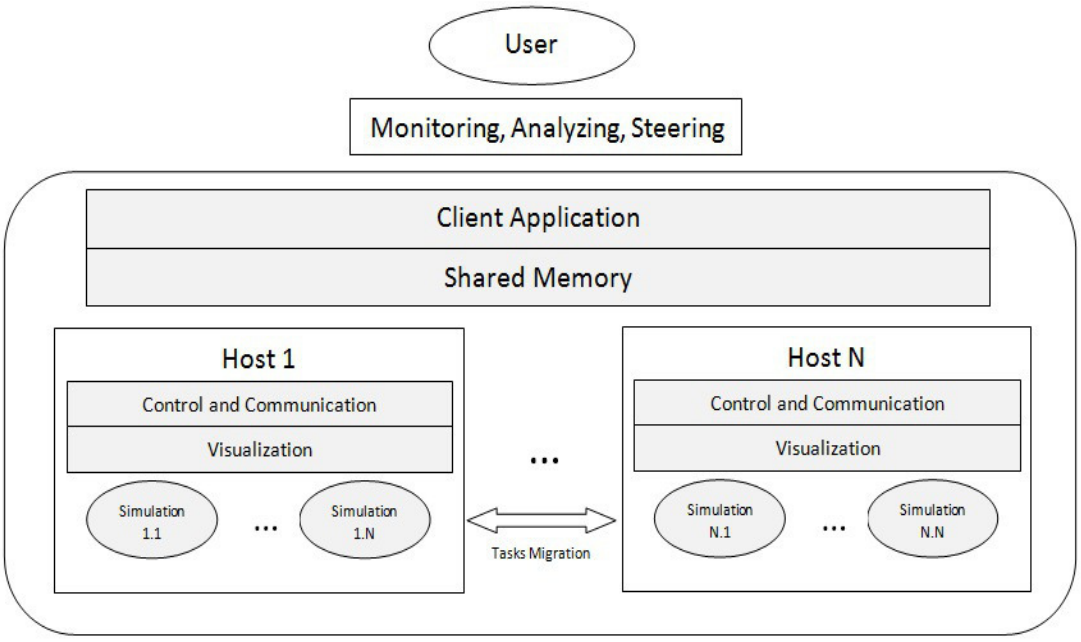

Fig. 2 State Machines-Based Distributed System's architecture.

The control and communication module is able to acquire data, forward output data towards the visualization pipeline while monitoring the available resources and executing steering commands.

As we are dealing with a decentralized architecture, the shared memory took the form of a distributed storage space and it holds the system's parameters (steerable variables).

The user analysis the output data filtered by the visualization pipeline, monitors the state of the computational resources as well as the execution distribution across nodes, and interacts with the system by launching new tasks (state machines), changing the execution parameters (stored in the shared memory), guiding the simulation towards the space of interest.

Concerning the applications development, SMBDS exposes a class library which facilitates the implementation of custom finite state machines which once created, will be passed to the state machines managers and executed.

Implementing new custom state machines requires the implementation of an interface (IParameter), representing the state machine's parameters, if not already implemented, and the extension of a state machine class (StateMachine). Based on these two, the framework's engine is able to manage the execution of state machines. Figure 3 illustrates the class diagram of the framework's execution engine.

The engine's main class is the StateMachineManager. Each host will launch a state machines manager which will run continuously until final states are reached. The main role of this class is to manage the execution of state machines but also migrate the state machines to (pack and send) and from (receive and unpack) other hosts (state machine managers). Packing a state machine consists of pausing the execution and extracting data from the state machine (extracting StateMachineData object), while unpacking restores the machine's execution by creating an instance of the corresponding state machine class, initializing the state machine with the StateMachineData object and lastly resuming the execution from the state where it has previously been paused. Any computations performed for the interrupted state, carried out before packing, will be discarded.

It becomes obvious that migrating a state machine consists of simply sending the StateMachineData object towards the destination host. The StateMachineData class holds execution data of a state machine: a list of parameters, a transition table, the current state, a unique identifier (needed for tracking the machine especially when dealing with migration), the type of the state machine (used to pick the correct state machine class when packing/unpacking the machine using .Net Reflection) and a list of final states.

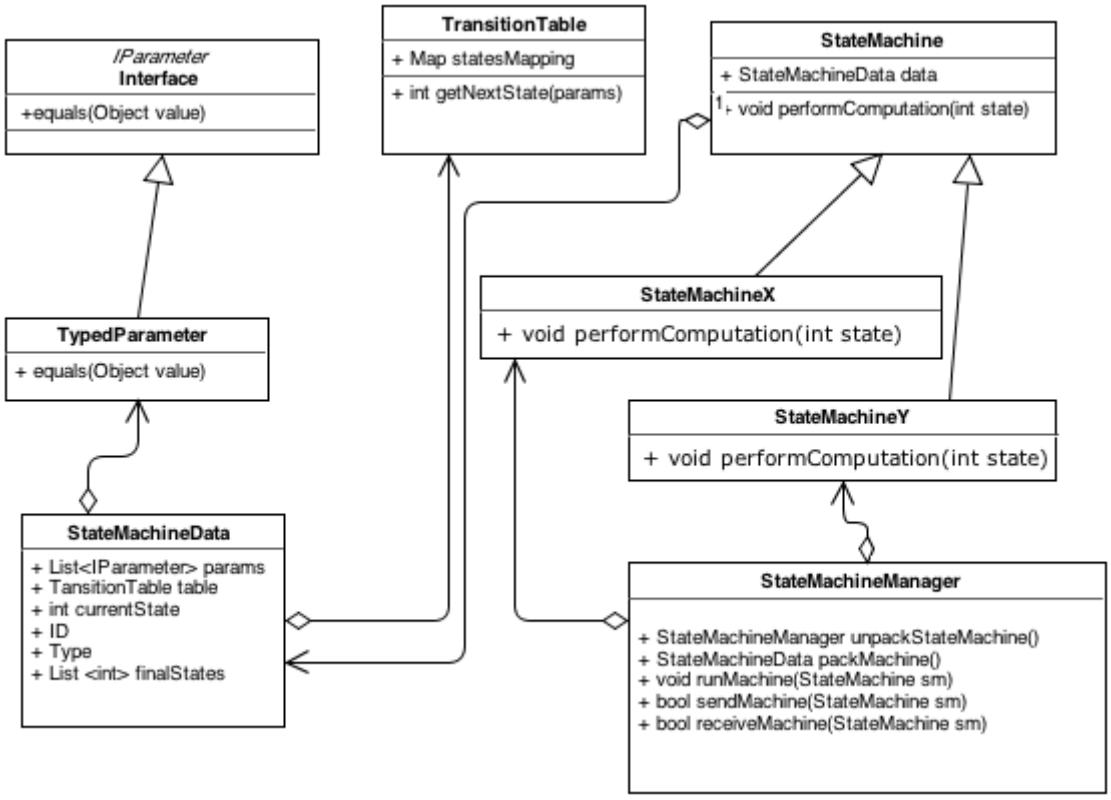

Fig. 3 SMBDS class diagram.

The StateMachine class exposed by the framework's library is an abstract class exposing an abstract method called performComputation which executes the code associated with the current state. This method is being invoked by the state machines manager after each transition. The computations are carried out taking as input the values of the machine's parameters. The parameters are usually altered by the computations of the current state. After the execution of the current state the machines manager invokes the getNextState() method of the machine's transition table which based on the current values of the parameters and the current state determines which is the next state to be transitioned. The manager loops again and invokes the performComputation method for the newly transitioned state unless the state is not final.

To make it more clear, we will include a sample template of how the performComputation method could look like:

```
void performComputation(List<IParameter>
  params,int currentState){
      switch(currentState){
       case: 1
           {//code for state 1}
           break;
       case: 2
           {//code for state 1}
           break;
       …..
       case: N
           {//code for state N}
           break;
       default:
           throw new Excetion
             ("Invalid state. Design time error")
      }
  }
```

It becomes obvious that the business logic of an application will reside in the performComputation method, in the parameter classes as well as in the transition table. This is why the application developer will be needed to derive from the StateMachine class and implement the performComputation method for every type of state machine.

The TranzitionTable class is nothing more than a mapping between <parameter values, current state> tuples and future states. The business logic in case of the TransitionTable class resides in the values it contains rather than in its implementation.

The parameter classes will implement the IParameter interface which exposes the *equals* method which is required to match the values of two parameters and return *true* if they are considered to be equal or *false* otherwise. The *equals* method's implementation might range from very simple equalities to very complex checkings against custom objects, depending on the business logic requirements.

That being said, we can resume the applications implementation requirements to three steps:

1. Implement the parameters classes
2. Implement a state machine class for each type of state machines needed by the application, by extending the StateMachine class
3. Define transition tables.

Here is where the main drawback of the system appears. Since the framework has been developed using a static language (C#) the newly developed state machine class needs to be available on all nodes in order for that node to be able to run state machines of that type. So we can easily identify three important drawbacks at this stage:

- Updating a running application may not be an easy task due to security restrictions.
- All state machines need to comply to one of the classes, which avoids building and executing custom state machines on-the-fly
- The development time increases by the fact that any change in code needs to be spread across the distributed environment in order to be well tested. Also if one needs to run a certain state machine only few times, the development time might exceed the usage time for that state machine.

IV. Dynamic Execution Model

To overcome the drawbacks identified in the previous section we have considered the use of dynamic languages. Instead of implementing classes every time we needed a new type of state machines, we can now include the code as string on the state machine object itself and invoke it dynamically when needed. This raises an important controversy specific to dynamic languages, namely code safety. As the code is not compiled prior to running it, it might contain erroneous code (typos, references to undefined variables or methods, etc) which can damage the execution Besides trying to overcome unsafe code at design time by considering all states that a machine can step into prior to writing the code, we could make use of an adequate development strategy like test driven development and we can increase code safety. However it is well known that dynamic programming requires a lot more attention when writing code than static programming. Assuming that we need to pay attention when writing code, and tediously test it before running it in production, this tradeoff gives us a lot of flexibility.

We can now run as many custom state machines as we want without having to implement classes and move code files across the running system, while reducing the development effort.

Extending the StateMachine class for each type of state machines is no longer needed. We simply make use of the StateMachine class and add a new attribute called *codeMapping* which will map states to their corresponding code represented as strings.

For example, in Ruby Language, the *codeMapping* attribute could be of type Hash and have as keys the state numbers, and as values string containing the code that needs to be run for the associated state:

```
codeMapping = {
   1 => "puts 'code for state 1'",
   2 => "puts 'code for state 2'",
   # …..
   N => "puts 'code for state N'",
}
```

In this context, the state machines manager, would simply invoke the code defined for the current state.
So, instead of calling:

```
performComputation(params, state)
```

it will simply invoke the code dynamically:

```
eval(machine.codeMapping[state])
```

At this stage, our state machines have become abstract collections of states which are nothing but objects that combine code and data, and define some kind of ordering between them resulted from the transition table.

Each state is very similar to a function which takes input parameters and input data, executes some custom code against them and outputs transition parameters and data needed by other states, and so on. If we were to represent the structure of states machines based on their states, data and transition table, it would look like a graph. The nodes of the graph would be the states or data objects, and the arrows would be the dependencies between states constrained by the value of the transition parameters (according to the transition table). Taking it further, we can represent all state machines running at a certain moment and we can conclude that we're dealing with a graph of states and data objects with dependencies between them and we no longer care to which state machine they belong to. Such a graph is illustrated in Fig. 4.

The figure includes the states of two finite state machines (S_{1i} for the former and S_{2i} for the latter) and their input/output data objects (d_i). The transitions between states are being conditioned by the machine's parameters (P) values. For example, machine 1 will move from state S_{10} to state S_{12} only if the value of P_1 matches the value on the arrow (relationship) between S_{10} and S_{12}, which is V_{12}. Each state can be launched only if all data dependencies are satisfied, and the state is considered to be executed completely only after all output data has been delivered. In case a state needs as input data, another state's output, the former state can't be launched unless the latter has been completed. The execution relies on the *execution pointers*. These are nodes in the graph and they point out the last executed state of each state machine. As the machine traverses throughout it's states the corresponding pointer will move to the new state.

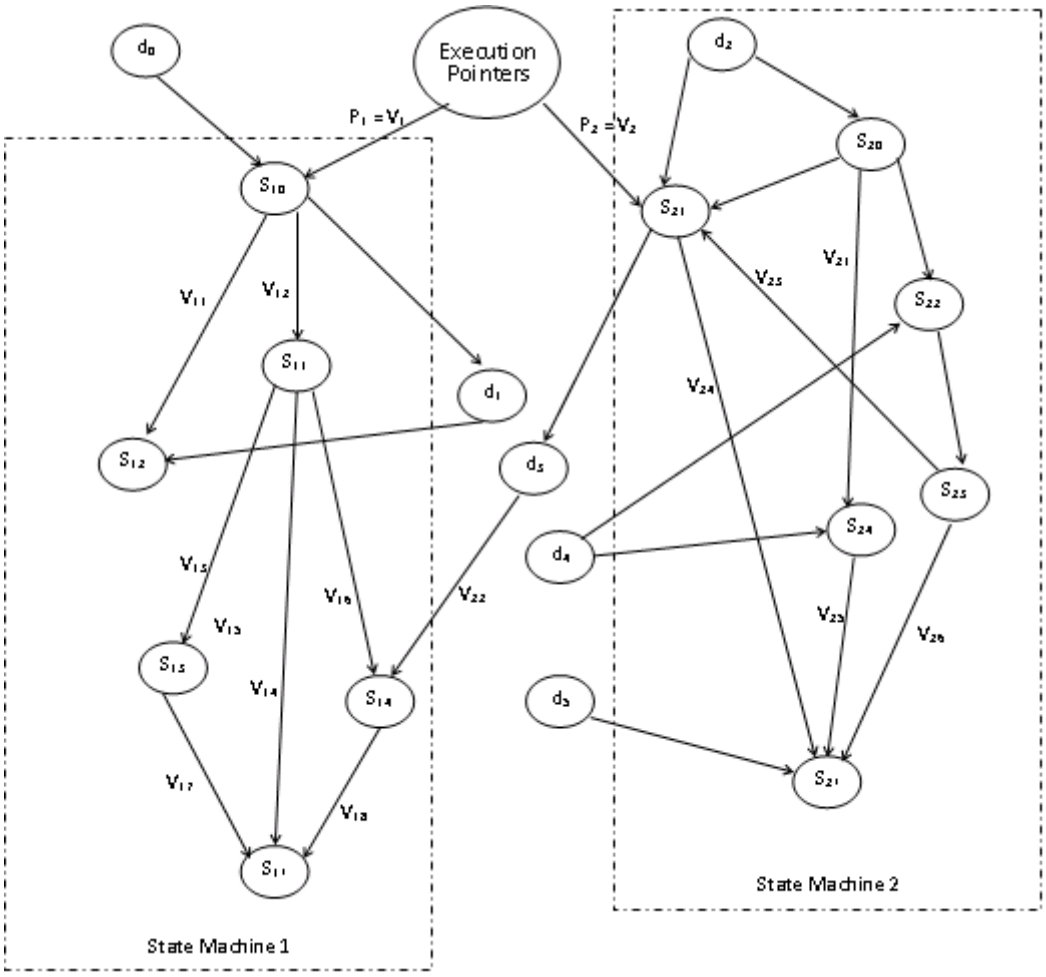

Fig. 4 Execution graph.

It becomes obvious that the execution graph has to be shared by all nodes (execution managers). Normally this would be an important loss for our architecture since the old architecture was not centralized. Keeping the graph in the shared memory area would not be very efficient since it has a distributed architecture and it would require important amount of synchronization communication which would slow down the system considerably.

Fortunately, graph databases and their spectacular evolution have allowed us to benefit from a very powerful infrastructure for distributed environments which has been discussed in section II.

Considering the new execution model we can easily observe that the simulation module of the old architecture no longer handles state machines entirely but states of machines.

For this reason the execution manager available on each host will be responsible for acquiring states that can be immediately executed, run them, save the output and then handle another state.

The algorithm can be resumed by presenting the approximate structure of the class that handles the database (GraphDB), and the main loop that keeps the engine running until the execution is finished.

```
class GraphDB

def exist_final_states
 execution_pointers.out.each do |state|
  return false if not state.is_final?
 end
 return true
end

def pick
 execution_pointers.out.out.filter
       {P = V && in(data).available}
end

def save_output(state)
 database.save(state.output_data)
 exec_pointer= state.in.in(exec_pointer)
 exec_pointer.save_params
    (state.output_params)
 exec_pointer.out = state
end

end
```

The exist_final_states method checks if all final states have been reached, in which moment the execution should stop, by traversing the graph starting from the execution pointer nodes, following the outgoing relationships and returning true if all states pointed by the execution pointers are final states, otherwise it returns false.

The pick method starts from all the execution_pointers, traverses down the tree through the last completed states, down to the next state by checking the current parameters' values and returns the first state found. The method can be easily adjusted to return more than one state depending on the load balancing policy.

The save_output method, saves the output data objects resulted after processing the current state into the graph, identifies the corresponding execution pointer and moves its position to the currently completed state.

The main loop run on every process (simulation process), is similar to the following piece of code:

```
while graphDB.exist_final_states
  current_state = graph_db.pick()
  //dynamically run the Ruby code
  eval(current_state.code)
  graph_db.save_output(current_state)
end
```

V. Conclusions and Future Work

The proposed architecture brings more flexibility to our distributed framework by allowing the developer to write dynamic code and at the same time reduces the development effort by not requiring the implementation of static code for each type of custom state machine. As a consequence the update process of a running application no longer requires sending code files across the distributed environment, but simply running finite state machines with embedded custom dynamic code.

The new graph execution model breaks the finite state machines into independent states and handles them all together. As new state machines arrive, their states get appended to the graph and dynamically allocated to computational resources (through each host's execution manager).

The new approach ensure fair load balancing by having the nodes acquire the processing tasks (machines' states) as their resources become available as opposed to static allocation (prior to launching the application) or centralized dynamic allocation algorithms.

Reducing the amount of work required by a task at the minimum of only one state also improves the load balancing.

Our near future research thoughts refer, to evaluating the performance of the new architecture and identify the performance gain as well as the weaknesses of the new platform architecture.

Dynamic load balancing algorithms have always been an important lead for us and they will be given special concern in the near future.

Data distribution plays a very important role when we deal with load balancing algorithms in distributed environments, as it is more efficient to move the processing towards data than the other way around, therefore special interest will be shown on this issue.

Creating tools for better monitoring and steering of the distributed environment, of both resources and execution is also on our to-do list.

Color Classifiers for 2D Color Barcodes

Marco Querini and Giuseppe F. Italiano

***Abstract*—2D color barcodes have been introduced to obtain larger storage capabilities than traditional black and white barcodes. Unfortunately, the data density of color barcodes is substantially limited by the redundancy needed for correcting errors, which are due not only to geometric but also to chromatic distortions introduced by the printing and scanning process. The higher the expected error rate, the more redundancy is needed for avoiding failures in barcode reading, and thus, the lower the actual data density. Our work addresses this trade-off between reliability and data density in 2D color barcodes and aims at identifying the most effective algorithms, in terms of byte error rate and computational overhead, for decoding 2D color barcodes. In particular, we perform a thorough experimental study to identify the most suitable color classifiers for converting analog barcode cells to digital bit streams.**

I. Introduction

BARCODES are optical machine-readable representations of data, capable of storing digital information. Barcode data are represented as a sequence of bytes, which are then mapped to analog signals (in this case, barcode elements) and transmitted over a printing and scanning (Print&Scan) channel which introduces noise, distortions and interference, corrupting the transmitted signal (in this case, the barcode image after scanning). At the receiver, the distorted barcode is mapped back to bytes. The received binary information is just an estimate of the transmitted binary information. Indeed, byte errors may result due to the amount of noise encountered in the transmission. Because noise and distortions always occur in practice, as a result barcode reading algorithms have to cope necessarily with errors, and the trade-off between reliability and data density of barcodes is a significant design consideration. To cope with errors, redundancy is added by channel coding, which is a viable method to increase reliability in a noisy communication channel (which in our case is represented by the Print&Scan channel) at the price of reducing the information rate. The higher the expected number of errors and the redundancy needed for coping with it, the lower the actual data rate (in our case, the barcode data density).

Traditional barcodes, referred to as one-dimensional (1D) barcodes, represent data by varying the widths and spacings of parallel lines. The amount of digital information stored in 1D barcodes is limited and can be only increased by laying out multiple barcodes. This approach has many negative effects, however, such as enlarged barcode areas, more complex reading operations, and increased printing costs. For this reason, the barcode technology has been deploying geometric patterns (such as squares, dots, triangles, hexagons) in two dimensions: such barcodes are referred to as bidimensional (2D) codes. Both the increasing demand for higher density barcodes and the wide availability of on-board cameras in mobile devices has motivated the need for 2D color barcodes, such as the colored DataGlyphs developed at Xerox Parc [1], the High Capacity Color Barcode (HCCB) developed at Microsoft Research [2], [3], the high capacity color barcode technique proposed in [4], and HCC2D, the High Capacity Colored 2-Dimensional code [5], [6]. Color barcodes generate each module of the data area with a color selected from 2^n-ary schemes (e.g., 4-ary color schemes encoding 2 $bit/module$ or 8-ary color schemes encoding 3 $bit/module$), where a module (or cell) is the atomic information unit of a 2D barcode.

Since black and white codes encode 1 $bit/module$, in principle the data density of a color barcode can be twice (4 colors) or three times (8 colors) as much as the data density of the corresponding black and white barcode. However, the actual capacity depends on the amount of redundancy added to the barcode data for correcting errors, which occur due to both geometric and chromatic distortions introduced by the Print&Scan channel. Since colors are more sensitive to the distorsions introduced by the channel, the measured error rate of color barcodes can be significantly larger than the measured error rate of black and white barcodes, all other conditions being equal (i.e., when all barcodes are generated, printed and scanned under same conditions, such as module size, amount of redundancy, printing and scanning resolutions). In our experiments, under the same operating conditions, black & white QR codes had an average byte error rate of roughly 2% while their 4-color counterpart (HCC2D codes) had an average byte error rate of roughly 10%. In this framework, the higher error rates of color barcodes can be mitigated by the use of larger redundancies in the coding, which in turn may reduce substantially the higher data densities potentially offered by color barcodes, thus reducing their benefits. For instance, in order to tolerate a byte error rate of 2%, we need to reserve at least 4% of the barcode area for an error correction code (such as Reed Solomon), thus obtaining less than 96% for its data density, while a 10% byte error rate implies that at least 20% of the barcode area must be used for error correction, reducing its data density to less than 80%.

In this paper we tackle this problem by designing and experimentally evaluating algorithms for retrieving digital data from color cells undergoing chromatic distorsions (due to printing and scanning), so as to minimize their error rates. In particular, we perform an experimental study of the practical performance of several color classifiers and clusterers for converting analog barcode cells to digital bit streams. This

978-83-60810-53-8/$25.00

allows to identify the most effective algorithms for decoding color barcodes in terms of their error rate and their total running times. Moreover, we investigate the trade-off between redundancy and data capacity for 2D color barcodes. This allows to optimize the data storage, addressing the need for high density barcodes (capable of storing as much information as possible in as small an area as possible).

To accomplish this task, we have developed a prototype capable of using different algorithms for color classification. We have chosen algorithms so that they are representative of general classes, such as minimum distance classifiers, decision trees, clustering, probabilistic classifiers and support vector machines. Our experimental findings show that the impact of different color classifiers on the error rate achieved in decoding can be significant. Furthermore, the use of more complex techniques, such as support vector machines, does not seem to pay off, as they do not achieve better accuracy in classifying color barcode cells. The lowest error rates are indeed obtained by means of clustering algorithms and probabilistic classifiers. From the computational viewpoint, classification with clustering seems to be the method of choice, since it is simple and it does not need time consuming training phases.

II. Related Work

To the best of our knowledge, there is little research in the literature on the color classification for 2D color barcodes. One of the first reported attempt to use color in a 2D barcode can be found in a patent by Han et al. [7], who used reference cells to provide standard colors for correct indexing. Bulan et al. [4] proposed to embed data in two different printer colorant channels via halftone-dot orientation modulation, that is, to print two colors at the same spatial location. This allows to nearly double the capacity of black and white barcodes, which is equivalent to use a 4-ary color scheme for encoding 2 $bit/module$. This work was extended in [8] by using three instead of two colorant layers and a interference mitigating design of the orientations of the three colorants to improve capacity. Microsoft HCCB uses a grid of colored triangles to encode data, using a palette of 4 or 8 colors (4-ary color or 8-ary color scheme). HCC2D, the High Capacity Colored 2-Dimensional Barcode [5] uses a grid of colored squares (using a palette of 4 or 8 colors) and has a symbol structure which builds upon a QR code [9] basis for preserving the QR robustness to distortions. Different color barcode technologies adopt different stategies for classifying colors, that is, for converting analog barcode cells to digital bit streams. For instance, the strategy adopted by the Microsoft HCCB decoder is to make use of a color palette, while Bagherinia and Manduchi [10] proposed an algorithm for decoding barcode elements in a color barcode that does not display its reference colors.

Despite the increasing interest in color barcodes, we are not aware of any previous attempt at performing a comparative analysis of the performance of different methods for color classification in this framework, which is the main contribution of our work. Experimentation in color classification has been previously addressed in other domains such as color recognition of objects in indoor and outdoor images [11], color recognition of license plates [12] or skin color detection in face localization and tracking [13] [14], where, similarly to our problem, there is the need to discriminate among different classes of color pixels. We emphasize that results from other domains (e.g., pixel classification into skin color and non-skin color) do not necessarily carry through the classification of color cells in barcodes, because the underlying conditions are rather different. Indeed, color classification in 2D barcodes mainly focuses on classifying color cells with minimal size (e.g., thousands cells per square inch) after undergoing a printing and scanning process, while in other domains color elements have other characteristics (e.g., colors in video frames representing natural images). Furthermore, the effective decoding of color barcodes requires much more accuracy and precision than the other applications considered for color classification.

III. 2D Color Barcodes

In this section, we introduce 2D color barcodes, which take advantage of colors for achieving higher data density than black and white barcodes. This is obtained at the price of coping with chromatic distortions during decoding. In order to introduce the typical decoding process of a color barcode, we describe next the HCC2D code, which will be used as a paradigmatic example throughout the rest of the paper. We remark that most of the findings reported in this paper about color classification for HCC2D codes apply to color classification for other 2D color barcodes as well.

A. The HCC2D code

In this section, we describe our HCC2D code, a 2D color barcode which is made of a matrix of square color cells, whose color is selected from a color palette. Figure 1 illustrates samples of HCC2D codes with 4 and 8 colors.

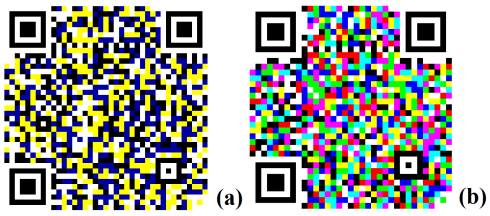

Fig. 1. Samples of the High Capacity Colored 2-Dimensional code (HCC2D): (a) 4 colors and (b) 8 colors. Figure taken from [5]. (Viewed better in color).

We have designed the HCC2D format with the main goal of increasing the data density while preserving the strong robustness to distortions of Quick Response (QR) codes. QR codes are black and white 2D barcode designed by the Japanese corporation Denso Wave which are quite widespread among

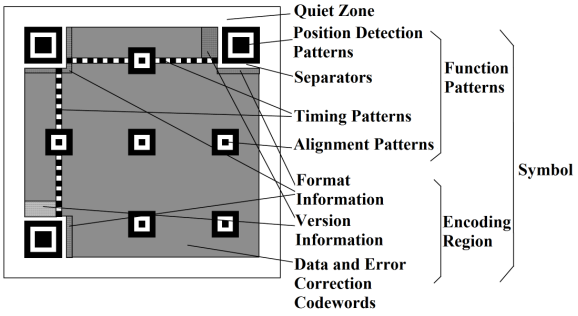

Fig. 2. Structure of generic QR codes and HCC2D codes, which inherit all function patterns of QR codes.

2D barcodes, because their acquisition process appears to be strongly reliable, and are suitable for mobile environments, where this technology is rapidly gaining popularity.

Structure of QR codes, and consequently, of HCC2D codes is illustrated in Figure 2, being composed of *Function Patterns* and *Encoding Regions*. The *Position Detection Patterns*, the *Alignment Patterns*, the *Timing Patterns*, and the *Separators for Position Detection Patterns* support the detection process in detecting the presence, the proper orientation and the correct slope of a code into an image. The *Format Information* describes the error correction level used in the code. As previosly introduced, the higher the correction level, the higher the redundancy and the reliability of the barcode reading process, but the lower the actual data density rate. The *Version Information* represents the code size, that is, the amount of cells (per side) making up the code. Note that the *Version Information* alone does not determine the final print out size (expressed in $inch^2$ or cm^2), which also depends on hardware parameters, that is, on the printing resolution and on how many printer dots make up each color cell. Finally the *Data and Error Correction Codewords* contains data plus redundancy.

We designed the HCC2D code preserving all the *Function Patterns*, the *Format Information* and the *Version Information* defined in the QR code. Maintaining the structure and the position of such patterns and critical information allows the HCC2D code to preserve the strong robustness to geometric distortions of QR code. Because the retrieval of the *Format Information* and of the *Version Information* is a crucial step during the decoding phase (it may led to reading failures) and its storage requirement is small, there is no significant advantage representing it by color cells. The most important changes are gathered in the *Data and Error Correction Codewords* area. The most noticeable difference with a QR code is that the modules belonging to the *Data and Error Correction Codewords* area are of different colors; in a HCC2D code with a palette composed of 4 colors each module is able to encode 2 $bit/module$, while 3 $bit/module$ are stored using 8 colors. Introducing colors in the *Data and Error Correction Codewords* area requires to address some issues, which we have described in details in [5]. Consider that during QR code reading only the brightness information is taken into account, while HCC2D codes have to cope with chromatic distortions during the decoding phase. Since the *Encoding Region* is made of color cells, the HCC2D decoder needs to know the complete color palette in order to decode the symbol. To consider the color palette as an *a priori* shared knowledge between encoding and decoding processes is not a reliable solution; this is because chromatic distortions would not be properly taken into account, arising differently in each printed and scanned image. The processing should be adaptive to each image for better performance. To make a parallelism with black and white barcodes, QR codes compute an adaptive threshold on each image for discriminating dark and light modules, rather than using static thresholds.

In order to ensure adaptation to chromatic distortions arisen in each scanned code, we have introduced in the HCC2D code an additional field, the *Color Palette Pattern*. This is because color cells of a *Color Palette Pattern* are supposed to be distorted in the same way color cells of the *Encoding Region* are. We make use of replicated color palettes either for cluster initialization or for training machine learning classifiers. Figure 3 illustrates *Color Palette Patterns* in HCC2D codes, located at the boundaries. Note that the *Color Palette Patterns* are not too close to the three *Position Detection Patterns* areas and are far away from each other, thus ensuring that they are robust to local distortion. Furthermore, *Color Palette Patterns* take only 2 rows and 2 columns from a symbol consisting of between 21 and 177 rows and columns, and thus, the overhead is small for high density barcodes.

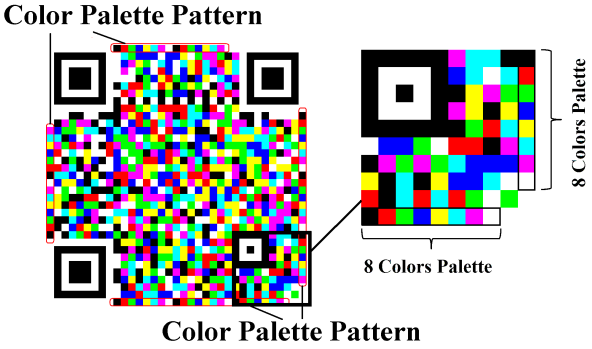

Fig. 3. The four *Color Palette Patterns* are pointed out in a HCC2D code using 8 colors. Figure taken from [5]. (Viewed better in color).

IV. Color Classifiers for 2D Color Barcodes

Since the printing and scanning processes introduce chromatic distortions in color barcodes, the decoding success rate depends on the capacity to correctly classify colors of barcode cells. A barcode cell is correctly classified if its original color (before printing) and the class assigned by the classifier to the cell (after scanning) corresponds to each other. A classifier is an algorithm that distinguishes between a fixed set of classes based on labeled training examples. Algorithms reading black and white barcodes may just use a threshold to separate the two classes (that is, dark and light elements), while cells of color barcodes need to be properly classified in many classes,

depending on the number of colors. We distinguish 4 or 8 classes (each representing a reference color) into which color pixels may fall, where each pixel is sampled from a cell of the 2D color barcode to decode. Each class reference color is associated with either a 2-bit sequence or a 3-bit sequence. The sequence length depends on how many bits are modulated into each barcode cell (as previously introduced, 4-ary color schemes encode 2 $bit/module$, while 8-ary color schemes encode 3 $bit/module$). Because no classifier is perfect, it is important to know whether a classifier is producing good results on real data sets.

A color classifier may have a training phase and a classifying phase. In the training phase, the classifier is provided with known samples. A known sample consists of a region in the barcode image containing the color to be learned and the corresponding label for that color. For every sample that is added during the training phase, the color classifier computes a color feature and assigns the associated class label to it. A color feature vector (to which a barcode cell is associated with) depends on the color space in which the image is encoded. Usually colors are defined in three dimensional color spaces. For instance, these could either be RGB (Red, Green and Blue) or YUV. The Y in YUV stands for "luma", that is brightness (for instance, black and white TVs decode only the Y channel of the signal). U and V provide color information and are "color difference" signals of blue minus luma (B-Y) and red minus luma (R-Y). Without loss of generality, assume that each color feature is a represented as a three-dimensional vector in the YUV color space, because the high correlation between RGB channels and the mixing of chrominance and luminance data does not make RGB a very favorable choice for color analysis and color-based recognition algorithms [13]. When all the trained samples (color feature with a label) are added to the classifier, we get a trained color classifier. After the training phase, barcode cells are classified into their corresponding color classes. In the classifying phase, the trained classifier is used on new observations (color features without labels). The classification engine calculates color features of unlabelled samples and classifies them, by associating a label (in our case, a color class) with each unlabelled color element. Once the classification is completed, the original bitstream (which was previously encoded in the 2D barcode) can be retrieved. This is made by concatenating bits from each bit sequence associated with a barcode cell, where the mapping between a barcode cell and a bit sequence is given by the classification output. For instance, without loss of generality, assume that a 2D color barcode is encoding 2 $bit/cell$ by using 4 different reference colors (e.g., black, cyan, magenta and white). Then, assume that each reference color is mapped to a binary sequence (e.g., black is mapped to $\{11\}$, cyan to $\{10\}$, magenta to $\{01\}$ and white to $\{00\}$). Under these assumptions, a dark cell carries the bit sequence $\{11\}$ whether the cell is labelled with the black class by the color classifier. Because a percentage of color cells is always misclassified in real scenarios, bit errors arise, and thus, original bit stream and decoded bit stream slightly differ from each other.

As previously mentioned, channel coding techiques are capable of correcting errors and restoring the original bit streams, under the assumption that the redundancy introduced in the encoding phase is enough. The main problem considered here is how much redundancy can be sufficient for 2D color barcodes. This depends on many parameters, including the algorithms used for color classification. In order to estimate the most suitable redundancy rate (RR), we implemented five different methods for color classification, each of them being representative of a general class of algorithms (minimum distance classifiers, decision trees, clustering, probabilistic classifiers and support vector machines), and measured their error rates. Next, we briefly describe these five algorithms.

A. Minimum Distance Classifiers (Euclidean distance)

Minimum distance classifiers assign unlabelled samples to classes which minimize the distance between unlabelled data and classes in the feature space. The distance is defined as an index of similarity so that the minimum distance is identical to the maximum similarity. We have used the Euclidean distance (in RGB, YUV, ...) for identifying similar colors (that is, colors with minimum distance), because it is one of the simplest and most popular distance measures. This can be taken as a basic reference method in our experiments: it is a very simple-minded method, and thus we expect all other methods to produce much lower error rates but to be much slower in their running times.

B. Decision Trees (LMT)

A decision tree is a classifier in the form of a tree structure, where each node is either a leaf node (which indicates the value of the target class) or a decision node, which specifies some test to be carried out on a single feature value, with one branch and sub-tree for each possible outcome of the test. There are a variety of algorithms for building decision trees; we have used the Logistic Model Trees (LMT), because they have been shown to be very accurate and compact classifiers. As in ordinary decision trees, a test on one of the attributes is associated with every inner node. Unlike ordinary decision trees, the leaves have an associated logistic regression function instead of just a class label.

C. Classification using Clustering (K-means)

Clustering is the task of assigning a set of objects into groups (denoted as clusters) so that the objects in the same cluster are more similar to each other than to those in other clusters. Hence, color cells are classified once clustering is completed. Clustering itself is not one specific algorithm, but the general task to be solved. It can be achieved by various algorithms that differ significantly in their notion of what constitutes a cluster and how to efficiently find them. We have used the K-means algorithm, which is an unsupervised learning algorithm that classifies a given data set through a certain number of clusters (exaclty k clusters) fixed a priori. Using the K-means algorithm, we can exploit the *a priori* knowledge about the number of colors in color palettes, so

that the algorithm generate exactly 4 or 8 clusters. The starting points (for centroid initialization) can be taken by averaging the series of color palettes.

D. Probabilistic Classifiers (Naive Bayes)

A probabilistic classifier is a function that maps an unlabelled sample to a distribution over class labels. There are a variety of probabilistic classifiers; we have used the Naive Bayes algorithm because it only requires a small amount of training data to estimate the parameters. A Naive Bayes classifier is a simple probabilistic classifier based on applying Bayes' theorem with strong (naive) independence assumptions. In simple terms, a Naive Bayes classifier assumes that the presence (or absence) of a particular feature of a class is unrelated to the presence (or absence) of any other feature. For example, assume that a color cell (in YUV space) is represented by luma (Y value) and by chroma (U and V values). Even if these luma and chroma values depend on each other, a Naive Bayes classifier considers all of these properties to *independently* contribute to the probability that this color cell is of a given color. The Naive Bayes classifier can be trained very efficiently in a supervised learning setting, using in our case a trained set of known samples taken from the color palette patterns.

E. Support Vector Machines (SVM)

Support vector machines (SVM) are supervised learning models, that is, machine learning tasks of inferring a function from labeled training data (in our cases, labelled color cells belonging to color palettes). A support vector machine constructs a hyperplane or set of hyperplanes in a high dimensional space (in our case, a three-dimensional color space such as RGB or YUV), which can be used for classification. Intuitively, a good separation is achieved by the hyperplane that has the largest distance to the nearest training data point of any class (denoted as functional margin), since in general the larger the margin the lower the error of the classifier. We have used the Sequential Minimal Optimization (SMO) algorithm for training support vector machines. This is because SMO efficiently solves the optimization problem which arises during the training, avoiding the use of time-consuming numerical optimizations.

V. Experimentation

We developed a prototype for generating and acquiring HCC2D codes. Even if we restricted our experiments to HCC2D codes only, most of the results (in relative terms) can be generalized to the color classification of any other color barcode. This is due the fact that our experiments focused only on the color classification task.

Barcode reading requires a detection and a decoding phase, where color classification is only one part of the decoding phase. The risk is that errors arising in steps other than color classification may affect the experimental results in an unpredictable way. To prevent this, we proceeded as follows. Even if many factors other than the classification algorithm affect the experiment (e.g., the specific hardware involved, routines for detecting or for sampling color cells which are specific to HCC2D codes), their impact has been kept constant through the use of a common set of barcode scans as input for each classifier, along with the use of common routines for every processing step other than color classification (such as image processing, barcode detection or grid sampling routines). For this reason, even if results of our experiments (in absolute terms) depend on the hardware involved and on the HCC2D code, the relative performance of the algorithms considered seems to be of more general extent.

A metric that we adopt is the byte error rate (ByER). By definition the byte error rate is the ratio of the number of incorrectly received bytes compared to the total number of bytes transmitted. It depends on characteristics of the channel such as the signal-to-noise ratio (SNR) at the reveiver and on the accuracy of the "sensors". In our case, the unreliable channel is a printing and scanning channel, while the "sensors" are represented by the classification algorithms and their accuracy is our parameter of interest. We performed an experiment for computing performance statistics for byte error rates (ByER) and computational time of classifier algorithms. By computing these error rate statistics, we are able to identify the most effective color classifier and the most suitable redundancy rate (RR) for it. This allows us to optimize the data rate (DR), that is, the actual data density of color barcodes.

A. Experimental Set-up

We collected 100 barcode scans which make up the sample upon which performance statistics (such as the mean error rate) are computed for each of the 5 methods. Our experimental set-up is as follows:

- We collected 100 barcode scans from real-life applications. Each barcode underwent a real printing and scanning process (i.e., no artificially distorted barcodes).
- Each scan was decoded by each one of the 5 classifiers.
- Color barcodes were printed and scanned at 600 dpi.
- The print out size of each code was 1 square inch.
- The size of each color cell was 4×4 printer dots.
- Each code was made up of 149×149 cells (out of which we had 512 known color cells to use for training classifiers and 19,720 color cells to classify).
- Each code stored 4,930 bytes in 1 square inch, considering data and redundancy from error correction.
- Each code used 4 colors for encoding 2 $bit/module$.
- Color features were expressed in the YUV space, because the explicit separation of luminance and chrominance components makes this colorspace more attractive for color analysis.
- Codes stored different input data so that results were not dependent on the specific barcode instance.

All our experiments were run on a low-end machine equipped with OS Linux Debian 6.0 running on a 1.73 GHz Intel dual core with 2 GB RAM. Documents were printed and scanned on low cost color laser multifunction printers.

TABLE I
SUMMARY STATISTICS FOR BYER CORRESPONDING TO EACH OF THE STUDIED ALGORITHMS.

	Mean	99% Confidence Interval for Mean	Standard Deviation	Standard Skewness	Standard Kurtosis
Euclidean	0.0956	0.0956 ± 0.0160	0.0610	5.8994	4.8087
LMT	0.0851	0.0851 ± 0.0177	0.0675	7.4592	6.9833
K-means	0.0454	0.0454 ± 0.0097	0.0369	5.7278	4.0926
Naive Bayes	0.0621	0.0621 ± 0.0124	0.0473	8.0778	8.9108
SVM	0.0809	0.0809 ± 0.0131	0.0500	3.8256	0.6889

B. Experimental Results

We now turn to the experimental results, by starting with the analysis of the byte error rates (ByER). We remark that in the application at hand, the byte error rate (ByER) is more meaningful than the bit error rate (BER). This is due to the fact that 2D barcodes use block error correcting codes, such as Reed Solomon codes (rather than codes protecting against single bit errors), since they have to withstand accidental damages such as ink spots, affecting a contiguous portion of the barcode.

A Box-and-Whisker plot for ByER data is depicted in Figure 4. Box-and-Whisker plots are convenient way of graphically depicting groups of numerical data through their five-number summaries: the smallest observation (sample minimum), lower quartile (Q1), median (Q2), upper quartile (Q3), and largest observation (sample maximum). Quartiles are the three points that divide the data set into four equal groups, each representing a fourth of the population being sampled. The red cross indicates the mean. Outliers, which are observations that are numerically distant from the rest of the data, are depicted too. They are often indicative either of measurement error or that the population has a heavy-tailed distribution.

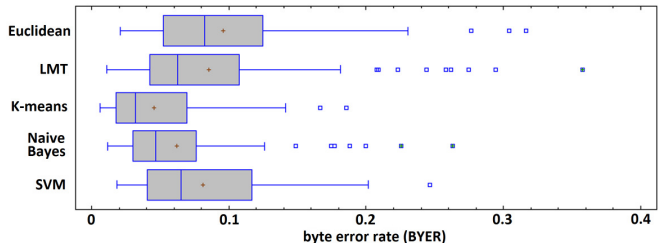

Fig. 4. Box-and-Whisker plot indicating the smallest observation, lower quartile (Q1), median (Q2), upper quartile (Q3), and largest observation. (Viewed better in color).

The shape of each distribution is asymmetric and with several strong outliers. Table I show summary statistics for ByER corresponding to each of the studied algorithms. It includes measures of central tendency, measures of variability and measures of shape. It turns out that the most effective algorithm (with the smallest mean and standard deviation) is the K-means clustering algorithm. The ByER of K-means is 4.54% on average; this sample mean, which has been computed on a basis of 100 input images, is close but different from the true mean of the distribution. We have computed the 99.0% confidence intervals for the mean of each ByER distribution, which are reported at the corresponding column in Table I. The classical interpretation of these intervals is that, in repeated sampling, these intervals will contain the true mean of the population from which the data come 99.0% of the time. In practical terms, we can state with 99.0% confidence that the true K-means ByER is somewhere between 0.0357 and 0.0551. Even if these intervals assume that the population from which the sample comes can be represented by a normal distribution (which is not the case here), the confidence interval for the mean is quite robust and not very sensitive to violations of this assumption. Confidence interval for the standard deviation would be quite sensitive, and thus, they are not computed. Of particular interest here are the standardized skewness and standardized kurtosis (reported at the last columns of Table I), which can be used to determine whether the sample comes from a normal distribution. Values of these statistics are outside the range of -2 to +2, indicating significant departures from normality. Figure 5 illustrates percentiles of ByER distributions. Percentiles are values below which specific percentages of the data are found.

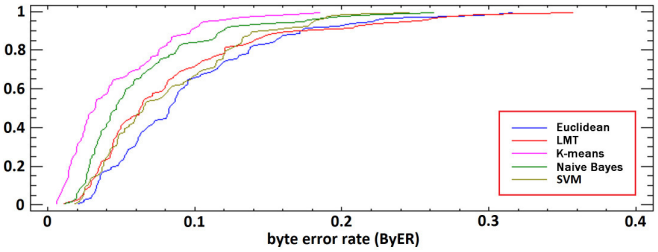

Fig. 5. Percentiles for ByER data of each algorithm. (Viewed better in color).

We can interpret the percentile plot as follows. Consider the 90-th percentile (the value below which 90% of the cases fall) for K-means ByER, its value being 0.0971. This means that 90 barcodes out of 100 would be decoded if the symbols were robust to ByER up to the 90-th percentile ($\approx 9.71\%$). If the K-means algorithm is used for color classification, we may state that $Prob(ByER < 10\%) \approx 90\%$, even if this is just an estimation of the probability on the basis of ByER data collected. Consider that if locations of errors are not known in advance, then a Reed Solomon code can correct half as many errors as there are redundant symbols. For this reason, in order to achieve a success rate of 90%, the redundancy rate (RR) should be around twice the 90-th percentile ($RR \approx 19.42\%$). Data Rate (DR) is therefore reduced to the 80.58% of the overall capacity. Because HCC2D codes are capable of storing 4,930 $bytes/inch^2$ (data plus redundancy), this would results in an effective data density of 3,972 $bytes/inch^2$ with a success rate of 90%. Table II shows this trade-off between data density and reliability (in terms of success rate) for each method. Error rates to tolerate for achieving the target success rate are illustated for three levels (80%, 90% and 95%), along with the corresponding data rate (DR), which is expressed as ratio of data bytes to overall bytes (data plus redundancy bytes). Redundancy rate (RR) is omitted being exactly twice

TABLE II
PERFORMANCE AS FUNCTION OF SUCCESS RATE FOR BARCODE READING.

	Error Rate to Tolerate ($ByER$)	Effective Data Rate (DR)	Effective Data Density $bytes/inch^2$
	85% Success Rate		
Euclidean	0.1547	0.6906	3,404.65
LMT	0.1399	0.7202	3,550.58
K-means	0.0837	0.8326	4,104.71
Naive Bayes	0.1081	0.7838	3,864.13
SVM	0.1320	0.7360	3,628.48
	90% Success Rate		
Euclidean	0.1723	0.6554	3,231.12
LMT	0.1717	0.6566	3,237.03
K-means	0.0971	0.8058	3,972.59
Naive Bayes	0.1190	0.7620	3,756.66
SVM	0.1463	0.7074	3,487.48
	95% Success Rate		
Euclidean	0.2223	0.5554	2,738.12
LMT	0.2511	0.4978	2,454.15
K-means	0.1126	0.7748	3,819.76
Naive Bayes	0.1755	0.6490	3,199.57
SVM	0.1818	0.6364	3,137.45

the ByER to tolerate (because of the Reed Solomon code). Finally, barcode data density is expressed in terms of data bytes per square inch. In order to state that K-means outperforms the other 4 algorithms, we did not just rely on data shown in Table II; we have addressed the statistical significance of our experimental results. Statistical hypothesis testing is used to determine whether an experiment conducted provides enough evidence to reject a null hypothesis. We are interested to reject the null hypothesis for which there is no (statistically significant) difference among the ByER distributions related to the 5 classifiers. We can consider ByER distributions two-by-two as paired samples. "Paired"samples means there are two measurements on each sample unit, e.g., measurements on the same subject before and after an intervention. This is the case here, because there are measurements on the same barcode scan before and after the "intervention" (i.e., substitution of the color classifier). We have run paired tests on these samples such as the sign test and the Wilcoxon signed-rank test, for testing the null hypothesis that there is "no difference in medians" between the distributions.

The result of each test is denoted as P-value, which is the probability of obtaining a test statistic at least as extreme as the one that was actually observed, assuming that the null hypothesis is true. If the P-Value is under 0.01, the medians of the samples are significantly different at the 99.0% confidence level. For instance, running the Wilcoxon test on the Naive Bayes ByER distribution and on the K-means ByER distribution results in a P-Value of $1.03 \cdot (10^{-9}) \ll 0.01$. Running paired tests on ByER distributions taken two-by-two as paired samples, we have rejected all null hypotheses but one; we can say nothing about the performance difference between logistic model trees and support vector machines. Values computed on 100 barcode scans suggest that SVM has smaller average ByER than LMT, but the difference was found not to be significant (P-value resulting from the Wilcoxon signed-rank test is $0.7413 \gg 0.01$ and from the sign test is $0.6170 \gg 0.01$). We cannnot use more powerful statistical tests (parametric tests such as the t-test) because the normality assumption would be violated. In summary, we can state that, at the 99.0% confidence level, K-means outperforms Naive Bayes, which in turn outperforms support vector machines and logistic model trees, which in turn outperform Euclidean classifiers.

Finally, we address the computational overhead introduced by the color classifiers considered. We stress that the overall running time is important, since in many applications a color barcode can be decoded on low-end devices, such as mobile phones or tablets. Figure 6 illustrates the Box-and-Whisker plot for computational time distributions (the sample size is 100 elements for each method). As expected, the Euclidean classifier is the simplest and fastest algorithm among the studied methods; it is capable of classifying 19,720 color cells in a few milliseconds. In our experiments, the K-means algorithm was also fast (order of milliseconds), while all other classifiers had a much higher computational overhead, as they required up to several seconds for the classification phase.

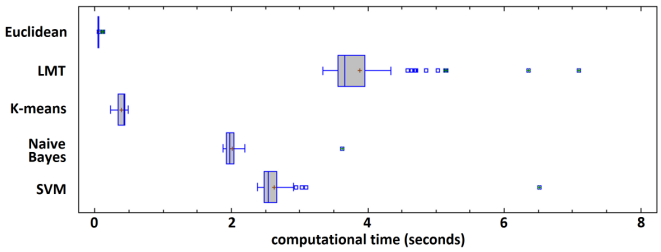

Fig. 6. Box-and-Whisker plot for computational time. (Viewed better in color).

C. Experiments with Mobile Phones

In this section we extend the experiments carried out previously on desktop scanners to other devices, such as mobile phones. The experimental setup is the same as in our previous experiment except that we use mobile phones (such as Samsung Galaxy and Google Nexus 4) for reading color barcodes and that we increase the print out size to 1.5 inch per side (with a cell size of 6×6 printer dots), in order to allow the camera focus to work properly.

TABLE III
SUMMARY STATISTICS FOR BYER DATA RELATED TO BARCODE READING BY MOBILE PHONES.

	Mean	99% Confidence Interval for Mean	Standard Deviation	Standard Skewness	Standard Kurtosis
Euclidean	0.1065	0.1065 ± 0.0382	0.1457	7.4383	5.4823
LMT	0.0851	0.0851 ± 0.0294	0.1122	9.3484	11.380
K-means	0.0832	0.0832 ± 0.0454	0.1729	15.406	31.354
Naive Bayes	0.1293	0.1293 ± 0.0329	0.1255	6.8177	6.0854
SVM	0.1023	0.1023 ± 0.0266	0.1016	8.1937	10.373

Table III reports, with exactly the same format used in Table I, the results of our experiments with mobile phones. It can be seen that the average error rate and the standard deviation are larger (in absolute value) for mobile phones than for desktop

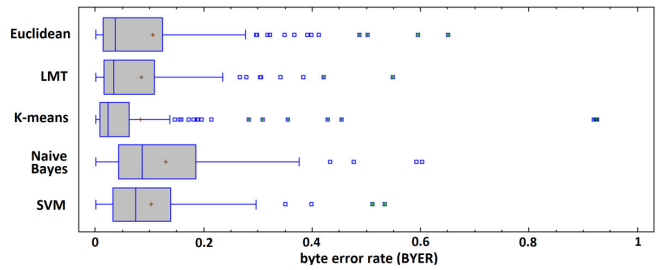

Fig. 7. Box-and-Whisker plot for ByER data related to barcode reading by mobile phones. (Viewed better in color).

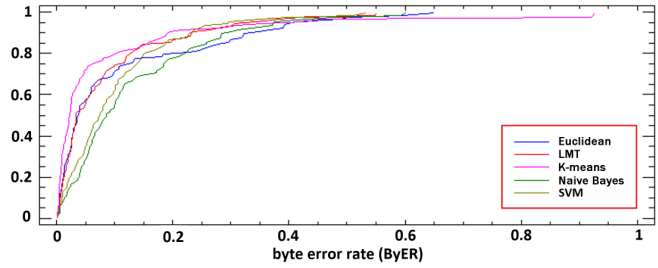

Fig. 8. Percentiles for ByER data related to barcode reading by mobile phones. (Viewed better in color).

scanners. This is due to the fact that desktop scanners have controlled light intensity, while pictures taken from phone cameras present a much larger variation in light conditions.

Beside the absolute values of error rates, which are dependent on the specific devices used for printing and scanning, it can be seen that, in any case, the choice of the classifier has a non-negligible impact upon the error rate distribution. Figure 7 illustrates, similarly to Figure 4, the Box-and-Whisker plot for byte error rate in mobile environment. The K-means algorithm is still the most effective, even if not as effective as in the previous experiment, because there are few cases in which the initial centers do not allow K-means to converge to the optimal solution. This situation occurs especially in case of strongly non-uniform illumination of the barcodes. Analogously to Figure 5, Figure 8 illustrates percentiles of ByER distributions, showing that the K-means curve tends to perform quite well in comparisons with the other curves, except for the fact that there are few observations with high error rates (the far right of the curve) in which the algorithm does not converge to the solution.

VI. Conclusions and Future Work

Our work addressed the trade-off between reliability and data density in 2D color barcodes, performing an experimental study in both desktop and mobile environments. The experimentation showed that the impact of the choice of the color classifier on the error rate is significant and that more complex classifiers do not necessarily achieve better accuracy in classifying color barcode cells. By means of this study, we identified the most suitable ways to convert analog color cells to digital bit streams. We have so far used the same algorithms in both desktop and mobile environments; those methods were found to be more suitable for desktop settings than for mobile scenarios.

For future work, we see a number of interesting directions where our study maybe extended, in particular for mobile devices. An important extension of this work will be to design specific approaches to decode color barcodes acquired by mobile phones. Optimizations for the mobile scenario will attempt to minimize the error rate by taking into account models of light variation for addressing the problem of strong non-uniform illumination, which is significant in mobile scenarios. Furthermore, this study could be extended to barcodes that use 8 instead of 4 color classes.

***Abstract*—In the last decade the need for portable Surface Plasmon Resonance (SPR) biosensors capable of on-site simultaneous multiple assays increased steadily. Several devices are available affected, however, by limitations in terms of costs, size, complexity and portability.**

A compact low-cost SPRi biosensor based on a novel method for multi-analyte detection is presented.

The prototype consists of a nanohole array biochip integrated with a compact optics and an elaboration system. A CMOS image sensor captures reflected light from the biochip surface irradiated by a 830 nm LED. The entire system is managed by an ARM9 processor.

The biosensor was able to detect a ~10^{-5} RIU change in the refractive index without analyte receptors at a glycerol concentration equal to 0.2%. Results are available in 14 seconds on LCD display and immediately stored to external SD memory. Preliminary experiments confirmed the strong biosensor's usability in a wide range of applications and fields.

I. Introduction

THE last 30 years have witnessed a rapid growth in the use of biosensors in both research and practical applications. Molecular biology, biotechnology together with genetic, protein and pharmaceutical engineering are the most common applications fields of these devices. This trend is due to technological innovations that increased their sensitivity, versatility and integrability within microprocessor-based electronics. However, most of these powerful instrumentations are only used in specialized laboratories because of their high cost. In particular the biosensors based on Surface Plasmon Resonance (SPR) have been developed into a very useful technology applications due to their high sensitivity but the majority of this devices are only for research use [1]. The Surface Plasmon Resonance is an optical phenomenon that offers specific advantages in bio-molecular studies. First of all, it is label-free technique that allows real-time direct detection of molecular binding, enabling the determination of their concentration during this interaction without the need for fluorescence or radioisotope labelling. Moreover, it can be applied for kinetic measurements and to perform simultaneous assays on the same biochip (SPR *imaging*-SPRi). Antibody–antigen interactions, peptide/protein–protein interactions, DNA hybridization conditions, biocompatibility studies of polymers, biomolecule–cell receptor interactions and DNA/receptor–ligand interactions have been well analyzed by means of this approach [1]. However the complex fabrication procedure to make the measures more accurate and fast, increases their cost (more than 10,000$) and their size (most of them are benchtop instruments). This limited the diffusion of SPR biosensors outside the industrialized countries, hampers significant improvement of hygiene and environmental conditions. We present a novel portable SPRi biosensor based on a nano-structured crystal biochip developed by [2]. It is a multi-parametric system for biological and molecular interaction monitoring using the Localized Surface Plasmon Resonance (LSPR) phenomenon. Our device allows to detect the presence and the amount of specific target molecules (called *analytes*) in a liquid samples without the use of an external computation device (like computer). The potential applications fields of this instrument are enormous: biochemical and chemical assays in medicine for diagnostic and monitoring of the patients, for water and soil pathogen detection, for process control in pharmaceutical chemistry and drug and food monitoring for toxins detection. This biosensor allows the acquisition of the light reflected from crystal's surface irradiated at a specific wavelength; the crystal is a biochip in which micro-spots of antibodies deposited on the surface are sensitive to different analytes to be identified in the sample. The estimate of the presence and concentration of the searched analytes is available in about 14 seconds on a LCD display and stored in a MicroSD card. This work will focus on the development of the prototype together with the implementation choices to realize a compact low-cost and low-power consumption SPR device. The Linux kernel-based modules conceived for the images acquisition and elaboration are also discussed with a novel method to identify analytes presence and amount. Finally, the detection capabilities of the device are provided

978-83-60810-53-8/$25.00

measuring bulk refractive index changes in glycerol solutions at different concentrations.

II. Integrated SPR System Available

The most common commercial SPR biosensors in the last decades are generally based on the Kretschmann's configuration where a laser source radiates a glass prism covered with a thin metal film. However this simple technique features sensitivity limitation for low molecular weight analytes [3]. The technology improvement allowed new approaches to SPR for increase the sensitivity (plasmon waveguide resonance, channel parallel array, etc...) but this made biosensors more expensive with less attention to an integrated, portable, low-cost and low-power consumption device.

Only recently the market geared toward the fabrication of compact instrumentations for the simultaneous detection of one or multiple analytes and this implied the miniaturization of each system's components and the develop of new SPR technology solutions.

The most best known example of marketed compact SPR devices is Spreeta (Texas Instruments, USA). These instruments measure approximately 1.5 cm x 0.7 cm x 3 cm and consist of a plastic prism assembled on a PCB that contained a infrared LED, a linear diode array detector and a non-volatile memory [4]. The LED light beam through a plastic sheet polarized, strikes a glass chip coated with a gold layer. The SPR waves produced are captured by the diode array detector. Spreeta cost is about 50$ [5] with a resolution of $5x10^{-6}$ RIU [4]. Spreeta, however, requires an integration with external fluidics systems and suitable elaboration units to manage acquisition and analysis. Another limitation is due to temperature which significantly affects the refractive index, requiring a control system to keep it constant.

Many research works exploit Spreeta technology to develop compact multi-analyte SPR instruments. Chinowsky's describes a semi-automatic 24-channel system for toxin identification, called “SPIRIT”. This lunchbox-size instrument weighs approximately 3 Kg and is made by eight replaceable three-channels Spreeta 2000, a 1 MHz analog-to-digital converter and a DSP microcontroller [6].

The device also contains a touch-screen LCD display and a flash memory for data storage, however needs a PC connection for long-term reaction monitoring and displaying of all the 24 channels.

Another low cost biosensor based on Spreeta is described by Hu et al. in 2009. This bioanalyzer uses a tree-channels Spreeta TSPR1K23 and three processors for temperature control, data analysis and display control [7]. Similarly to the previous one, this instrument needs a high precise temperature sensor and uses a PID algorithm control for temperature regulation. Only three analytes for sample are detectable and its considerable weight makes it unsuitable to perform on-site assays also in unfavourable environments.

In addition to Spreeta devices, different approaches can be considered to optimize the Kretschmann configuration. For example, in 2010 Cai et al., developed a portable SPR biosensor based on the image scanner chip LM9833. A wedge shape laser beam radiated a cylinder prism and the reflected light was captured by a CCD camera driven by the image scanner [8]. A single board industrial PC was used to provide the analysis results featuring about 1 Kg weight. The refractive index sensitivity was about 6×10^{-5} RIU, however this device required 30 minutes of baseline stabilization before each analysis.

A palm-size biosensor based on light source modulation was developed by Shin et al. in 2010. The beam of a diode laser was modulated by a rotating mirror and the reflected light was captured by a CMOS [9]. The refractive index resolution was quite interesting (about $2.5x10^{-6}$ RIU at a 3% glycerol concentration) but this device requires temperature control and PC for elaborating signals via LabVIEW code. It also suffers from mechanical solicitations that require an highly synchronization between the frame rate of the CMOS image sensor and the revolution speed of the mirror, to limit the noise level due to the present artefacts that compromise the portability.

Another solution has been adopted by Wichert et al. His team used the Plasmon Assisted Microscopy of Nanoobject (PANOMO) technique with FPGA technology and CCD camera. However it allows to detect only specific viruses [10].

In parallel to Kretschmann-based systems, optical fibers and waveguide structures have been used to fabricate miniaturized biosensors (Tzyy-Jiann et al., 2004). The use of waveguides is similar to Kretschmann configuration since by coating the fiber with a metal film, each reflection of light, corresponds to the reflection spectrum of a Kretschmann configuration. However this solution requires a careful choice of the fiber type and complex design and assembly that increase fabrication costs [11].

Another technique uses diffraction gratings to couple the plasmon resonance with the optical wave. In 2009 a 4-channel compact biosensor has been presented by Piliarik et al. [12] and one year later Vala and his team developed a device capable of simultaneous detection of 10 analytes [13]. The beam reflected by the grating is collimated by lens and captured by a CCD camera that evaluate the average over 50 frames by onboard electronics and transmits it via USB. Although featuring both a high resolution ($3x10^{-7}$ RIU and $6x10^{-7}$ RIU respectively when the RI index change of a NaCl water solution is 0.00312 in both cases) and compact size they need an external PC for elaborating images.

In the last years the significant progress in nanotechnology have led to remarkable results in the study of Localized Surface Plasmon Resonance (LSPR) phenomenon. The use of nano-scaled metallic structures provides a new route to overcome the limitations described before, allowing to perform SPRi (see Section 3).

We describe here the design, implementation and characterization of a new SPR imaging biosensor based on LSPR with a novel efficient analysis method overcoming temporal light variations and noise. This approach considers two control regions in the sensible area of the nanostructured

biochip and one macro area where the sample will be injected. The entire system doesn't require the use of external PC for the elaboration and does not have moving parts or additional temperature control sensor.
The goal of our research is to develop a palm-size low-cost instrumentation that allows relatively untrained user to perform rapid multiple simultaneous assays outside of specialized laboratory for a wide range of applications.

III. Principles of Local Surface Plasmon Resonance and imaging

Surface plasmons (SP) are longitudinal charge density waves along the interface between a metal and a dielectric [14]. When a P-polarized beam radiates the interface between the media at a specific resonant angle and the wave component parallel to the surface matches the wavevector evanescent component of the plasmonic mode, it can resonantly couple and excite the mode. The coupling to the plasmonic mode results in an energy loss and then in an intensity reduction of reflected light.
In a SPR biosensor, receptor molecules are chemically immobilized on the metal surface. Therefore, when the target substance diluted in a liquid sample reacts with the receptor, a change in the resonance conditions is observed. Analyte/receptor reaction produces a refractive index change close to the surface which can be related to analyte concentration [14]. Typically, SPR system maximum sensitivity is about 10^{-7} RIU [15].
The rapid development of nanotechnologies, stimulated the study of the physical properties of metallic nanostructuctured, whose optical response can be exploited to improve surface plasmon resonance technique.
Metallic nanostructures support charge density oscillations called *Localized Surface Plasmons* (LSPs). Metal conduction electrons can be excited through a light beam to a collective oscillation state with a specific resonant frequency that depends on the size, shape, composition, dielectric properties of the material and spatial distributions of nanoparticles [16, 17]. Haes and Van Duyne, in 2004, demonstrated that LSPR has a sensitivity which is approximately equivalent to traditional SPR techniques. As a consequence, SPR systems can be miniaturized without significant sensitiveness loss.
The strongly dependence on the type of metal, shape and size of nanostructures, pushed researchers to identify the optimal design improving optical sensing.
In the last 10 years, significant results have been reached: basically, two possible approaches can be exploited.
In the first, metallic nanoparticles are immobilized on a glass substrate, while in the second one a glass substrate is covered with a metal thin film in which a periodic array of nanoholes is carried out [18]. A significant difference between these structures was explored in 2009 by Parsons et al. who demonstrated that the optical response of nanoparticles is independent of interparticle separation, while the response in periodic subwavelength nanohole arrays is largely dependent on interhole separation [19]. In particular, experiments highlighted that the peaks of transmittance spectrum were correlated to the period between nanoholes and that the amount of transmitted light was greater than that predicted by the classical theory. This phenomenon is called *Extraordinary Optical Transmission* (EOT) effect [20].
The possibility of producing nanostructured plasmonic surfaces with versatile and simple techniques such as lithographic one, makes this approach more compatible with the SPR imaging method.
An imaging SPR biosensor allows to detect multiple types of molecules simultaneously on a single chip. The binding interaction between the receptor substances attached to the metal surface and the molecules to be detected is monitored by a CCD or CMOS camera. The simplicity of the entire structure with no moving parts and the use of nanoholes array structure allows to overcome the difficulty to develop a multi-channel efficient biosensors for high-throughput analysis [18].

IV. Instrument design

According to the previously described state-of-the-art, our device combined the high performance of nanohole biochip with an embedded elaboration system to realize a new portable SPRi biosensor.

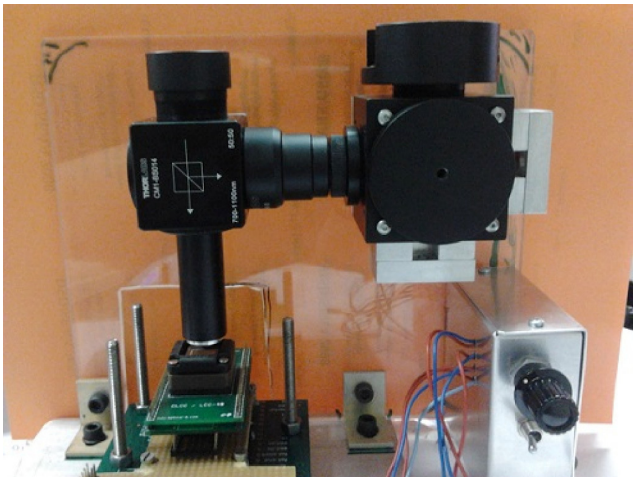

Fig 1. The biosensor prototype

The developed prototype showed in figure 1 is composed by two main parts: a bio-sensing surface with optical set up and an electronic unit for images acquisition and data elaboration.

A. Bio-sensing device

In a typical EOT biosensor, a collimated light beam is focused on the sensing region and the reflected light is captured by a spectrometer.
Many researches about EOT sensors performed by [21, 22, 23] demonstrated that their refractive resolution measured is similar to conventionally SPR system sensitivity (~10^{-6} RIU).

For our prototype we used a nanostructured biochip realized by [2] in 2011. Its sensitive surface is composed of an nanoholes array embedded in a gold film [2].
The chips were produced through a colloidal lithographic technique: a glass substrate was covered by plasma polymerized poly-acrylic acid via plasma enhanced chemical vapour deposition (PE-CVD) and a subsequent layer of polystirene beads (PS) are deposited on the top of the ppAA. In order to form a grating structure of a regularly spaced pillars, the layers were exposed to oxygen plasma *etching*. A gold layer is deposited on the nanostructure by vapour deposition to fill-in the gaps between pillars. Then, the residual PS mask is removed using lift-off by an ultrasonic bath in ultra-pure water. The obtained biochip features periodic gold cavities with shapes that widen to their bottom. The opening width is in the range of 50-250 nm, the bottom of 100 to 450 nm with a cavity periodicity of 200 to 1000 nm [2].
A recent work performed by Giudicatti et al. shows that this particular asymmetric pillars geometry increased the electric field in the cavities where the analytes receptors are located, contributing to strengthen the EOT effect and increasing the sensitivity in the order of 10^{-5} RIU [2].
Furthermore, the reflectance measured from the glass side of the biochip is sensitive to the refractive index at the opposite side. This characteristic allows to measure the optical

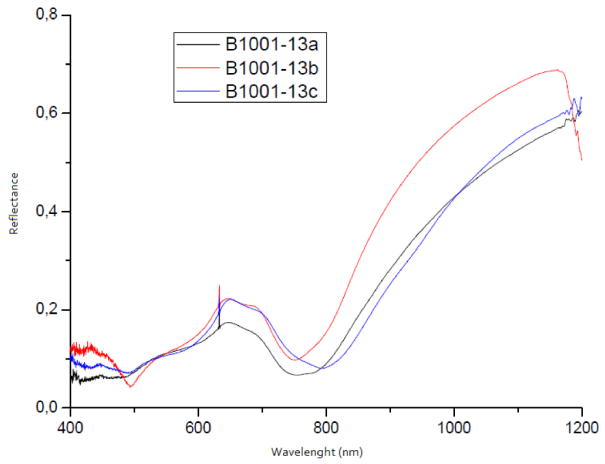

Fig 2. Reflectance spectra of different biochip used on trials. The minimum of reflectance is located in the 700-850 nm region.

response without expensive optical apparatus and collimated light source [24].
We studied the biochip reflectance spectra to identify the correct signal region where the resonance occurs. The trend showed in figure 2 highlights that the sensible region is located between 700 and 850 nm. Accordingly to this study we chose a LED light source (Vishay TSHG8200 IR LED) with 830 nm wavelength peak.
The light beam passes through one cube beamsplitter (CM1-BS015 by Thorlabs Inc.) and an achromatic lens (AC127-025-b by Thorlabs Inc.) to ensure the proper uniform irradiation of the sample minimizing aberrations. Run-time, the sensor is orientated so as the light beam illuminates the cavities from the widest bottom side while the detector captures the reflected light as shown in fig. 1.
The simple lithographic techniques together with no complex optics required allow the biochips mass production, providing an efficient solution for low-cost SPR biosensors fabrication.

B. *Electronic unit*

The electronic platform is composed by the image detector and the elaboration system. For capturing the reflected light of the biochip surface, we selected an APS CMOS. Since 1995, the increasing interest in CMOS image sensors was related to their design flexibility, reduced costs and low power consumption. The Active Pixel Sensor (APS) CMOS differs from the traditional passive CMOS for its robustness to noise due to the pixel amplification. Studies demonstrated that APS CMOS performance is comparable to their CCD equivalent [25]. We choose the MT9M001C12STM (Aptina Corporation), a monochromatic 1024x1280 pixel APS CMOS with a quantum efficiency (QE) suitable for our purposes. A 10 bit onboard analog-to-digital converter (ADC) codifies each pixel directly to the elaboration unit responsible for image processing and controlling the sensor via I^2C protocol.
In particular this unit acquires each image by the sensor, elaborates them, shows the analysis results on a LCD display and stores all the information on a MicroSD. This kind of approach requires a low power consumption and low costs flexible architecture for the portability and robustness of the instrument. For these reasons we selected the ARM9 family (AT91SAM9260 Atmel Corporation). The processor is mounted on the SAM9-L9260 development board developed by Olimex Ltd. The board features 64 MB SDRAM and 512 MB Nand Flash, an Ethernet 100 Mbit controller and a SD/MMC card connector directly linked to the processor.

V. Software platform

The primary tasks of the realized software platform are to ensure the communication between all the devices components, run the analyte detection algorithm and interact with the end user for the trials configurations and results visualization. These services must be managed by a specific software designed to optimize the performance but easily modifiable to add or change functionalities.
Since many years Linux has become an efficient solution to perform these tasks. It is a Unix-like, modular and multitasking operating system that supports a wide range of devices and configurations [26]. Furthermore, the open-source code availability allows software designers to modify the code according to their own needs improving costs and efficiency.
A typical Linux operative system scheme is a monolithic kernel where user applications run in the user space and operate on a virtual address to protect the internal memory.

The users program cannot directly access the system hardware but can request services to kernel by primitive system calls.
A specific *bootloader* at the starting time, initializes the hardware, defines the memory space map, enables the MMU (Memory Manage Unit) if present, and configures the processor for loading the operating system's kernel.
In our case, the onboard bootloader U-boot (http://www.denx.de/wiki/U-Boot/SourceCode with the Olimex board patches available on https://www.olimex.com/Products/ARM/Atmel/_resources/u-boot-olimex-patches-20090717.tgz) has been used to initialize the ARM9 processor.

A. Linux-based Operating System

The basis of our prototype is a minimal operating system called SSW realized by A. Rubini in 2010 and release under GNU General Public License (GPL). It is a small Linux-based operating system derived from THOS (www.gnudd.com/wd/thos.pdf). It is conceived for several family processors that we modified and extended to include the biosensor configuration and management.
The SSW operating system uses ARM9_v5 architecture composed by the MMU initialization, exceptions handlers, a simple I/O model, the module interface, and the tasks scheduler.
The Memory Management Unit controls the memory access and translates virtual to physical addresses. In our operating system the 4 GB virtual memory is divided in 1 MB sections with no cache [27].
The ARM exceptions are implemented through a vector table with branch instructions to specific code that saves registers and performs the right operations. The seven types of exceptions supported drive the processor in specific privileged modes accessing to different registers, stack and handler.
The kernel modules are initialized through a suitable initcall routine. At the system boot, modules set up is performed according to a specific hierarchy. At first, the modules with no dependencies like the serial port and the interrupt controller. Then, the architecture modules like the memory controller and timers, the peripheral devices and lastly the tasks modules.
The interface to modules is defined by two suitable macros *request()* and *provide()*.
The application programs that use modules can be activated periodically or not. A simple Round Robin scheme was implemented for the tasks scheduling. The tasks are kept in two doubly linked lists: one for the running ones and one for the idle ones. The initialization function prepares the first set up parameters (activation time, periodic execution or not, other parameters) and put the task in the idle list, from which it will be selected according to the Round Robin scheduling. This approach is a simple timeline-based scheduling where the system design chooses the activation time and period for each task. The scheduler temporization is implemented using timer interrupts. Specifically, a processor timer is programmed to generate an interrupt signal every 10 ms.

B. Biosensor device drivers and application

We extended the previously described operative system with an hierarchical collection of modules and drivers that use the simple GPIO pins to peripherals management and an application program to allow the biosensor utilization. The AT91SAM9260 configuration drivers, the acquisition interface for the image sensor, the LCD display and SD/SDHC modules are implemented using the minimal hardware and configuration required. This approach assures the software reusability with different hardware or other Linux-based operating systems with the possibility to easily add or change functionalities.
The biosensor application program realized configure the initial parameters of the biosensor, sets the trials periodicity and the number of images acquired, invoke the modules needed and provide to the end users the analysis results.
The main part of the described software platform is the communication management between the board, the image sensor, the display and the external SD memory.
The image sensor device uses I^2C protocol to read and write the internal sensor registers. These registers control various features like black level calibration, integration time for the pixels and readout modes of the sensor. The data output is controlled by three different signals: the pixel clock, the line valid and the frame valid.
The image data is read out sequentially. Each 10 bit pixel is ready on the falling edge of the pixel clock signal when both the line valid and frame valid are activated.
We developed specific modules for the images acquisition using the GPIO processor interface via a simple PWM signal. Each image is elaborated in about 4 seconds by the application software that makes available on LCD display the trial results and stores on SD memory in 14 seconds. A FAT16 partition is created on external memory during the application software boot to neatly memorize them on specific files.

VI. Analytes detection method

The goal of the biosensor is to provide a robust detection of the presence and amount of the target analyte on a liquid sample. This required a fast and efficient identification algorithm. The conducted research about the raw pixels of the images has highlighted temporal fluctuations of the light intensity acquired from the sensor that significantly influences the analysis results. In particular, the main effect is an upward trend of the pixels grey level average observable in figure 3.
Experiments conducted with different black level calibration, integration times and LED sources, demonstrated that not homogeneous light diffusion and photons accumulation on the sensor during long time exposition are the major causes of this phenomenon.
The study also revealed a saturation level not time-predictable, but affecting each image region.

To overcome the instability we used the pixel average ratio between specific image areas.
The approach is to normalize the grey level pixel average of the area where the antibodies are deposited, with the average of an external area of the same surface designed as control region where there is no active molecules.
With this method when the antibody-analyte reaction takes

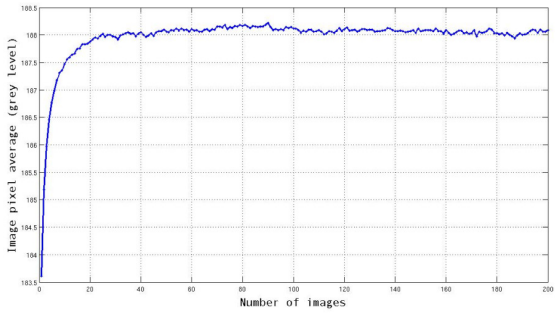

Fig 3. Gray levels pixel average measured during 200 images acquisition without antibodies on the biochip surface. After 50 images the light intensity reaches a saturation level.

place, the different light intensity measured is only influenced by the LSPR phenomenon without light aberrations.
Figure 4 a) shows the pixel average ratio of three regions of the biochip surface without immobilized antibodies. Two areas (2 and 3) are used as control regions and in the third distilled water was injected after 10 images acquired. The normalization applied eliminates the previously described

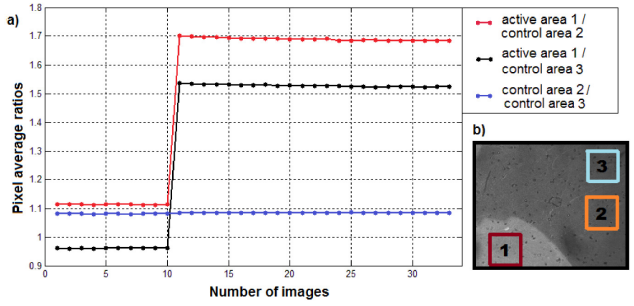

Fig 4. (a) Trend of pixel average ratio between three biochip regions without antibodies. After the tenth image distilled water was injected on the area 1; (b) 128x128 pixels areas used for the experiment. Areas 2 and 3 are control region.

instability and the ratios values are perfectly constant before and after the water injection.
It can be also seen the different average ratios measured are independent of each other since relative to biochip regions with different illumination. All the relevant information is included on the deviation before and after the water injection that corresponds to refractive index change due to LSPR phenomenon.

On this basis, we used the time derivative of average ratio as a suitable measurement of the refractive index variation on the biochip surface. Fig. 5 illustrates the average ratios and time derivatives of three areas, two control regions (area 1 and area 2) and a sample area (area 3). Distilled water was used as reference baseline, then (after 14 acquired images) a 5% glycerol solution was injected on the sample area.
The figure shows the time derivative change due to the refractive index variation on the sample area. Peak position and ratio increase of course correspond perfectly.
Such as in previous case (injection on area 1), we observed a change in the measured ratio according to refractive index variation of the biochip surface in contact with the sample.
The developed algorithm measures the amplitude of the time derivative peak that is compared with a specific refractive index calibration curve in the internal memory of the processor. The obtained value is used to define the target analyte concentration in a sample.

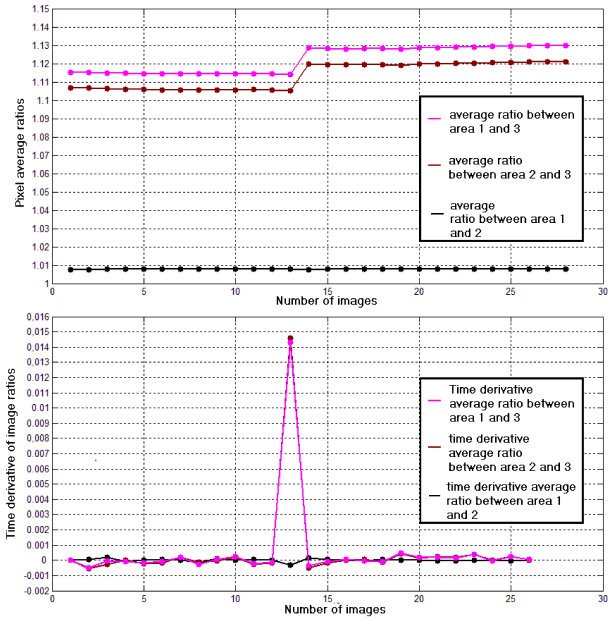

Fig 5. Pixel average ratio and time derivative when the sample area 3 is filled with distilled water (refraction index = 1.333) and then with a glycerol solution with concentration 5% (refraction index = 1.339).

VII. Results and Discussion

A. Sensitiveness of the biosensor

In order to evaluate the biosensor sensitiveness to changes in refractive index of bulk solutions and define a preliminary calibration curve for the algorithm developed, we prepared glycerol solutions with different concentrations (0.2% - 5%).
The biochip surface is subdivided in three rectangular areas (150x800 pixels), two taken as control regions and one selected region where the solutions were injected.
Distilled water is flowed on selected region as stable baseline reference for a few number of images (5-10) and

then the glycerol solution was introduced. The acquisition session relative to each concentration took 20 minutes.
Fig. 6 shows the linear correlation between the peak amplitude of the time derivative of average gray level pixel ratio at the various glycerol concentrations.

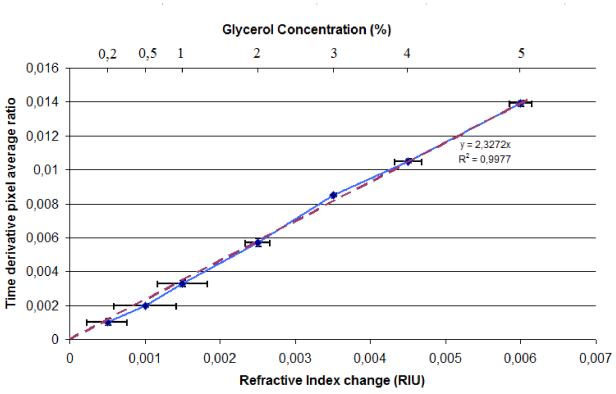

Fig 6. Trend of the time derivative pixel average ratios vs. refractive index change. Distilled water (n = 1,333) was assumed as reference. Biochip model B1001-13b was used.

Each experiment was repeated three times to assure measurements repeatability and the pixel average values are filtered with a moving average filter to eliminate outliers during the acquisitions.
The refractive index change was measured as the difference between the refractive index of distilled water and the solutions ones measured with an Abbe refractometer.
The correlation coefficient (R^2) of standard y-intercept and the measured data was 0.9977.
The variation of the response with respect to small changes in refractive index is caused by various factors as the detector noise and the LED fluctuations. The CMOS image sensor parameters as black level calibration and properties as the quantum efficiency at the wavelength used, may cause statistical fluctuations in the quantity of light captured. In the same way the electrical properties of the LED may affect the measurement.
Fig. 6 shows also a resolution limit for bulk refractive index respect to the baseline noise (measuring the standard deviation), equal to ~10^{-5} RIU for a glycerol concentration of 0.2%, which corresponds to the theoretical detection limit of the biochip [24]. This value increases as the concentration to 10^{-6} RIU for a glycerol concentration of 4% that corresponds to 10^{-3} Refractive Index change. This is sufficient in many fields and biodetection applications.
Furthermore this novel method allows to exploit the entire biochip surface for achieving multiple analytes detection, by simply distributing different antibodies spots and control areas along the surface.

B. *Future work*

Future work will involve tests of biological samples with antibodies immobilized on the biochip surface. The goal is to monitoring the adsorption and evaluate the real sensitivity limit for small molecule analyte detection.
Another important future step concerns the integration of the device with a microfluidic cell for the injection of the sample and the connection with a touch-screen monitor for display the signal response for the reaction kinetics observation.

VIII. Conclusions

The multiparametric SPRi biosensor described here provides efficient solution to the limit of the available SPR instrumentation, in terms of portability, power consumption, low-cost (about 1000$) and simplicity design. This device offers a real-time analytes detection useful for a large number of applications as medical diagnostic, monitoring of food allergens, toxins and pathogens detection in water and soils without the aid of specialized research laboratories.
A simple embedded system is used to elaborate images of a nanostructured biochip surface irradiated by a IR LED. Specific modules and device drives for Linux-based operating system have been developed to manage the biosensors components.
In particular, the pixels captured by a CMOS sensor are sent to an ARM9 processor via its GPIO interface and elaborated with a novel detection method. This new approach uses the time derivative pixels average ratios to identify change of refractive index on the biochip surface. The analysis results are available on LCD display in about 14 seconds and all the information are stored in an external SD memory.
The sensitivity for bulk refractive index changes is also measured to test the biosensor potential. The results for glycerol solutions at different concentrations indicate a best resolution of 10^{-5} RIU, suitable in several applications and fields. This detected biosensor response corresponds to the biochip theoretical response estimated by [24].
The device peculiar characteristics and the results achieved so far highlight a promising direction for a massive use for on-site analysis in thirdworld countries.

Acknowledgments

The authors are very thankful to prof. Alessandro Rubini for his help during the development of the ARM9 modules.

ABSTRACT

In this paper we propose an inference based packet recovery technique which considers past scores indicating retransmission success of the peers. Past scores are calculated by considering several parameters such as requested packets availability and round trip time. The importance of packets to be retransmitted is also considered in the proposed model. In order to obtain comparable results, we also implement a different retransmission approach similar to the models proposed in the literature. The ns3 simulations show that retransmission model increases the Peak Signal to Noise Ratio (PSNR) value even under high peer churn and limited resource index. Furthermore, score-based approach provides a decrease in reset counts and the number of duplicate packets, when it is compared to different retransmission approaches.

Keywords - peer-to-peer networks, live video streaming, packet recovery

1. INTRODUCTION

Peer-to-peer (P2P) video streaming systems represent one of the applications having a huge effect on the network traffic and there are remarkable live streaming systems proposed in the literature for both wired and wireless networks. Although most of these applications fall into two main categories as push-based and pull-based, several hybrid systems bringing the advantages of these two approaches have reported their success [1, 2]. In pull-based systems the nodes in the system send and receive video data chunks from one or more nodes [1] whereas each node has one parent and one or more children node in push-based systems [3]. In hybrid push-pull-based streaming; video data are divided into substreams. Nodes in the system connect one or more parents to receive these substreams and play video by combining them. During streaming, buffer maps, indicating the received blocks of each substream periodically, are exchanged between partner nodes in order to detect congestion and determine the candidate parents in case of parent re-selection.

We implement a hybrid push-pull system having the main properties of CoolStreaming [1] as to be used as an underlying framework. Although such systems have remarkable success, the system performance may degrade if there are not enough special-aimed nodes such as Content Delivery Network (CDN) nodes or super peers in the system. In this case, stream can be supported via retransmission of important packets. One may discuss if parent selection algorithms proposed for pull-based systems can be implemented in the selection of node which will send retransmission packets. Nevertheless, retransmission or packet recovery has more limited time to receive the requested packets when compared to the required time to receive packets from parents during streaming. The reason is that the packets received from the parents are generally obtained before their playout time since they are kept in buffer for a while whereas buffering time for retransmitted packet is relatively small. Since requested packets must be received in short time period, the selection of node sending retransmission packets should be realized considering more constrained time period.

In this work, we propose a new packet recovery technique based on retransmission. The contributions of this paper can be listed as follows: (*i*) We propose a pull-based retransmission model designing as to run combined with hybrid push-pull systems. It is shown that the performance of the hybrid system is significantly improved under high peer churn with the proposed model. (*ii*) The selection of the retransmission packets is based on the frame type and the selection is done in the sender side. (*iii*) Proposed model considers past behaviors of the peers, and the algorithm has low computational complexity and easy to implement.

The rest of the paper is organized as follows: In section 2, we give the summary of the related work. In section 3, we introduce the main contribution of this paper, namely score-based retransmission approach. The simulation results and conclusion are given in section 4 and 5, respectively.

2. RELATED WORK

Packet recovery techniques for missing packets can be classified into two categories, namely Forward Error Correction (FEC) and retransmission. FEC algorithms can

*This work is funded by the Scientific and Technological Research Council of Turkey (TUBITAK) Electric, Electronic and Informatics Research Group (EEEAG) under grant 111E022.

978-83-60810-53-8/$25.00

recover lost packets if the necessary number of packets is received. However, these techniques may not be useful in case of burst packet lost [4]. Furthermore, finding optimal FEC redundancy rate is a difficult problem due to the unestimated packet loss nature of P2P video streaming applications [5]. With the usage of retransmission techniques, there is no need to use redundant recovery packets introduced by FEC algorithms. Although there are well-known retransmission algorithms such as Automatic Repeat Request (ARQ) for classical server-client model [6], there are also some approaches proposed in the literature for retransmission in P2P video streaming systems [7, 8]. In [9], lost packets are obtained by retransmission at each hop from source to destination in the application overlay. This approach may cause retransmitted packets to reach lately to the destination nodes especially in leaf positions. A model in which parent nodes deciding retransmit some packets according to received NACK from children is proposed in [10]. Nevertheless, retransmission of missing packets from the same node, i.e. from the parent as proposed in [9, 10] has some disadvantages in case of parents do not have missing packets. In this case, requesting retransmission from a node other than the parent node provides higher continuity index [5, 11]. In [11], while selection of the node to request lost packets, the availability of the requested packets is not considered since this information is not available to the nodes in hybrid push/pull system. However, in pull based P2P video streaming systems, nodes have the information about the chunk availability and the selection of nodes to request lost packets can be done by taking into account this information [5]. On the other hand, when considering the high success of pull-based P2P video streaming systems, requesting missing packets from a set of nodes may improve the performance of the system. In [12], authors proposed a model for selecting this set of nodes. This selection is done by considering two criteria, the distance in terms of Round Trip Time (RTT) between requester node and the node retransmitting packets, and the position of the node retransmitting packets in the multicast tree.

This paper presents a work based on recovery of missing packets via pull-based retransmission. We prefer to use the term "retransmission parent" for the node which sends retransmission packets. Our study differs from the literature in several dimensions. First, we select more than one retransmission parents by considering the packets that they have. Second, after retransmission parent selection, we implement packet selection and give more priority to the retransmission of packets carrying I frames. Furthermore, we also propose a new algorithm to select candidate retransmission parents by considering their past behaviors, which provides increase in Quality of Experience (QoE) in terms of reset counts and decrease in message complexity.

In order to evaluate the performance of the proposed algorithm and to give the comparable results, we also implement a different retransmission approach similar to related studies proposed in the literature. The obtained results show that the performance of the proposed method exceeds the performance of the state-of-the-art solutions in terms of continuity index and total number of reset counts, as will be discussed in the following sections of this paper.

3. SCORE-BASED RETRANSMISSION

We used substream based, i.e. hybrid push-pull-based P2P live video streaming system as an underlying framework since it is reported that users can obtain higher continuity index than that of users in pure pull systems [1]. As mentioned before, each node in the system connects one or more parents to receive substreams in hybrid push-pull-based streaming. After joining the P2P system, the nodes obtain the list of online nodes in the system by communicating with the tracker server and construct partnership table by selecting a subset of these nodes. Parents of the nodes are selected from partnership table and parent selection is done according to the buffer maps of the partners, in other words, candidate parents. Each buffer map indicates the latest received packet of the related substream, thus if the video data are partitioned into the k substreams, buffer maps are the k-dimensional vectors. Buffer maps are periodically exchanged between partner nodes in order to watch the buffer condition of the partners. We embed additional data such as playout index, i.e. the current position of the video and the buffer indicating lost and existing packets between playout index and latest received packet into these messages.

In order to recover lost packets, a node must obtain them before their playout time. After streaming started, each node tries to recover lost packets by requesting them from their partners. An example scenario showing the buffer of a peer and the packets received from the substream parents and retransmission parent is given in Fig. 1. According to the figure, the peer is subscribed four parents to obtain four substreams. The packets numbered with 55 and 60 are not received from the parents hence these can be received from the retransmission parent. Note that 52^{nd} packet is not received and will not be requested from the retransmission parent since the playout time is passed for this packet. In packet recovery process two selections are made: selection of which partner(s) to request retransmission and selection of which packet(s) to request.

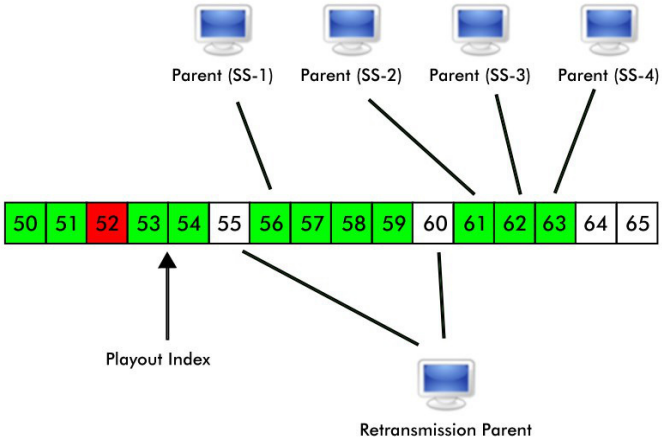

Fig. 1. An illustration of a retransmission scenario.

For retransmission parent selection, we propose a new approach based on previous scores of partners. A partner score is determined as the success ratio of received requested packets. Parent selection algorithm for determining candidate partners to request lost packets is given in Fig. 2.

$S_{requested\_packets}$: the set of packets which will be retransmitted

for each substream k
  for each node p_i in partnership table
    fullness_p_i = number of requested packets /
        number of requested packets existing in p_i's buffer;
  end for
  normalize fullness and RTT for all pi;
  for each node p_i in partnership table
    expected_score_p_i = α.fullness_p_i + (1-α).(1/RTT_p_i);
    expected_score_p_i = β.expected_score_p_i
        + (1-β).(previous_score_p_i);
  end for
  //rank all p_i according to their expected scores
  construct $\gamma(p)$; // ranked list
  while $|S_{requested\_packets}| > 0$
    p_{first} = first partner in $\gamma(p)$;
    S_p = the set of existing packets within requested packets
        in p_{first}'s buffer;
    add packets in S_p to the list representing requests from p_{first};
    $S_{requested\_packets} = S_{requested\_packets} - S_p$;
    calculate expected scores for new set of request packets and
        construct $\gamma(p)$;
  end while
end for

Fig. 2. Selection algorithm for retransmission parent.

Selection algorithm for retransmission parent starts with assigning fullness ratio of each partner in the partnership table. This value is calculated by examining the buffer map messages received from partners. In the next *for* loop, expected score for all candidate retransmission parents are calculated by considering three parameters, the fullness, the RTT value and previous expected score of the partners. Note that RTT is an important parameter to consider since requested packets need to be received before playout deadline. In the second step of the calculation of expected score, past scores of the partners is evaluated since even if a partner has high fullness and low RTT value, it may have limited available upload bandwidth or it may not be a stable node. For partners whose previous score is not calculated yet, this value is given as 0.5. After expected scores of each partner are calculated, the ranked list according to these values, $\gamma(p)$, is constructed. Requested packets which also exist at the first partner in the ranked list are put in a list representing the requested packets from the first partner in $\gamma(p)$. After the set of requested packets is reconstructed again, the expected scores are recalculated by considering new set of requested packets and $\gamma(p)$ is re-ranked. This process continues until retransmission parents are selected for all requested packets or remaining requested packets does not exist in the buffer of any partner.

Since the size of the partnership table is limited and quite small when compared with the size of the system, the space and the computational complexity of the algorithm given in Fig. 2 are negligible.

After request messages are sent, requester node waits for a period to receive the packets and to evaluate the performance of the retransmission parent for this session. This period is completed if the video playout index reaches to the playout time of the requested frame. In each buffer map exchange, retransmission parent selection is done again for the previously requested and not received packets. But, requester nodes may select the same retransmission parent with high probability since previously selected parent is not evaluated yet and still have the highest score. There are three

reasons for this choice of evaluation period, in order to evaluate the performance of the retransmission parent fairly, to decrease the number of request messages and to prevent the number of duplicate packets. With the completion of this period, the success ratio S_R is calculated by dividing the number of received packets to the number of requested packets and previous score of the partners is updated by the smoothing function given in (1).

$$previous\_score = \lambda . S_R + (1-\lambda) . previous\_score \quad (1)$$

Since the loss of I or P frames causes more distortion on display, sender node gives more priority to the packets containing I and P frames. In order to make nodes to detect which packet carries a part of an I or P frame, video server marks the packets according to its type and each node matches the received packet to its frame type.

4. SIMULATION

The simulations are implemented on ns3 [13] with the networks consisting of 50, 100, 150, 200 and 300 nodes. All the topologies used in simulations are generated randomly with BRITE topology generator [14] and Barabasi model [15]. Simulations are repeated several times in order to obtain averaged performance results.

There are one video server and one tracker server in the system. The video server has an upload capacity that provides the server to handle 20 percent of all peers in the system. Besides, we do not employ any CDN or super peer to support the video data dissemination. However 10 percent of the peers are selected as robust nodes which have higher bandwidth and tend to stay longer in the system. The tracker server is assigned to serve as the entry point of the streaming system. All newly joined peers connect to the tracker server first to request a random list of online peers to establish their initial connections.

In our simulations we use Foreman video sequence having QCIF resolution. The video is looped several times as to be used in 30 minutes length of simulations and encoded at 300 Kbps. We use frame copy as an error concealment method for missing frames. The original stream is divided into 4 substreams in each simulation in order to increase the potential suppliers of video. An exponential distribution which has an expected value of 1000 seconds for online and 400 seconds for offline periods is used to generate on/off intervals. Furthermore, we employ 10 percent of the nodes as free riders. The cumulative upload bandwidth distribution of all peers is given in Table I. We choose to send all messages including control and video over TCP in order to be able to connect all users even located behind a firewall. Retransmission requests are embedded to buffer map exchange messages, hence requests messages do not cause an extra load.

TABLE I. THE CUMULATIVE UPLOAD BANDWIDTH DISTRIBUTION

Percentage	Upload Bandwidth
10%	<50 Kbps
50%	<300 Kbps
90%	<1000 Kbps
100%	<3000 Kbps

In order to compare the performance of the proposed approach with the performance of other studies proposed in the literature, a different approach is also implemented for retransmission of missing packets. As proposed in [5], the selection of the retransmission parent is done randomly among the partners having requested packets and among the partners located close to the server, i.e. the position in the tree [12]. In this approach, if the node cannot receive the requested packets, it concludes that the current retransmission parent has not sufficient upload capacity and requests these packets from another node at the next buffer map exchange period. For this reason, we prefer to use the term “greedy-based” for this approach. In the simulations, buffer map messages are exchanged in every 2 seconds, hence if the requester node cannot receive retransmission packets within 2 seconds; it repeats the requests whereas in score-based retransmission, the nodes do not re-send request messages with high probability. Both greedy and score-based approaches give priority to the packets carrying I and P frames for fair comparison.

We measure PSNR, continuity index and total reset count as the video quality metrics. If a node consumes all data in its buffer, stops to receive video packets and cannot find suitable parent to connect, it resets itself, in other words, leaves the system and then joins immediately. The reset procedure causes the duration of the video playout for a while. As we observe, the time of this duration can change from 15 seconds to 20 seconds. The change on the average PSNR and the total reset count metrics are presented in Fig. 3 and Fig. 4 with respect to the change in network size. The PSNR of packet recovery techniques is higher than sole hybrid push-pull as expected. Although the greedy pull technique is slightly better than the score-based pull technique in terms of PSNR values, this difference is not easily observable at the end-user. In Fig. 4, an example frame received in hybrid push-pull, greedy-based and score-based approaches is given. As it can be seen from the figure, the distortion in the frame is similar in greedy and score-based approaches even the difference of the PSNR values of both approaches bigger than the difference of the averaged PSNR values given in Fig. 3.

The greedy pull technique has a higher control overhead and higher reset counts which can be seen in Fig. 5. The total reset counts are calculated by summing the number of resets of each node in the system. As it can be seen from the figure, the total reset count of proposed score-based pull packet recovery technique are always lower than sole hybrid

push-pull and greedy pull packet recovery techniques except for 50 peers. Furthermore, resets of the system implementing score-based retransmission stay almost identical in network size of more than 100 nodes. The greedy pull packet recovery technique causes receiving the most part of the packets via retransmission. Since stream parents have not sufficient residual upload bandwidth due to the over-requested packets, hence this technique has the highest total reset count.

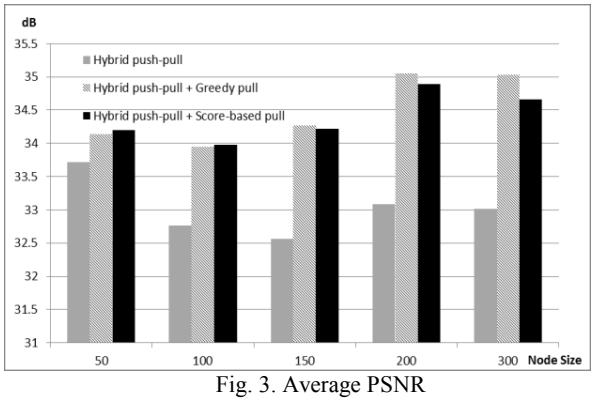

Fig. 3. Average PSNR

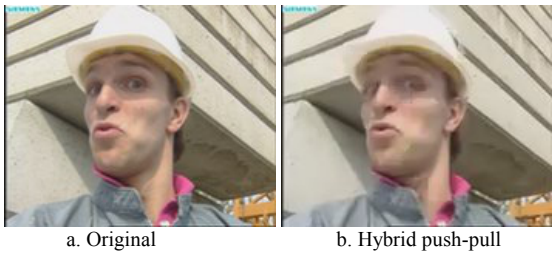

a. Original

b. Hybrid push-pull (PSNR: 31.21 dB)

c. Greedy (PSNR: 35.30 dB)

d. Score-based (PSNR: 34.66 dB)

Fig. 4. Example frames from the videos obtained in different P2P systems.

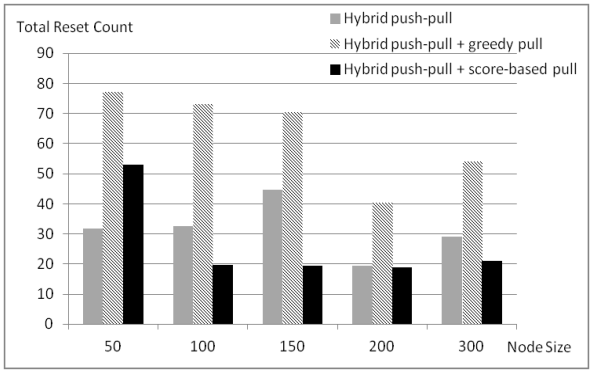

Fig. 5. Total Reset Count

In order to observe the inference performance of the score-based retransmission with respect to time, we measure two parameters, the ratio of the requested retransmission packets to the received retransmission packets and the change of continuity index, in Fig. 6 and Fig. 7, respectively. Since the greedy pull technique sends more request messages than the score-based pull, the score-based pull has higher reception ratio than the greedy pull technique on requested packets.

The graph given in Fig. 6 shows that the selection of retransmission parents is more successful in the score-based approach when compared to the greedy-based approach. This achievement provides the increase in continuity index by time as it can be seen in Fig. 7. In this figure, the graph shows that the inference process of large size of networks may be longer than that of small size of networks. Thus, it is expected that an increase in PSNR values for especially large size of networks such as network containing 300 nodes by time. Note that the most difference in PSNR values is observed between the greedy pull and the score-based pull for the network size of 300 nodes. This difference can be closed if the simulation lasts longer or if the nodes stay longer in the system. In Fig. 7, the observed change in continuity index for greedy-based retransmission shows a random pattern since it does not use any inference mechanism.

Finally, we give the comparative duplicate packet ratio values for greedy and score-based retransmission technique in order to indicate message complexity overhead in Fig. 8. The ratio is calculated by dividing the number of received packets to the number of requested packets. The graph shows that 50% of retransmitted packets are duplicate packets in the greedy-based approach.

5. CONCLUSION

In this paper, we have introduced a new packet recovery technique based on retransmission for hybrid push-pull P2P live video streaming system. For selection of retransmission parent, an inference based approach has been discussed. The proposed retransmission strategies provides an increase in QoE parameters in terms of PSNR, total reset count and continuity index. Furthermore, the score-based retransmission approach achieves PSNR values similar to the greedy-based retransmission approach while the number of duplicate packets is relatively small. It is shown that the performance of the score-based approach increases by time. With the help of node clustering, it is also possible to improve the effectiveness of the proposed inference-based approach in P2P systems consisting high number of nodes.

We plan to implement the proposed score-based retransmission approach for the live P2P video streaming systems using different type of video codecs as our future direction. In this case, for example, some additional parameters such as packet priority or layer information may be considered during the selection process of the retransmission parent for scalable video codec.

Education, Curricula & Research Methods

ECRM is a FedCSIS conference area aiming at interchange of information, ideas, new viewpoints and research undertakings related to university education and curricula as well as recommended methods of doing research in all computing disciplines, i.e. computer science, computer engineering, software engineering, information technology, and information systems. This area spans typical FedCSIS events (conferences, workshops, etc.) with rigorous paper submissions and review processes as well as panels, PhD and research consortia, summer schools, etc. Events that constitute ECRM are:

- DS-RAIT'13 - Doctoral Symposium on Recent Advances in Information Technology
- ISEC'2012 - Information Systems Education & Curricula Workshop

Doctoral Symposium on Recent Advances in Information Technology

THE first international Doctoral Symposium on Recent Advances in Information Technology (DS-RAIT 2013) will be held in Cracow (Poland) on September 8-11, 2013 as a satellite event of the Federated Conference on Computer Science and Information Systems (FedCSIS 2013) and Education, Curricula & Research Methods (ECRM 2013) conference.

The aim of this meeting is to provide a platform for exchange of ideas between early-stage researchers, in Computer Science, PhD students in particular. Furthermore, the symposium will provide all participants an opportunity to get feedback on their studies from experienced members of the IT research community invited to chair all DS-RAIT thematic sessions. Therefore, submission of research proposals with limited preliminary results is strongly encouraged.

Besides receiving specific advice for their contributions all participants will be invited to attend plenary lectures on conducting high-quality research studies, excellence in scientific writing and issues related to intellectual property in IT research. Authors of the two most outstanding submissions will have a possibility to present their papers in a form of short plenary lecture.

Topics

DS-RAIT 2013 invites the submission of papers on all aspects of Information Technology including, but not limited to:

- Automatic Control and Robotics
- Bioinformatics
- Cloud, GPU and Parallel Computing
- Cognitive Science
- Computer Networks
- Computational Intelligence
- Cryptography
- Data Mining and Data Visualization
- Database Management Systems
- Expert Systems
- Image Processing and Computer Animation
- Information Theory
- Machine Learning
- Natural Language Processing
- Numerical Analysis
- Operating Systems
- Pattern Recognition
- Scientific Computing
- Software Engineering

***Abstract*—The inexact Newton method is commonly known from its ability to solve large-scale systems of nonlinear equations. In the paper the classical inexact Newton method is presented as a tool for solving differential-algebraic equations (dae) in fully-implicit form $F(\dot{y}, y, t) = 0$. The appropriate statement of dae using the backward Euler method makes the possiblity to see the differential-algebraic system as a large-scale system of nonlinear equations. Because a choice of the forcing terms in the inexact Newton method significantly affects the convergence of the algorithm, in the paper new variants of the inexact Newton method were presented and tested. The simulations were executed in Matlab environment using Wroclaw Centre for Networking and Supercomputing.**

***Index Terms*—differential-algebraic equations, systems of nonlinear equations, inexact Newton method.**

I. Introduction

DIFFERENTIAL-algebraic equations (dae) play a key role in control science and engineering [16], [17]. Describing the system with equations that incorporate dynamics and conservation laws, creates new opportunities for the development of the numerical methods and has a direct application in the industry [2], [3]. Design and control of chemical reactors and motor vehicle requires precise knowledge of the links between the system and the signals flowing from the environment, as well as between the internal elements of the system. Needs arising from the control of the large complex installations always outweight the modern computing capabilities, and are becoming a cause for the progress of both the hardware as well as the algorithms and the numerical methods.

The question raised in the article refers to the situation when the considered system is described by differential-algebraic equations in a general way possible. This approach has a chance to wide and common use in industry. The presented method is part of a widely used approach, which reduces infinite dimensional task to the large-scale finite-dimensional problem.

The paper is constructed as follows. In the next section the backward differential formula (bdf) is presented as the tool for solving dae systems. New aspects of the inexact Newton method were presented in $3rd$ and $4th$ sections. The presented algorithms were tested on the kinetic batch reactor model. The results were presented in $5th$ section.

II. The backward Euler method

The codes for solving dae in the $fully-implicit$ form are based on a technique which was introduced by Gear [12]. The backward differential formula is the first general technique for the numerical solution of dae and have emerged as the most popular. The idea of this technique is that the derivative $\frac{dy(t)}{dt}$ can be approximated by a linear combination of the solution $y(t)$ at the current mesh point and at several previous mesh points ([14]).

Bdf was initially defined for the systems of differential equations coupled to algebraic equations. This method was soon extended to apply to any fully-implicit system of differential-algebraic equations

$$G\Big(\frac{dy(t)}{dt}, y(t), z(t), t\Big) = 0. \tag{1}$$

The simplest method for solving differential-algebraic systems is the first order bdf, or the backward Euler method, which consists of replacing the derivative in (1) by a backward difference

$$F\Big(\frac{y_n - y_{n-1}}{h}, y_n, z_n, t_n\Big) = 0. \tag{2}$$

where $h = t_n - t_{n-1}$.

The resulting system of nonlinear equations for y_n at each step is then usually solved by the Newton method [4]. In this way, the solution is advanced from time t_n to time t_{n+1}. It is assumed, that $y(t_0)$ is known. Assume too, that t (time) is the independent variable. In practical applications in chemical enginnering, as the independent variable is used usually the lenght of the reactor. If the time interval, in which the system has to be considered, is known, it can be scaled to the interval $[0, 1]$.

III. The inexact Newton method

The methodology presented in the previous paragraph leads to the following equation

$$F(x) = 0. \tag{3}$$

This equation is very general and is often found in scientific and engineering computing areas. We assume that the function F is considered, where $F : \mathcal{R}^n \to \mathcal{R}^n$ is a nonlinear mapping with the following properties

978-83-60810-53-8/$25.00

(1) There exists an $x^* \in \mathcal{R}$ with $F(x^*) = 0$.
(2) F is continously differentiable in a neighborhood of x^*.
(3) $F'(x^*)$ is nonsingular.

There are a lot of methods for solving this nonlinear equation. One of the most popular and important is the Newton method. The Newton's method is attractive because it converges rapidly (quadratically) from any sufficiently good initial point. Its computational cost can be expensive, particularly, when the size of the problem is very large, because in each iteration step the Newton equations

$$F(x_k) + F'(x_k)s_k = 0 \tag{4}$$

should be solved. Here x_k denotes the current iterate, and $F'(x_k)$ is the Jacobian matrix of $F(x)$ at point x_k. The solution s_k^N of the Newton equation is the Newton step. Once the Newton step is obtained, the next iterate is given by

$$x_{k+1} = x_k + s_k^N. \tag{5}$$

In 1982 Dembo, Eisenstat and Steihaug proposed the inexact Newton method, which is a generalization of the Newton method [8]. The inexact Newton method is any method which, given an initial guess x_0, generates a sequence x_k of approximations to x^* as in Algorithm 1.

ALGORITHM 1. The inexact Newton method
1. Given $x_0 \in \mathcal{R}^n$
2. For $k = 0, 1, 2, \cdots$ until x_k convergence
  2.1 Choose some $\eta_k \in [0, 1)$
  2.2 Inexactly solve the Newton equations and obtain a step s_k, such that $\|F(x_k) + F'(x_k)s_k\| \le \eta_k \|F(x_k)\|$. $(\star)$
  2.3 Let $x_{k+1} = x_k + s_k$.

In the Algorithm 1, η_k is the forcing term in the k-th iteration, s_k is the inexact Newton step and $(\star)$ is the inexact Newton condition.

In each iteration step of the inexact Neton method a real number $\eta_k \in [0, 1)$ should be chosen. Then the inexact Newton step s_k is obtained by solving the Newton equation approximately with an iteration solver for systems of nonlinear equation. Since $F(x_k) + F'(x_k)s_k$ is both residual of the Newton equations and the local linear model of $F(x)$ at x_k, the inexact Newton condition $(\star)$ reflects both the reduction in the norm of the local linear model and certain accuarcy in solving the Newton equations. Thus the role of forcing terms is control the degree of accuracy of solving the Newton equations. In particular, if $\eta_k = 0$ for all k, then the inexact Newton method is reduced into the Newton method.

The inexact Newton method, like the Newton method, is locally convergent.

Theorem 1 ([8]): Assume that $F : \mathcal{R}^n \to \mathcal{R}^n$ is continously differentiable, $x^* \in \mathcal{R}^n$ such that $F'(x^*)$ is nonsingular. Let $0 < \eta_{max} < \beta < 1$ be the given constants. If the forcing terms η_k in the inexact Newton method satisfy $\eta_k \le \eta_{max} < \beta < 1$ for all k, then there exists $\varepsilon > 0$, such that for any $x_0 \in N_\varepsilon(x^*) \equiv \{x : \|x - x^*\| < \varepsilon\}$, the sequence $\{x_k\}$ generated by the inexact Newton method converges to x^*, and

$$\|x_{k+1} - x^*\|_* \le \beta \|x_k - x^*\|_*, \tag{6}$$

where $\|y\|_* = \|F'(x^*)y\|$.

If the forcing terms $\{\eta_k\}$ in the inexact Newton method are uniformly strict less than 1, then by Theorem 1, the method is locally convergent. The following result states the convergence rate of the inexact Newton method.

Theorem 2 ([8]): Assume that $F : \mathcal{R}^n \to \mathcal{R}^n$ is continously differentiable, $x^* \in \mathcal{R}^n$ such that $F'(x^*)$ is nonsingular. If the sequence $\{x_k\}$ generated by the inexact Newton method converges to x^*, then

(1) x_k converges to x^* superlinearly when $\eta_k \to 0$;
(2) x_k converges to x^* quadratically if $\eta_k = \mathcal{O}(\|F(x_k)\|)$ and $F'(x)$ is Lipschitz continuous at x^*.

Theorem 2 indicates, that the convergence rate of the inexact Newton method is determined by the choice of the forcing terms.

IV. A CHOICE OF FORCING TERMS

In the literature, researchers proposed some strategies to determine a good sequence of forcing terms. Here, four representatives strategies were selected.

(1) The choice of Dembo and Steihaug [9]:

$$\eta_k = \min\left\{\frac{1}{k+2}, \|F(x_k)\|\right\}. \tag{7}$$

The two strategies given by Eisenstat and Walker are more popular [11]. Among this two strategies, choice (2a) reflects the agreement between $F(x)$ and its local linear model at the previous step. Choice (2b) reflects the reduction rate of $\|F(x)\|$ from x_{k-1} to x_k.

For computational purposes of preventing the forcing terms from becoming quickly too small, some safeguards were added. The following strategies were obtained.

(2a) Given $\eta_0 \in [0, 1)$, choose

$$\eta_k = \begin{cases} \xi_k, & \eta_{k-1}^{(1+\sqrt{5})/2} \le 0.1, \\ \max\{\xi_k, \eta_{k-1}^{(1+\sqrt{5})/2}\}, & \eta_{k-1}^{(1+\sqrt{5})/2} > 0.1, \end{cases} \tag{8}$$

where

$$\xi_k = \frac{\|F(x_k) - F(x_{k-1}) - F'(x_{k-1})s_{k-1}\|}{\|F(x_{k-1})\|}, \tag{9}$$

$k = 1, 2, \ldots,$ or

$$\xi_k = \frac{|\,\|F(x_k)\| - \|F(x_{k-1}) + F'(x_{k-1})s_{k-1}\|\,|}{\|F(x_{k-1})\|}, \tag{10}$$

$k = 1, 2, \ldots.$

(2b) Given $\gamma \in (0, 1]$, $\omega \in (1, 2]$, $\eta_0 \in [0, 1)$, choose

$$\eta_k = \begin{cases} \xi_k, & \gamma(\eta_{k-1})^\omega \le 0.1, \\ \max\{\xi_k, \gamma(\eta_{k-1})^\omega\}, & \gamma(\eta_{k-1})^\omega > 0.1, \end{cases} \tag{11}$$

where

$$\xi_k = \gamma\left(\frac{\|F(x_k)\|}{\|F(x_{k-1})\|}\right)^\omega, \tag{12}$$

$k = 1, 2, \ldots$.

(3) Choice of H.-B. An et al. [1]. Assume, that x_k is the current iterate and s_k is the step from x_k. The actual reduction $Ared_k(s_k)$ and predicted reduction $Pred_k(s_k)$ of $F(x)$ at x_k with step s_k are definned as follows

$$Ared_k(s_k) = \|F(x_k)\| - \|F(x_k + s_k)\|, \tag{13}$$

$$Pred_k(s_k) = \|F(x_k)\| - \|F(x_k) + F'(x_k)s_k\|. \tag{14}$$

Furthermore, let

$$r_k = \frac{Ared_k(s_k)}{Pred_k(s_k)}. \tag{15}$$

In this approach, r_k is used to adjust the forcing term η_k. Considering the value of r_k, one can distinguish four situation, which can have a place in computations.

(a) If $r_k \approx 1$, the the local linear model and nonlinear model will agree well on their scale and $\|F(x)\|$ usually will be reduced.

(b) If r_k nears 0, but $r_k > 0$, then the local linear model and nonlinear model disagree and $\|F(x)\|$ can be reduced very little.

(c) If $r_k < 0$, then the local linear model and nonlinear model disagree and $\|F(x)\|$ will be enlarged.

(d) If $r_k \gg 1$, then the local linear model and nonlinear model also disagree, but $\|F(x)\|$ will be reduced greatly.

The acceptable situations are, when $r_k \approx 1$ or $r_k \gg 1$, because in this cases the local linear model and nonlinear model agree well or at least leads to a great reduction point.

According to the property of r_k, one can choose forcing terms as follows.

$$\eta_k = \begin{cases} 1 - 2p_1, & r_{k-1} < p_1, \\ \eta_{k-1}, & p_1 \le r_{k-1} < p_2, \\ 0.8\eta_{k-1}, & p_2 \le r_{k-1} < p_3, \\ 0.5\eta_{k-1} & r_{k-1} \ge p_3, \end{cases} \tag{16}$$

where $0 < p_1 < p_2 < p_3 < 1$ are prescribed at first and $p_1 \in (0, \frac{1}{2})$. Assume, that η_0 is given.

The choice of forcing terms proposed in [1] is to determine η_k by the magnitude of r_{k-1}.

It is worth to note, that the current forcing term η_k is determined by the previous value r_{k-1} and η_k determines the value r_k through solving the Newton equations approximately.

V. Numerical results

As an example the kinetic batch reactor was choosed. This example is known from the literature [2], [6], [7] The concentrations are modeled by the system of differential and algebraic equations. The desired product AB is formed in the reaction

$$HA + 2BM \rightarrow AM + MBMH. \tag{17}$$

For the formulation given here the differential and algebraic variables are denoted by y_j and z_j respectively (Table 1).

The kinetic model is stated in terms of six differential mass balance equations

$$\dot{y}_1 = -k_2 y_2(t) z_8(t), \tag{18}$$

y_4	Differential State	$[AB]$
y_5	Differential State	$[MBMH] + [MBM^-]$
y_6	Differential State	$[M^-]$
z_7	Algebraic State	$[H^+]$
z_8	Algebraic State	$[A^-]$
z_9	Algebraic State	$[ABM^-]$
z_{10}	Algebraic State	$[MBM^-]$

$$\dot{y}_2 = -k_1 y_2(t) y_6(t) + k_{-1} z_{10}(t) - k_2 y_2(t) z_8(t), \tag{19}$$

$$\dot{y}_3 = k_2 y_2(t) z_8(t) + k_3 y_4(t) y_6(t) - k_{-3} z_9(t), \tag{20}$$

$$\dot{y}_4 = -k_3 y_4(t) y_6(t) + k_{-3} z_9(t), \tag{21}$$

$$\dot{y}_5 = k_1 y_2(t) y_6(t) + k_{-1} z_{10}(t), \tag{22}$$

$$\dot{y}_6 = -k_1 y_2(t) y_6(t) - k_3 y_4(t) y_6(t) + k_{-1} z_{10}(t) + k_{-3} z_9(t), \tag{23}$$

an electroneutrality condition

$$z_7(t) = -0.0131 + y_6(t) + z_8(t) + z_9(t) + z_{10}(t) \tag{24}$$

and three equlibirum conditions

$$z_8(t) = \frac{K_2 y_1(t)}{K_2 + z_7(t)}, \tag{25}$$

$$z_9(t) = \frac{K_3 y_3(t)}{K_3 + z_7(t)}, \tag{26}$$

$$z_{10}(t) = \frac{K_1 y_5(t)}{K_1 + z_7(t)}. \tag{27}$$

with initial conditions $y_1(0) = 1.5776$, $y_2(0) = 8.32$, $y_j(0) = 0.0, j = 3, 4, 5$, $y_6(0) = 0.0131$, $z_7(0) = 0.5(-K_2 + \sqrt{K_2^2 + 4K_2 y_1(0)})$, $z_8(0) = z_7(0)$, $z_j(0) = 0.0, j = 9, 10$.

The following values of rate and equlibirum constants were used $k_1 = 21.893(hr^{-1} \cdot Kg \cdot gmole^{-1}), k_{-1} = 2.14E09(hr^{-1}), k_2 = 32.318(hr^{-1} \cdot Kg \cdot gmole^{-1}), k_3 = 21.893(hr^{-1} \cdot Kg \cdot gmole^{-1}), k_{-3} = 1.07E09(hr^{-1}), K_1 = 7.65E-18(gmole \cdot Kg^{-1}), K_2 = 4.03E-11(gmole \cdot Kg^{-1}), K_3 = 5.32E-18(gmole \cdot Kg^{-1})$.

The equations were considered in the time domain $t \in [0, 2.5]$. Then the equations were discretized into equidistant points with distnace 0.025. It resulted in 600 differential and 400 algebriac state variables. Then, 1000 equality constraints from the backward Euler method were imposed. The Jacobian matrix was obtained analitically and stored as the 1000×1000 sparse matrix.

This large-scale system of the linear equations was solved using GMRES algorithm [15]. The inexact Newton backtracking method [10] was used with four presented approaches for adjusting the forcing terms.

The results in Table 2 indicate, that the considered problem is difficult to solve. Iterations quickly converge to the locally optimal solution. The parameter r_k gives an answer, what

10	0.0833	1.1966e3	1.0000	0.5000	1.1420e3

is the relation between linear model and the whole system. The linear model agrees with the nonlinear model only at the beginning of the solution process. It is worth to note, that only the approach presented in [1] idicates, that after 7 iterations some difficulties can occur.

The simulations were executed with the parameters: $\gamma = 0.5$, $\omega = 1.5$ for proposition $2b$ and $p_1 = 0.25$, $p_2 = 0.6$, $p_3 = 0.8$ for the choice proposed in [1].

There are results for forcing terms adjusted in other manners in Table 3. The forcing terms adjusted as presented in [9] were decreased monotonically, but there is no information about agreement between $F(x)$ and its local linear model.

The forcing terms, adjusted as presented in [11], did not decrease monotonically to 0. Its main drawback is, that either the agreement between $F(x)$ and its local linear model at the previous step or the reduction rate of $\|F(x)\|$ are reflected in adapatation of forcing terms.

The simulations were executed in Matlab environment using Wroclaw Centre for Networking and Supercomputing.

As one can see, the results presented in the Table 2 and 3 are not the optimal solutions. If the initial guess for the inexact Newton method is close enough to the desired solution, then the convergence is very fast provided that the forcing terms are sufficiently small. But a good initial guess is generally very diffcult to obtain, especially for nonlinear equations that have unbalanced nonlinearities. Then the step length is often determined by the components with the strongest nonlinearities [5]. The nonlinearities are "unbalanded" when the step length is determined by a subset of the overall degrees of freedom.

VI. CONCLUSION

In the paper the new apsects of the inexact Newton method for solving differential-algebraic equations were presented, then the dae systems in the fully implicit form were considered. The methods for the choice of forcing terms for the inexact Newton method were presented and tested on the difficult and highly nonlinear kinetic batch reactor.

The authors would like to indicate, that the choice of forcing terms, which reflects both the agreement between $F(x)$ and its local linear model and the reduction rate of $\|F(x)\|$ are especially usefull for solving the large scale differential-algebraic equations. As the next step, the new preconditioned Jacobian-free optimization algorithm, which could solve the large-scale optimization tasks, will be studied and adjusted for new challenges in solving the optimal control problems [13].

***Abstract*—The quality measures for bipolar linguistic summaries of data, as proposed in our previous work [1], are further developed. The summaries introduced in [2] are assumed to be an extension of the "classical" linguistic summarization (cf. [3], [4]), a human-consistent data mining technique revealing complex patterns present in data. This extension consists in using the "and possibly" to build a summary and introducing the notion of context to determine the validity of the summary. We present a more detailed description of summaries quality measures/criteria and reports results of more extensive computational experiments.**

I. Introduction

THE AIM of data mining is to discover patterns in data in a form interesting and clear to the end user. A promising way to achieve this is to use (quasi) natural language. This has been a motivation for the *linguistic data summaries* introduced by Yager [3] and further developed by him [5] and other contributors, notably Kacprzyk and Zadrożny [6], [7].

Recently, an important role of bipolarity of user preferences, in particular in fuzzy linguistic querying [8], is noticed. Its essence is in considering both positive and negative evaluations of objects in question which are not necessarily complements of each other. An important and most interesting line of research focuses on the treatment of negative evaluations as obligatory while the positive evaluations as somehow secondary. This results in the introduction and study of the "and possibly" logical connective [9]. Moreover, the concept of bipolar queries involving such a connective has been proposed [10] to better model user preferences as exemplified by the query "Find a house, cheap *and possibly* located close to a station".

In our previous papers [1], [2] we began to study if relation between fuzzy linguistic queries and linguistic data summaries may be adopted for bipolar queries. The results were positive and led us to the concept of bipolar linguistic summaries of data. In this paper we focus on two quality criteria of such new type of linguistic summaries, introduced in [1] and referring to the notion of the context of a summary.

The structure of the paper is as follows. In Section II we briefly remind the basics of the fuzzy linguistic queries and "classical" linguistic summaries, and introduce the notation to be used in the rest of the paper. In Section III we discuss the concepts of bipolar queries and bipolar linguistic summaries. Section IV reports on the computational experiments focused on comparing different summary contexts and discusses the results obtained.

II. Fuzzy linguistic queries and linguistic data summaries

A. Fuzzy linguistic queries

In classical query languages, such as SQL, preferences of users must be expressed precisely. However, due to the fact that their original form is a natural language expression, they are very often imprecise. For example, one may be concerned primarily with the cost while looking for an apartment to rent and express his or her preference as:

Find *cheap* apartments for rent in Kraków. (1)

In an approach, referred here to as fuzzy linguistic queries, such imprecise terms (e.g. *cheap*) are represented by fuzzy sets defined in the domains of respective attributes.

Usually, a dictionary of linguistic terms is assumed as a part of an implementation which contains predefined linguistic terms and corresponding fuzzy sets as well as terms defined by the users. Linguistic terms collected in a dictionary are a starting point to derive meaningful *linguistic summaries* of a database.

B. Linguistic summaries of data

As linguistic summaries we understand a (quasi) natural language sentences that grasp some characteristic features of data collected in a database. We use Zadeh's calculus of linguistically quantified propositions as the underlying formalism. The statement representing a linguistic summary points out some properties shared by a number of data items and the proportion of these data items is expressed using a *linguistic quantifier*. Yager [3], [5] first proposed the use of linguistically quantified propositions to summarize data in a user consistent

978-83-60810-53-8/$25.00

way. That idea has been further developed, cf., e.g., Kacprzyk and Yager [11], and Kacprzyk, Yager and Zadrożny [4], [6].

Assuming $R = \{t_1, \ldots, t_n\}$ is a set of tuples (a relation) in a database, representing, e.g., a set of employees; $A = \{A_1, \ldots, A_m\}$ is a set of attributes defining schema of the relation R, e.g., salary, age, education_level, etc. in a database of employees ($A_j(t_i)$ denotes a value of attribute A_j for a tuple t_i), the linguistic summary of a set R is a linguistically quantified proposition which is an instantiation of one of the following abstract *protoforms* [12] of type I and type II, respectively:

$$Q_{t \in R}\ S(t) \tag{2}$$

$$Q_{t \in R}\ (U(t), S(t)) \tag{3}$$

then a linguistic summary is composed of the following elements: a *summarizer* S which is a fuzzy predicate representing, e.g., an expression "an employee is well-educated", formed using attributes of the set A; a *qualifier* U (optional) which is another fuzzy predicate representing, e.g., a set of "young employees"; a *linguistic quantifier* Q, e.g., "most" expressing the proportion of tuples satisfying the summarizer (optionally, among those satisfying a qualifier); *truth (validity)* T of the summary, i.e. a number from $[0, 1]$ expressing the truth of a respective linguistically quantified proposition.

In Yager's original approach [3] the linguistic quantifiers are represented using Zadeh's definition [13]. A *proportional*, *non-decreasing* linguistic quantifier Q is represented by a fuzzy set in $[0, 1]$ and $\mu_Q(x)$ states the degree to which the proportion of $100{\times}x$ % of elements of the universe match the proportion expressed by the quantifier Q. Thus, the truth degree of the linguistic summaries of type I (here we use only type I summaries, thus type II is omitted) is:

$$T(Q_{t \in R} S(t)) = Z_Q(S) = \mu_Q[\frac{1}{n} \sum_{i=1}^{n} \mu_S(t_i)] \tag{4}$$

III. Bipolar queries and bipolar linguistic summaries of data

A. Bipolar queries

In classical approaches to preferences modelling, notably in database querying, it is usually assumed that an alternative (tuple) is either accepted or rejected. However, the results of many studies, cf. [10], seem to suggest that the decision maker often comes up with somehow independent evaluations of positive and negative features of alternatives in question. This leads to a general concept of *bipolar query* against database, evaluation of which results in two degrees corresponding to the satisfaction of the positive and negative condition.

Most of the research on bipolar queries are focused on a special case where the positive and negative conditions are interpreted in an asymmetric way [10]. Namely, the latter is treated as a *constraint*, denoted C, which has to be satisfied, while the former plays the role of a mere *preference*, denoted P.

We follow the approach of Lacroix and Lavency [14], Yager [15], [16] and Bordogna and Pasi [9], adapted for database querying by Zadrożny and Kacprzyk [17], which combine both conditions using the "and possibly" operator which aggregates their satisfaction degrees depending on the possibility of a simultaneous matching of both conditions.

Thus, the bipolar query's condition may be formally written as:

$$C \text{ and possibly } P, \tag{5}$$

and may be illustrated with query: Find employees that are *young* and possibly earn a *high* salary. Such a bipolar query would be denoted (C, P) and interpreted as follows. If there is a tuple which satisfies both conditions, then and only then it is actually *possible* to satisfy both of them and each tuple of data has to do so, and, on the other hand, if there is no such a tuple, then condition P can be ignored. The matching degree of the (C, P) query against a tuple t may be formalized as [14]:

$$T\left(C(t)\ and\ possibly\ P(t)\right) = C(t) \wedge \left(\exists s\left(C(s) \wedge P(s)\right) \Rightarrow P(t)\right) \tag{6}$$

B. Bipolar linguistic summaries

The main idea behind the bipolar linguistic summaries is to relate the "and possibly" to *a part* of the database instead of the whole database. Let us consider the following example:

> *Most* employees have a *short* seniority *and, if possible with respect to similarly educated colleagues*, earn a *high* salary.

An employee matches such a summary if:

1) he or she has a short seniority (to a high degree) and earns a high salary (to a high degree), or
2) he or she has a short seniority (to a high degree) and there is no other *similarly educated* employee who earns a high salary.

A characteristic feature of such a summary is the use of a summarizer employing an extended version of the "and possibly" operator, which we will refer to as the "contextual and possibly" operator. This operator may be expressed as:

$$C \text{ and possibly } P \text{ with respect to } W. \tag{7}$$

For the purposes of bipolar queries (and, thus, bipolar linguistic summaries) the predicates C and P should be interpreted as the required and desired conditions, respectively, while the predicate W denotes the *context* in which the possibility of satisfying both C and P will be assessed, separately for each tuple. Then, the formula (7) is interpreted as:

$$T\left(C(t)\ and\ possibly\ P(t)\ with\ respect\ to\ W\right) = C(t) \wedge \left(\exists s\left(W(t,s) \wedge C(s) \wedge P(s)\right) \Rightarrow P(t)\right) \tag{8}$$

Our preliminary computational experiments show that usage of the standard De Morgan triples[1], both with the S- and

[1]As standard De Morgan triples we understand $(\wedge_{\min}, \vee_{\max}, \neg)$, $(\wedge_{\Pi}, \vee_{\Pi}, \neg)$ and $(\wedge_{\mathrm{L}}, \vee_{\mathrm{L}}, \neg)$ with t- and s-norms: Minimum $(\min(x, y))$ and Maximum $(\max(x, y))$; Product $(x \cdot y)$ and Probabilistic sum $(x + y - x \cdot y)$; and Łukasiewicz's $(\max(0, x + y - 1))$ and $(\min(1, x + y))$, respectively.

R-implication, in (8) may lead to somehow counter-intuitive results in terms of bipolar queries evaluation.

Thus we use the MinMax triple and Goguen $R-$implication which turns (8) into:

$$T\left(C(t)\ and\ possibly\ P(t)\ with\ respect\ to\ W\right) = \begin{cases} \min(C(t),1) & \text{for } \exists WCP(t)=0 \\ \min\left(C(t), \min\left(1, \frac{P(t)}{\exists WCP(t)}\right)\right) & \text{otherwise} \end{cases}, \tag{9}$$

where $\exists WCP(t)$ denotes $\max_{s\in R}\min(W(t,s),C(s),P(s))$.

C. Summary context quality criteria

In [1] we stated that the quality of the summary context $W(t,s)$ itself and the whole implication premise in (8) have to be considered when measuring the quality of the bipolar linguistic summaries.

Namely, if P and/or W are such that the premise of the implication in (8) is true to a very low or a very high degree *for most* of t's, then the summarizer (7) does not make much sense even if the truth value of a summary is high. This is due to the behaviour of the bipolar query "C and possibly P" which turns into "C" and "C and P", respectively, when the truth degree of $\exists_{s\in R}C(s)\wedge P(s)$ is close to 0 and close to 1.

The introduction of the context W partially alleviates this problem but W has to be chosen carefully. If for most t's there does not exist s such that $W(t,s)$, then the premise of the implication is most often false and the summary is true to a high degree for any P. We propose a solution to this problem in a form of quality measures expressed using the following linguistically quantified propositions:

$$Q_{t\in R}\exists_{s\in R\setminus\{t\}}W(t,s) \tag{10}$$

$$Q_{t\in R}\exists_{s\in R\setminus\{t\}}C(s)\wedge P(s)\wedge W(t,s). \tag{11}$$

Namely, if the truth of (10) for a summary is too small (lower than some threshold value), then such a summary should be discarded. Also, if the truth of (11) is too high (too close to 1; larger than the second threshold value) or too small (too close to 0; lower than the third threshold value), then the summary also shouldn't be taken into account. Obviously, if the first threshold is violated, then also the third one is. On the other hand, even if the first threshold is satisfied, the summary may still fail to satisfy thresholds two or three and should be discarded.

Tuple t is excluded from the range of the existential quantifiers in (10)–(11) as if the only tuple related via W with t is only t itself, then, naturally, the resulting summary is of no interest.

IV. Computational experiments and discussion

Data on the rates of return (RORs) of selected investment funds[2] (IFs) (Tab. I), are used to present examples of bipolar linguistic summaries and their semantics in scope of summary context quality.

[2]URL: http://www.analizy.pl/fundusze/ as of May 24, 2013.

Table I
Selected investment funds (IF)

No.	IF rating[a]	1-month ROR[b]	12-month ROR

6						1.0	1.0	1.0		1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0

Empty cell indicates no *similarity* ($W(t,s)=0.0$).

Fuzzy predicates are represented by trapezoidal membership functions and instantiated as (see Fig. 1):

- C: has "high"/"average"/"low" 12-month ROR,
- P: has "high"/"average"/"low" 1-month ROR,
- $W_{1/2/3}$: of "the same"/"very similar"/"quite similar" Rating, the former true iff IF rating(t) = IF rating(s) and the latter two defined over |IF rating(t) − IF rating(s)|.

In Tab. III we present summaries with truth value (evaluated using Zadeh's approach) $T>0$ obtained for data in Tab. I and compare the results in scope of proposed quality criteria (10) and (11).

In order to focus the interpretation on summaries contexts we consider only one linguistic quantifier Q with the membership function indicating the proportion of tuples satisfying the summarizer below 30% and above 80% as, respectively, totally

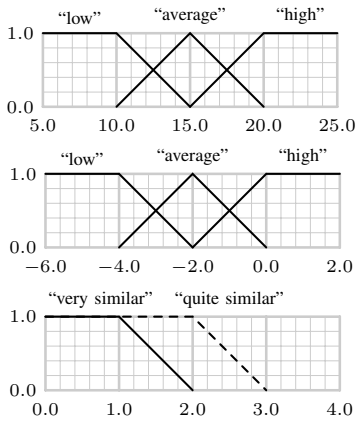

Figure 1. Membership functions of 12-month ROR (condition C – upper plot), 1-month ROR (condition P – center plot) and "similar" Rating (condition $W_{\text{Rating II/III}}$ – lower plot) predicates.

Table III
OBTAINED BIPOLAR LINGUISTIC SUMMARIES (USING ZADEH'S (Z_Q) APPROACH)

No.	Linguistic summary (Q, C, P)	W_1 [a]	W_2 [a]	W_3 [a]
1	*"Most" of IFs have "low" 12-month and possibly "high" 1-month ROR with respect to...*	*1.00; 0.50; 0.00*	*1.00; 1.00; 0.00*	*1.00; 1.00; 0.00*
2	*"Most" of IFs have "low" 12-month and possibly "average" 1-month ROR with respect to...*	0.55; 0.50; 0.23	0.52; 1.00; 0.89	0.30; 1.00; 0.74
3	*"Most" of IFs have "low" 12-month and possibly "low" 1-month ROR with respect to...*	0.75; 0.50; 0.41	0.46; 1.00; 0.71	0.46; 1.00; 0.68

[a] Truth degrees of the linguistic summary (Z_Q) and values of quality criteria (10) and (11) computed for the unitary quantifier Q for corresponding W predicates.

incompatible and compatible with the meaning of "most", while all intermediate proportions are treated as compatible to a degree in [0,1].

We focused here on showing the benefits of using contextual and possibly operator in the scope of linguistic data summarization, presenting both a theoretical and semantic justification of this concept and intuitively appealing examples.

Nine linguistic summaries (based on three different triples Q, C, P) reported in Tab. III clearly argue in favour of introduced additional quality criteria (measures) (10)–(11).

First, criterion (10) values 0.5 and 1.0 indicates that all selected contexts are meaningful (see Tab. II).

On the other hand, summaries with highest truth values (all three variants of No. 1 summary) clearly should be discarded — there are no IFs with "high" one-month ROR, which, as we stated at the beginning of section III-C, turns (7) in those summaries into a simple summarizer C (i.e. whole summary into *"Most" of IFs have "low" 12-month ROR.*).

Last three columns of Tab. III confirm that the use of (10) and (11) helps to distinguish interesting summaries (No. 2 and 3 with different W instantiations) from among all with high truth values (rejected summaries are italicized). Additional studies are needed in order to clearly determine the best summaries, yet already the results are promising.

V. CONCLUDING REMARKS

Preliminary computational results of the extension of linguistic data summaries, i.e. bipolar linguistic summaries proposed in [2], demonstrated the need for new quality criteria to determine usefulness of the summary. In [1] we introduced two of them, which have been studied deeper here. The results presented (Tab. III) show that proposed criteria fulfill their role and help select bipolar linguistic summaries valuable and interesting for an end user. Future works in this subject will mainly cover combining introduced criteria with other known quality measures, in order to determine a single value of quality of linguistic summary on one hand, and for evaluating and selecting linguistic summaries by means of heuristic methods, on the other hand.

***Abstract*—In this paper we present an intelligent consensus reaching support system within the group of individuals under fuzzy preferences and fuzzy majority. Our solution is based on the idea of soft degree of consensus proposed by Fedrizzi, Kacprzyk, Nurmi and Zadrożny, which is meant as the statement: "most of the individuals agree with the most of the options". Our new comprehensive model provides an effective support for the discussion guidance in the form of quantitative indices, i.e. sensitivity of individuals, option consensus degree and the cost of preference's changes. This additional measures support and simplify consensus reaching process and improve the degree of total agreement among decision makers.**

I. Introduction

CURRENTLY, any activity that a human being does involves solving problems, making choices, thus in general, involves some decisions. The essence of decision making is unified and short: there are some options to choose between and only one has to be chosen [2].

We accept the statement that the goal-directed decisions are difficult to make alone. Thus, we assume a session with a group of individuals and make the *group decision making process* the groundwork of our further consideration [3]. What matters here is respecting the preferences of all decision makers and arriving at a joint solution meant as an agreement of individuals as to the final decision. This interactive and iterative process is meant in the literature as a *consensus reaching process* and it requires: time, active participating of all individuals, creative thinking and being open-minded, active listening, etc [1]. The model of consensus reaching process is manageable only if individuals are able to negotiate and change their preferences.

Consensus reaching support system is commonly known as an intelligent, computer-based system that helps a team of decision makers solve problems and make choices [10]. The main role of this computer-based system plays *moderator*. His most important task is to support the discussion, i.e. he stimulates the exchange of knowledge, encourages appropriate individuals to change their opinions, focus the discussion on the relevant issues, etc. This is repeated until the group gets close to acceptable consensus or until some time limit is reached [6].

All of these features of consensus reaching process developed a need for a modern computer-based support with sophisticated tools which simplify this dynamic process and allow to achieve consensus in a more efficient way. There are many different methods that facilitate multi-stage consensus reaching process, but in this paper we show the implementation of the one of computer-based support systems. We consider either the improvement of consensus achieved or the cost of entire decision making process meant as a cost of total changes of individuals preferences.

II. Framework of the Consensus Reaching Model

A. Fuzzy Preference Relations

The core of our system is a human consistent representation of preferences. Preference relation is a very useful tool that gives relevant information about the comparison of options in decision making process [11].

Formally, there is a finite set of $n \geq 2$ options, $S = \{s_1, s_2, ..., s_n\}$, and a finite set of $m \geq 2$ individuals, $E = \{e_1, e_2, ..., e_m\}$. Each individual $k \in E$ presents his opinion as to the particular pairs of options in S. These testimonies are assumed to be individual *fuzzy preference relation* R_k defined over the set of options S (i.e. in $S \times S$) [3].

This work was partially supported by the Foundation for Polish Science under International PhD Projects in Intelligent Computing. Project financed from The European Union within the Innovative Economy Operational Programme 2007-2013 and European Regional Development Fund.

An individual fuzzy preference relation of expert k, R_k, is given by its membership function $\mu_{R_k}: S \times S \to [0,1]$. Namely, $\mu_{R_k}(s_i, s_j) > 0{,}5$ denotes that the alternative s_i is preferred to the alternative s_j, $\mu_{R_k}(s_i, s_j) < 0{,}5$ indicates that the option s_j is preferred to the option s_i and $\mu_{R_k}(s_i, s_j) = 0{,}5$ denotes that there is no difference between two considered options s_i and s_j [11].

We assume cardinality of S to be small enough to allow us to represent individual fuzzy preference relation R_k by a $n \times n$ matrix $R_k = [r_{ij}^k]$, such that $r_{ij}^k = \mu_{R_k}(s_i, s_j)$, *i,j=1,...,*n; *k=1,...,m*. R_k is also assumed to be reciprocal, i.e. $r_{ij}^k + r_{ji}^k = 1$, moreover, $r_{ii}^k = 0$, for all i, j, k [5].

B. Fuzzy Majority and Fuzzy Linguistic Quantifiers

An important part of our consensus reaching model is a fuzzy majority in the sense of fuzzy linguistic quantifiers, i.e. most, almost all etc. It is represented by the fuzzy logic-based calculus of linguistically quantified statements due to Zadeh [12].

A linguistically quantified statement is understood as "most individuals are satisfied" which can be written as

$$Qy\text{'s are } F \tag{1}$$

where Q is a linguistic quantifier (e.g., most), $Y = \{y\}$ is a set of objects (e.g., individuals) and F is a property (e.g., satisfied).

Our task is to find the degree of truth value of this linguistically quantified statement (1). First, a fuzzy linguistic quantifier is equated with a fuzzy set in [0,1]. For instance, "most" may be given as

$$\mu_{\text{"most"}}(x) = \begin{cases} 1 & \text{for} \quad x > 0.8 \\ 2x - 0.6 & \text{for } 0.3 \le x \le 0.8 \\ 0 & \text{for} \quad x < 0.3. \end{cases} \tag{2}$$

Property F is defined as a fuzzy set in the set of objects Y, and if $Y = \{y_1, \ldots, y_p\}$, then we suppose that truth value $(y_i \text{ is } F) = \mu_F(y_i), i = 1, \ldots p$. The degree of statement (1), that is, truth value (*Qy's are F*), is now calculated in two steps:

$$r = \frac{1}{p} \sum_{i=1}^{p} \mu_F(y_i) \tag{3}$$

$$\text{truth value}(\textit{Qy's are F}) = \mu_Q(r). \tag{4}$$

C. Soft Degree of Consensus

Here, we define a consensus measure which indicates the agreement between decision makers' opinions. We consider a "soft" degree of consensus as proposed by Kacprzyk and Fedrizzi [4]. In our context it is meant as the statement that: *"most of the* individuals agree in their preferences to most of the options.*"* Except of total agreement or disagreement between individuals as to the final decision, this approach allows some partial, acceptable consistency in the range [0,1].

The "soft" degree of consensus in the above sense is now obtained in three steps [5]:

1) for each pair of individuals we indicate a degree of agreement as to their preferences between all the pairs of options,

2) we aggregate these degrees to derive a degree of agreement of each pair of individuals as to their preferences between Q_1 (a linguistic quantifier as, e.g., "most") pairs of options,

3) we combine these degrees to obtain a degree of agreement of Q_2 (a linguistic quantifier similar to Q_1) pairs of individuals as to their preferences between Q_1 pairs of options and this is meant to be the degree of consensus.

We start with the degree of a sufficient agreement (at least to degree $\alpha \in [0,1]$) of individuals k_1 and k_2 as to their preferences between options s_i and s_j defined by

$$v_{ij}^{\alpha}(k_1, k_2) = \begin{cases} 1 & \text{if} \quad |r_{ij}^{k_1} - r_{ij}^{k_2}| \le 1 - \alpha \\ 0 & \text{otherwise} \end{cases} \tag{5}$$

where, $k_1 = 1, \ldots, m-1$, $k_2 = k_1 + 1, \ldots, m$, $i = 1, \ldots, n-1$, $j = i+1, \ldots, n$.

Then, the degree of agreement between individuals k_1 and k_2 as to their preferences between all the pairs of options is:

$$v(k_1, k_2) = \frac{2}{n(n-1)} \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} v_{ij}^{\alpha}(k_1, k_2). \tag{6}$$

Next, the degree of agreement between individuals k_1 and k_2 as to their preferences between Q_1 pairs of options is:

$$v_{Q_1}(k_1, k_2) = \mu_{Q_1}(v(k_1, k_2)). \tag{7}$$

The degree of agreement of all the pairs of individuals as to their preferences between Q_1 pairs of options is:

$$v_{Q_1} = \frac{2}{m(m-1)} \sum_{k_1=1}^{m-1} \sum_{k_2=k_1+1}^{m} v_{Q_1}(k_1, k_2). \tag{8}$$

Finally, according to the third step, the degree of agreement of Q_2 pairs of individuals as to their preferences between Q_1 pairs of options, called the degree of consensus, is:

$$\text{con}(Q_1, Q_2) = \mu_{Q_2}(v_{Q_1}). \tag{9}$$

III. INDICES OF CONSENSUS

A. Sensitivity of Individuals

The above definition of the "soft" consensus concerns most individuals as to most options without any distinguish between the individuals or the options. In this paper, we adopt a more flexible concept of a consensus reaching process which takes into account a sensitivity of individuals. This important component of the decision-making process is defined by the perturbation of every particular fuzzy preference relation matrix R_k.

If the fuzzy preference relation matrix is defined as $R_k = [r_{ij}^k]$, then the perturbed fuzzy preference relation matrix may be identified by $R_k^p = [r_{ij}^{kp}]$, such that: $[r_{ij}^{kp}] = [r_{ij}^k \pm a], a \in (0,1)$, for $i = 1,\ldots,n-1;\ j = i+1,\ldots,n,$ $k = 1,\ldots,m$. We also assume that $[r_{ji}^{kp}] = 1 - [r_{ij}^{kp}]$.

After matrix perturbation, we compute the degree of consensus for each individual which is now denoted as $con_k^p(Q_1, Q_2)$. Then, the measure of distance between $con(Q_1, Q_2)$ and $con_k^p(Q_1, Q_2)$ is obtained as:

$$d_k = | con(Q_1, Q_2) - con_k^p(Q_1, Q_2) | \qquad (10)$$

where $k = 1,\ldots,m$.

It is relevant for which individual small changes in fuzzy preference relation matrix cause the biggest change in the consensus degree. We obtain an ordered argument vector B where the b_i is the $i-th$ largest element (the most sensitive individual) among $\{d_1,\ldots,d_m\}$. B is called an ordered argument vector if each $b_i \in [0,1]$, and $j > i$ implies $b_i \geq b_j$, $i-1,\ldots,m$.

B. Option Pair Related Consensus Degree

Calculating the degree of "soft" consensus might derive additionally some partial indicators of consensus, like e.g. the option consensus degree which points out to the most controversial or popular options. Thus, this indicator facilitates the work of moderator by providing him with some hints as to the most promising directions of a further discussion.

The option pair related consensus degree [7] for options s_i and s_j, $OCD(s_i, s_j) \in [0,1]$, is the degree of truth value: "most pairs of individuals agree in their preferences in respect to the pairs of options s_i and sj ." It may be formally defined as:

$$OCD(s_i, s_j) = \mu_{Q_2}\left(\frac{2}{m(m-1)} \sum_{k_1=1}^{m-1} \sum_{k_2=k_1+1}^{m} v_{ij}^{\alpha}(k_1, k_2)\right). \qquad (11)$$

C. Cost of Changes

The cost of the entire consensus reaching process may be defined as the sum of absolute values of all changes in decision makers' preferences until the session ends [9], i.e.

$$cos\, t_{ij}^k(q) = \sum_{q=1}^{s} | r_{ij}^k(q) - r_{ij}^k(q-1) | \qquad (12)$$

where q denotes the iteration, $q \in [0, t]$.

IV. CONSENSUS REACHING SUPPORT SYSTEM

To clarify, initially preferences of the decision makers are far away from each other and this system aims at minimizing these distances [3]. Therefore, the moderator measures distances between individuals on each stage of the process and checks whether the consensus is reached (and process can be stopped)

$$con(Q_1, Q_2) \geq \beta \qquad (13)$$

where β indicates the acceptable degree of the consensus.

If the consensus level is not acceptable the moderator encourages appropriate individuals to update their preferences in order to improve the level of total agreement.

After calculating the consensus indicators (10) and (11), the moderator has to suggest the most sensitive decision makers to change their preferences in the most promising direction for a further discussion. Among the selected group of the most sensitive individuals the moderator finds the "typical preference relation" equited with their preference relations with respect to the pairs of options pointed out in (11). The "typical preference relation" is calculated by:

$$r_{ij}^c = \frac{\sum_{k=1}^{m} r_{ij}^k}{\sum_{k=1}^{m} r_{ij}^k + \sum_{k=1}^{m} (1 - r_{ij}^k)}. \qquad (14)$$

Then the moderator checks the relation:

$$| r_{ij}^k - r_{ij}^c | \leq \delta \qquad (15)$$

If the inequality (14) is not fulfilled then the new value of preference relation for each individual k is defined as a mean value between the typical preference relation and the former value of the preference relation of individual k, i.e., as an arithmetic average:

$$r_{ij}^k(q+1) = \frac{r_{ij}^k(q) + r_{ij}^c(q)}{2}. \qquad (16)$$

V. APPLICATION OF PROPOSED COMPUTER-BASED SYSTEM

The parameters applied to the group consensus reaching support system are:

a) $M = 10, N = 10$
b) Acceptable degree of the soft consensus (13) is: $con(Q_1, Q_2) > 0.7$

c) $\alpha = 0.8$ in $v_{ij}^{\alpha}(k_1, k_2)$ in (5)

d) $\delta = 0.1$ in (15) which denotes that almost everyone is supposed to update his opinion even with the small step.

The initial degree of consensus was equal to $con(Q_1, Q_2) = 0.38$ which was definitely below the acceptable agreement.

The sensitivity of individuals calculated in (10) was: $B = \{0.026;0.024;0.021;0.01;0.01,0.006;0.006;0.004;0.004,\ldots$ $\ldots 0.002\}$.

Hence the ordered argument vector of the most sensitive individuals was: $E = \{e_5, e_2, e_8, e_6, e_3, e_4, e_{10}, e_1, e_9, e_7\}$.

After calculating the indicator (11) for each pair of options, we discovered that there were almost no difference between the ordering options from the most preferred (promising) to the worst and inversely. This dependency is exemplified on Fig.1.

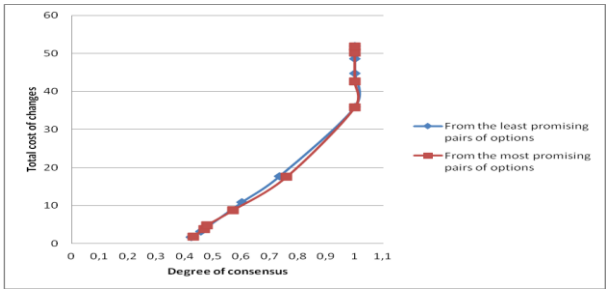

Fig. 1 Comparison of the degree of consensus and the total cost of changes for different direction of option consensus degree for 10 decision makers

However, for a smaller group of individuals (3,4 or 5) this exponential growth has differences in favor of the direction from the most promising pairs of options. TableI presents the maximum degree of the consensus obtained by a different number of sensitive individuals during the update process.

TABLE I.
MAXIMUM DEGREE OF CONSENSUS OBTAINED BY A DIFFERENT NUMBER OF SENSITIVE INDIVIDUALS COMPARED WITH THE TOTAL COST

Number of most sensitive individuals	Degree of Consensus	Total cost
3	0,61	16,86
4	0,67	22,13
5	0,77	26,73
6	0,87	32,63
7	0,99	37,23

Clearly, we can easily see an improvement in the value of the degree of consensus achieved in the group of individuals. It is also noticeable that at least the group of 5 allows us to obtain an acceptable agreement among decision makers.

VI. CONCLUSION

In this paper we proposed a new method for improving the degree of total agreement among decision makers in a consensus reaching process. We applied different procedures to find some useful indicators which allow us to run the process in the more efficient way. These procedures are to be further extended so that the improvement might take into account many aspects of this multi-criteria problem, e.g. the new optimization methods to find a best solution in the sense of aggregation either the improvement of the final degree of consensus or the total cost of changes between the decision makers during the process.

***Abstract*—Experts are able to predict sales based on approximate reasoning and subjective beliefs related to market trends in general but also to imprecise linguistic concepts about time series evolution. Linguistic concepts are linked with demand and supply, but their dependencies are difficult to be captured via traditional methods for crisp data analysis. There are data mining techniques that provide linguistic and easily interpretable knowledge about time series datasets and there is a wealth of mathematical models for forecasting. Nonetheless, the industry is still lacking tools that enable an intelligent combination of those two methodologies for predictive purposes. Within this paper we incorporate the imprecise linguistic knowledge in the forecasting process by means of linear regression. Bayesian inference is performed to estimate its parameters and generate posterior distributions. The approach is illustrated by experiments for real-life sales time series from the pharmaceutical market.**

***Index Terms*—linguistic knowledge, time series analysis, Bayesian linear regression, posterior simulation**

I. Introduction

HUMAN-BEINGS have the unique ability to process imprecise information and solve complex problems based mostly on their intuition and expertise [14]. This ability allows us to easily interpret and describe temporal data in natural language with words and propositions. Such information, often imprecise, is called *temporal linguistic knowledge* within this paper.

As observed in a selected pharmaceutical company experts were able to predict future sales and make related decisions based on approximate reasoning about imprecise information driven from visual inspection of time series data sets. It was observed that experts recognized important dependencies between linguistic temporal knowledge even in situations when analysis of crisp time series datasets showed no significant correlations. We pose the question whether linguistic temporal knowledge may bring information about new correlations useful for the time series forecasting process.

The linguistic knowledge about temporal data is provided by the experts of selected domain or is extracted automatically thanks to the knowledge discovery and data mining techniques. Among the recent developments in the field of intelligent computing there are efficient methods that provide interpretable knowledge from huge datasets.

The problem of time series abstraction and labeling meaningful intervals by means of clustering, machine learning and function approximation methods, statistical test or multiscale methods is addressed e.g. in [2], [10], [13]. The concept of pattern recognition has been widely discussed for example in [7], [8], [9], [11], [12]. One of the goals of data mining research is to provide linguistic and human-consistent description of raw data. Within this paper we take data mining results as the input for the forecasting procedure.

We provide a predictive model to support decision making in the international pharmaceutical sales market. Linguistic knowledge about temporal data is transformed into imprecisely labeled sequences that are incorporated into the probabilistic model as explanatory variables. We adopt Bayesian linear regression model and perform posterior simulation. We operate on parameters for which linguistic concepts are transparent and could easily be interpreted by experts.

The structure of this paper is as follows. Next chapter introduces basic definitions related to temporal linguistic knowledge about time series. Chapter 3 presents the forecasting process with temporal linguistic knowledge incorporated into the regression model. The description of the experiments and results for time series from the pharmaceutical industry are gathered in chapter 4. Paper concludes with general remarks and further research opportunities.

II. Linguistic concepts about temporal data

In this section we define formal language for temporal linguistic concepts that we consider most appealing for predictive purposes.

Let $O = \{o_1, o_2..., o_q\}$ denote a finite set of objects in a considered domain. The properties of objects are measured by observables. Let $M = \{m_1, m_2..., m_r\}$ denote a finite set of observables in the considered domain.

Definition 1: ***Object's property***
A pair (o, m) *such that* $o \in O$ *and* $m \in M$ *is called object's property.*

The sequence of measurements for object's property is treated as discrete time series.

978-83-60810-53-8/$25.00

TABLE I
ILLUSTRATIVE EXAMPLES FOR IMPRECISE LABEL, OBSERVABLE AND OBJECT.

Domain	Object	Observable	Imprecise label
Pharmaceutical market	Product 1	sales	high
	Product 1	supply	high
	Product 1	sales	increasing
	Europe	inflation	increasing
Mood tracking	Patient A	anxiety	high
	Patient A	weight	constant
	Patient A	hours slept	constant
	Patient B	medication	increasing

Definition 2: ***Discrete time series***
Discrete time series $\{y_t\}_{t=1}^n \in \Psi_n$ *is a sequence of observations of given object's property* (o, m) *such that* $o \in O$ *and* $m \in M$ *measured at successive* $t \in T = \{1, ..., n\}$ *moments and at uniform time intervals. For each* $t \in T$ *the observation* y_t *is a realization of the random variable* Y_t*. Random variables* Y_t *are defined on the probability space* (Ω, A, P)*, where* Ω *is the set of all possible outcomes of the random experiment,* A *is a* σ*-field of subsets of* Ω*, and* P *is a probability measure associated with* (A, P).

As stated in [1] during visual inspection people perceive and process shapes rather than single data points. We describe the evolution of time series with adjectives like *high, medium, low, light, heavy, interesting, increasing, constant, decreasing, interesting, long, short, strong, weak, slight, etc.* Such adjectives refer to imprecise values, trends, judgments or features and are called *imprecise labels* within this paper.

Let $S = \{s_1, s_2..., s_l\}$ denote a finite set of imprecise labels referring to either qualitative or quantitative measurements for observables applicable in the considered domain. Depending on the context, values for the imprecise label are assigned subjectively by experts or are calculated based on the fuzzy numbers and membership functions. For basic definitions related to the fuzzy sets theory see e.g. [6].

In real-life situations understanding and interpretation of imprecise labels depends on context and may change in time. Within this approach we assume one interpretation that is constant in time.

As presented in Table I for application *sales, supply* and *inflation* are observables when considering application in *pharmaceutical market*. If the problem of *mood tracking to support medical diagnosis* is considered, the observables measure the *anxiety* or *weight* of a patient. However, the general idea of visual inspection and processing trends is the same regardless of the practical context.

Definition 3: ***Imprecise labeled sequence***
Let $f : \Psi_n \times S \times T \rightarrow [0, 1]$ *denote function assigning the degree of truth that label* $s \in S$ *applies at the moment* $t \in T$ *for object's property measured by time series* $y \in \Psi_n$*. Imprecise labeled sequence* $\{x_t^{s,y}\}_{t=1}^n$ *is calculated from* $x_t^{s,y} := f(y, s, t)$.

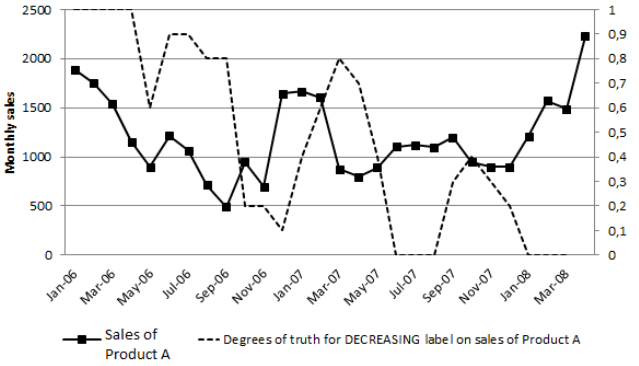

Fig. 1. Example of time series and imprecise labeled sequence.

Fig. 1 presents an illustrative example of sales time series and its imprecise labeled sequence. In this context, for each observation of time series representing sales of Product A, the expert subjectively assigned the degree of truth for *decreasing* trend. Imprecise labeled sequences are processed within the presented approach.

III. BAYESIAN REGRESSION WITH LINGUISTIC KNOWLEDGE

The forecasting procedure consists of the phase of processing temporal data and the posterior simulation. As outlined in Fig. 2 the input for the model are discrete time series and definitions of the linguistic concepts. As a result of the model, the forecast and its regressive components are provided.

A. Processing temporal data

Let $Y_n^k = \{\{y_t^1\}_{t=1}^n, ..., \{y_t^k\}_{t=1}^n\}$ denote k-vector of multivariate discrete time series. Let $\{y_t^1\}_{t=1}^n$ denote a time series of object's property to be predicted. For clarity reasons, we limit considerations to the one-step-ahead forecast and the vector of interest ω contains one element $\omega = \{y_{n+1}^1\}$. Predictions for longer horizons are iterated by repeating the procedure.

For $s \in S$ and $k-1$ time series $y \in \{\{y_t^2\}_{t=1}^n, ..., \{y_t^k\}_{t=1}^n\}$, imprecise labeled sequences $\{x_t^{s,y}\}_{t=1}^n$ are created based on data mining techniques or as a result of subjective expertise. Sequences $\{x_t^{s,y}\}_{t=1}^n$ interpreted as degree of truth that the imprecise label is valid at each moment for given object's property, represent the linguistic knowledge for the regression model.

B. Posterior simulation

Imprecise labeled sequences $\{x_t^{s,y}\}_{t=1}^n$ are included into the linear regression as explanatory variables. We adopt the multiple normal linear regression model which can be written as:

$$y = X\beta + \epsilon,\ \epsilon\ \sim N(0, \sigma^2 I_n)$$

where X is the $n \times ((k-1) \times l)$ matrix of explanatory variables, y is the $n \times 1$ vector of dependent variables and ϵ is an $n \times 1$ vector of independent identically distributed normal

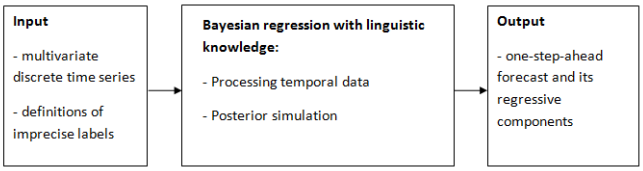

Fig. 2. Overview of the forecasting procedure based on Bayesian regression model with temporal linguistic knowledge.

random variables. We perform Bayesian inference to estimate the vector of parameters $\theta = (\beta, \sigma)$.

Following definition of Geweke [4], [5] the complete model A for Bayesian inference consists of:

1) the observables density

$$p(Y_t|\theta_A, A) = \prod_{t=1}^{T} p(y_t|Y_{t-1}, \theta_A, A)$$

in which $\theta_A \in \Theta_A$ is a $k_A \times 1$ vector of unobservables

2) the prior density $p(\theta_A|A)$

3) the vector of interest density (the posterior density)

$$p(\omega|y^o, A) = \int_{\Theta_A} p(\omega|y^o, \theta_A, A)p(\theta_A|y^o, A)\mathrm{dv}(\theta_A)$$

$$p(\theta_A|y^o, A) = \frac{p(\theta_A|A)p(y^o|\theta_A, A)}{p(y^o|A)}$$

The problem statement is to find a decision, known in Bayesian theory as an action a, which minimizes the following equation:

$$E[L(a, \omega)|y^o, A] = \int_{\Theta_A} L(a, \omega)p(\omega|y^o, A)\mathrm{d}\omega$$

Posterior predictive distributions are approached by means of Markov Chain Monte Carlo Methods (MCMC). Posterior simulation yields a pseudo-random sequence of the vector of interest to estimate its posterior moments. MCMC were initially developed in 1940s and gained popularity thanks to their great success in practical applications [5].

For simplicity, we assume that prior for β is independent from prior for σ and we apply Gibbs Sampling which leads to sampling from multivariate probability density. The sampling procedure begins with arbitrary values for β^0 and σ^0, computes mean and variance of β^0 conditional on the initial value σ^0, uses the computed mean and variance to draw a multivariate normal random vector β^1 and uses the β^1 with a random draw to determine σ^1.

Details for posterior density, drawings construction and sampling algorithm are available in [5]. Gelfand and Smith [3] proved that with Gibbs Sampler large sets of draws converge in the limit to the true joint posterior distribution of parameters.

The results for the linear regression model with linguistic knowledge are the predictive distribution for the future observations of the time series of interest and the model parameters. Parameters are easily interpreted in a natural language as they are directly linked with imprecise labels.

IV. Experimental results

The purpose of this experiment is to illustrate the performance of the forecasting method for real-life data at the example of sales time series from the pharmaceutical industry.

Train dataset consists of 6 normalized time series representing monthly sales of different products in the period from Jan'05 to Dec'09. Fig. 3 shows exemplary time series from the train dataset. The test dataset contains 6-month-long sales continuation for each product and is used for evaluation.

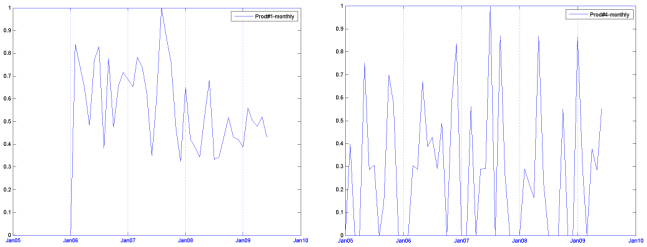

Fig. 3. Exemplary time series from the train dataset representing monthly sales of Product No.1 and Product No. 4.

We consider following 6 imprecise labels in the experiment: *low, medium, high, increasing, constant, decreasing*. Values for imprecise labeled sequences referring to *increasing, constant, decreasing* labels are defined based on experts' subjective beliefs. For labels: *low, medium, high* triangular fuzzy numbers are constructed based on the minimum, average and maximum values calculated from the time series. Then, imprecise labeled sequences are calculated from appropriate membership functions.

We first analyze correlations between the time series to be predicted and the imprecise labeled sequences to verify whether the imprecise linguistic knowledge may bring valuable information in the linear regression model. For each product we compare Pearson correlation coefficient between its sales time series and the imprecise labeled sequences derived for other products.

As demonstrated by the results in Table II correlations between sales time series and imprecise labeled sequences range from 0,10 to 0,14 and are on average by 20% higher than between different sales time series itself. Correlation coefficients are on average higher for labels of imprecise trends than values.

TABLE II
Correlation coefficients between sales time series and imprecise labeled sequences (ILS)

	Mean	Median	StdDev
Sales vs Sales	**0,10**	**0.08**	**0.05**
Sales vs Increasing	0,14	0.14	0.04
Sales vs Constant	0,12	0.13	0.06
Sales vs Decreasing	0,13	0.10	0.07
Sales vs Low	0,11	0.10	0.05
Sales vs Medium	0,12	0.12	0.05
Sales vs High	0,10	0.08	0.04
Sales vs All ILS	**0,12**	**0.11**	**0.05**

Table III provides detailed correlations per product. It is interesting to observe that for example the correlation coefficient (0,21) between sales time series of Product No. 2 and decreasing trends of other products is higher than correlation coefficient (0,17) between Product No. 2 sales time series and other sales time series itself.

TABLE III
CORRELATION COEFFICIENTS PER PRODUCT

	P1	P2	P3	P4	P5	P6
Sales vs Sales	0,16	**0,17**	0,05	0,09	0,04	0,07
Sales vs Increasing	0,17	0,18	0,10	0,11	0,16	0,11
Sales vs Constant	0,13	0,21	0,12	0,13	0,03	0,07
Sales vs Decreasing	0,22	**0,21**	0,09	0,10	0,06	0,09
Sales vs Low	0,19	0,17	0,11	0,07	0,06	0,09
Sales vs Medium	0,19	0,14	0,16	0,05	0,09	0,08
Sales vs High	0,13	0,15	0,06	0,09	0,07	0,08

The second step of the experiment is the comparative analysis of the forecasts' accuracy of the Bayesian regression model with linguistic knowledge (BRLK) and the traditional Vector Autoregression (VAR). Table IV summarizes mean absolute percentage error (MAPE) and deviation (MAPD).

TABLE IV
MEAN ABSOLUTE PERCENTAGE ERROR(MAPE) AND DEVIATION(MAPD) FOR 6- AND 1-STEP-AHEAD FORECAST OF BRLK AND VAR

	h=6 MAPE BRLK	h=6 MAPE VAR	h=6 MAPD BRLK	h=6 MAPD VAR	h=1 APE BRLK	h=1 APE VAR
P1	0,173	0,199	0,101	0,129	0,036	0,129
P2	0,425	0,509	0,193	0,165	0,202	0,317
P3	0,696	0,476	0,210	0,278	0,900	0,745
P4	0,282	0,396	0,371	0,237	0,026	0,326
P5	0,389	0,459	0,317	0,177	0,188	0,364
P6	0,444	0,371	0,281	0,222	0,703	0,559
All	**0,402**	**0,402**	**0,246**	**0,201**	**0,342**	**0,407**

As demonstrated by results in Table IV absolute percentage error for 1-step-ahead forecast is 0,342 and 0,407, respectively for BRLK and VAR. For 6-month-long forecast MAPE is the same and relatively high for both models, and amounts to 0,402. Forecasts generated by VAR are characterized by a lower standard deviation.

We conclude that Bayesian regression model with linguistic knowledge and VAR models are comparable in terms of forecasts' accuracy. The Bayesian regression model with linguistic knowledge delivers forecasts of a higher interpretability than traditional VAR as its components are naturally linked with the linguistic concepts.

V. CONCLUSION

The performed experiment confirmed that the approach with additional linguistic knowledge is adequate to support sales forecasting. Imprecise labeled sequences enable to discover new correlations in the dataset that lead to construction of the linear regression model. Produced forecasts are accurate on a similar level as forecasts provided by Vector Autoregression.

The main advantage of the proposed solution is the easy interpretation of predictions and model parameters required for forecasting process, which is of special importance for experts involved in real-life forecasting for large datasets. The proposed solution is in line with visual pattern recognition capabilities of humans and delivers additional knowledge about dependencies in multivariate time series datasets.

Next experiments for multivariate time series from other domains and on benchmark data are planned in order to analyze further benefits and limitations of the proposed technique. Another topic planned to be explored is the introduction of multiple interpretation for imprecise labels.

Within the approach simple forms of linguistic knowledge are considered. The potential to include advanced forms of linguistic knowledge like imprecise features, frequent temporal patterns, association rules and temporal linguistic summaries remains open for future research.

***Abstract* — The article presents the concept and pilot implementation of wireless (Blutetooth-based) integration of the Braille notetaker environment and the environment of touchscreen-based devices (such as smartphones) operating under the Android system. Advanced functions of Android-based devices are hardly accessible to the blind using a touchscreen; one aim of such integration is to enable accessing them with a notetaker. Another is to allow the blind who work with notetakers on a daily basis and use common touchscreen-based smartphones and tablets to write using the physical Braille keyboard of a notetaker as well as its editing functions; this would solve many problems encountered and prevent numerous errors made by the blind when using the virtual QWERTY keyboard of a touchscreen-based device. Pilot implementation of the concept included developing a communication protocol for a notetaker operated under Windows CE and an Android-based smartphone; services to be provided to notetakers by smartphones have been developed as well. The implemented services dealt with managing contacts and composing messages – operations that normally require considerable interaction with a QWERTY keyboard. Favourable results of initial research on pilot implementation conducted among the blind indicate a need for further development of this concept.**

I. Introduction

TOUCHSCREENS intended for the operation of graphical user interfaces are increasingly common in mobile devices and computers both used privately and made available to the public. Such solutions are hardly accessible to the blind: it is difficult for them to locate and select items visualised on the screen. Assistive technologies offered by mobile device manufacturers, such as Apple's VoiceOver used in iOS-based devices or Google's TalkBack and BrailleBack used in Android-based devices, do improve accessibility, but do not eliminate all the obstacles. One example of such barrier is the virtual QWERTY keyboard, where punctuation marks and other special characters are difficult to enter (it requires switching keyboard operation mode) and there is no point of reference like the bossed "J" key of a physical keyboard. Other examples include lack of haptic points on the screen (these would improve spatial orientation) and poor suitability of touchscreen gestures for the blind (they prefer gestures starting on the edge of the screen or in its close vicinity). The existing barriers create a need for research and new solutions that would improve the accessibility of touch interfaces. The concept of such solution presented in this article is based on two assumptions, tested positively for example in [3] and [4]:

- most of the tested blind smartphone users deem notetakers to be indispensable, especially for taking notes quickly;
- the use of a linear-sequential Braille interface by the blind, especially for entering text using a physical Braille keyboard, is much more efficient than the use of a virtual QWERTY or Braille keyboard.

Since, according to the research, smartphones and notetakers are indispensable in daily use for most of the blind, the main idea of the concept is to take advantage of the synergy obtained by functionally integrating devices of both types. This synergy results from combining their essential qualities: the efficient Braille interface of a notetaker and the advanced functions of smartphones and tablets. The use of a notetaker to improve touch interface accessibility gives more than just the possibility of using a physical Braille keyboard (which is accomplished by using BrailleBack app). Notetakers – computers operating under systems such as Windows CE – can provide programmable access to smartphone functions, which makes these functions available via the Braille interface. Besides, combined with a smartphone, a notetaker serves as a smart Braille keyboard with functions for efficient (quick, less error-burdened) text editing.

Advanced smartphone functions are made available through specific software that has been developed as part of concept implementation, operates under the Android system of a smartphone, and provides services for the notetaker. These services are called by specific software operated under system (Windows CE) of the notetaker and developed as part of the concept. The lowest level of integration includes communication software that runs on both devices and connects either the smartphone to the notetaker (for example for text editing) or the other way (in order to access the selected advanced smartphone function to use it as a remote service on the notetaker).

978-83-60810-53-8/$25.00

The pilot implementation of the concept involved a Samsung Galaxy S III smartphone and a Polish notetaker Kajetek SD, see [9]; it included access to contact management and message composing services as well as editing text functions (remotely serving by the smartphone, realized by a blind user on the notetaker). Results of pilot implementation tests conducted on 7 blind users with different Braille and technical experience indicate a need for further development of the concept. The testers confirmed that the initiative was heading in the right direction: for solving touch interface accessibility problems encountered by the blind. The presented considerations and research results consist the area of dissertation work of the co-author, Daniel Kocieliński.

II. Related work

The research is focused on overcoming the two greatest difficulties faced by the blind when using touchscreen-based mobile devices: enabling efficient navigation through graphical elements and their correct selection and developing a method for quick and correct text input. There are many different ways to interact with interfaces of touchscreen-based devices: a simple single tap, several simultaneous or successive taps, directional and scanning gestures as well as fixed and adaptive layouts of function fields comprising the screen.

However, software developers often neglect to adapt their methods to the needs of a blind user. Findings of Kane et al. presented in [1] point to differences in preferred gestures and ways of making them between sighted and blind users. Oliviera et al. demonstrated in [2] that the blind input text using different methods more or less efficiently depending on their personality traits and personal experience. D'Andrea found out that most of the tested blind students prefer using smartphones with Braille notetakers and value their Braille skills, especially for the possibility of taking notes, see [3]. Southern et al. in turn noticed lower erroneousness in case of entering text in Braille, using a physical or virtual keyboard, see [4] and [2]; according to [4], the use of a physical Braille keyboard is the most efficient method. Azenkot et al. confirmed these findings in [5] and [4], comparing the more efficient various Braille text input methods to entering text using a QWERTY keyboard and with the aid of Apple's VoiceOver. The virtual QWERTY keyboard has been enhanced e.g. by Findlater et al. in [6], applying extensions available through specific user gestures. In [7] Costagliola and Capua suggest implementing into the virtual keyboard an additional menu displayed upon making certain gestures around a given character. In [8] Ruamviboonsuk et al. suggest entering numbers sightlessly (to enable quicker dialling), using specific multi-touch combinations. Improvements suggested in [6], [7] and [8] have not been tested by the blind nor designed for this group of users.

In [4] the authors suggest a fixed virtual Braille keyboard that would have 6 keys: 3 on the left and 3 on the right side of the screen, near its edges. [5] in turn suggests a dynamic virtual Braille keyboard appearing where 3 fingers of one hand or 6 fingers of two hands are placed.

III. Integration concept

The main idea behind the presented research is to provide blind users with intuitive, friendly access to the advanced functions of touchscreen-based devices (such as smartphones). As a mean of improving accessibility of smartphone and tablet (hereafter referred to as smartphones) functions we propose using Braille notetakers, which are common among the blind, and Bluetooth communication mechanisms for exchanging data between touchscreen-based devices (such as smartphones) and notetakers. The adopted concept assumes that establishing a wireless connection between the notetaker and a specific smartphone will allow the user to access its advanced functionalities (given by services of Android OS and installed apps) using the physical keyboard of the notetaker and its well-known, convenient Braille interface.

As opposed to the case of graphical smartphone interfaces, where users interact with applications by making touch gestures on items displayed on the screen, operation of notetakers is based mainly on Braille keystrokes and sequential-hierarchical access to functions. Preferred interaction methods, which speed up and facilitate blind users' actions and are usually integrated in notetakers, include:

- function selection lists activated by pressing appropriate navigation keys,
- handy command menus available through hierarchical navigation or called using keystrokes,
- sets of Braille keystrokes that provide access to all the important notetaker functions at any time,
- editing functions that allow to enter text using six- and eight-dot Braille and navigation through the text quickly.

The aim of our research is to find ways of translating the graphical interface of touch-based devices (specially of smartphones) into a Braille interface that would include navigation and text input methods preferred by the blind. Our pilot work resulted in formulating basic assumptions concerning wireless operation of a smartphone with the Braille interface of a notetaker.

Such integration of the two environments – dedicated software of the notetaker and Android OS of the smartphone – allows a blind user to easily use such advanced functions of smartphones as speech recognition, cloud data (e.g. contacts) management, file sharing (e.g. Dropbox), web-based search engines, instant messaging, phonecalls or GSM and GPS navigation. Our concept makes it possible to use all the functions of a smartphone, as remote services, via a notetaker and eliminates the need for development aimed at implementing smartphone functions into notetakers. This way the blind would be able to use, conveniently, common touchscreen-based devices.

IV. Methodology

A. Implementation technology and test equipment

In order to test the concept we have developed pilot software consisting of two interacting modules: one running on an Android-based smartphone and one on a Kajetek SD

notetaker operated under Windows CE 5. Both modules support wireless Bluetooth connectivity and allow:

1) operating the smartphone with the physical keyboard of the Kajetek notetaker and
2) direct access to the advanced functions (as dedicated services) of the Android-based device.

The Android software has been implemented in Java, using Android API level 17, and tested on a Samsung Galaxy S III smartphone. During tests (navigation the contact list and input new contacts by virtual QWERTY keyboard) feedback was realised using text-to-speech, with the TalkBack screen reader.

The notetaker software is a C++ library that extends Kajetek application with support for a protocol used to communicate with the Android module. The communication protocol for the research has been developed as a sequence of XML query-response messages; the Bluetooth protocol serves as the transport layer.

B. Scope

During the research the basic concept assumptions have been tested by managing contacts using the remote interface between smartphone and notetaker. The pilot software allows the user to operate the smartphone's contact services using braille interface of Kajetek. In this way he or she can quickly navigate through contact items using notetaker keystrokes. The following contact management services have been implemented, as the remote interface, for the Kajetek notetaker:

- browsing contact lists (using specific Braille keystrokes),
- reviewing details of selected contacts,
- adding new contacts (using the editing functions integrated in Kajetek software),
- deleting contacts.

To find an appropriate input method that provides fast text entry we also measured performance of different input methods. We considered three ways of composing messages to selected recipients: using a virtual QWERTY keyboard, a virtual Braille keyboard, and the editing functions of the notetaker. Practical tests of text input speed have been conducted on a virtual QWERTY keyboard and on the physical keyboard of the Kajetek notetaker.

So, the test scenario included:

- navigating the contact list using the manufacturer's contact management app and TalkBack screen reader,
- navigating the contact list remotely, using the Kajetek Braille interface and appropriate services on the smartphone,
- adding new contacts using the manufacturer's contact management app and a virtual QWERTY keyboard,
- adding new contacts using Kajetek with its editing functions and the remote notetaker operation services on the smartphone.

C. Pilot test group

The tests have been conducted on a group of 7 users with different experience in the use of smartphones. Three of users are experienced in the use of smartphones: from a few weeks to a couple months; where one of the testers is an experienced iPhone and VoiceOver user. Next 3 of the users were able to use smartfone after training part of the tests. Seventh person said that touchscreen is too big challenge and gave up in tests on a virtual QWERTY keyboard of smartphone.

All testers know Braille well and are experienced in the practical use of Braille notetakers (5 of them are using Braille notetakers in daily work).

V. RESULTS

The results of tests proved that:

- item selection (tested on a list with 100 items) by interface of Braille notetaker is 2-3 times quicker than the item selection by the standard app of Android system (approximately from 4 to 10 seconds when using notetaker, and from 11 to 28 seconds when using standard app);
- the use of the editing functions of a Braille notetaker is much more efficient than using a virtual QWERTY keyboard (the text input speed for the slowest and the fastest tester reached, respectively, from 11 to 38 characters per minute – CPM when using a QWERTY keyboard, and from 87 to 173 CPM when using a notetaker).

Feedback from the test group confirms that the existing accessibility mechanisms of the Android system (such as TalkBack and BrailleBack), especially the ones related to navigation based on the available gestures (e.g. implemented through TalkBack) and text input using a virtual QWERTY keyboard, are subject to significant limitations. The tests have proven that managing contacts with the interface of the Kajetek notetaker and its physical Braille keyboard is more efficient than doing so using the standard smartphone application for managing contacts combined with the TalkBack screen reader, gestures and the virtual QWERTY keyboard. Selecting desired contacts from the list using Kajetek is more efficient primarily because of lesser erroneousness of browsing actions; operating a touch interface requires greater manual precision. One of the testers suggested extending the list item selection functionality of Kajetek e.g. with a quick search function looking for the first few entered letters of a contact.

The received feedback also confirms that the existing smartphone accessibility mechanisms related to text input are insufficient. Message composing tests indicated a significant advantage of the physical Braille keyboard of a notetaker over a virtual QWERTY keyboard.

VI. CONCLUSIONS

The results of preliminary research on pilot implementation into the Android system, concerning functions like managing contacts and composing messages to selected recipients, confirm that the adopted concept of using interaction mechanisms for touchscreen-based devices and Braille notetakers is a promising direction for further research and give grounds for continuing works. Practical tests of pilot application have shown that the use of a notetaker to operate the interface of a smartphone is not only

a solution that improves a blind user's work efficiency and convenience. The tests proved that quick navigation and editing functions of a Braille notetaker can be great solution for the blind users for example with a dysfunction of touch of sense. The research suggests new ways of solving the essential problem, which is the inaccessibility of new, advanced technologies to the blind. The main cause of this problem is that hardware manufacturers and software developers usually marginalise this group of users by providing (mostly behindhand) only accessibility tools (such as screen readers) that rather adapt methods of operating graphical touch interfaces than provide other, suitable ones. The proposed solution for improving the accessibility of touch interfaces is quite unusual compared to those currently provided in smartphones: it is based on using a Braille interface, smart notetaker mechanisms and a dedicated communication protocol for convenient operation of advanced mobile device functions and services. Results confirm that the our concept is a promising direction for further research and development towards a complete and efficient working environment of touch devices for the blind users.

***Abstract*—Information protection is one of the most important issues in every domain, especially when we are talking about enterprises. Information safety can be translated into three key terms: integrity, availability and data protection. There is a great number of means used in order to achieve the three objectives simultaneously. The most popular is cryptography because it offers a lot of techniques which nowadays are impossible to fail. In this paper we want to prove their efficiency by comparing the different types of crypto algorithms and by presenting their weaknesses and strengths. In order to maximize the benefits of the crypto techniques, we propose a hybrid approach that combines three crypto algorithms.**

I. Introduction

WHEN we are talking about information security we refer to it as the mean we use to protect our information from unauthorized access, use, disclosure, disruption, modification, perusal, inspection, recording or destruction.

The main concepts that a security system has to respect are: confidentiality, integrity, availability and authentication. These concepts represent the information security goals and must be achieved by every security system that aims to be functional. Most security systems use cryptography because it offers various algorithms and techniques practically impossible to break because of their complexity. Cryptography, not only protects data from unauthorized access or alteration, but it can also be used for user authentication. There are three main types of cryptographic algorithms used to accomplish these goals: secret key (or symmetric) cryptography, public-key (or asymmetric) cryptography, and hash functions (Fig. 1).

In this paper, we will analyze these three ciphers: symmetric, asymmetric and hash function. After we present each of them with their strengths and weaknesses we will point out the main attacks that an efficient security system has to face in each case.

To conclude, we propose a hybrid approach of the presented cryptography techniques which combines them for taking benefits from all of their strengths and tries to reduce as much as possible the weakness of one technique with the advantages of the other, in the following manner:

- The original message's message digest is digitally signed (the digital signature uses RSA algorithm)
- Symmetrical cipher is used to code the original message (AES algorithm). The secret key is obtained using a key generator and it is periodically changed.
- The private key used for symmetric cipher is coded using also RSA algorithm, but with different keys.
- The coded private key is attached to the encrypted message together with the digital signature

These techniques will be incrementally introduced and combined into a unitary security system for small and medium enterprises. The purpose of this system is to face the vulnerabilities and threats these enterprises might encounter, by ensuring all the security components in the company's information flow.

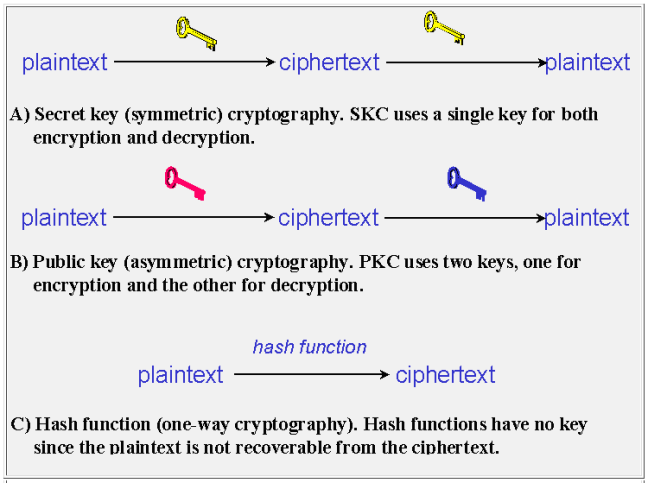

Fig. 1 The main three Cryptography Techniques [1]

II. Theoretical Background

A. Symmetric cryptography

This kind of cryptography uses a single key for both encryption and decryption, and it is also called secret key cryptography (SKC) [1]. This technique works by the following principles:

1. The plaintext is encrypted with the key and the ciphertext is sent to the receiver
2. The receiver uses the same key to decrypt the ciphertext and recover the plaintext.

978-83-60810-53-8/$25.00

The key is a set of rules, and both the sender and the receiver must know the key in order to use the technique.

The most known secret key cryptography schemes are stream ciphers and block ciphers. The stream ciphers generate a sequence of bits used as a key called a keystream, and the encryption is accomplished by combining the keystream with the plaintext. This is usually done with the bitwise XOR operation. The keystream can be independent of the plaintext and ciphertext, in which case the stream cipher is synchronous, or it can depend of the data and its encryption, in which case the stream cipher is self-synchronizing. A block cipher transforms a fixed-length block of plaintext into a block of ciphertext of the same length. The same secret key is used for the decryption by applying the reverse transformation of the ciphertext block [2].

B. Asymmetric (Public Key) Cryptography (PKC)

This technique requires two types of keys: one to encrypt the plaintext and one to decrypt the ciphertext, and it doesn't work without one or another. It is called asymmetric cryptography because it is used a pair of keys: one is the public key that can be advertised by the owner to whoever he wants, and the other one is the private key and it is known only by the owner. The most common public key algorithm is the RSA algorithm, used for key exchange, digital signatures, or encryption of small blocks of data. It uses a variable size key and a variable size encryption block. The security of the RSA algorithm is based on the factorization of very large numbers. Two prime numbers are generated by a special set of rules, and the product of these numbers is a very large number, from which it derives the key-set [3].

C. Hash Functions

A hash function offers a way of creating a fixed-size blocks of data by using entry data with variable length. It is also known as taking the digital fingerprint of the data, and the exit data are known as message digest or one-way encryption. If the data is modified after the hash function was generated, the second value of the hash function of the data will be different. Even the slightest alteration of the data like adding a comma into a text, will create huge differences between the hash values. The hash values solve the problem of the integrity of the messages. MD5 and SHA1 are algorithms for computing a fingerprint of a message or a data file. SHA-1 is described in the ANSI X9.30 standard and produces a 160-bit (20 byte) message digest. It is slower than MD5, but it has a larger digest size, which makes it stronger against brute force attacks. The advantage of MD5 is that it can be implemented faster, due to its 128 bit (16 byte) message digest [4].

III. Threats and Vulnerabilities

The main dangers an enterprise information system faces can be divided into:

- Threats –potential danger to information resources
- Vulnerabilities – weakness in application systems, network, business process or management procedures

The attacks that cryptography based security systems may suffer are dived into:

- Cyphertext-only - attempt to recover plaintext from encrypted text sent in the message.
- Known-plaintext - attempt to discover the key used when the analyst has access to the plaintext of the encrypted message.
- Chosen-plaintext same as Known-plaintext attack, but the analyst gets to choose the known plaintext.

A. Symmetric cryptography (secret key)

Although is the strongest technique that cannot be practically broken if we choose a proper complexity for the secret key, the symmetric crypto algorithms have to face a big threat in order to achieve its benefits: to safely transmit the secret key to the other part of the communication – where the decryption process is made.

Depending of the symmetric type of cipher, the usual attacks are as followed [5]:

- Block Cipher: shortcut attacks and brute force attacks. The shortcut attacks try to minimize the computational complexity required to find the correct key by exploiting the analytical and statistical characteristics of the algorithms. The most used shortcut attacks are differential cryptanalysis. The brute force attacks try one possible encryption key after another to obtain information on the correct key and/or the plaintext (For triple DES, both two-key and three-key triple DES has already been academically broken).
- Stream Cipher: its security depends on the pseudo-random number generator. If the pseudo-random numbers can be efficiently predicted from the past numbers, then the algorithm will be easily broken.

B. Asymmetric cryptography (public key)

The possible attacks on RSA are [6]:

- Searching the message space - if the message space is small, then the attacker could simply try to encrypt every possible message block, until a match is found with one of the ciphertext blocks. In practice this would be an insurmountable task because the block sizes are quite large.
- Guessing *d* - a known ciphertext attack (The attacker knows both the plaintext and ciphertext and he tries to find out the private part from the key)
- Cycle attack – it is the same as "Guessing *d*", but the coded text it is encrypted repeatedly until the original text is obtained. This number of re-cycles will decrypt any ciphertext.
- Low exponent
- Factoring the Public Key – it is considered to be the most efficient attack

C. Hash function (one way cryptography)

In the hash function case, the main vulnerability is the high probability of collisions appearance. Collisions represent the cases when two different inputs, using the same

hash function, generate the same output and therefore can be easily exploited.

In February 2005, Wang, Yin, and Yu [7] published research results which concluded that SHA-1 collisions can be found with the computational complexity equivalent to 2^{69} hash function operations. In addition, Wang, Yao, and Yao claimed that SHA-1 collisions can be found with the computational complexity equivalent to 2^{63} hash function operations.

IV. RELATED WORKS

Nowadays, small and medium enterprises use different techniques in order to achieve information protection. Some of them are based on cryptography [8, 9], others on PKI [10, 11]. All these architectures ensure a certain level of security that could be sometimes too small for the threats and the vulnerabilities that they have to face.

We propose a hybrid approach that wants to offer a complex solution with the following characteristics:

- Unified system – all the crypto techniques are combined to solve each other's threats and weaknesses
- Structured system – encapsulating different types of ciphers to maximize the efficiency

V. HYBRID ENCRYPTION SYSTEM

Data encryption is an important element of an organization's response to security threats and regulatory mandates. The enterprises are facing the fact that while encryption is not difficult to achieve, managing the associated encryption keys across their lifecycle quickly becomes a problem that creates a new set of security vulnerabilities and risks. The administration of keys must itself have built-in protection against internal maliciousness.

Encryption resources such as keys, hash algorithms, certificates, and digital signatures are dynamic and fluid. They must be changed, cycled, or renewed regularly. Furthermore, they must be archived under time-based management so that they would be available for retrieving.

By combining different cryptography techniques, this approach offers a solution for various weaknesses that must be faced in a security crypto system including:

- Key encryption management: key generator, key storage, key transmission
- Computing time
- Ensure all the security goals: integrity, availability, authentication and confidentiality

This crypto security system ensures (Fig. 2):

- Data integrity – using hash function
- Authentication and authenticity – using digital signature (DSA – asymmetric cryptography)
- Data confidentiality – using AES (Advanced Encryption Standard – symmetric cryptography algorithm)

A. Digital signature

For digital signature we can use RSA algorithm or DSA algorithm. In RSA algorithm, the message digest (the

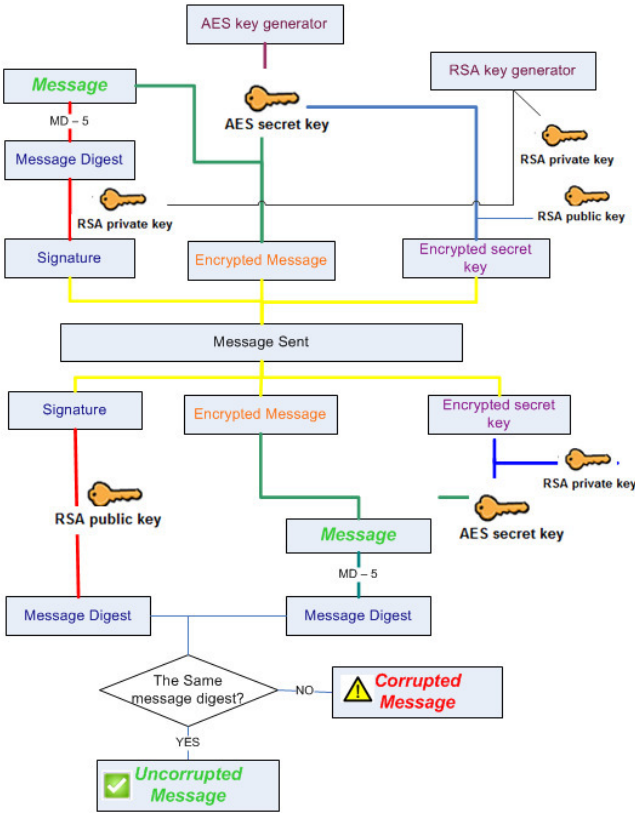

Fig. 2 Encryption schema

message hash) is encrypted with the RSA private key. This encryption represents the signature and it is attached to the message. It is obvious that this approach is impractical because:

- The ciphertext signature is the same size as the corresponding plaintext, so the messages sizes are doubled, consuming large amounts of bandwidth and storage space.
- Public key encryption is slow and places heavy computational loads on computer processors, so network and computer performance can be significantly degraded.
- Encrypting the entire contents of information produces large amounts of ciphertext, which can be used for cryptanalysis attacks, especially plaintext attacks (where certain parts of the encrypted data, such as e-mail headers, are known beforehand to the attacker).

National Security Agency developed DSS (Digital Signature Security Standard) which defines Digital Signature Algorithm. This algorithm is similar to RSA, but it does not encrypt message digests with the private key/ decrypt the message digest with the public key. Instead, DSA uses mathematical functions to generate a digital signature composed of two 160-bit numbers that are derived from the message digest and the private key. DSA uses the public key to verify the signature, but the verification process is more complex than RSA. DSA requires the use of the SHA-1 message digest function to ensure strong digital signatures and because of that and of the verification process, RSA digital signature

process generally provides better overall performance. Beside that DSA it never used to encrypt the message (for example you cannot use DSA to transmit the secret key of a symmetric cryptography algorithm).

Taking in count all these factors we will use RSA digital signature together with a RSA key generator – an algorithm used to generate secure RSA private and public keys.

B. Hash function

We use MD5 as a hash function hash function because it is faster than SHA – 1. Although it is weaker than SHA -1, we consider that the computing time is an important aspect which has to be optimised as much as possible.

C. Rijndael AES – symmetric encryption

AES algorithm has the following steps:

- Key generation
- Message encryption/decryption
- Key transmission: key encryption/decryption

Key generation is made using a cryptographically secure pseudo random number generator. We chose PRNG1 core because it is secure in wireless communications, RFID, Smart cards, electronic financial transactions. The key management system also includes the necessity of secure servers used for the key archiving and storage under time-based management so that historic data availability is ensured.

Message encryption is made using the generated key and Rijndael AES (Advanced Encryption Standard) algorithm. We chose this technique because, according to NIST, it has better security and efficiency characteristics than DES. Rijndael was designed based on the following three criteria [13]:

- Resistance against all known attacks;
- Speed and code compactness on a wide range of platforms;
- Design simplicity

Message decryption is made by the receiver using the same secret key as the sender.

Key transmission includes:

- Secret key encryption using RSA private key (generated by the key generator)
- Attach to the sent message the encrypted secret key

For the secret key transmission, we chose the most usually algorithm RSA because the practise has proved the fact that this technique successfully faces all the threats.

VI. Conclusions

Today's business environment is compliance-driven, competitive and increasingly fraught with from financially motivated hackers and frustrated employees. This creates a mounting demand for effective, practical, automated and risk-mitigating ways to manage keys throughout their lifecycle, so that only authorized users are granted access and the unauthorized user are thwarted. User and application access to these resources must be controlled, managed and audited so that authorized access is quick and reliable, all while preventing malicious attacks.

A strong crypto system together with a secure Key encryption management system can ensure all security goals. The combination of different cryptography algorithms provide a maximized efficiency, correcting or compensating each other's weaknesses.

***Abstract*—This article focuses on the performance evaluation of the response time for signalling through a home Internet Protocol based Multimedia Subsystem (IMS), separately for each of IMS core nodes (Proxy-Call Session Control Function, Interrogating-CSCF, Serving-CSCF and Home Subscriber Server) and then on the investigation of the trend-line functions and their equations to describe these delays for various measured intensity of signalling generated load by high-performance tool – IxLoad. In this article, we have found out the trend-line function of response times for each measured message. Thanks to the showed results, some performance parameters like delay in selected IMS core node and their behaviour can be predicted and evaluated.**

***Keywords*—DIAMETER, IP based Multimedia Subsystem, IxLoad, Response time, SIP.**

I. Introduction

THE current trends in telecommunications lead to the network convergence and to effort the greatest number of telecommunication services through one type of transport networks and for one multifunction terminals. Therefore in the past, the operators and vendors were looking for an IP-based connectivity concept allowing the convergence network technologies and opportunities for optimization at all levels of designed communication system. Nowadays, the IMS (IP Multimedia Subsystem) in role of the IP-based service control architecture represents the standard of fixed-mobile network convergence. However to this optimization, it is necessary to know exactly the behaviour of these systems for various real conditions. One of the possible ways how to determine the behaviour of the whole IMS subsystem or only some IMS nodes is the performance analysis either based on the mathematical modelling using queueing theory or performance benchmarking (see *Section II* of this article).

The methodology of IMS/NGN (Next Generation Networks) performance benchmarking is standardized by European Telecommunications Standards Institute (ETSI) in multipart deliverable that is divided into four separate parts [1]: *Core Concepts*, *Subsystem Configurations and Benchmarks*, *Traffic Sets and Traffic Profiles*, and *Reference Load network quality parameters*. The overall concept of IMS test-beds including the IMS benchmark information model, test parameters and benchmark metrics examples is defined in the first part of this technical standard. The SUT (*System Under Test*) configuration parameters, use-cases and scenarios with metrics and design objectives are presented in the second specification. In the third part, the traffic set, traffic-time profile and test procedures are defined. The reference load network quality parameters for use-cases defined in the second part of [1] are presented in the last part of this specification.

II. Related Work

There are various research papers, documents or studies that describe the performance analysis of whole IMS. The OpenIMS Core project (in role of SUT) and IMS Bench SIPp project (in role of TS - *Test System*) are often used tools for the performance analysis of IMS subsystem. The related work concerning the performance evaluation of IMS networks can be divided into three main categories, the performance evaluation of maximum load [2]–[4], the performance evaluation of delays of SIP (Session Initiation Protocol) signalling [5] and evaluation of delays of IMS procedures like IMS registration or IMS session setup procedures [6]–[7].

In our previous works, we were mainly focused on the performance analysis using the IMS queuing network model [8] and on the performance evaluation of maximum load signalling over our laboratory IMS network [9] according to specification [1]. In [9], we investigated that the value of the maximum signalling load for these hardware and software configurations is $500cps$ for defined IHS threshold 0.025% and the HSS entity was the failure point of simulated IMS network. The same bottleneck was described in [3] for even lower values of load (during execution of registration procedures). The similar test-beds are described by others researchers in [2]–[4] and the results of maximum loads correspond to the results measured in our test-bed which is described in [9] and in this section. In [8], we presented the design of IMS mathematical model based on separated M/M/1 queuing system with feedbacks that consists of the same IMS entities, signalling and services as our laboratory IMS network. In this M/M/1 model, the new load balancing methods, that can be used for a selection of S-CSCF server during the registration procedures of subscribers, were designed and evaluated. The obtained results showed that the service latency of the whole IMS core subsystem can be optimized with the help of implemented methods into mathematical network model based on M/M/1 queuing system. However, the service times are not exponentially distributed in the real networks. Therefore, the *main motivation of this article* is targeted at the measurement of delays for each SIP and DIAMETER signalling of IMS core elements using the performance analysis of IMS core elements and standards [1]. Thanks to the obtained results, we will be able to simulate the behaviour of IMS nodes using M/G/1 queuing systems and

978-83-60810-53-8/$25.00

evaluate the designed methods for load balancing under more realistic network conditions.

III. IMS TEST-BED

The experimental topology of the test-bed (see Fig. 1) consisted of IMS core subsystem, VoD Application Server and Media Streaming Server with the same following hardware and software configurations: 4x Intel Core i5-2400S CPU @2.50 GHz with 6144k L3 cache, 8 GM RAM (DIMM 1333 MHz), 82574L Intel Gigabit Network Connection, OS GNU/Linux (Debian distribution, AMD64 architecture, kernel v3.2), the software implementations of CSCF nodes are based on the SER (SIP Express Router) and the HSS based on FHoSS (FOKUS HSS) server created by Fraunhofer FOKUS Institute.

The SIP load signalling of selected multimedia services (Video on Demand, Voice over IP and File transfer) with defined intensity (see λ in Fig. 1) of the Poisson arrival process is generated with the help of the high-performance IxLoad application (see TS in Fig. 1). Each of services consists of three phases: registration procedure with subscription , session establishment and termination procedures (only for registered subscribers), and de-registration procedure. The registration phase consists of the registrar and subscription transactions. The generated signalling flows are created with the help of the standardized document 3GPP TS 24.228.

We can define the test-bed architecture with the help of queuing theory that is often used to evaluate the performance parameters of whole networks or only some network nodes. In the Fig. 1, the IMS core nodes are shown as the M/G/1 queuing system. One of the most important performance parameters is the response time of system (see eq. (1)). The mean value of this parameter can be calculated using the Pollaczek-Khinchine formula (known as P–K mean value formula [10]):

$$\frac{T}{\bar{x}} = 1 + \rho * \frac{1 + C_b^2}{2 * (1 - \rho)} \tag{1}$$

Where the $\rho = \frac{\lambda}{\mu}$, C_b^2 is the coefficient of service time variation and the parameter $\bar{x}$ is the mean service time.

The way to calculate these values is following. In the case of P-CSCF server, the response time is always the time difference between the received and forwarded SIP messages. The response time of SIP signalling through S-CSCF server equals to the signalling through P-CSCF except the registration and de-registration procedures. In the case of these procedures, the response times of signalling through S-CSCF server are determined as the transactions between SIP and DIAMETER (DIAMETER uses TCP as its transport protocol). It means that the service times are determined as differences between the SIP request received from I-CSCF and DIAMETER request sent to HSS (sending time of DIAMETER MAR - receiving time of the first SIP REGISTER) or the DIAMETER answer received from HSS and SIP response sent to I-CSCF (sending time of SIP 401 - receiving time of DIAMETER MAA). The same way to determine the signalling response times is used for I-CSCF server. In the case of times for DIAMETER signalling through HSS database, the value is calculated as difference between the times of received DIAMETER request and sent DIAMETER answer.

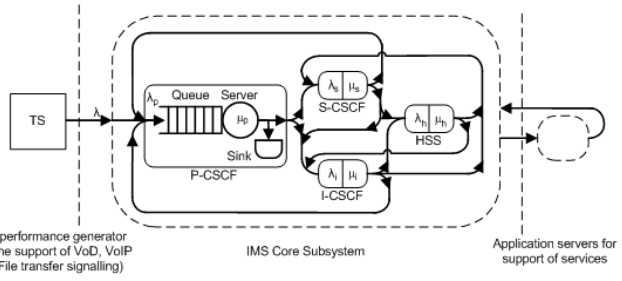

Fig. 1. The test-bed architecture as the queuing system network with feed-backs.

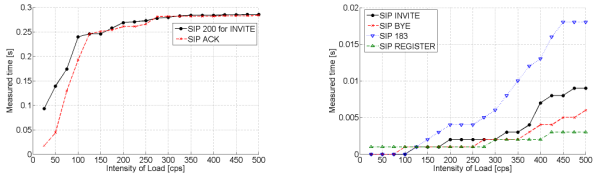
IV. RESULTS AND ANALYSIS

The traffic of three advanced telecommunication services (Video on Demand, Voice over IP and File transfer using SIP/RTSP/MSRP and RTP/RTCP signalling) over IMS experimental network is evaluated for various load intensities separately (from $25cps$ to $500cps$) for each of IMS core nodes (the P-CSCF, I-CSCF, S-CSCF and HSS) and for each of SIP or DIAMETER messages. The most important results are shown in Fig. 2 to Fig. 3(b) and Tab. I to Tab. IV. The maximum value of signalling load ($500cps$) for used hardware and software configurations was investigated in [9]. The SUT (whole IMS network) was very unstable for the load greater than $500cps$. In Tab. I to Tab. IV, the trend-lines of response times for each message through selected IMS servers are shown only for messages with the measured service time greater than $1ms$. This limitation, shown in all tables and figures, is the measurement accuracy. The measured messages are displayed in the first column of the shown tables, the formulas of trend-lines of the response time for defined range of signalling load are shown in the second column. The parameter x is the signalling load generated by IxLoad application in role of TS (see λ in Fig. 1). The delay calculation methodology has been described in the previous section of this article. The measured characteristics of the response times into arrival signalling load through SUT (see λ in Fig. 1) are shown in the Fig. 2–4.

The P-CSCF trend-lines of response times (see Tab. I and Fig. 2) are mostly defined with the exponential or logarithmic time complexity. Other measured SIP request or response times (SIP 180, SIP 200s for REGISTER, BYE, SUBSCRIBE, UPDATE and PRACK, SIP 401, PRACK and UPDATE) are set to $1ms$ (the measured times are less than $1ms$). In the graphs (see Fig. 2), the mean values of measured times within the generated load (see λ in Fig.1) for SIP messages with response times greater than $1ms$ are shown. From these graphs, it can be seen that the ACK and 200 for INVITE messages have the

TABLE I. THE FUNCTIONS OF RESPONSE TIMES FOR EACH MESSAGE THROUGH THE P-CSCF

SIP requests and responses	The trend-line function
SIP Session in Progress	$f(x) = (0.0009) * exp(0.0067 * x)$
SIP OK for INVITE	$f(x) = (-2.346) * x^{(-0.7343)} + 0.3137$
SIP REGISTER	$f(x) = (5.171e-11) * x^{(2.838)} + 0.0009$
SIP INVITE	$f(x) = (0.0003) * exp(0.0075 * x)$
SIP ACK	$f(x) = (-3.804) * x^{(-0.7923)} + 0.3139$
SIP BYE	$f(x) = (0.0004) * exp(0.0055 * x)$



(a) The messages with higher measured times. (b) The messages with lower measured times.

Fig. 2. The mean values of response times vs. signalling load through the P-CSCF.

highest response times. However, the SIP Session in Progress and SIP INVITE messages have the greatest increase of the response time within the analysed interval.

The I-CSCF server is the next evaluated IMS node (see Tab. II and Fig. 3(a)). In our test-bed of a home IMS network, this server is active only during the registration or de-registration procedures. Only the SIP 401 response has different time complexity (it has the constant complexity, the measured times are less than $1ms$) than other SIP messages. The SIP REGISTER $\rightarrow$ DIAMETER UAR processing has the shortest rise of measured response times (see Fig. 3(a)).

The last node, which was evaluated within the CSCF core, is the S-CSCF server (see Tab. III). This IMS node presents the central node of the whole IMS network and therefore it can be expected that this node has the greatest response times (see Fig. 4). Actually, there are two interesting facts in this obtained results. First, the highest values of response time are associated with the SIP responses (SIP 200 for REGISTER or SIP 401) created by S-CSCF node during the registration or de-registration procedures when the DIAMETER answers (MAA or SAA) are received from the HSS node. The second interesting result is that the SIP ACK and SIP 200 for INVITE

TABLE II. THE FUNCTIONS OF SERVICE TIMES FOR MESSAGES THROUGH THE I-CSCF

SIP and DIAMETER requests and responses	The trend-line function
SIP 200 for REGISTER	$f(x) = \begin{cases} < 1ms & \text{if } x < 100cps \\ 1ms & \text{if } x \in \langle 100, 375 \rangle cps \\ 2ms & \text{if } x > 375cps \end{cases}$
SIP REGISTER $\rightarrow$ DIAMETER UAR	$f(x) = (-6.146e-11) * x^{(2.956)} + 0.0009$

(a) The messages with higher measured times. (b) The messages with lower measured times.

Fig. 4. The mean values of response times vs. signalling load through the S-CSCF.

messages have the highest response time of all SIP messages forwarded by this server. The similar result was measured also in the case of the forwarding this SIP message by P-CSCF node. The measured values of other request or response times (for SIP 180, 183, SIP 200s for BYE, UPDATE and PRACK, SIP PRACK and UPDATE) are not showed in Tab. III because the measured values are less than $1ms$.

The last measured node of IMS network is the HSS database (see Tab. IV or Fig. 3(b)). In our test-bed, the database server is active only during registration and de-registration procedures. It can be seen that the response time of all measured DIAMETER requests/answers has the logarithmic time complexity with relatively low difference between the value of minimum load and the value of maximum load.

In our case, the tested IMS core subsystem is in the role of a home IMS network. The signalling goes through each of evaluated IMS core server (see Fig.1) only the case of the de/registration procedures. The delay of IMS core, which is calculated as formula (2), consist of IMS core element delays and transport delay through network infrastructure.

$$D = \sum D_P + \sum D_I + \sum D_H + \sum D_S + \sum D_T \quad (2)$$

TABLE IV. THE FUNCTIONS OF RESPONSE TIMES FOR MESSAGES THROUGH THE HSS

DIAMETER Command-Codes	The trend-line function
300 (UA$\{R, A\}$)	$f(x) = (-1.293) * x^{(-1.792)} + 0.004$
301 (SA$\{R, A\}$)	$f(x) = (-0.046) * x^{(-0.569)} + 0.008$
303 (MA$\{R, A\}$)	$f(x) = \begin{cases} 1ms & \text{if } x < 100cps \\ 2ms & \text{if } x \geq 100cps \end{cases}$

Where $\sum D_P$, $\sum D_I$, $\sum D_S$ and $\sum D_H$ are the investigated times that the messages spent in CSCFs and HSS and $\sum D_T$ is the time the messages spend within the network infrastructure. Each of core node delays is composited from the queueing and processing delays defined in [7]. The values of $\sum D_I$ and $\sum D_H$ are greater than zero if the signalling is from the registration or de-registration procedures, else the values are equal to zero. The theorem is valid for the home IMS network simulated in this paper.

The successful registration procedure (see eq. (3)) is influenced by three delay parts, thereof two delays are influenced by time the signalling spent in SUT (the tested IMS core) and the response times of TS (IxLoad application).

$$D_{REG} = \underbrace{\sum D_{(REG1\rightarrow 401)}}_{\text{SUT}} + \underbrace{\sum D_{(401\rightarrow REG2)}}_{\text{TS}} + \\ + \underbrace{\sum D_{(REG2\rightarrow 200)}}_{\text{SUT}} \tag{3}$$

We do not tie the effect of $\sum D_{(401\rightarrow REG2)}$ and transmission delay in the following equations. The first of SUT delay is shown in eq. (4). We can define the second one based on assumptions from the first SUT delay.

$$\begin{aligned} \sum D_{(REG1\rightarrow 401)} &= \underbrace{D_{(REG1\rightarrow REG1)} + D_{(401\rightarrow 401)}}_{\text{P}} + \\ &+ \underbrace{D_{(REG1\rightarrow UAR)} + D_{(UAA\rightarrow REG1)} + D_{(401\rightarrow 401)}}_{\text{I}} + \\ &+ \underbrace{D_{(UAR\rightarrow UAA)} + D_{(MAR\rightarrow MAA)}}_{\text{H}} + \\ &+ \underbrace{D_{(REG1\rightarrow MAR)} + D_{(MAA\rightarrow 401)}}_{\text{S}} \end{aligned} \tag{4}$$

If we neglect the effects of lower signalling delays and the impact of delays outside IMS core elements (see eq. (2)–(4)) then we can define for conditions of our test-bed the delay of successful registration procedures as:

$$D_{REG} \approx \underbrace{D_{(MAA\rightarrow 401)}}_{\text{from first SUT delay}} + \underbrace{D_{(SAA\rightarrow 200)}}_{\text{from second SUT delay}} \tag{5}$$

The percentage ratio of derived D_{REG} (see eq. (5)) is 94.4% of measured D_{REG} (see Fig. 2–Fig. 4). From the characteristics and eq. (5), it can be seen that the delay of IMS procedures is mainly influenced by measured delays of S-CSCF server that is in role of IMS networks as IMS central core element.

V. Conclusion

This paper deals with the evaluation of response times for signalling through the experimental IMS core subsystem, separately for each IMS core node and message, and for various values of network load. Three advanced telecommunication services were generated by the high-performance IxLoad application. All selected IMS core nodes were situated in the servers with the same hardware configurations.

From the showed characteristics (see Fig. 2–Fig. 4), it can be seen that the central node of the whole IMS network (the S-CSCF server) has the highest values of response time and its influence on delays of signalling through whole home IMS network from eq. (5). Based on assumption from eq. (2)–(5), we can obtain the similar results for other tested IMS procedures like session establishment and that the S-CSCF server has the highest impact on delay of signalling within a home IMS network. However, the influence of S-CSCF server is not very high in the case of session termination procedure. Therefore, our future work will focus on the problem how to optimize the latency of the whole IMS network e.g. during registration procedures using load-balancing of S-CSCF servers.

Also, we have found out the trend-lines with the correlation (the lowest R-squared index was approximately 0.95, the most commonly value of R-squared was 0.98) that are described by the help of the exponential or logarithmic functions for each evaluated message and IMS core node. In the case of HSS node, only logarithmic function is used to define trend-lines of DIAMETER signalling. This functions could be used to predict the delay either in the node of IMS network or within the whole IMS network.

***Abstract*—In this paper we shall present a serial driver chip creation on FPGA. We created this serial driver chip for the RS-232 interface and we programmed it to 115200 baud rate to be able to communicate with the Lynxmotion AL5 type robotic arms. This serial driver chip was made for bidirectional communication to be able to send and receive SCPI (Standard Commands for Programmable Instruments) commands on the serial interface. If we create the layout of this chip we can create our own ASIC (Application-Specific Integrated Circuit) and this way we shall have a standalone chip which can control a robotic arm.**

I. Introduction

THIS paper presents the creation of the serial driver chip. Serial driver chip is very useful in controlling many measuring equipments, power supplies, industrial test systems and even robotic arms. No too many types of equipment have USB interface or if they have they have only USB connector, but they still emulate the COM port. This means that the serial interface is still widely used in the industry, even though it's speed it's not the highest. Basically we had to create the UART diver chip ad after it to connect whatever connector to we wish to connect DB9 or DB25, depending on what kind of robotic arm do we wish to control. In our case the Pmod (Peripheral Module) connected to our FPGA board had DB9 connector which was perfect for the Lynxmotion AL5 type robotic arm, but for the Scorbot ER-III robotic arm we needed DB25 connector which we solved with a serial converter from DB9 to DB25.

We can control robotic arms with a PC, but if we have an embedded solution is always better, because it's more portable, and consumes less power. If we find an embedded solution that is implemented in hardware, it's even better, because we shall have no issues regarding to propagation times and we don't' have problems likes bug in software or issues like the system can freeze.

II. Problem Formulation

We had a Lynxmotion AL5 type robotic arm (Fig. 1) and a Scorbot ER-III robotic arm (Fig. 2).

We had also more FPGA boards one NEXYS 2 board (Fig. 3) with Spartan-3E FPGA and one ATLYS board (Fig. 4) with Spartan-6 FPGA + and Pmod RS232 (Fig 5).

Fig. 1 Lynxmotion AL5A robotic arm

Fig. 2 Scorbot ER-III robotic arm

Fig. 3 NEXYS 2 FPGA board with Spartan-3E FPGA

Fig. 4 ATLYS FPGA board with Spartan-6 FPGA

Fig. 5 Pmod RS232 for the ATLYS board

978-83-60810-53-8/$25.00

We had all the hardware, but we needed to create the serial driver to make the communication and to control the robotic arms. For the ATLYS FPGA board we needed to use the Pmod RS232, because the board has only micro USB connector to its UART interface and that not the best solution, because it needs software driver to emulate the serial port on USB and the connector is not suitable for us too, because we need not micro USB, but DB9 or DB25. The USB UART is Ok just when the PC is the master and the FPGA board is the slave, because on the PC we can easily install the USB to serial converter driver. In our case the FPGA board is the master and the robotic arm's servo controller is the slave, this way is really hard to impellent a software driver for the serial to USB converter chip. In our case the standard serial port with DB9 connector is the best solution, this way we had to use a Pmod for the ATLYS board.

III. Problem Solution

A. Theoretical Background

The SCPI (Standard Commands for Programmable Instruments) for controlling the robotic arm will be presented next, these commands are sent on the serial driver chip and with these commands the robotic arm is moved.

```
// SSC-32 VERSION
\r\rVER\r

// INITALIZE MOTORS
QPL0\rQP0\r
QP1\r
QP2\r
//...
QP31\r

// ALL SERVOS 1500
#0P1500S0\r#1P1500S0\r#2P1500S0\r#3P150
0S0\r#4P1500S0\r#5P1500S0\r

// GRIPPER
#4P1500S1000\r

// WRIST ROTATE
#5P1500S1000\r

// WRITST
#3P1500S1000\r

// ELBOW
#2P1500S1000\r

// SHOULDER
#1P1500S1000\r

// BASE
#0P1500S1000\r
```

Somehow from these commands we managed to create some formulas too, to know the correspondence between the angles and robotic commands.

To know exactly the angles we can simply calculate with equation (1).

$$\alpha = \frac{\Delta\omega}{180° - 0°} = \frac{2500 - 500}{180° - 0°} = 11, (1)\ robotic\ values \tag{1}$$

This means the following shown in equation (2).

$$1°{\sim}11,(1)\ robotic\ values \tag{2}$$

The block diagram of the experimental setup with the ATLYS board and the Pmod RS232 is shown on Fig. 6.

The block diagram of the experimental setup with the NEXYS 2 board is shown on Fig. 7.

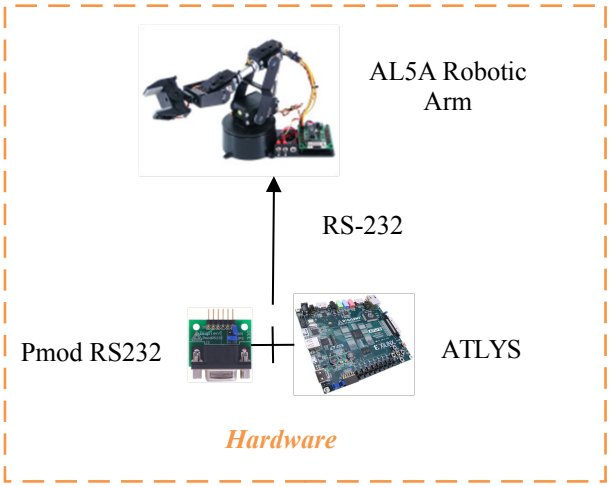

Fig. 6 The block diagram of the experimental setup with the ATLYS board and the Pmod RS232

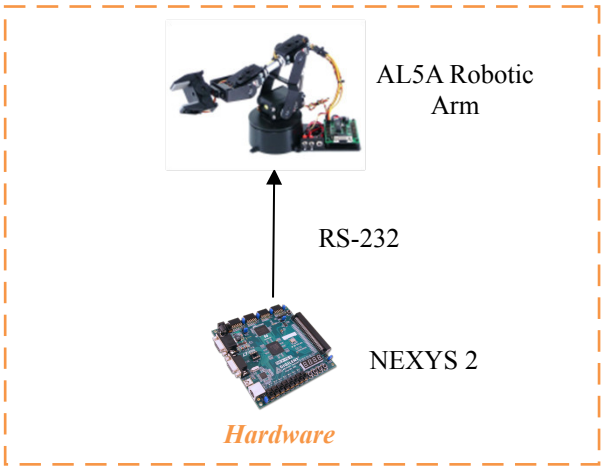

Fig. 7 The block diagram of the experimental setup with the NEXYS 2 board

B. Circuit Diagrams

These circuit diagrams were created from VHDL code in Xilinx ISE. These circuits are what we have inside the serial driver chip.

On Fig. 8 we can see the bidirectional serial driver chip, which has both the transmit (TXD) and receive (RXD) ports.

On Fig. 9 we can see the UART chip which we included in the bidirectional serial driver chip, this chip is actually the serial protocol.

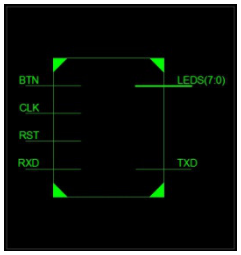

Fig. 8 The bidirectional serial driver chip structure with transmit (TXD) and receive (RXD) functions

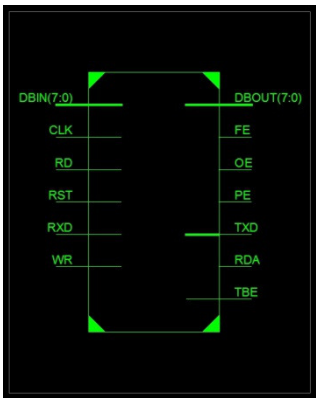

Fig. 9 The UART chip which is included in the bidirectional serial driver chip

On Fig. 10 we can see the circuit structure inside the bidirectional serial drive chip.

On Fig. 11 we can see the circuit structure inside the UART chip.

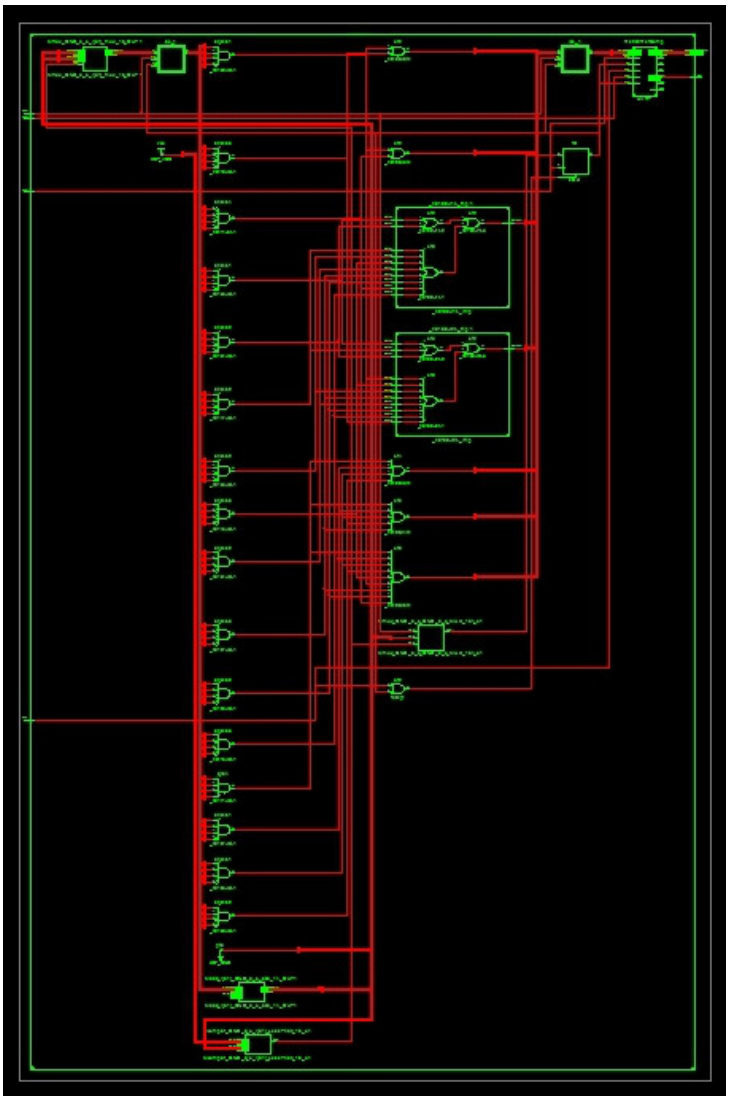

Fig. 10 The bidirectional serial driver chip's circuit (inside the bidirectional serial driver chip)

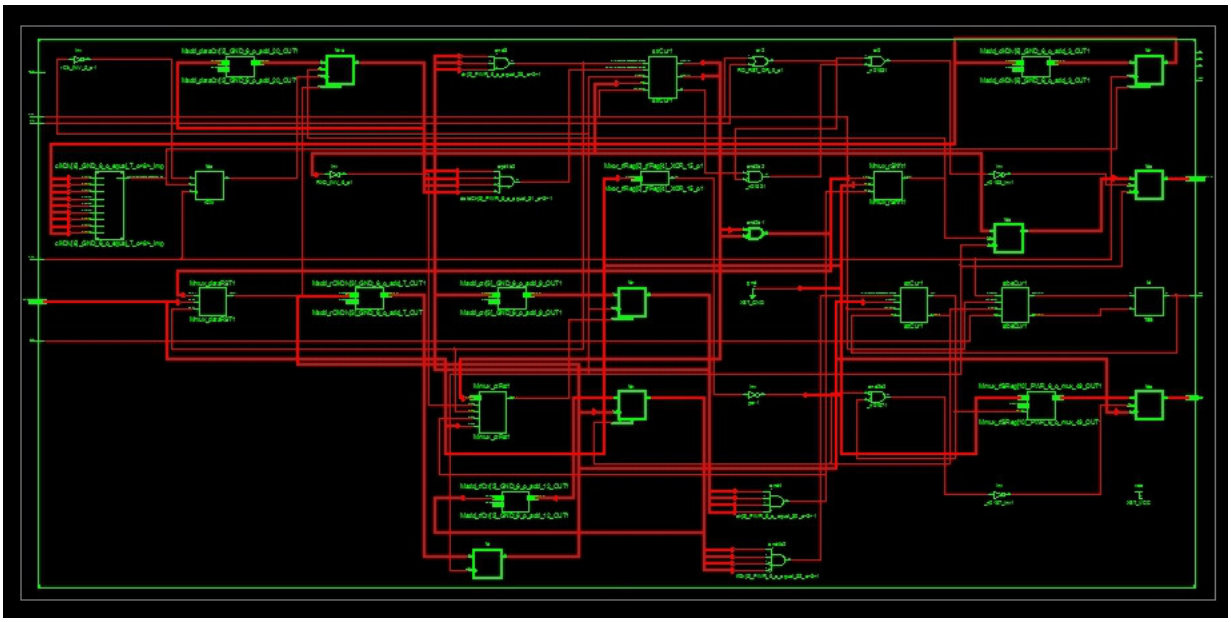

Fig. 11 The UART module's circuit (inside the UART chip)

IV. Conclusion

As we can see, we have created a serial driver chip which can control measuring equipments, power supplies, industrial equipments and even robotic arms.

With this chip we can control any equipment which has an RS-232 serial interface; the only change is that we have to load the specific SCPI commands for the specific equipment we want to control.

We created only in FPGA in two platforms on NEXYS 2 board with Spartan-3E and on ATLYS board with Spartan-6 + Pmod RS232.

After this we plan to convert the FPGA code in Verilog code and with the Mentor Graphics tools to create the chip's layout. After this we can send it to the production to create the silicon die, we shall do the packaging and with this we shall have our own serial driver ASIC.

This ASIC can be than put on a PCB (Printed Circuit Board) with a DB9 connector and some electronic components and we shall have an embedded control board for almost any equipment which has serial port or even a control board for the robotic arms. The only task is to load in a ROM memory the specific SCPI commands for each equipment which needs to be controlled.

Fuzzy-Based Multi-Stroke Character Recognizer

Alex Tormási and László T. Kóczy
Széchenyi István University
1 Egyetem tér, Győr, H-9026, Hungary
Email: {tormasi, koczy}@sze.hu

***Abstract*—In this paper an extension for multi-stroke character recognition of FUzzy BAsed handwritten character Recognition (FUBAR) algorithm will be presented. First the basic concept of a single-stroke version will be overviewed; in the second part of the paper the new version of the algorithm with multi-stroke symbol support will be introduced, which deploy the same algorithm overviewed in the first part and use flat and hierarchical rule bases.**

I. Introduction

LALOMIA defined the user acceptance threshold in 97% [1], however most multi-stroke character recognition methods known from the literature that are applicable for 26 symbols are well below, on the other hand with a stricted set of symbols (16 gestures) the $N recognizer reached 96.7% [2]. Despite the high accuracy these methods are not always usable for on-line (real-time) handwriting recognition as a result of their high computational complexity and processing time. It is very important to find a recognition engine, which is able to process the input strokes in a short period even on devices with limited resources such as tablets.

In this paper we present a new attempt to recognize multi-stroke letters (26 symbols) with rather good recognition rate (however definitely below LaLomia's 97% threshold). As the starting point the FUBAR algorithm that was very successful for single-strokes will be used, with modifications towards multi-stroke symbols (up to 3 strokes).

After the introduction in this paper the basic steps of the single-stroke FUBAR (Fuzzy Based Recognition) algorithm [3] will be overviewed. In Section 3 the results of the new method with the capability of recognizing multi-stroke symbols are presented. In Section 4 the average recognition rates are analyzed, for the case of the same multi-stroke recognition method with a hierarchical rule-base. In Section 5 the results of the new algorithms and other known recognition algorithms are compared.

II. The Single-Stroke Fuzzy Based Recognition Method

A. Algorithm Properties and Features

During the design of the algorithm the most important goal was to create a recognition engine which is able to process the input strokes with at least the same accuracy of other already published recognition methods, while taking less computational time. Most of the methods published in literature are using geometrical transformations, like rotation and trapezoid correction are complex and resource consuming; to reduce the complexity of the recognition method the use of such transformations was ruled out. The designed recognition method is online, which means that it uses digital ink information to represent the strokes. The alphabet used there is based on a slightly modified version of the Palm's Graffiti single-stroke symbol set [4].

B. Input Processing

The method collects the positions of the digital pen used during the writing process; the strokes are stored in a time ordered list of two-dimensional coordinates. To provide a better input for the next phases of the processing, the input stroke should be re-sampled to provide a low-level anti-aliasing (noise reduction) and provide almost equal distance between the sampled points.

Details of the input processing phase are overviewed in [3, 5].

C. Parameter Extraction

The algorithm uses two kinds of parameters to recognize symbols; the first is the width/height ratio of the stroke while the second type is formed by the average numbers of stroke points in the rows and columns of the fuzzy grid drawn around the stroke. The fuzzy grid approach was introduced in details in [3], in order to handle italics and thus replace the stroke rotation phase used by other methods. The rows and columns of the grids are represented by fuzzy sets [6], which allow a point to belong to two different rows or columns at the same time.

D. Inference

The parameters extracted from a collection of 60 single-stroke character samples were used to determine the rule base for the fuzzy system.

Each symbol in the used alphabet is described by a single rule. The antecedents of the rule are the previously collected parameters and the consequent part represents the degree of matching.

For inference a discrete Takagi-Sugeno method [7] with standard t-norms was used. The algorithm returns with the symbol assigned to the best matching rule.

This paper was supported by the National Scientific Research Fund Grant OTKA K75711 and OTKA K105529, a Széchenyi István University Grant and EU grants TÁMOP 4.2.1 B, TÁMOP 4.2.2/B-10/1-2010-0010.

The detailed description of the single-stroke algorithm and inference can be found in [3, 5].

III. Multi-Stroke Symbol Support

In this part, the results of a new Fuzzy-Based Recognition Engine (FUBAR) family member are presented. This new method is able to process multi-stroke symbols. The method handles each symbol as one non-continuous stroke with "empty" spaces between the sampled points.

The samples were collected from 10 male and 10 female Hungarian participants in the age group 18 to 40. Each subject has provided 20 samples for each 26 multi-stroke symbol. The etalon writing style for the symbols was determined by pre-collecting samples for the most widely used symbol types in the local area for the 26 letters of the English alphabet.

Symbols with obvious errors were identified and removed from the collection and the number of samples per symbols was limited to 180 for a better comparison with the single-stroke system, in which there is the same number of (different) samples was used during the tests in [8, 9, 10].

A similar method was used for data collection as overviewed in [8, 9, 10] with a modification to transform multiple strokes into a single one. This approach gives the capability to the algorithm to process multi-stroke input.

After this step the joint stroke is re-sampled to ensure almost equal distance between the neighbor points.

Each normal trapezoidal fuzzy set describing the stroke parameters in the antecedent part of the rules was constructed according to the statistical process of the parameters extracted from the first 60 samples for each symbol. Each letter is represented by one rule, where the input parameters are collected from a fuzzy grid drawn around the multi-stroke symbol. The analyzed stroke parameters are the width/height ratio and the average number of points in the rows and columns of the fuzzy grid drawn around the stroke (described in previous section); the details of the feature extraction method are the same as in [3, 5].

The same method was used for data collection as overviewed in [3, 5, 8]. The output parameters of the rules are representing the degree of matching between the parameters of the processed input stroke and the information stored in the rules for the described letter.

For the inference a discrete Takagi-Sugeno method was used with standard t-norm (Zadeh t-norm), which returns the symbol assigned to the rule with the highest matching value for the input stroke.

The average recognition rates for the symbols and for the complete alphabet were calculated for the method by the results for 120 samples from the sample set using different fuzzy grid sizes. These are the same conditions as overviewed in [8, 9, 10].

Similar single-stroke method was used for data collection as described in [3, 5], which may give a better environment to compare the results.

The best result for the multi-stroke alphabet was achieved by the algorithm using a 3x4 fuzzy grid; the letter-wise average recognition rates are listed and compared with the results of the similar single-stroke method with various modifications in Table I.

As shown in Table I, the accuracy of the system for the multi-stroke alphabet is 93.4% which is 6.03% and 5,42% less than the results of the single-stroke method (using 6x6 and 6x4 fuzzy grid).

The results have been analyzed in depth including the search for the reason of the false results. Each recognition process that has returned with false result could be traced back to the fuzzy sets describing the rule antecedents. It means there were no false-positive results caused by the overlapping sets of different parameters; and the accuracy might be increased by redefining the rule base.

IV. Hierarchical Rule-Base for Multi-Stroke Alphabet

There are many papers dealing with the use of hierarchical rule bases in fuzzy systems in different areas [11, 12, 13]. A previous work presents the results of the single-stroke method using hierarchical rule base. The details of building the hierarchical rule structure by rule input parameters for single-stroke alphabet were presented in [10].

In the modified system with multi-stroke capability the numbers of strokes were used to determine the meta-level of rules, selecting the group of rules consisting of the given number of strokes. During the tests the same data were used as in the previous section.

This method processes only the selected rules, this way the number of evaluated rules is reduced. The average recognition rates for multi-stroke and single-stroke systems are presented in Table I.

The accuracy of the system for multi-stroke alphabet is the same with flat and hierarchical rule bases. It can be explained by the results presented in the previous section in which it has been stated that there were no false-positive results and all the mistakes were caused by the limited rule base and not by an overlap of the different symbols.

V. Conclusions and Future Work

It was shown that, after the modification, the system was able to recognize multi-stroke alphabets with 93.4% average recognition rate. The results indicate that the accuracy might be further increased by a redefinition of the initial rule base. Finally in this work a similar method with multi-stroke alphabet support using hierarchical rule base was presented. The topology of the hierarchy was built based on the number of the used strokes. The modified system reached the same accuracy as the original one with flat rule base, but the computational cost of the recognition process was considerably reduced by the limited number of rules to evaluate.

The results of the previously introduced altered FUBAR methods are shown and compared to other commercial and academic methods in Fig. 1.

As you may see in Fig. 1 the recognition rates of FUBAR for single-stroke alphabet are higher than other systems.

TABLE I.
AVERAGE RECOGNITION RATES OF THE ALGORITHM FOR SINGLE-STROKE AND MULTI-STROKE ALPHABETS

Symbol	Average Recognition Rates of FUBAR (%)

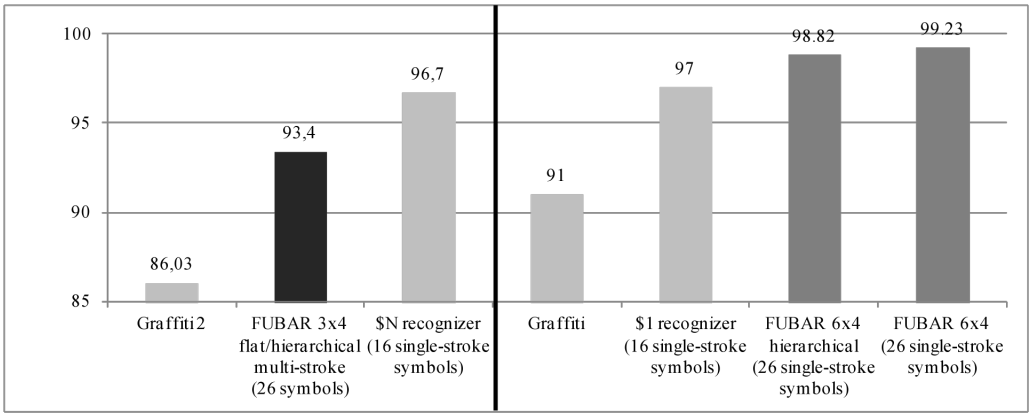

Fig. 1 Average recognition rates of various recognition engines (multi-stroke engines on the left, single-stroke engines on the right)

The $1 recognition method reached 97% average accuracy for only 16 different symbols [14], while the single-stroke version of the designed system reached over 99% recognition rate for 26 different symbols. Another advantage of the new algorithm is the computational cost of the recognition, which is linear in each phase.

Fleetwood et al. showed that users could reach only 91% average recognition rate with the original Graffiti recognition method [15], which is less than the accuracy of the presented system. The Graffiti alphabet contains 26 different English letters and other control symbols.

The average recognition rate of the modified Palm Graffiti with limited multi-stroke support (known as Graffiti 2) was studied by Költringer and Grechenig in [16]. The method reached only 86.03% accuracy. Both the single-stroke and multi-stroke versions of FUBAR performed well over the results of Graffiti 2.

The $N recognizer [2] (the multi-stroke version of the $1 method mentioned above) achieved 96.7% average recognition rate for 16 different symbols.

It is important to highlight the fact, that the computational complexity of the proposed recognition engine is linear, while most of the commercial and academic systems have a quadratic or higher computational complexity. This means that, other systems need much more time to compute the results even if the alphabet is extended by one symbol. The computational cost of FUBAR method increases however only linearly.

Currently we are working on a new method to build the initial rule base for the system, which may increase the recognition rate of the algorithm.

Another extension for the method is under development, in which the output rules are presented by discrete type-2 fuzzy sets. The preliminary results of the test are showing that the recognition rate can be increased by the mentioned modification without a significant increase of the computational cost.

In the future we intend to investigate an extension of the present algorithm, where the possibility of applying two or more rules representing a single character will be considered.

Abstract—This paper describes a system for recognition of objects in traffic scene from multiple moving vehicles. The system is based on query and image processing. It allows image recognition along with a spatial relation. A user or a machine makes a query in which description of searched objects are defined. Then the query is sent to vehicles in order to process in real-time. If any vehicle recognizes object of interest given by the query, the answer is returned to query author.

I. Introduction

AT the present time VANET (Vehicular Ad hoc NETwork) is considered as one of the most important technologies in ITS (intelligent traffic systems) [1][2]. It refers to an ad-hoc network in which vehicles communicate each other or with the infrastructure. Nowadays this is a promising research area, in which many researchers and vehicle manufacturers have proposed and developed many applications expected to improve traffic safety or increase comfort of users.

In this paper we propose one of the applications focused on image processing. It allows recognition of objects in traffic scene using a camera placed in a vehicle. It proposes a novel approach based on a query processing in which a user or a machine is able to make a complex query whereby objects are detected and recognized.

II. Similar Works

VANET networks are prospective future of the automotive industry, as it provides tremendous opportunities in terms of improving safety or comfort for users. In the field of image processing and analysis, many applications have been proposed such as a vision-based active safety system for driver assistance in intersection scenarios [3], See-Through System [4] in case of passing large vehicles and vehicles with darkened rear windscreen, which are difficult to see through and make the situation before them unpredictable. Another example is a system for locating wanted vehicles [5] based on license plate recognition and also a surveillance system proposed by Badura [6].

All applications, however, are problem specific. They solve a particular problem of exactly defined area for which they were designed. Our research has not yet identified any existing solution that would be able to search for general information – the objects contained in the image on the request.

Although many methods for real-time detection and recognition of objects have been developed using MPEG-7, QBIC / CBIR systems, we have to point out that generic object detection and recognition system suitable to be used in VANET is missing. Thus we are proposing a solution for detection of traffic objects and also general objects appeared in traffic scene visible from vehicle.

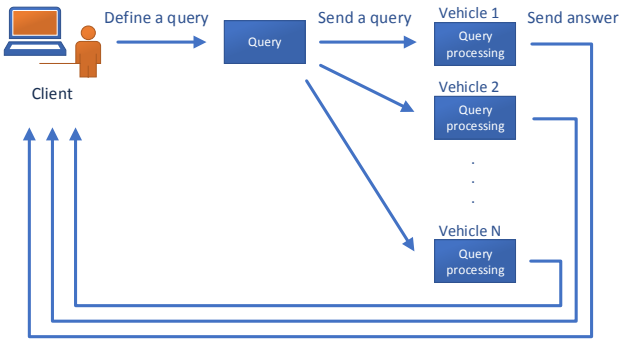

Fig. 1 Outline of the proposed query system

III. The Query System

The idea of the proposed system is very simple. It consists of following steps:

1. Query definition – a query is created manually by a person or automatically by an application. In a query an object of interest is defined, as well as required output and processing length.
2. Query sending to vehicles – a query is sent to one or more vehicles (query processing) according to defined target area in which the image is supposed to be processed (the area is defined, for example, using IP broadcast or geocast).
3. Query processing and output return – since a requested object can appear sporadically, the image captured by a camera could be processed periodically until a condition is met. Thus the length of processing can be limited either by certain time (e.g. 15 minutes), by

978-83-60810-53-8/$25.00

event (e.g. after required object was found, an engine of a vehicle was turned off) or by geographical range in space (spatial definition specified by GPS location).

The basic principle is also shown in Fig. 1.

A. Image Objects

The base of the system is image object, which constitutes either a real object or segmented part in an image. In order to recognize real objects we performed dozens of test drives in surroundings of Žilina city (Slovakia). We have identified some important objects, which could be recognized in the system:

- Sky (sun, clouds, weather condition)
- Mountains
- Roads (traffic lane, sidewalk) and intersections
- Horizontal traffic signs
- Vertical traffic signs
- Traffic lights
- Texts
- Vehicles
- People
- Animals
- Buildings and poles
- Trees, bushes
- Lakes, rivers
- Objects moving in the air (flying objects)

In order to recognize unknown objects, we define the so-called general object which is composed of a model consisting of set of templates with a description. This model will be directly incorporated into query so it will be possible to refer to it and be used in querying.

After analysis we suggest that the general object model would contain following parts:

- Unique model identifier should be included in order to refer to it in a query.
- Object characteristics – deformability, motionlessness, size etc.
- Views of model are expressed either in form of a set of source images, features or in the form of model with value parameters of a machine learning algorithm. In order to recognize an object, source images would represent the object from different viewpoints (especially if the object is not symmetric) and also capture its various visual aspects in case of deformability and especially in such positions it can frequently be seen.
- Described parts of the model which make up the model (e.g. in case of vehicle if there is a view of rear part of it, we can see a trunk, right and left light, part of right and left wheel etc.). Parts are defined for every viewpoint and will have certain position in order to refer to them in querying and e.g. to find out if they are visible or if they are in relation with other objects.

A general object can be expressed for example by using templates of still images, SIFT (Scale Invariant Feature Transform), ANN (Artificial Neural Network), or other state-of-the-art methods. Thus a general object could be represented by defining the source data such as images, descriptors, or weights as required by chosen method.

B. Querying Image Objects

We can look at querying image objects as a complex task which can be decomposed into simpler tasks and their interconnections (Fig. 2). Thanks to these interconnections the sets of image objects will pass in left-to-right direction in order to process these sets in elementary tasks.

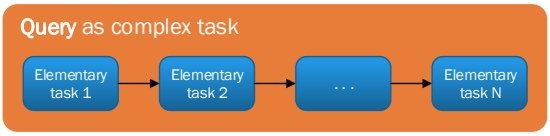

Fig. 2 Query as complex task composed of N elementary tasks

When we get to the last elementary task N, it depends on its output what happens next (Fig. 3). If the output is non-empty set, the answer will be sent in form which is defined at the end of the query. Otherwise, it depends on definition of the query whether the requirement is to be re-processed or terminated and if it terminates whether to send an answer. This behavior was chosen for a reason that it is very often necessary to search for an object in an image which is likely not to be present there. Therefore we need cyclic query processing until the answer (non-empty set) is obtained. Actually, an empty set will represent insufficient output (i.e. required object is not found).

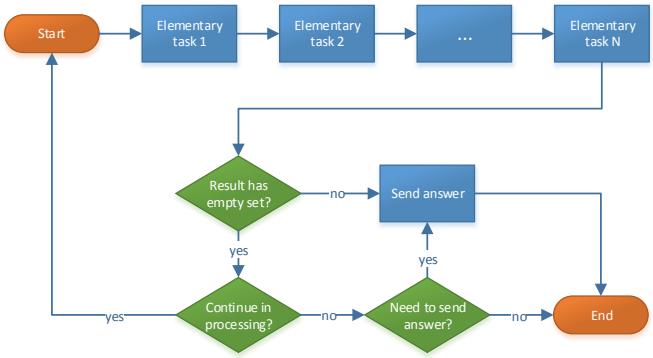

Fig. 3 The proposed system of processing a query as complex task

Processing of an image query therefore means executing of elementary tasks involved in sequentially concatenating sequence. Elementary task represents any basic operation with the image, which can be in a form of detection, localization or classification of objects, relations between them, choosing and other basic image processing algorithms built and supported in the system.

C. Inputs

The input is defined by a client. In this query, it is important to determine what to perform, when to finish the

processing and what to send as an answer. Such information is possible to write in a certain defined format, e.g. XML, JSON or others. Since we will work in VANET environment, the format should be as compact and small as possible because of the transmission. Our aim is not exactly to define exact format in which data will be transmitted via the network, but only query format in which it will be processed (i.e. what and which parts are important in a query). Therefore, we define following required and optional fields:

- `INPUT` – defines a unique query name, which is also used in the output answer.
- `MODEL` – a definition of general object recognition model. Definition of the model is optional, unless we require recognition of an unknown and undefined object in the system.
- `TERMCONDITION` – a termination query condition. It is optional in case of a query with quick response (only one image processing obtained from the camera is requested) and necessary if we want to process images cyclically (video sequence). Specified condition then determines when the processing loop finishes.
- `REQANSWER` - determines whether we always require an answer, even if the query returns an empty set.
- `QUERY` – a definition of a query. It is a mandatory field, which forms the core and allows you to define what objects with characteristics are required to obtain. The last elementary task will define the output of the query.

D. Outputs

As a result of the output can be everything what is needed by original request, e.g. original image captured by the camera or only some parts of the image where are one or more objects of interest. In addition it could contain GPS coordination, common value (number, text, logical value) containing required information (the number of objects, recognized text, licence plate number etc.) or their combination.

IV. The Query Operations and Operator

In query definition we could use many elementary tasks sequentially connected each other. These tasks constitute possible operations connected by separation operator.

A. Operations

For purpose of manipulating image objects we have introduced operations as following:

- Input and output functions
  - `GETIMAGE` – captures an image from a camera or another image source and converts it to an image object. Captured image represents traffic scene as a root image object.
  - `RESULT` – returns a set of objects defined by an expression being its argument as query result. The result should be sent back to the querying vehicle.
- Object searching operation
  - `FINDOBJECTS` – detects and recognizes requested image objects in the input set of image objects. The used algorithm of object recognition depends on the system where the query is executing. It can be used any state-of-the-art recognition algorithm.
- Manipulation operations
  - `WHERE` – selection is an operation for filtering the input set of image objects by the given condition.
  - `SELECT` – collection; it is an operation for transforming each item from the input set using the expression given as the operation argument.
- Set operations
  - `UNION` – standard set union between the input set and the set given as an operation argument.
  - `INTERSECTION` – standard set intersection between the input set and the set given as an operation argument.
  - `MINUS` – standard set difference between the input set and the set given as an operation argument.
- Temporal data storage operations
  - `SAVE` – stores its input into temporal data storage.
  - `LOAD` – loads data from temporal data storage and passes it as its output.
- Spatiotemporal operations
  - `RIGHTOF` – selects all image objects on the input that are on the right side of the objects given as operation argument.
  - `LEFTOF` – selects all image objects on the input that are on the left side of the objects given as operation argument.
  - `ABOVE` – selects all image objects on the input that are above of the objects given as operation argument.
  - `BELOW` – selects all image objects on the input that are below of the objects given as operation argument.
  - `IN` – selects all image objects on the input that are inside of the objects given as operation argument.
  - `OUT` – selects all image objects on the input that are outside of the objects given as operation argument.
  - `NN` – selects nearest object to the objects from the set on the operation input from object set passed as the operation argument.
  - `DISTANCE` – selects all objects from the set on the operation input with its distance to any object from set passed as the operation argument.

B. Separation Operator

As separator between operations, operator | was introduced. Using that operator we can express following sequence of operations:

```
operation1 | operation2 | ... | operationN
```

where the last operation `operationN` will be a result of the query.

V. Example of Usage

To demonstrate the proposed system and language we have presented some examples of using it.

A. Image of Traffic Scene

The simplest query is returning single image from a camera:

```
GETIMAGE
```

Here we do not have to use separation operator and also RESULT operation since we do not require any additional information. If we would like to return more information and from rear camera, we can use query as following:

```
GETIMAGE('rear camera') |
RESULT(image => image, GPS.GetPosition)
```

This query means to return image and current GPS position of the car.

B. Car Detecting

If we would like to find a red car, we should use sequence of following operations:

1. Get an image from a camera (`GETIMAGE`).
2. Detect car objects in the image (`FINDOBJECT`). The result of this step is a set of image objects containing a car.
3. In order to find only a red car, we can then use `WHERE` operation to select only a car with red color.

Final query will be composed as follows:

```
GETIMAGE | FINDOBJECTS('car') |
WHERE(car => car.Color = 'red')
```

It depends on a person how he defines a query. There are many possibilities how to make the same search for a red car. We could use the color segmentation at first and then apply finding objects operation:

```
GETIMAGE | FINDOBJECTS('red segment') |
FINDOBJECTS('car')
```

C. More Complex Example

To demonstrate a more complex example, we define a query in which we will detect a red car with a license plate starting with ZA and ending with AB. In addition there was a specific picture (for example skull with crossbones) on right side of the license plate number. Therefore we define a general object consisting of wanted picture in query format, so we could use it in query. Then result query by that definition could be like this:

```
GETIMAGE | FINDOBJECTS('car') |
WHERE(car => car.Color = 'red' AND
             car.View = 'rear') |
FINDOBJECTS('license plate') |
WHERE(plate => plate.Text.StartWith('ZA') AND
               plate.Text.EndWith('AB'))|
SELECT(plate => plate.ParentObject.Crop(
       plate.Location.Increase(0,100,400,100))) |
FINDOBJECTS('skull') |
RESULT(skull => skull.ParentObject, GPS.Position,
                GPS.Heading)
```

As result of that code is an image of a car (ParentObject), GPS position and heading.

Other examples of proposed system are introduced in [7][8].

VI. Conclusion

In this paper we proposed a novel application for the VANET, whereby we are able to recognize objects from images captured by a camera placed in a vehicle. We described a query system and language based on object oriented manner. Using that language we can detect any objects along with relations defined by a query.

***Abstract*—Energy management systems (EMS) are necessary when smart grids and microgrids are considered. Simulation of energy consumption is very useful in planning and testing such systems. In this article we present the problems of simulating energy consumption and show concept of a very general load simulator. The simulator can generate time series of consumption from fixed profiles and also from the defined rules describing use of energy by the devices. The rules describe the probabilistic distribution of the device behaviour. The architecture of the implementation is also presented.**

I. Introduction

THE possibilities to test the energy management system in reality are very limited due to lack of existing microgrid infrastructures. But they may be tested using simulators. Data about wind speed, irradiance and temperature required for renewable energy sources simulation can be obtained from direct measurements or meteorological models.

Simulators of consumed energy described in the literature are usually simple as main effort is channelled towards creating management systems for the next generation of electric networks. They usually are based on general profiles collected from few devices. Each device has its own profile of energy requirement that varies in time. The amount of energy used by given equipment can be measured, but the general, statistical data of how frequently and how long people use devices are missing. Attempts have been done to measure the average amounts of power that different groups of consumers use during longer period. A report about the energy usage in Spain [1] is the most complete in that field (in [2] the short summary of the [1] in English is presented). Due to huge differences in culture, climate and wealth of the regions, the results of such research cannot be directly used in simulation of grids in different geographical locations, making the ability to simulate systems in defined localisations difficult.

The contents of the paper is as follows. The following section II will explain the idea of a microgrid and the context of the simulation. An idea of the character of the microgrid considered in this work will be also presented. In section III, the overview of the energy production consumption is described. The next section IV presents different methods of describing consumer behaviours, section V describes the concept of the simulator. The last section concludes the article.

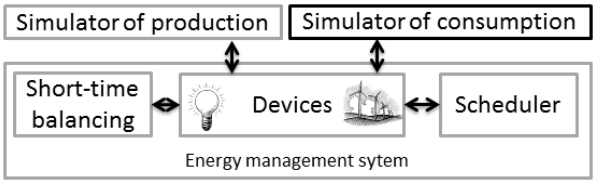

Fig. 1. A diagram of the elements of the considered system, where devices are represented by agents being parts of the Short-Time Balancing System, which uses production levels of controllable power sources from the Scheduler.

II. Smart grids and microgrids

Smart grids and microgrids seem to be the future trend in the energetic revolution that is ahead. A *smart grid* is a concept of introducing exchange of information between different elements of electrical grid (consumers, producers, storage units and prosumers). Thanks to that, controlling and coordinating of supply and demand of energy can be introduced to ensure quality of electric power in the grid, reduce the cost and promote renewable energy sources. A *microgrid* is a part of the grid, that might include producers, consumers, energy storage units and prosumers, which has the ability to connect or disconnect to/from the external power grid and balance the energy within itself.

These new technologies require an advanced control system that can use the potential of bidirectional communication. Implementing such systems requires working in real time operation mode. It is a challenge, as consumption and production is changing very dynamically, due to users activities and weather conditions.

In this article a small microgrid consisting of few buildings and connected to an external distribution network is considered. The general overview of this grid is presented in Fig. 1. The microgrid is a research and education centre with a hotel and a restaurant. Its energy producers and consumers are controlled by the complex Energy Management System (EMS), which can be divided into two main parts: the Scheduler and the Short-Time Balancing System. Detailed description of this system can be found in [3].

The Scheduler (under development by Wroclaw University of Technology) is a program that arranges the planned events and tasks in order to minimise the cost of the microgrid

978-83-60810-53-8/$25.00

operation (the cost of obtaining energy necessary to power all the tasks). The input data to the Scheduler are information on planned events, e.g. organization of a conference, a training, conduction of an experiment, hosting a person in the hotel, etc. All these events have defined time constraints, usage power profiles and locations where events can take place. The Scheduler is using a heuristic algorithm to place a task in a location at a certain interval of time.

The Short-Time Balancing System is dealing with deviations from the schedule. Its main goal is to balance the produced and consumed energy as fast as possible. It is implemented as a multi-agent system. Wooldridge in [4] defines an *agent* as a program that fulfils its goals by taking autonomous decisions based on the data received from the environment (sensors, input information). The concept of a multi-agent system as considered in [5] and [6] fits well to handle the problems of power grids. In the Short-Time Balancing System an agent is assigned to each source, energy storage unit and load node of the network. A node is an aggregation of consuming devices, e.g. one line of sockets on one floor of a building. The load nodes are divided into two groups: the ones that have to be powered (the reserved nodes) and the ones that can be switched off under power deficit (the unreserved nodes). An agent receives information about the state, the energy produced or required from its device. When the device is in an unbalanced state, the agent negotiates with other agents to contract energy for its device (both in case of its excess or deficit).

EMS is ready and working, but testing it requires running it for a certain amount of time, e.g. one year, and multiple times, to get the average time of balancing and the number of imbalances. In [7] authors assume that a test of multiagent system is statistically significant with the simulation size of at least 200.

III. Simulation of energy consumption

Simulating the amount of energy produced by renewable sources requires simulating the weather conditions. The data such as temperature, wind speed and water flow are available for us for a large number of years, but insolation was measured for much shorter time and might not be sufficiently long for an exhaustive testing.

In any case, the gathered information is not sufficient if long time simulations have to be done (e.g. to test how system copes with seasonal differences). It is necessary to generate long time series of data. We used for this a block-matched bootstrap method which samples available data and assembles them to create a time series that has statistical properties close to the original data, and is of the required length [8], [9].

Simulation of energy consumption is more complex, because there is usually a large number of heterogeneous loads considered. Consumers can be considered at different aggregation levels. In a household, usually single devices, as oven or microwave, are considered [2]. In larger networks, at levels of groups of houses, general profiles are used (like in [10]). In large networks profiles are grouped by sectors, like commercial, residential, industrial.

For some purposes the general profiles are sufficient, e.g. in [11] they are used to verify the design of the network (to identify possible overloads or violation of constraints). Only eighteen exemplary load-flow calculations are presented there, with 19 profiles for different categories of loads, but they cover all extreme situations, like e.g. extremely high consumption with no production from renewable sources. The tests confirmed that the network was well designed and there is no threat of overload. But such load profiles are not good enough (values of a profile are 1-hour averages, so there are only 24 different load values for a day) to test the dynamic behaviour of the microgrid.

Profiles for a big group of consumers can be easily derived, as any outstanding or not common behaviours tend to be compensated by each other, so they do not vary very rapidly. On the country scale they can be easily obtained from large power producers. Profiles show cycles of daily and weekly changes that reflect the human activities. Night is usually the time of lower energy usage, and its peak usage is around late afternoon. Weekends and holidays are introducing disturbances to the working day cycles. Moreover, seasonal differences are visible, caused by changes in the outer temperatures (e.g. large amount of power is used for air-conditioning), long holiday seasons and changes in labour structure [1].

On the contrary, in microgrids each consumer has a relatively bigger influence on the profile than in large grids, e.g. a 4kW induction cooking plate will not be visible in profile on the regional level, but can dominate the energy usage in a single household. Thus, profiles are not sufficient for microgrid simulation purposes.

The most comprehensive research about structure of energy usage has been done in Spain [1]. Users presented in the report are divided in 5 groups: residential, commercial, touristic, large consumers and others, whith the total contribution of power usage 20%, 6%, 0.5%, 25%, and 48.5%, respectively. These values might differ among regions and countries and depend on the method of categorisation. The authors of the report emphasise the big differences in the energy usage between user groups, as for example households, tourist facilities or companies. Other factors that influence the amount and structure of power usage are e.g. seasons of the year, days of week, times of day, months, holiday distributions, structure of labour and economic situation. It demonstrates the difficulty to obtain one reliable description of consumer structure even within small area.

The EMS considered in the present paper governs a relatively small microgrid. The maximum necessary load does not exceed 900 kW. In this situation, a room where a computer lesson takes place can use easily 4.5 kW, which is a considerable amount. Such lessons can be planned and entered to the Scheduler that would inform energy management system about an increase in power. Power usage of computers in a room, projector, air conditioning and lights are gathered and their

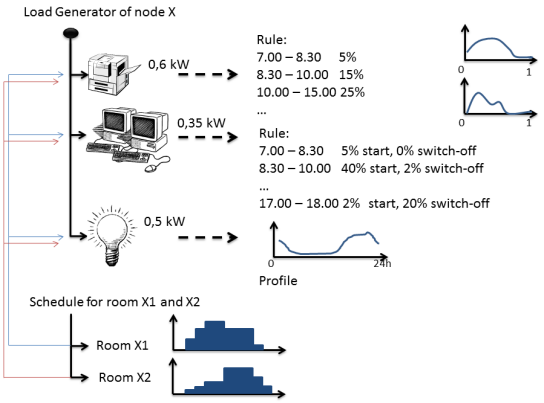

Fig. 2. A diagram of different possible descriptions of energy consumption.

average power usage is placed in the schedule for a specific time with a duration of e.g. 1.5 hour.

For the Short-Time Balancing System, the execution of the task ”computer lesson” would mean the increase of power on two nodes of network, the one that would power the computers (which is reserved, i.e. the node has priority in receiving power) and the other for lights and additional equipment. That means that two agents would ”sense” the increase of power usage and start the balancing procedure. The load simulator generates the power that is consumed in certain nodes. It also knows which nodes in what level contribute to the supplying energy for the location that Scheduler chose for the executed task. Considering both Scheduler locations and node division, it is required to perform the load simulation in smaller parts of the microgrid than belonging to one node. Simulating the power usage of each device gives much more accuracy, makes the simulation less abstract and gives possibility to base the model on existing devices, whose parameters might be measured or found in the literature. In [12] a detailed analysis of representative office environment was conducted to test the model designed. 500 electrical devices were identified, mostly usage dependent. The modelling of users behaviour regarding the use of electric equipment is the most difficult part of simulation, as people do not like to be interrogated. Unfortunately, knowledge of typical human behaviours of using devices is crucial to carry out reliable power load simulators.

IV. Description of consumer behaviour

Devices consume power because people placed them there, switched them on and use them. The load simulator, in reality, tries to mimic the patterns of human behaviour. It cannot model the whole complexity of human reasoning, but can derive general patterns and statistical distribution of certain human actions.

Usage of energy by some devices can be described as a profile, which is an approximation of a function of energy usage of the device. Device profiles are made to represent energy usage by a device during a certain time period. Such profiles come from real measurements and are applicable for the devices (or group of devices) that have stable and defined work cycles. Examples may be a coffee machine, a fridge or a freezer. Profiles are also reliable when there are many small consumers of energy, for example light bulbs. In this case a single device has little influence on the overall power consumption and multiple small deviations tend to level the usage. Profiles define the average, typical behaviour and are not suitable to describe events that happen with low frequency or of extreme power usage. For example, the profile of a coffee machine is repeatable and can be measured, but the information of how often and when users make coffees has to be derived from statistical behaviour. Simulators based on profiles encounter troubles to represent small variability in the generated data, even when random disturbances are introduced.

Simulator might increase the diversity of generated data by using multiple profiles for a single device, e.g. there might be 10 profiles for a computer. It can be switched on for 1 hour or for 24 hours, might be used for energy demanding calculations or might be in a sleep mode for most of the time. This approach would require a large number of different profiles that would represent certain cases and still would not show all possible combinations.

Power consumption of employees’ computers might be dependent on the current circumstances, the work the person is doing, the habits of different people and it is difficult to obtain a general profile. The method of describing that behaviour may be a probability distribution of switching on the device. That means describing loads by a set of rules. This type of description is introduced in [1] according to the Spanish behavioural data. The work of elements like dishwashers, ovens, etc. is described by the probability of their operating in a certain time. For example, an electric kitchen (a stove) is mainly used around 9:00, 13:00, and 21:00 hours with the respective probability around 20% at the 21 o’clock, 10% at the 13 o’clock, and 2% at the 9 o’clock [1](page 100).

We required that the simulator developed should be as general as possible, to be able to simulate operation of most of existing devices. That can be obtained by combining the ideas of rules and profiles. The example of such description for devices connected to one node is presented in Fig. 2. For devices described by a profile, like for a fridge or a freezer, the profile is used. Devices that are activated by a person and person actions control them, are described by rules. For the loads that have defined profiles for actions, but the actions are executed by users with a certain probability, the simulator uses both the profile and the rules. Rules define a probability of starting an action at certain time. When a device is active, the simulator generates consumption data according to its profile. A rule is a set of parameters that describe the operation of a device. These parameters describe the probability, the activation time and the intervals in which certain use of electric power happens. Different types of rules may define the time and the probability when the state of the device changes. For

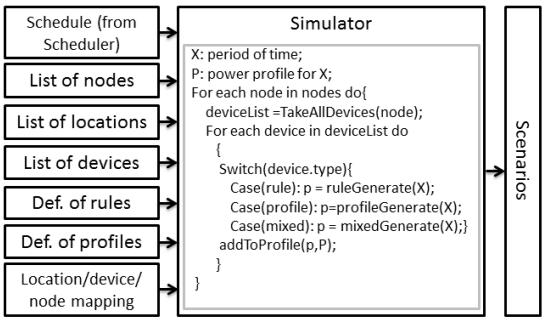

Fig. 3. Concept of the Simulator of consumption with data sources, outcome and general description of the algorithm.

example, the computer is switched on and continues this state until the user switches it off, which is also defined by a rule. Simulator use a definition of a consumption described as a set of rules with probabilities of activating an action. One rule is bound to one type of device but may be a complex one and consist of a probability of switching on, off and changing the working point of devices.

V. Concept of the simulator

The simulator is designed to generate load data for each node for a certain period of time, with a given start date and a time. Generated data are stored as test scenarios which allows to repeat the test with different configuration of sources. The schema of the system is presented in Fig. 3.

Data that have to be available for the simulator consists of the schedule made by the Scheduler, the list of nodes with information how many and what type of devices are connected to them, the mapping between devices, nodes localisations (e.g. rooms), the profiles of nodes and individual devices that are connected to a node, and the rules for devices without profiles. The outcome of the simulator are power values aggregated for each consumption nodes of the network, with the sampling frequency defined by a parameter.

The simulator processes each node separately in order of their numbering. It queries all the devices connected to the node and then generates for each device the load for the requested time period. Then it sums up all power consumptions of the loads connected to the node, at each sampling time. Each device is processed depending on the type of the device, and the load is generated from the profile or from the rule. The most important factor is the date and the time, as both rules and profiles are parametrised by them.

VI. Conclusion

Testing is an important step in developing EMS, especially when systems work in a microgrid environment, where small changes in load have a big impact on overall balance. To have statistically significant data about microgrid operation, a large number of long-term tests has to be made. A real infrastructure for testing purposes is often not available. Detailed profiles of energy usage of devices can be measured, but they do not reflect the way people use devices. User behaviour is very varied and influenced by many factors. Simulator of energy consumption has to mimic this behaviour with all its impreciseness and unpredictabilities, which requires using probabilistic distribution combined with fixed profiles. Presented energy consumption simulator requires rules and profiles that define device's behaviour. Based on that it creates time series of energy consumption aggregated per node, which is a tool for EMS testing.

It is clear that more efforts should be made to examine the nature of different energy consumers to obtain the statistical distribution of loads considering different social and environmental factors. That would also help to find where energy is wasted and how to avoid it. The next stage of the research is exhaustive testing of the EMS and then connecting it to real devices.

***Abstract*—In this paper we propose new approach in data set dimensionality reduction. We use classical principal component analysis transformation. Instead of rejecting features we generate new one by using nonlinear feature transformation. The values of transformation weights are changed evolutionary by using genetic algorithms. Results show better classification rates in smaller feature space. Visualization results also look better.**

I. Introduction

NOWADAYS data visualization is one of the important fields in knowledge discovery. Human beings can perceive data up to three dimensions. Although dimensionality of datasets is often enormous. To solve this issue, dimensionality reduction methods were proposed. There are two main directions: feature selection and feature extraction. The subject of this paper will be related only with second approach. In this work we propose new approach by extending functionality of PCA transformation.

The paper is organized as follows. In section II the most popular data visualization methods will be described. In section III proposed nonlinear data transformation method will be presented. In section IV the results of experiments with UCI repository data will be shown. Finally in the section V main conclusions and directions for future research will be presented.

II. Data visualization methods

There are many different methods to visualize multidimensional data. One of the oldest and popular also in nowadays is principal component analysis. First proposed by Karl Pearson in 1901. Good review of this method is given by Jollife [2]. Another data visualization technique is multidimensional scaling, which firstly was used in psychometry. It is based on minimization of squared differences between distances of points in original and reduced feature space. Overview of this method is given in [4].There is also neural network approach called self-oragnizing maps (SOM) introduced by Kohonen in [3]. Good overview of recent visualization techniques is also given in [1].

III. Proposed nonlinear transformation

Main idea of this work is extension of PCA transformation with additional information provided with new feature. Our goal is to encode rejected features after principal component transformation into one number and append it to reduced data set. Encoding scheme is based on principles of fundamental theorem of arithmetic, i.e. that every natural number can be written as a product of prime numbers rised to appropriate power. This product is unique

$$a = \prod_{i=1} p_i^{k_i},$$

where p_i is prime number and k_i is power. In this case powers are natural numbers (including zero). It can be extended to rational powers due to the same cardinality. In this case numbers are also unique. In this work we will simplify initial requirement by using rational fractions between 0 and 1 instead of prime numbers. These numbers will be called weights. The initial formula is now written in such way

$$a = \prod_{i=1} w_i^{x_i},$$

Due to the fact that we do not know values of weigths we have to solve optimization problem. We will use genetic algorithm to optimize weights. Our fitness function will be result of classification made with nearest neighbour classifier. The algorithm is presented on page 684.

Let us comment several moments of this algorithm. First we perform initial data normalization into interval [0,1]. It is done because of possible different scales of features. We have chosen the nearest neighbour classifier because of small number of

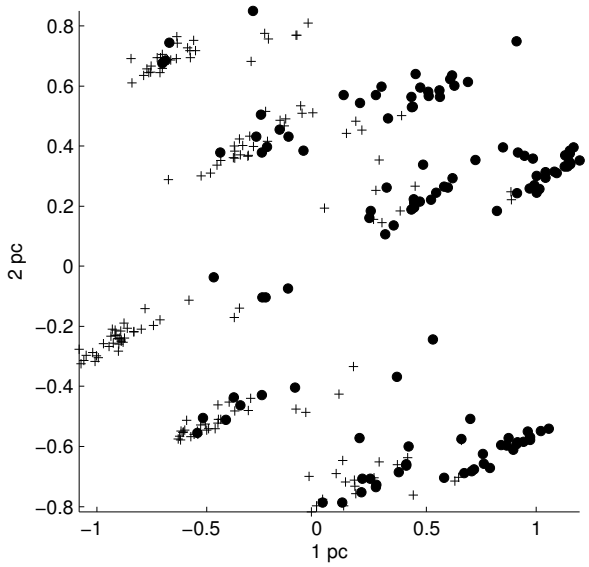
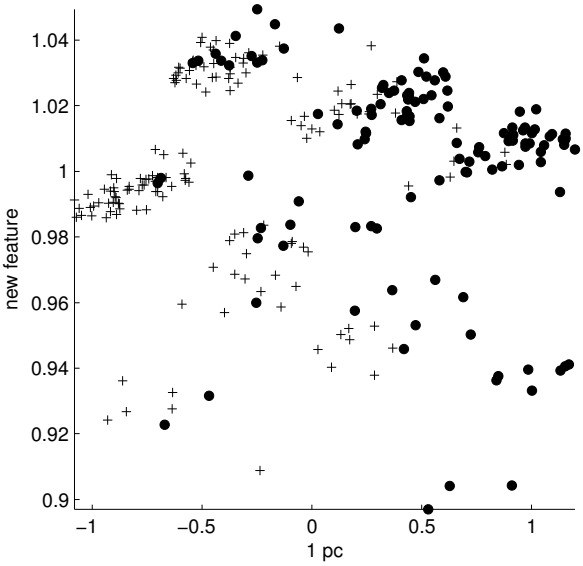
parameters (only number of neighbours and distance measure, in this case it is Euclidean distance). First tests of algorithm showed that proposed method has tendency to overfit the data. As a result new task appeared - to formulate early stop criterium. Brumen et al work [5] gave an idea how to solve this problem. In this work we use more simple criterium, i.e. "if error starts to grow break evolution process". To measure change of the error rate we use internal 5-fold crossvalidation. Only by using early stopping criterium we reduce number of iterations to perform. Internal crossvalidation provides also very important property, i.e. that classification error does not increase very rapidly. To prevent rapid increasing to infinity (decreasing to zero) of the generated feature value we let weights to vary only in interval $[1 - \varepsilon, 1 + \varepsilon]$, where $\varepsilon = \exp(1/number\_of\_rej\_comps) - 1$

IV. Experimental results

The experiments were performed on datasets from UCI Repository. These are: Glass, Teaching Assistant Evaluation, Heart and Chess. More details about each set is given in table I.



(a) Two principal components space



(b) First principal component and new feature space

Fig. 1. Heart dataset visualizations.

Datasets were chosen because the percent of total variance is not mostly covered by the several first principal components. The experiments were performed by reducing principal component space into 2 and 3 dimensions. Later the same experiments were made with the same datasets but with new additional feature appended. The number of features in both cases is equal. Results are shown in table II. We can notice that additional feature generated by nonlinear transformation in many cases gives better results.Visual analysis of datasets was also performed. Due to limited space we will show only several comparisons in two dimensional space. Let us look at plots of Heart dataset shown on figure 1. Classical PCA

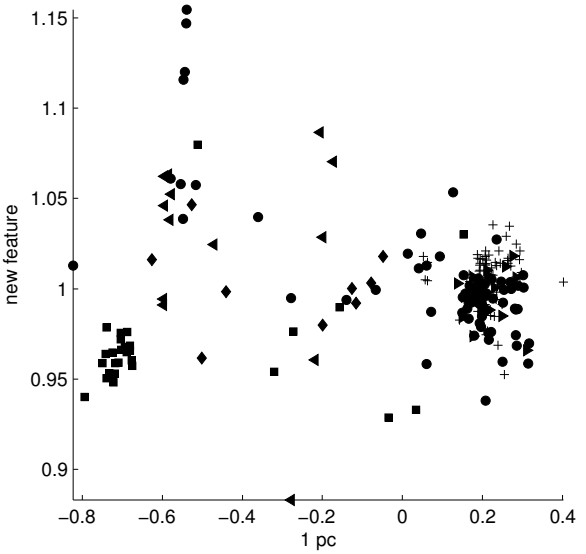
(a) Two principal components space



(b) First principal component and new feature space

Fig. 2. Glass dataset visualizations.

shows that classes are scattered, our approach on the other hand makes points of one class to be concentrated in certain part of space. Now let us analyze vizual data of Glass dataset. Both cases are shown on figure 2. As we can see objects of some classes are groupped more closer to each other. As a result using e.g. k-nearest neighbour classifier we can obtain better classification rates.

V. CONCLUSIONS

Proposed approach extends popular and quite simple data transformation. The computational cost of new feature is not that large as e.g. computing pairwise distance matrix (in case of multidimensional scaling) As it has been presented earlier proposed transformation made positive influence on analyzed data sets. First it increased classification rates with small number of components. In next step it provided more clear visualization results. Unfortunately this approach has one minus - it can be used only with numerical features. Of course we can encode categorical features into numbers, but this method is rather artificial and classification results can depend on way how features were encoded. The problem of big data sets is also actual. In this work small datasets were rather used. In future the proposed technique will be also tested on larger ones, e.g. KDD Cup 1999 data set. For solving such type of problem we will make some optimizations. One of them could be use of architectures that are based on parallel computing paradigm, such as clusters or GPUs.

Information Systems Education & Curricula Workshop

ISEC goal is to promote the discussion about the convergence between Computer Science and Information Systems topics, so that researchers can present a complete and detailed specification of their educational curricula by means of these two topics. We inspect papers that contribute to the better understanding of emerging and important educational fields of Computer Science (CS) and Information Systems (IS). Authors are invited to submit their papers in English, presenting the results of original research or innovative practical applications in the field.

Regarding the selection process, we plan to perform a triple review process.

Topics

Key issues in this workshop will focus on (but are not limited to):

- Convergence between IS & CS in higher Education
- Specification of IS Education Curricula
- General IS Theory
- IS Scope
- IS Educational Fields
- Student participation in research
- Adaptation to the European Higher Education
- Assessment of students
- Innovative teaching methods
- Training for career and skills development
- Definition of "knowledge" in IS
- Quality and evaluation of teaching
- Social and environmental commitment
- Curriculum organization and curriculum
- The Fundamental Concepts Underpinning IS
- Merge from IS to CS and vice versa in higher Education

***Abstract*—In this article we present the results of a pilot programme for student placement on the university, comprised of a preparation course, the GCE Ordinary level test in Computing, which students perform afterwards as a placement test, and a post-course questionnaire. The aim of the research programme is to identify weaknesses in the student placement tests and set the road map for improved first-time entrant placement and preparation. The study shows that common placement tests are far from giving strong predictions and they should be complemented with other metrics, such as high school grades or social factors. Test outcomes show that placement test results per se do not yield enough data to predict student success. However, we discovered it as a quite helpful tool for revealing anomalies at the institutional and methodological level, such as very different outcomes among campuses of the same university, or remarkable difficulty to answer certain questions. In order to enhance student placement accuracy and preparation for university, these issues will need to be addressed in forthcoming research.**

I. Introduction

UNIVERSITIES use placements tests to assess the students' academic abilities. In theory, test results give enough information about alumna skills to place them in the right level and determine which classes are suitable for each student. However, studies seem to indicate that accurate student placement is problematic [1].

At King Abdulaziz University we have started research in this area by requiring a set of first-time entrants to enrol a pilot programme for students placement, including the CPIT100 preparation course, the GCE Ordinary level test in Computing, which students perform after the course as a placement test, and a post-course questionnaire. Placement tests are broadly used to determine the level at which each student should be placed. However, studies agree in the fact that such exams perform poorly at proper student level placement. Therefore, we have carried out a review of studies about placement tests reliability, which is show later in the article.

The objective is to review placement tests as an instrument to predict student performance and to assess the outcomes to identify issues that need to be addressed and set the basis for the development of improved placement mechanisms.

The following section shows statistical data about study subjects (students). Section III describes instruments that have been used for the experiment, namely the course, the test and the questionnaire. Section IV describes the procedure for placement and preparation, which is basically taking the course, then the test and eventually filling in the questionnaire. In Section V, statistical data are extracted from test and questionnaire outcomes for analysis. Finally Section VI concludes with discussion of achieved results, studies reviews, discussion and requirements for further research.

II. Subjects

A total number of 2685 students distributed among three campuses took the course, specifically 1083 from Alsulaimanyah campus, 992 from Alsharafiyah campus and 610 from Alsalamah campus. Students also came from different educational backgrounds; 1387 of them came from a scientific scope, 1283 from administrative scope and 15 were previous regular students.

Finally, students were divided in two categories for the questionnaire: regular and distance students.

III. Instruments

A. GCE Ordinary Level in Computing

GCE Ordinary level in Computing is a qualification created by ©Pearson Education to encourage candidates to develop an understanding of computer systems, software, data and hardware and their implications for communications and people. It also aims to help students acquire necessary skills to apply computer-based solutions to problems. Candidates who successfully follow the syllabus will have a good practical understanding of computing and its applications. Namely, they will: develop an understanding of the main principles of using computers to solve problems; appreciate the range of applications of computers and the effects of their use; understand the organizations of computer systems, software, hardware and data and their implications; acquire the skill necessary to apply computer-based solutions to problems[2].

We considered that meeting the objectives of GCE Ordinary Level in Computing Test requires a skill level

978-83-60810-53-8/$25.00

suitable for students beginning post-secondary education. Therefore, we decided to use materials provided for the qualification as tools to prepare first-time entrants and also as a possible way to assess their knowledge and predict at which level should students be placed at, once the university courses start. This means not entirely leveraging GCE as at qualification itself, but as a placement test that would allow predicting students performance. Placement tests are discussed below.

B. CPIT100 Preparatory Course

CPIT100 is the preparatory course developed by King Abdulaziz University to help the students to achieve the assessment objectives of GCE Ordinary Level in Computing.

The course aims to provide the students with advanced skills to operate and make use of a personal computer in different environments such as in academia, in business, and at home. It introduces the students to the main concepts and terminologies of information technology, and equipped them with the knowledge to administer one of widely/used operating systems. The course also aims to provide the students with the practical skills to utilize an office productivity package for different purposes. The course will prepare the students for new learning methodologies, namely distance learning and e/learning. The delivery of the course contents will be based on a hands/on approach.

Apart from preparing students from the GCE placement test, our purpose was to reinforce computing and information technology skills of first-time entrants to the university. For skilled students, the course was expected to refresh and stimulate their capabilities. Nevertheless, underprepared students were the key, since the course was specially intended to bring them to the adequate level for post-secondary education. We considered the course as a mixture of a qualification, placement and remedial course.

Remedial education is a kind of teaching that is bellow university level work. It is designed to bring unprepared students to the level expected of entrants to the university. This kind of education has received criticism due to the “double billing” problem, which for unprepared students means to spend more than the amount needed for students that perform successfully by just following regular courses [3].

Although remedial/preparatory education is a controversial issue because of its expenditures, supporting arguments present remedial education spending as an investment. The hypothesis made here is that, in the long term, educating underprepared entrants will decrease the likelihood of their future dependency on social programs and as students that eventually obtain the degree, they would potentially contribute to the state taxes in the future [4].

C. Placement Tests

Universities use placements tests to assess the academic abilities of the students. In theory, the results of these tests give enough information about students to place them in the right level. However, studies seem to indicate that the accurate student placement is problematic. Many students are misplaced in remedial courses or wrong levels where they should be not in.

Some studies indicate that any model that uses final course grade as the criterion for the validity of a placement rule would likely fail [5].

The nature and validation of placement tests is rarely discussed in the language testing literature, yet placement tests are probably one of the commonest forms of tests used within institutions which are not designed by individual teachers and which are used to make decisions across the institution rather than within individual classes[1].

The predictive power of placement exams is still quite good given how short they are. But overall the correlation between scores and later course outcomes is relatively weak, especially in light of the high stakes to which they are attached. Given that students ultimately succeed or fail in college-level courses for many reasons beyond just their performance on placement exams, it is questionable whether their use as the only determinant of placement can be justified on the basis of anything other than consistency and efficiency. Allowing more students directly into college-level coursework (but perhaps offering different sections of college-level courses, some of which might include supplementary instruction or extra tutoring), could increase the numbers of students who complete university-level coursework in the first semester, even if pass rates in those courses decline [6].

Summing up, testing student abilities needs to be complemented with other several indicators such as high school grades and good teaching standards. A more suitable metric seems to be the combination of placement tests with other metrics such as high school grades, social factors, years since graduation in high schools, etc.[7],[8].

D. Questionnaire

At the end of the course, students were asked to fill in a questionnaire were they were asked a series of questions about their daily use of new technologies and their level of satisfaction with the course to evaluate teaching quality. Since course experience questionnaires have proven to be a useful tool to evaluate teaching performance [9], we included it to help us improve future courses and also to get an indicator of the access students have to new technologies, which would give as an idea of whether they need more equipment at the campuses or they can carry out some work at home.

IV. PROCEDURE

Before the academic course started, CPIT100 course was imparted to first-time entrants as preparation teaching for the GCE Ordinary Level in computing test. Individuals taking the course were classified by campus (Alsulamaniyah, Alsharafiyah and Alsalamah), by educational background (scientific, administrative or regular previous students) and by delivery mode (distance/external and regular students).

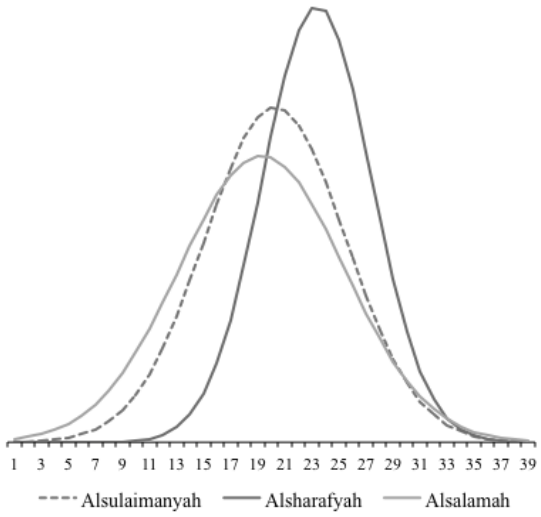

Fig 1 *Average score by campus*

After test administration, results were collected and analysed with Qualtrics research software [10]. We monitored mean score and number of correct answers by campus to assess how they perform individually.

Eventually, the post-course questionnaire was delivered to students to collect information about their personal opinion and their access to new technologies.

V. Results

Test outcomes data are categorized into three campuses, Alsulamaniyah, Alsharafiyah and Alsalamah. Fig 1 shows the normal distribution of scores by campus. Alsharafyah campus clearly outperforms the other two with an average score of 17.31 and a smaller deviation.

Alsulaimanyah campus achieved an average score of 14.23 and Alsalamah comes right after with an average score

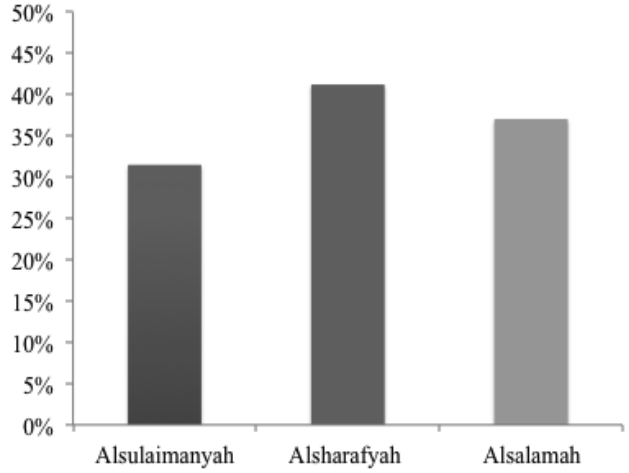

Fig 2 *Percentage of correct answers by campus*

of 13,23, although the latter shows more dispersion. Having such a different average score among campuses from the same university reveals an anomaly that we need to pay attention to.

Another interesting metric we monitored is the number of correct answers, shown in Fig 3, also distributed by campus and showing the average of all students as well.

Section A (questions 1 to 7) shows higher scores than section B (from question 8 on). Clearly average score goes down when the section B starts with question 8. Lower scores in section B might be caused by either by an increased difficulty or by different question type; while section A contains short questions, section B is comprised by a set of longer questions based on a case of study.

Some questions have been especially difficult for students. For instance, question 2.3 "*Data entry clerks use a keyboard to enter text into a computer. Another method of entering text into a computer is.*" only shows a correct answer percentage of 11%. Few students were able to state alternative text entering methods.

The figure also shows Alsharafyah campus performs better than the two other campuses, regardless of the

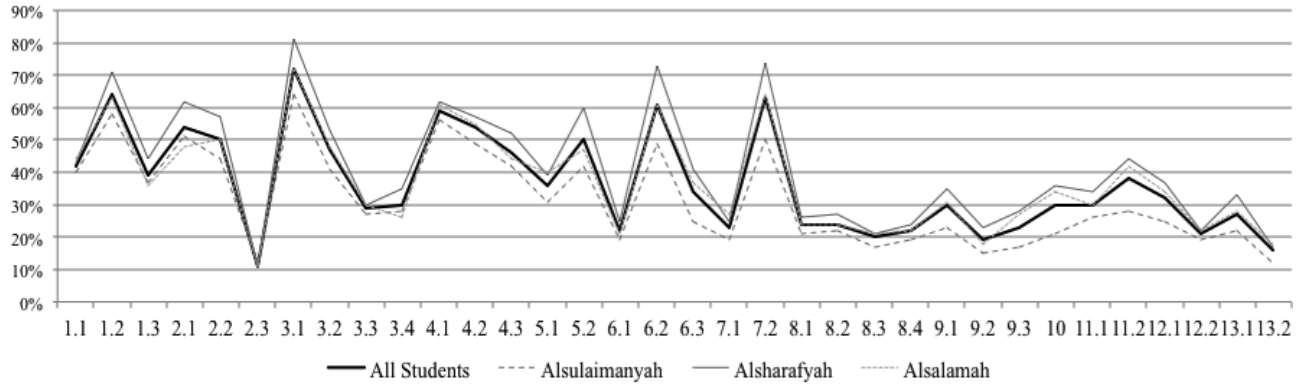

Fig 3 *Average score by question for each campus*

question. On the contrary, Alsulaimanyah campus gets the lowest score in almost all the questions. This can also be seen in Fig 2

With regard to the questionnaire, students were divided in three groups: scientific, administrative, and previous regular students. The questionnaire evaluates the following questions: use of computers in the student's daily life, student's expectation fulfilment, course outcomes achievements, students' command of MS Windows, student's command of MS Office. The latter three ask the students whether they think they would be capable of resolving a problem or they would need to ask for help.

Near 100% of students are used to perform tasks with their computers at home and at the school. Also almost all of the students have Internet connection in their houses.

With regard to course outcomes and aims, regular students do not show much confidence. Despite of the fact that 57% got the basic concepts and knowledge, only 21% acquired system administration and maintenance concepts, such as downloading and properly installing software without help, and only 22% thought he or she had fully understood computer programming.

Distance and external students show similar results, although performing a bit better on system administration concepts (27%) and not doing so well in basic knowledge (51%).

Course expectations were met for the 44% of the students, partly for the 48% and not met for the 8%.

In general, command of MS Windows shows good results. Regular students perform better than external & distance students. Basic Windows usage and tasks are well performed by more than 80% of the users, except for formatting the hard-drive and re-installing the operating system, which only was executed by a 48% of the students without help.

Microsoft Office also shows good results but not as high as Windows results. Easy tasks, such as writing an essay and using tables, charts and pictures are executed without help by more than 90% of the students. Working with analytical data and preparing presentations is done without help by more than 73% of the students. Finally, the hardest tasks for the students where database management, arranging appointments for meetings, create email groups.

Lastly, Fig 4 shows a slightly lower percentage of positive indicators in external and distance students, which can occur because of a lower engagement factor.

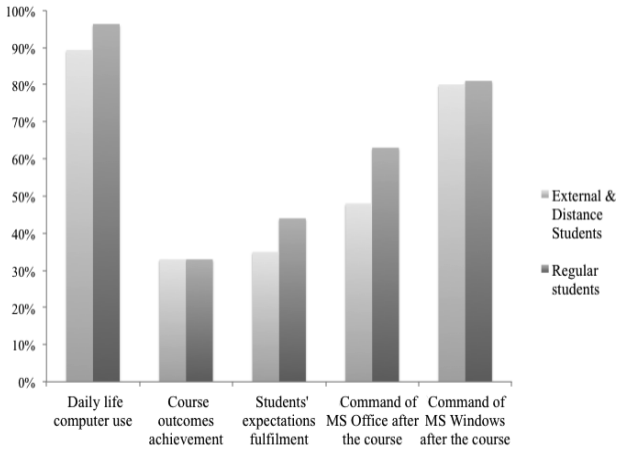

Fig 4 Final positive indicators

VI. CONCLUSIONS

In this paper we described how we employed the GCE Ordinary level in computing qualification as a placement test. Also, a questionnaire has been given to the students to gather information about their daily use of new technologies and opinion about the process.

First question to address is why does one campus clearly performs better than others. It is important to perform a more exhaustive study on students' skills for each campus. High school grades need to be part of the equation to effectively know if different campuses are receiving students with different levels. Social environment data would be also helpful to adapt campuses pedagogical methods if they are receiving students from areas with lower high school grades.

Moreover, Pearson GCE Ordinary level certificates are being replaced by the new International GCSEs, available from 2009. The equivalent for the old Computing certificate is the GCSE in Information and Communication Technology, updated to the requirements of modern society. In the future we plan to adapt the CPIT100 course new GCSE qualification.

With regard to placement test predictions, they need to be complemented with secondary education grades in subjects related to computing (namely, math, physics and computing) and students commitment during the preparatory course. Again, having information about the social environment will be important, especially to get more information about students daily use of information technologies. We must perform research on how to extract this data from the questionnaire and act accordingly. Thus, with such improved indicators we could know the kind and amount of homework that is given to students, based on the facilities they have at home.

As for level prediction rates we ought to assess the prediction rate of our approach by performing research on how students perform in the tasks that have been covered in the course. A good measure would be to correlate tests data with students skills on the specific topics covered during the course. However, before carrying out this assessment better student classification is needed for future exams, namely, get statistical data for scientific and administrative background students.

Finally, our GCE tests should be compared with results from other institutions that have also used the same tests. The comparison should be accompanied with social, environmental and educational information about the students of both institutions and consequently draw the correct conclusions. The main aim of this is to share knowledge and be aware of the areas we need to improve.

***Abstract*—Assessment of students and the evaluation of their satisfaction has been an important element in the improvement of teaching quality in all the Higher Education areas. Specifically the student participation in Computer Science (CS) and Information System (IS) has been highlight valued. Thus a large number of methodologies and standard tools regarding student evaluation has been developed. Specifically, the Students´ Evaluation of Education Quality (SEEQ) is a tool that is validated for international use. But its use leads to several problems, such as the low voluntary participation of students. To solve these problems, a short version of this questionnaire developed using statistic tools is proposed. After using the proposed new version, the voluntary participation of students increased. The reduction of the number of questions facilitates the analysis of data, improving the flow of information and feedback between professors and students.**

I. Introduction: Quality in Higher Education

CONCEPTS of quality from the entrepreneurial world are increasingly being incorporated into the university field [1]. According to the "Declaration of Prague" (2001), quality should be an important and determinant aspect of Europe´s international attractiveness and competitiveness [2]. In 2003 in Berlin (Berlin, 2003), the Ministers responsible for Higher Education stressed that "the quality of Higher Education has proven to be the heart of the setting up of a European Higher Education Area" [2].

When these ideas have been translated into action, the "teaching quality" concept has become outstanding. According to Kember, "it might be noted that concern about Teaching Quality is growing at the national level. This appears to be a worldwide phenomenon" [3]. In 1992, Stones pointed out [4] that "quality teaching is more properly conceived of as a unified field embracing both theory and practice in which teachers, teacher educators and researchers are jointly responsible for the development of theoretical understanding and the improvement of teaching".

Currently, there remains a high degree of concern about the improvement of teaching quality at the higher education level. Specifically, the improvement of teaching quality is one of the primary matters that must be addressed continuously by universities. The question is how to achieve this continuous improvement.

Continuous improvement is not a tool or a technique but rather a way of life (or at least a cultural approach to quality improvement) [5]. According to the UNE 66178:20004 model [6], there are three steps that should be taken into account during an improvement process:

1. analysis of the information for the improvement;
2. the improvement project; and
3. monitoring, evaluating and reviewing the improvement.

One method of attaining continuous improvement is the PDCA Cycle (also known as the Shewhart or Deming cycle: Plan-Do-Check-Act) [7], which emphasizes the continuous, never-ending nature of process improvement. The PDCA Cycle highlights and demonstrates that improvement programs must start with careful planning, result in effective action, and move back to careful planning in a continuous cycle. Figure 1 shows this global idea.

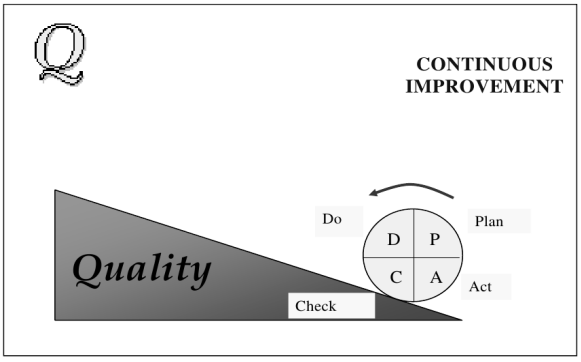

Fig. 1 The PDCA Cycle as a tool to continuous improvement [8], [9]

Clearly, it is necessary to collect and evaluate data in order to obtain conclusions. Improvement actions should be based on the data and the conclusions of the evaluation.

This point of view is completely applicable to the university environment, especially to lecture theatres. To improve the teaching quality, it is necessary to evaluate the teaching process and its results. In this evaluation, the students' opinions about learning and the teaching process are crucial due

to the students' roles as the primary consumers in higher education [10].

This paper focuses on students' evaluations of the quality of higher education. The extensive body of research regarding student evaluation of teaching leads us to look for standard tools and methodologies (section 2). Section 3 details a widespread method that can be used internationally, the Students' Evaluation of Educational Quality SEEQ) questionnaire, and considers the problems that teachers identified after its application. To solve these problems, section IV presents a proposal for the reduction of this questionnaire. Sections V and VI show an example of its application and give several guidelines regarding the use of this short version of the SEEQ questionnaire. The final conclusions are explained in section VII.

II. Review of the Standards

Spooren and Mortelmans underlined the value of student evaluations of teaching. They found that students reward good teachers with higher ratings on several scales of teacher performance [11]. The literature contains an overwhelming number of data collection instruments and scales. Several authors chose to develop their own form (see, for instance, [12] or [13]). In some cases, the forms were developed by faculty committees [14]. In general, there is an extensive body of research regarding student evaluation of teaching and how students contribute to assessments of teaching effectiveness [15], [16]. Thus, it is possible to conclude that there is a need to unify and standardize the approaches and specific tools used to evaluate the teaching quality.

Standards are public technical documents that establish common terminology in a field (in this paper, quality). They set specifications extracted from experience, knowledge, and available technology [17], [18] and [19].

There are several international and national standards developed for the teaching field that are applicable to this work [20].

* UNE 66931 is a Spanish standard that aims to provide guidelines for the application of the ISO 9001 model in educational organizations. It is equivalent to the document IWA 2 published by ISO [21].

Section 8.2 (concerning monitoring and measurement) points out that the educational organization must have reliable methods to measure and control the satisfaction of the client (8.2.1.). Moreover, the educational organization should define and use methods to monitor the results of the educational product (8.2.4). Furthermore, the customer and stakeholder satisfaction surveys are described as important data (section 8.4).

* The ISO/IEC 19796 family, focused on the information technology field, is an international standard under the general title "Information technology – Learning, education and training – Quality management, assurance and metrics" [22] and [23]. This family is a framework used to describe, compare, analyse, and implement quality management and quality assurance approaches. It will serve to compare different existing approaches and to harmonise these approaches towards a common quality model. [17] [22]. The ISO/IEC 19796-3 [23] is an instrument for the implementation and adaptation of the first quality standard ISO/IEC 19796-1 and, in particular, for the specification of the individual process descriptions [24].

According to Campo [25], this family has been defined abstractly and without specific guidelines to provide a mechanism to its implementation.

Thus, it is possible to conclude that international and national standards specially developed for the teaching field provide professionals with frameworks and guidelines to improve the quality of education. However, these standards do not provide specific tools or mechanisms to evaluate teaching quality.

In addition, other models and standards regarding quality that are widely used in the entrepreneurial environment can be applied to lecture theatres. The use of these standards helps institutions respond to the EHEA (European Higher Education Area) quality requirements [26]. In the present case, two standards could be applicable: UNE 66178:2004 and UNE 66176:2005.

* UNE 66178:2004

The standard entitled "Quality management systems. Guide for the management of process for improvement" is focused on continuous improvement. This standard is based on the idea that every organization needs to improve. Its capability to satisfy the requirements of its stakeholders (such as the customers, staff and social environment) determines the survival of the organization. Furthermore, these needs are changeable [27]. This point of view is completely applicable to the university environment, especially to lecture theatres [26]. In Appendix A, teachers can find a list of techniques and tools that can be used in the improvement process. The cycle of Deming is listed in this Appendix.

* UNE 66176:2005

This Spanish standard is titled "Quality management systems. Guide for measuring, monitoring and analyzing customer satisfaction". According to its title, this standard specifies guidelines for the definition and development of a measuring process for customer satisfaction [6]. Its guidelines are generic and can be applicable to any organisation, regardless of its size or activity. Of particular note is Table 1 of the standard, which contains different techniques for data collection and indicates their advantages and disadvantages. Professors interested in its application will find appendices A to E significant [26].

The analysis of standards UNE 66176 and UNE 66178 produces the same results as the previous models (UNE 66931 and ISO 19796): they provide professionals with frameworks and guidelines but do not provide specific tools or mechanisms to control the satisfaction of students.

The global conclusion of this section is that there is a high number of collection instruments for obtaining data about student satisfaction of teaching quality. Thus, it is necessary to look for other standard tools. The review of international and national standards can provide guidelines and global methodologies. Their application will allow for the extraction of ideas for improving traditional working

methods at the university level [26]. However, to apply the previously cited standards, professors who wish to use them must carry out a tailoring process. Thus, the standards do not provide any specific tool to evaluate the students' opinions about teaching quality.

III. Description of the SEEQ

The lack of a standardised tool to evaluate students' opinions about teaching quality leads us to look for a widespread method that can be applied internationally.

In terms of the more formal, internationally validated questionnaires in use in higher education, five are particularly worth mentioning [28]:

- The Students' Evaluation of Educational Quality (SEEQ),
- The Course Experience Questionnaire (CEQ),
- The Module Experience Questionnaire (MEQ),
- The Postgraduate Research Experience Questionnaire (PREQ), and
- The Experiences of Teaching and Learning Questionnaire (ETLQ).

Richardson recommended using either the SEEQ or the CEQ, as both have been validated for international use through research studies [29]. Keane pointed out that the SEEQ and MEQ have potential because they have been statistically validated [28].

In the present study, the SEEQ questionnaire was chosen. There are several reasons for this choice: a robust factor structure, excellent reliability, and reasonable validity [30]. Furthermore, as has been mentioned, the SEEQ has been validated for use internationally. It is possible to find universities in many different countries that use the SEEQ. Although not exhaustive, the following list presents several examples: the Universities of Manitoba [31], Saint Mary's [32] Mount Allison [33] and Saskatchewan [34] in Canada; Fordham University [35] and the Schreyer Institute for Teaching Excellence [36] in the U.S.; Oxford University [37] and University of Leicester [38] in the U.K.; Semnan University [39] in Iran; Curtin University [40] in Australia; and the Universities of Navarra [41] and Vigo [42] and the Polytechnic University of Catalonia [43] in Spain. This international use will enable the development of comparative analyses in the future.

The SEEQ was developed by Dr. Herbert Marsh of the University of Western Sydney [44]. Dr. Marsh is an internationally recognised expert in the area of psychometrics. Now in the public domain, the SEEQ has been extensively tested and used in more than 50,000 courses with over one million students at both the graduate and undergraduate levels [33].

Using a five-point scale, the SEEQ questionnaire examines different characteristics of effective teaching. Each of these categories contains three or four questions.

It is possible to find different versions of the SEEQ [45], [46]. The version used in this work consist of 37 questions. It is detailed in references [43] [33].

* The questionnaire finishes with three open questions.

This SEEQ questionnaire was used in seven subjects in three cities and three different centres: Polytechnic School of Teruel (Spain), School of Engineering of Terrassa and Faculty of Engineering and Architecture of Zaragoza (University of Zaragoza (Spain).

The use of the SEEQ enabled professors to identify strengths and weaknesses and to improve the teaching-learning process. However, the main problem was the low participation of students: a high number of students did not answer the questionnaire or answered only the first questions on the form [47]. Moreover, Verdugo and Cal remarked upon the fact that rapid feedback is needed. These authors explained that teachers could be overloaded with work and not provide rapid feedback [46]. In order to solve these problems, this paper proposes a reduction of the SEEQ questionnaire developed in collaboration with a student [48] in order to encourage the students' research.

IV. Proposal of Reduction

To maintain the reliability of the short SEEQ questionnaire, statistical parameters should be used. Computing tools can help researchers in this process. In this work, analyses have been developed with SPSS® [49]. Specifically, this statistical package enables the calculation of the Cronbach's Alpha and Pearson's r parameters [50]. The values of Cronbach's Alpha and Pearson's r Correlation Coefficient for the long SEEQ questionnaire (37 questions-items) were calculated. To develop the analysis, a sample of 111 polls was used and items with different scales were recoded [48]. Table I shows the value of the global Cronbach´s Alpha.

TABLE I.
STATISTICAL VALUES OF RELIABILITY FOR THE LONG SEEQ QUESTIONAIRE (37 ITEMS)

Number of Items	Cronbach's Alpha
37	0.920

The Cronbach's Alpha can be used in the reduction process, as Cronbach's Alpha is an index of reliability.

According to Santos [51], this coefficient ranges in value from 0 to 1 and may be used to describe multi-point formatted questionnaires or scales (i.e., in this rating scale, 1 = poor and 5 = excellent). The higher the score is, the more reliable the generated scale. Nunnaly [52] (cited by Santos) indicated 0.7 to be an acceptable reliability coefficient, but lower thresholds are sometimes used in the literature [51]. Table II show the same data after the reduction process, using Cronbach's Alpha as reduction criteria.

TABLE II.
STATISTICAL VALUES OF RELIABILITY FOR THE SHORT SEEQ QUESTIONAIRE (22 ITEMS)

Reduction criteria: Cronbach's Alpha

Number of Items	Cronbach's Alpha
22	0.936

The global reliability for the initial long SEEQ questionnaire was 0.920, and the value for the short SEEQ is 0.936.

Thus, there is an improvement of the internal consistency of the questionnaire.

Several statistics experts recommend developing the reduction process using two criteria: Cronbach's Alpha and Pearson's r Correlation Coefficient. Although both analyses tend to give similar results, the combination is useful because it provides more information with which to make decisions [50].

With the initial data, a new reduction process was developed using the correlation as new criteria (third column in our tables). Table III shows the statistical results after completing the process.

TABLE III.
STATISTICAL VALUES OF RELIABILITY FOR THE SHORT SEEQ QUESTIONAIRE (22 ITEMS)

Number of Items	Cronbach's Alpha
22	0.936

Both analyses lead to the same results:

- the fifteen deleted items are the same;
- there are no negative correlations; and
- the final value of reliability (global Cronbach´s Alpha) is the same, 0.936, and there is an improvement in the questionnaire's internal consistency.

The short version of the SEEQ questionnaire proposed in this work is detailed below (the item number from the long version is in brackets).

*** Learning.**

1 (1) - I find the course intellectually challenging and stimulating.

2 (2) - I have learned something that I consider valuable.

3 (3) - My interest in the subject has increased as a consequence of this course.

*** Enthusiasm**

4 (5) – The instructor is enthusiastic about teaching the course.

5 (6) – The instructor is dynamic and energetic in conducting the course.

6 (7) – The instructor enhances presentations with the use of humour.

7 (8) – The instructor's style of presentation holds your interest during class.

*** Organisation**

8 (9) – The instructor's explanations are clear.

9 (10) – The course materials are well prepared and carefully explained.

10 (12) – The instructor gives lectures that facilitate taking notes.

*** Group Interaction**

11 (13) – Students are encouraged to participate in class discussions.

12 (14) – Students are invited to share their ideas and knowledge.

13 (15) – Students are encouraged to ask questions and are given meaningful answers.

14 (16) – Students are encouraged to express their own ideas and/or question the instructor.

*** Individual Rapport**

15 (17) – The instructor is friendly towards individual students.

16 (18) – The instructor makes students feel welcome in seeking help/advice in or outside of class.

17 (19) – The instructor has a genuine interest in individual students.

*** Breadth**

18 (21) – The instructor contrasts the implications of various theories.

19 (22) – The instructor presents the background or origin of ideas/concepts developed in class.

20 (23) – The instructor presents points of view other than his/her own when appropriate.

21 (24) – The instructor adequately discusses current developments in the field.

*** Examinations**

22 (27) – The examinations/graded materials test the course content that is emphasized by the instructor.

In conclusion, fifteen questions, approximately 40%, have been eliminated with this method.

V. EXAMPLE OF APPLICATION

The new short version of the SEEQ questionnaire was used in different university subjects. For instance, in Circuits and Electric Drives the previous academic year, students filled out the long version of the SEEQ questionnaire. As the teacher is the same, a comparison is possible. Table VI shows the level of student participation (number of completed questionnaires versus number of registered students). The percentage of voluntary involved students has increased.

In table IV, the items corresponding to the four lowest-scoring questions from both versions are listed. In this case, two items are equal. In addition, higher-valued items are listed, and there are three equal items.

TABLE IV.
PARTICIPATION LEVEL

Version	% Participation
Long	53.16%
Short	69.23%

Thus, the SEEQ questionnaire helps professors to detect weaknesses and strengths. These results can be used as the starting point of the following improvement plan.

The proposed short version of the SEEQ questionnaire has been used in other subjects in which the teachers were not the same as those in previous years. Nevertheless, in this academic year, the long version was used voluntarily in three subjects. The average percentage of participation was 69.41%. In addition, the short version was used voluntarily in three other subjects, with an average percentage of participation of 86.84%.

The conclusion is clear: the use of the proposed version increases the voluntary participation of students.

VI. Guidelines for the use of the proposed short version

Several guidelines can help professors use the proposed short version of the SEEQ questionnaire.

- As explained in the introduction, the SEEQ questionnaire can be used as a tool to develop improvement processes.
  Professors can distribute the questionnaire in the middle of the academic year.
- It is advisable to give the questionnaire to the teachers before the analysis of the data [53], [47].
- After the analysis of the data, instructors should identify the lowest- and highest-scoring questions on the questionnaire. These results can help instructors develop a plan to improve the weaker points while maintaining the strengths. The next step is to implement the plan. It is recommended that the questionnaire is used again at the end of the academic year and that the lessons learned be recorded in order to remember or to explain them to colleagues.

Table V.
The detected strengths and weakness

Version	Weakness
Long	– Students are encouraged to participate in class discussions. – Students are invited to share their ideas and knowledge. - How does this course compare with other courses you have had at this university? – Your level of interest in the subject prior to this course
Short	- My interest in the subject has increased as a consequence of this course. - The instructor enhances presentations with the use of humour. - The instructor's style of presentation holds your interest during class. – Students are encouraged to participate in class discussions. – Students are invited to share their ideas and knowledge.
Strengths	
Long	– The instructor is friendly towards individual students. – The instructor makes students feel welcome in seeking help/advice in or outside of class. – The instructor has a genuine interest in individual students. – The instructor is adequately accessible to students during office hours or after class. – The examinations/graded materials test the course content that is emphasised by the instructor.
Short	- The instructor is enthusiastic about teaching the course. – The instructor is friendly towards individual students. – The instructor makes students feel welcome in seeking help/advice in or outside of class. – The instructor has a genuine interest in individual students. – The examinations/graded materials test the course content that is emphasised by the instructor.

- Students require feedback as an element of motivation. As Chen remarked [54], "This study employs expectancy theory to evaluate some key factors that motivate students to participate in the teaching evaluation process. The results show that students generally consider an improvement in teaching to be the most attractive outcome of a teaching evaluation system. The second most attractive outcome was using teaching evaluations to improve course content and format. (…) Students' motivation to participate in teaching evaluations is also impacted significantly by their expectation that they will be able to provide meaningful feedback." Thus, teachers can give students feedback on the evaluation results.
- According to Centra [55], student evaluations of teaching can only facilitate improvement when professors are able to access new and valuable information from them. Teachers must then understand how to translate the new evidence into action and must be motivated to do so [55] and [56].
- The short SEEQ questionnaire can be used in combination with other methods [57] [28].

VII. Conclusions.

Concepts of quality taken from the entrepreneurial world are increasingly being incorporated into the academic field. Currently, there remains a high degree of concern about the improvement of teaching quality at the higher education level. Specifically, the improvement of teaching quality is one of the primary matters that should be addressed continuously by universities.

To improve teaching quality, it is necessary to evaluate the teaching process and its results. In this evaluation, students' opinions about learning and the teaching process are crucial because the students are the primary consumers in higher education.

The extensive body of research regarding student evaluation of teaching leads us to look for standard tools and standard methodologies. The review of national and international standards enables us to obtain guidelines and global methodologies. Their application will allow for the extraction of ideas for improving universities' traditional working methods. However, they do not provide any specific tool to evaluate the opinion of students regarding teaching quality. International organizations should work together to define standard tools and methodologies to evaluate students' opinions.

The SEEQ, developed by Dr Herbert Marsh, is a tool validated for use internationally. It has a robust factor structure, excellent reliability and reasonable validity. However, there are two problems with its use: the low participation of students (there are 37 questions to be answered) and the teachers' sense of being overloaded if they try to provide rapid feedback.

To solve these problems, a short version of the questionnaire is presented. It was possible to reduce the form using statistical methods. The proposed version consists of twenty-two questions. After using this new short version, the voluntary participation of students increased.

The short SEEQ questionnaire can be used as a tool to develop a teaching improvement process as its use detects teaching weaknesses and strengths. It is recommended that the questionnaire be used in the middle and at the end of the academic year in order to establish an improvement cycle. The reduction of the number of questions facilitates data

collection and the analysis of the data, in both cases, with software tools. Also it improves the flow of information. In this way, the proposed version of the SEEQ questionnaire helps produce feedback intended to motivate students' participation in the teaching evaluation process. In addition, the short questionnaire helps professors receive new and valuable information about their teaching from student evaluations more quickly. Professors can use the short SEEQ questionnaire with other tools.

The proposed short SEEQ questionnaire can be used by other university professors regardless of the subject or the degree course.

ACKNOWLEDGMENT

The authors would like to acknowledge the "Chair in Innovation and Technological Quality" and the CTP for their help. Thanks to the IEEE Foundation "Gobierno de Aragón" and to the "Fondo Social Europeo" for their support to the EduQTech group.

***Abstract*—Current vocational education characteristics as well as the dropout rates and compared to students' motivation, suggest the need for a system that allows and supports students to work towards the ultimate goal of their training: "Incorporating vocational students into the workforce". In this paper, we present a learning platform designed and developed to empower vocational and college students; a second aim is to provide students, faculty and staff a system to control and acquire new qualifications based on the official curriculum and work experience. The curricula-based improvement of the individual student's curriculum can be strengthened and improved when using the system, for the areas teachers determine necessary for each student. Consequently, the end system supports and contains official curricula information based on workers' professional qualifications, skills and competencies.**

I. Introduction

VOCATIONAL education operates to serve the labor market needs for specialized technicians. Currently, vocational education in Spain is far from the enrollment rates recorded within the European Union's average. The rate involves early school leavers who do not get a post-compulsory degree or Bachelor or vocational education; these dropout rates have increased in 2000; the rate was 29.1% of the total, while in 2007 it was increased to 31% and 31.9 in 2008, compared to 14.9% of the EU average. We also found a graduation rate in intermediate vocational education in Spain at 39%, far from the 51% of the European average, and from the 45% of the average within the European Economic Community [2].

Currently there are 639,887 pupils within vocational education, of whom 312,441 students study middle level vocational training, 288,861 students study upper undergraduate studies, and 385,86 students study distance vocational education. With some recent changes in 2012, 15.7% of the students, compared to the previous year 2011, have decided to pursue distance learning and dropout data with previous years has declined to 26.5% [3]. Based upon such data, we found that the 20.5% of the jobs in Spain are actually technical derived from vocational education. In fact, the industry has experienced an increase of 1.32 points and 9.62% of this specific labor supply related to technical staff from vocational education. Finally, the number of jobs for new graduates has been increased by 35.22% and 9.62% of these offers refers to technical jobs again obtained from vocational education [4].

The vocational education cycles are related to the technical and professional skill levels degree obtained in Spain. Thus, the educational ministry is in a process of adapting the current titles to the professional qualifications in Europe (European Qualifications Framework, EQF).

For the titles to be valid, the professional qualifications are structured based upon associated curricula, and thus, they directly affect the teachers' schedules. To follow this curriculum, the students are on a six years' formal training, to achieve professional qualifications specified by the training cycles. The structure associated with the vocational education teachers, facilitates the creation of activities tailored to the current companies' needs, the in situ immediate environment, and sometimes it involves a car provided to the students depending on the labor market needs. Currently, one of the real problems is that the professional qualification a student acquires is not related to the real knowledge, skills and competencies he needs, compared to the ones acquired in the academic courses (i.e. improve the level of basic skills in foreign languages).

In this paper, we conduct a study on tutors' needs for a platform to support vocational education students, workers and college students. This tutor-based platform is seeing from two perspectives, the official curricula and each student's personal curriculum, in order to meet college, students, and companies' needs. First, we present the current situation in vocational education in Spain for LOMCE[1] [1] and the ways it affects Spanish vocational education, the curriculum structure as well as the associated training cycles. Secondly, based on needs analysis, we define the targets to achieve. Having established the aims and objectives, and based on cloud architecture, we propose the design and development of a platform as well as the ways to use it. Lastly, we finish with conclusions and future work.

II. Structure And Classification of Professional Qualifications

Professional qualifications structures with associated curriculum provide the basis for comparison as well as the inter-relationships so to establish the main features of the vocational education units in relation to a system design and development. The professional qualifications characteristics and structure are described below [5] [6] [7]:

[1] LOMCE: Ley Orgánica de Mejora de la Calidad Educativa

978-83-60810-53-8/$25.00

I. Identifying properties:

- **Family:** It identifies the "Family" feature by name, and consists of 26 professional families, of which every family has 5 levels classification, depending on the professional competence required for productive activities in accordance with knowledge required for the specific level.
- **Name:** It identifies the professional qualification that is within each of the families, also following specific levels.
- **Code:** It is a unique identifier, an alphanumeric code, consisting of the first letters of the family and the numeric code identifier.

II. Properties that define objectives and scope:

- **General Competition:** Competition is defined as "the set of knowledge and skills that allow exercising professional activity in accordance with the requirements of production and employment."
- **Professional Scope:** The productive sectors and occupations or jobs are related to specific professional qualification.
- **Productive Sectors:** This is a sector in the economy that produces a material. The productive sector includes mining, forestry, fisheries, agriculture, industry and energy, but excludes government activity and social services.
- **Units of competence:** Competence is to perform each qualification functionality. Therefore, the unit of competency is the minimum aggregate susceptible to recognition, evaluation and accreditation part.

III. Identification Data:

- **Name**: It identifies the Competence Unit (UC). It is related to one of the aspects that describes the general competence of the professional qualification, which is associated with the UC.
- **Level of qualification:** The level of professional competence qualification to which UC is associated with, according to the degree of complexity, autonomy and responsibility required to perform a work activity (these are five levels).
- **Alphanumeric code:** It allows locating systematically the units in the qualification competition with which they are associated.

IV. Professional Achievements:

The Professional Achievements are accomplishments as competition elements that set an individual's expected behavior, in the form of consequences or results of the functions or activities s/he performs.

V. Performance Criteria:

They express the professional performance acceptable level of a certain function, so as to meet the associated productive organizations' objectives. Thus, they construct a guide towards the professional competence assessment.

VI. Professional Context:

Describe, as a mentor, production media, products and results of the work, information used or generated and the ways several items of a similar nature are considered necessary to frame the unit of competency.

This professional qualifications system applies on vocational education to ensure that students receive formal training according to a regulated system within the European Union. There is no tracking application in the market for vocational education students, unemployed, and job seekers to support the professional qualifications management according to the rules and the training they receive.

III. System Description

VII. Definition and Objectives:

Having dealt with the qualifications system and its relationship with the educational system and vocational education in particular, and in addition to understanding the professional qualifications system structure, we present the design and development of a supporting platform. This platform automatically establishes a student's acquired professional qualifications via a combination of competency units. An example is provided for students' new professional qualifications acquisition as follows:

- Workers: Describes the student's successful work expertise and competence units during his/her vocational education, in addition to several more free settings competency units s/he may acquire new professional qualifications.
- Student training: The student can acquire new qualifications in addition to previous ones via training units adapted to student's needs. In this way, students can complete their degree with more professional qualifications susceptible to recognition within the training courses that are in the same professional family, see section II-point A.
- College students: Students can gain relevant professional qualifications through the courses curricula corresponding to professional families, or students may opt for an acquisition of professional qualifications advised by their teachers or following their own criteria.

The system also identifies and distinguishes student diversity and competence; gifted students may develop more skills and students who do not meet the minimum requirements for the qualification have a professional qualification on a level they could complete. As a result, an increase on students' motivation is possible as well as they can improve their professional qualifications through formal training in universities and also in schools where vocational education is provided.

VIII. Teaching Methodology:

In regard to the teaching methodology and the minimum knowledge students should acquire in associated taught subjects, specific teaching methods were developed. The ones that allow student's abilities maximum development using learning technologies are related to the constructivist methodology; the student builds upon their own methods using provided tools to solve a given situation or problem [8] [9].

To achieve this, the main aim of the platform is to design an annual training plan for each student built upon the objectives set at the beginning of their academic year. Thus, they can be aware of what the qualifications acquired once evaluated, in addition to what content they should study and work with the help of their teacher or tutor. Therefore, our duty as instructional designers is to build a training plan that includes all the educational stages a student can follow, or an academic plan. In case of a worker, a tutor academic plan is provided, that encompasses professional qualifications completed over a period of time to achieve these objectives.

IX. Architecture:

A system in a cloud can enable and support the students, teachers and workers to interact. This system allows the inclusion of ancillary services and associated performances. We have chosen cloud architecture, because, in addition to supporting phased development over time and adding new services, it facilitates their deployment and growth and can be integrated within diverse systems built by other agencies.

Figure 1 shows the system architecture: it operates in two hybrid clouds that receive information from outside, and in turn, it communicates such information within these clouds.

The platform begins with data collection, based on data from institutions and actors who interact in the platform; these are the teachers, students and workers.

In green color The "Qualifications CTutor" cloud is depicted with green color; it provides services for data collection and maintenance for professional qualifications. Also the data "Integration Services" is represented; these services collect data from students' curricula in order to normalize the data and adapt it to specific needs. What we ensure is data normalization and structure by following the structured criteria, previously presented in section two. Thus, once the data is structured and validated, the curriculum profile for students and workers is created.

Separated into two distinct groups, students and workers, the connection to obtain new skills and create the workers' curricula is established; also a map of the obtained qualifications exists as well as the professional qualifications they may obtain from their studies (student or worker). The tool also indicates the specific qualifications to update or enhance. This cloud contains students' curriculum profile adapted to the national qualifications system, which allows and supports the growth of students' professional qualifications, keeps updated these professional qualifications on the profile, and adapts it to possible changes.

- Students: It contains the data obtained by the official curriculum and the objectives that the students have achieved in each of the official training courses; this is in order to have enough data to seek the needed professional qualifications according to their training needs and establish a curriculum to obtain professional qualifications that can be obtained by their studies.

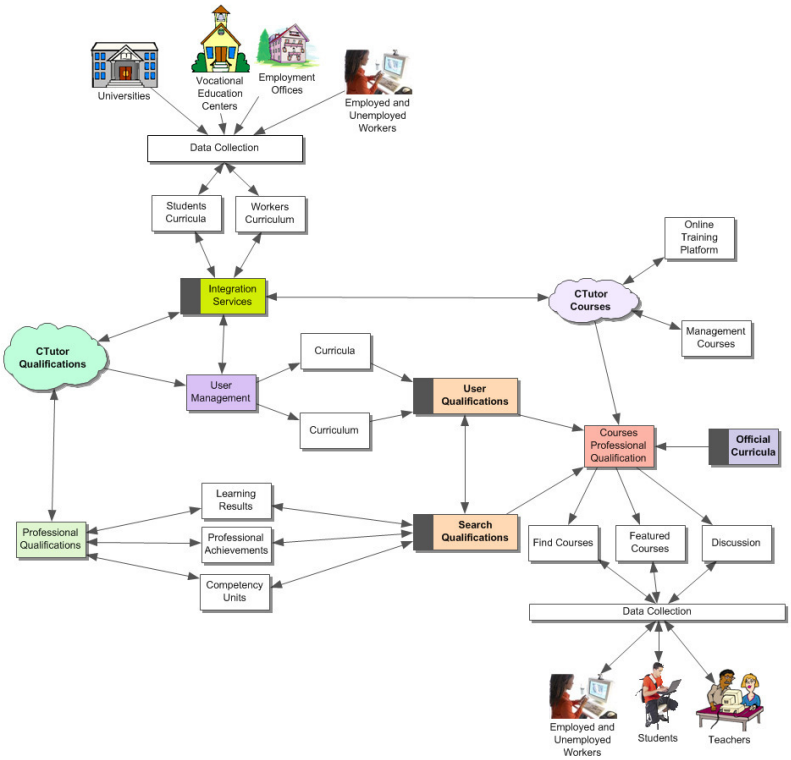

Fig. 1 System Architecture

- Workers: The data come from their curricula vitae; the CV must certify and accredit workers to obtain professional qualifications and training required for other professional qualifications; we also need to keep updating qualifications achieved to date.

The cloud "CTutor Courses" in purple color contains the services that facilitate the teaching and learning process. This cloud is fed by the data sent from the "Qualifications CTutor" cloud, and contains the necessary parameters to find the courses and users' profiles. The tool offers three options for choosing courses:

- **Find Courses:** Users can search for courses that best suit to their profile and then they can choose and start the registration process in the course, so to obtain the associated skills.
- **Featured Courses:** Users can access the recommended courses from their profile; this is the interface where teachers and human resource centers can recommend students what the way forward should be for training in accordance with the criteria to establish and improve the curriculum for pupils according to their official studies. In the case of workers, it is related to the needs that the company has about the qualification the company's employees must have, and also new expertise acquisition.
- **Discussion:** Students, teachers and community members enter into the debate educational course selection; as such, students can follow and solve any doubts on the process of choosing new courses. Sometimes it can be the case that a student or a worker is not aware of the comprehensive curriculum, so they can take advantage of the system and proceed to required corrections. At this level tests are included to accurately assess the student's knowledge, also including the necessary tests for languages found as required for the workers' skills as well as students' reinforcement in their language subjects.

It is important to keep the system updated, for that we include the official curricula of vocational education courses. As for the inclusion of qualifications in training courses, the target is to obtain formal qualification training at the end of several professional qualifications collection.

IV. How The Systems Works

The ways a student acts on the systems is represented here: after reviewing his/her profile, s/he has access to existing courses within the platform. The student detects that the platform recommends more courses than he already has, so to obtain better professional qualification. The platform offers him/her the possibility to start the acquisition process with these new courses, by, first, selecting them, and later, request the tutor's approval.

Fig. 2 Courses Screen

Figure 2 shows the information and actions that a student can visualize i.e.: students can view the detailed information about specific courses, a list of recommended courses and expected professional achievements. Therefore, based on such information, the student can work to obtain the best possible professional qualifications. The platform also offers a set of actions like:

- Consult personal data: The student can visualize his personal data and request the needed changes.
- Course Registration: The student can ask for registering with a set of courses at the beginning of each semester.
- Registration Errors Correction: If the student identifies registration errors, s/he may ask for corrections, and follow the request process.
- Courses Schedule: It shows the student his/her academic calendar (list of courses, rooms, time, etc.)
- Selecting favorite courses: The student may identify a course as a favorite course, so that both the tutors and the platform can list associated recommended courses for the student to study, so to improve his professional qualification specifically for this specific field.
- Searching for recommended courses: The student may ask for a list of recommended courses associated with his/her degrees.

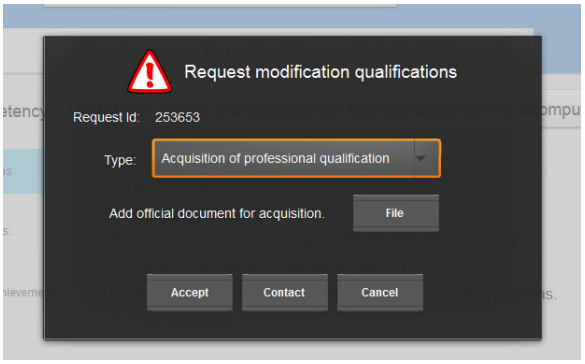

Fig. 3 Data Acquisition

Once a student observes that s/he already has the capabilities to acquire a competency unit, s/he may start the process of adding it to his/her professional qualifications, as in Figure 3. The student also has to argue about the merits with the administrators so to launch the validation process.

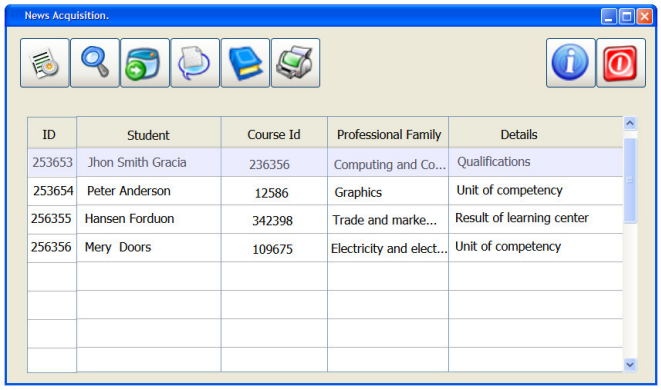

Fig. 4 System, new acquisition

During the acquisition process, the system sends a notification to inform the student about the process and the steps s/he has to follow, as in Figure 4. Once the student performs the requested information, s/he receives the notification informing him/her that the request is resolved; this service uses a message center.

V. Conclusion

The presented system aims to ensure students' and workers' improvement on the curriculum under the qualifications set within the European framework. Such system can keep the curriculum updated and allow the students to develop new qualifications based on skills acquired in formal training courses. The system interacts with users and provides all necessities related to the academic teaching methodology supporting the curriculum internationalization according to the European Qualifications Framework (EQF); an example is the language courses as they are becoming preparatory in Spain. As for the educational process, the students are able to perform additional studies, and thus, achieve more skills and be empowered in their curriculum subjects.

Following the platform design and development, future possible legislative changes are considered to adjust the platform to any new legislation structures and professional qualifications, as well as to adapt it according to the public academic administrations.

***Abstract*—At the time students' finish their academic educational level within a current educational system, a big gap appears to exist between the acquired knowledge and the needed knowledge to enter the job world. This situation provokes certain disconcert about the necessity for adaptation period to be properly integrated in the working environment. For this reason, the inclusion of a new subject into the educational system is proposed serving as a nexus and a channel between the academic institution and the company. This subject focuses on the company employees' educational level required to be hired and that of the students needed to enter the working field. Thus, based on the specific job characteristics, the educational institutions as well as companies collaborate to establish a plan to follow. A company actually proposes the basic milestones a student must have to become a worker with the required skills. In this way, we, as university teachers, support students who, at the end of their academic educational stage have the needed knowledge, skills and competencies to begin their working life without the problems related to ignorance about the work to do.**

***Keywords*—Subject; Educational System; Educational Institution-Company Relation; Work; University.**

I. Introduction

IN THE current educational system, and in conjunction to the subsequent studies on the secondary education level, a problem appears to exist related to the students' preparation when starting their working life. To be more specific, the student needs an adaptation period so to work in any position of a specific company when s/he finishes high schools and universities (not as much at the vocational education). This situation provokes a feeling of insecurity to a student due to not getting the acquired knowledge and skills that are required and appropriate so to immediately perform at work. On the other hand, the students do not only suffer the consequences but also, the contracting companies have to estimate a time of adaptation for the new workers, which is costly in both time and money.

As a result, this paper describes a solution consisting of including a new subject at the last phase of the academic studies focusing on the company's work. The subject serves as a bridge and communication channel and collaboration between the educational institutions and companies; in this way, at the end of the student academic education, students can be incorporated in the working field without the need of any type of adaptation period or with a minimum one, which, in turn, does not cost to the contracting company as much. Thus, students, educational institutions, and companies take advantage of such subject, and also, the country's overall economy is improved as a response and consequence of a drastic diminution of the young people's unemployed rate. This is because companies do not require dedicating human and financial resources for the adaptation period and consequently, hiring is dramatically more effective.

There is increased importance in the aforementioned as nowadays, there are numerous and diverse factors that badly affect a country's economical growth. Among these facts, the unemployed rate is called the brain drain or the capable people's unhappiness caused by the low salary. One of the consequences is loss of interest towards completing their education to a university degree. This is probably because they know from the beginning that they will spend a great amount of money they possibly do not have and/or have to acquire support from their families or a loan from the banks. Moreover, for the time needed to study, the student will not have monetary benefits but problems with, for example, housing. Last but not least, in case of acquiring the degree, such certificate does not guarantee a job, which is rather a disappointing concept in regard to higher educational levels.

For these reasons, we propose the inclusion of this new subject to increase students' interest on higher educational levels, in order to becoming more familiar with the working life and with the job they have been studying for. This generates expectations and hope for the students and if hiring is more probable then there will be added value benefits.

The following sections are presented as follows: the current educational system situation, a global vision of how the subject can be included into the academic plan, the

978-83-60810-53-8/$25.00

channels of communication between institutions and companies, the evaluation criteria for the students in that subject, and finally, and the work that we are doing to improve this proposal.

II. State of Art

With respect to university academic education, a solution exists to reduce the problem previously highlighted; this is the gap between the finishing the academic education and starting the working life. This solution is called "company practices". It consists of a student working in a company, who asks for this kind of practice. This type of work is remunerated, in some cases, and it is a bridge between the student, as a worker, and the company, which helps the student. On the other hand, in many occasions, the work done by the students inside a company does not reflect students' expectations. In other words, students think that they are going to learn about the working conditions and skills needed in a company within the field that they have been studying, however, they usually acquire a job unrelated to their academic education. Definitely, in some cases, companies use this kind of opportunities to hire people at low salary or no salary to perform very low-level tasks or tasks that nobody of the current workers wants to do.

With respect to the vocational education, the gap is not as wide as with university academic education. It is rather more focused on supporting the students entering the work world and for this reason; a closer relation with the local companies exists. In addition, there are studies to prepare the students who would like to enter the working life as soon as possible. Those studies are called "Programas de Cualificación ProfesionalInicial" (PCPI), in English, Initial Professional Qualification Programs; and previously called "Programas de Garantía Social" (PGS), in English, Social Guarantee Programs [1].

Despite the aforementioned problems, any help that the educational system could provide to improve the integration of the students in the working life would be well received by the society. For that, we are going to explain our proposed idea to ease this process.

III. Global Vision

The proposed subject is included in the last course of the corresponding studies plan. Thus, the students have the academic concepts as fresh as possible and the companies can identify a person to cover a vacant in short notice. This subject is optional, as it occurs within the company practices, and prepares the student with the needed knowledge to start working in a specific job. For that, the student identifies the kind of position he wants to occupy, when he finishes his studies, his spurting tutor and mentor etc. as the support provided by the university has to be as realistic as possible. After that, it will be clearer for the student to have a list of themes related to the desired job. This list of themes is established in a base shared between the institution and the company in order to know the essential milestones the student has to achieve to obtain the desired job.

As this is a subject in constant evolution, the companies will not be always the same and for this reason, the required essential milestones have to change occasionally. For example, two companies establish an agreement with the university where the needed criteria are established for a student to work in a vacant job as a Computer Science Engineer. One of the companies' jobs requires good knowledge of the CMS[1] Joomla![2] and the other .NET[3] Technology. Both vacancies require a Computer Science Engineer to develop the work. However, it is highly likely that the student at the end of his/her studies does not have enough knowledge and skills on any of the previous technologies. In addition, those technologies are different, so it is impossible to establish a common list of themes for both because the student will not be specialised to the required degree.

Taking into account the previous concepts, we are creating two different types of lists of themes associated with the current company necessities, which can be selected by the students who would choose the subject. One of the lists of themes is focused on the work on Joomla! where the student must study themes related with PHP[4], free software licenses, databases with MySQL[5], managing of a Apache server, etc. The other list of themes focuses, differently, on the programming language C#, the study of the .NET Framework, the architecture in layers, the client side programming language JavaScript[6], the SQL Server[7] database, etc.

Once we know the different lists of themes available for a specific course, the academic institution passes the information to the students so they can choose the closest to their necessities. If there is not enough number of students, more academic load will be dedicated to a subject with one

1CMS. Content Management System.
2Joomla!. Open code CMS, developed on PHP and under GPL license.
3.NET. Microsoft Framework for developing applications.
4 PHP. Server side programming language usually used for web development.
5 MySQL. Relational database management system of Oracle.
6 JavaScript. Client side programming language used to improve the performance and the interface visualization.
7 SQL Server. Relational database management system of Microsoft.

list of themes, and another list of themes will be rejected as non-viable (as occurs at the current educational system).

At the end of the academic stage, the students will have the required skills for the current working life for a set of companies that focus on specific technologies. In addition, the companies collaborating with the university can provide the bases for future workers to have at their availability qualified personnel so to work on the moment as they enter the company; this increases the students' or ex-students hiring rate by the specific institution. Such targets combination avoids the existing gap between the student and the company due to the lack of information and/or resources.

IV. Educational Institution-Company Communication

Finally, a communication channel is needed to bridge educational institutions and companies. This communication channel is of great importance because the successful collaboration between them determines the success or the failure of the whole project. So, if we establish the correct methods and level of understanding, the results obtained will be beneficial for all, the students, the institution, and the companies.

Therefore, different meetings between the interested parties can provide, as a result, the bases to establish the knowledge and capacities that students have to acquire to reach a determined job in a specific company. Moreover, we obtain real work-related profiles of qualified personnel to occupy a vacant job when finishing his/her education, which is nowadays not offered by the university.

This type of relationship is beneficial for everyone involved and even for not explicit parts, as for example, the employment system. Below we detail the resulting possibilities:

- For the students. The proposition improves the student self- esteem and attitude towards a future job. The student knows that the subject will be really useful for his/her working future. In addition, due to the fact that the company is already continuously immersed in this process, it increases the possibilities of hiring a student by that company or another, which works with the specific kind of technologies and/or methodologies.
- For the university. Improving students' attitude results on choosing the subject that will open the working world, and increase the number of students deciding to register for that subject, which in turn, directly affects the university's strongbox. Moreover, if there are a lot of companies that present their technologies and methodologies and due to this several plans created, an increase in the number of job vacancies can be established. Thus, this increases the number of subjects to teach, which would be great for teachers with problems appeared as lack of opportunities. Lastly, however, not less important, is the increase in possibilities of hiring students, therefore, the university's prestige would grow, raising the "graduated student-hired student" rate.
- For the company. As a consequence of this relationship, the company needing specific employees does not overspend on human and financial resources searching for suitable candidates who fit the job requirements; this is because the potential future employees have already studied the subject that is in accordance with the company plan. In addition, the adaptation period for a new worker is removed or drastically reduced. This increases the initial productivity and, consequently, the profits.
- For the employment system. The employment system is indirectly related to the communication channel between the educational institution and the company. This is due to different reasons; for example, and as aforementioned, is the number of plans about the subject increases, the number of vacancies for teachers needed also increases, which in turn decreases the number of unemployed people. Another factor is related to the direct relation between a company, the university and the subject with the specific list of themes for a job in that company and this is due to the communication channel; as the number of hired students recently graduated increases, the unemployed young people rate decreases.

To conclude, if we establish an effective, organized and structured communication channel between the educational institutions and the companies, more global benefits are obtained. These benefits are applied to every part and improve the educational and working system as such.

V. Evaluation

Finally, evaluation of this proposition is needed to assess that the studied concepts by the students are rooted enough and they have been useful to them. For this, and as a result of the conversations between the university and the company, evaluation criteria are needed to impart the subject and to obtain qualitative conclusions referred to the capacities of each student.

The evaluation need to be composed of theoretical parts as well as practical parts, depending on where the company assigns weight to the most important parts; these are the parts which have more weight at the time the teacher evaluates the work presented by the student. As for the degrees, for instance, in engineering or architecture, the evaluation criteria can be related to practices. However, for the rest of the degrees, if for example related to Arts, practical applications appear to be better and more positive

for the student because as they refer to real cases; these can be found and implemented inside the company, related with the study plan for the subject or other similar competences.

To increase the students' interest, we can establish agreements; companies are obliged to hire a specific and minimum number of students (if the students have finished the subject with appropriate qualification). Thus, at the end of students' studies, there will be interviews between the company and the selected students.

VI. Conclusions and future work

Nowadays, serious problems exist with respect to the rate of unemployed young people and the difficulty of the recently graduated people related to getting a job based on their studies inside of the frontier. For that reason, in this paper we proposed the inclusion of a new subject to the study plan of the educational institutions. This subject foments the communication channel between companies and educational institutions to achieve beneficial goals for everyone. Thus, the result is efficient and effective for all, students, company, educational institution and the public employment system. This is due to the creation of new work vacancies that help companies to find adequate people fitting with the company profile. Furthermore, students' efforts are rewarded with the possibility of being hired by the company, which manages the plan for the subject, or by companies with methodologies and/or technologies similar to that plan.

It is also necessary to mention that we are working towards managing different generated plans for adapting the conversations and agreements between educational institution and companies having a big part of their contents common to others. Thus, not only do the students achieve the goals of a particular company and their own but also within many companies, and thus, increasing the possibilities of hiring them. Getting more prepared students whose skills are open to a wider number working possibilities. Therefore, the improvement of the studies model plan of a subject for higher studies have to be considered, and also, aspects on studies of a lesser grade. For this, we are studying different forms for the students who do not want to follow higher studies; however, they can acquire a good career opportunity following the same paradigm of bridging subjects and communication between educational institutions and companies.

Improving learning methods through student's opinion into teacher's curricula Using graphical representations

Habib M. Fardoun, Daniyal M. Alghazzawi, Lorenzo Gonzalez
Faculty of Computing and Information Technology, King Abdulaziz University,
Jeddah, Saudi Arabia
Email: {hfardoun dghazzawi, lgonzalez}@kau.edu.sa

***Abstract*—Nowadays in curricula of university teachers doesn't appear anything related with the way to do the classes or the efficiency of the methods used with the students. We must have to take into account that a teacher is not only defined by his knowledge about a specific field but he is defined also by the way to pass it. For that reason we propose the inclusion inside of the teacher curricula of a section expressly dedicated to the student's opinion about the execution of his classes. This information is obtained through surveys and it will be displayed graphically with the goal of localizing the aspects which the teacher must improve and of maintaining an historic register that helps to check the progression. In addition, it will serve to the competent educational organisms to know the different skills of their employees.**

Keywords—Graphical Stadistics; Curriculum; Usability; Evaluation; Study; Student's opinion; Surveys.

I. Introduction

IN THE current higher education system in Castilla-La Mancha the teachers are evaluated by the students by mean of surveys which will be taken into account later for future bonuses or others [1]. These types of surveys performed by the students evaluate different aspects of the learning of a determined teacher. This kind of proposal is a good idea for keeping a good teachers attitude with the students inside the system. In addition, it means that not only it's needed a good base of knowledge of the teacher but a good way to express them and to show them to the students for a better understanding and acquisition of them. However the results of the surveys don't have enough influence inside the system in general and the teachers in particular.

In this paper we propose the study and inclusion of student surveys inside the teacher's curricula. Thus, a historic related with the attitudes and aspects to improve and improved, is kept in the system. But this is not only useful to study the learning aspects related with the teacher but also it forces the teacher to get interest for his work of knowledge transference of a more active form. That is because it will be displayed at the curricula and visible for the competent institutions.

The inclusion of this type of elements will be captured of a graphic manner inside the curricula to ease their understanding. Thus, with a quick sight we will know the strongest and weakest points of a determined teacher in particular. Moreover as the obtained results by the surveys won't be ephemeral (stored in a history), this foments a care for part of the teachers to give the classes. With all of it we don't only get to take into account the experience and knowledge of a determined teacher to evaluate his skills but also to take into account his work with the students and the way to foment the learning.

II. State of Art

Nowadays the evaluation of the teachers is performed by mean of surveys. These surveys were passed to the students,

Fig. 1. Survey of practical part.

978-83-60810-53-8/$25.00

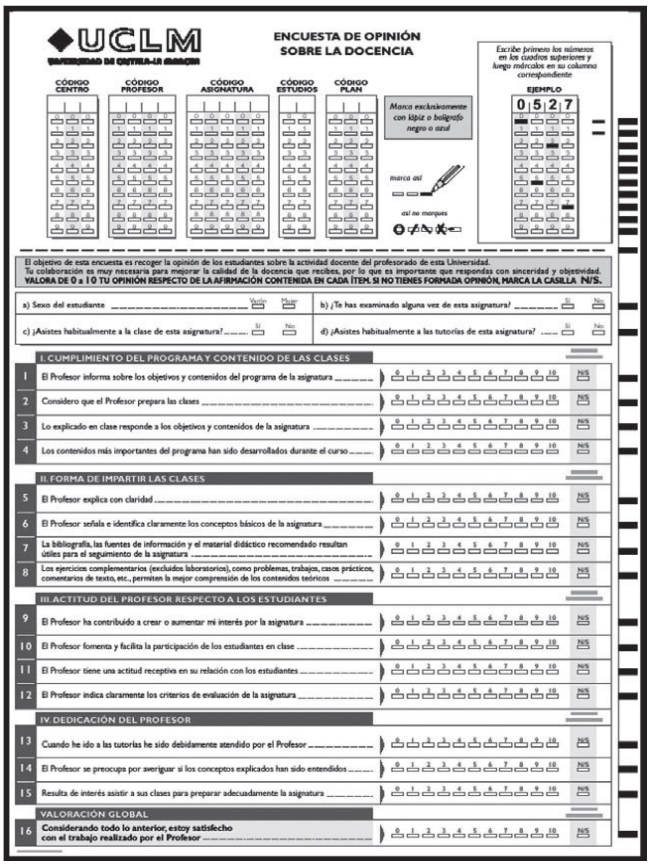

Fig. 2. Survey of theoretical part.

until this kind of fact started to be done electronically in 2011, at the final part of the teaching of each subject and in relation with a determined teacher. In that moment the students qualified the different attitudes of the teacher in an anonymous form. Thus, the results referred to the teaching period of a specific subject are obtained.

Surveys were determined by formularies which the students must paint the specific value inside of each category. At the following images we can see a form related with a theoretical part and another related with a practical part of a subject.

Actually the process can be developed by mean a web application. Thus, we reduce the costs and we promote the use of the electronically media. In addition, through this application the teachers may download the reports referred to the students' opinion to check if the methodological aspects of the teaching are adapted to the current students.

By observing these data, we propose the inclusion of the surveys' results in the personal curricula of each teacher. With it everyone can know the progression of a determined teacher and if the teacher's capacities satisfy to the students of the subject. Thus, we get various goals:

- To foment the dedication of the teaching stuff to improve their learning skills.
- To guarantee that the students are agree with the learning and with the taught knowledge.
- To obtain a history for the teachers can see what facets to improve.
- To include in the teacher's curricula not only the technical skills but also the learning skills.
- A control by the educational institution of their employees, by checking if they reach the expected expectatives.

III. Evaluation and Study

If we take into account the figures 1 and 2, we can see that there exist four main factors to evaluate inside of the capacities of a determined teacher. In function of it is theory or practices respectively, these are:

- Compliance of the program and content of the classes (or practice sessions).
- Way to teach the class (or to develop practice sessions).
- Teacher attitude with students.
- Teacher dedication.

Each of these capacities comes also determined by more specific aspects inside of them which form the global. These aspects will be evaluated by mean of the students' opinion and will be treated to avoid extreme values which go out of the real estimation. Knowing that the valuations of the students usually have a normal distribution [2], different mathematical and statistical methods are used, as for example the empiric rule which use the standard deviation as selector element of the data range used to the evaluation [3].

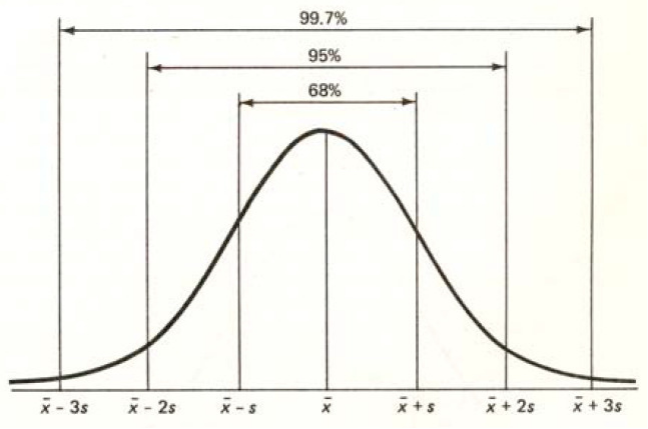

Fig. 3. Empiric rule.

Once we have the validate data inside of the sample set, we will proceed with the calculation of the mean of each of these data in reference to each question of the survey. After that we will evaluate at the same form the global capacity in function of these specific data. With it, we will obtain tangible data to be used by teachers and pertinent educational institutions.

IV. Inclusion into teacher's curriculum

Knowing the punctuation provided by the students to a teacher in a determined subject, next thing to do is the inclusion of these data inside of the teacher's curricula. Nowadays this information is available through a web application, thus the teacher may download the reports when he wants. However this type of methodology doesn't foment a increment on the teacher's interest to improve his classes. For it, in this paper we propose the insertion of the data inside of the teacher's curricula for giving it importance and this is taken into account. With this option, students and educational institutions will have more opportunities to visualize it.

All those things drive the teacher attitude to a restructuration of his classes in case of these classes don't give the expected result in a specific field or to a maintenance of the form of doing them in case of the evaluations were successful. Thus, we obtain a greater control over the learning for the knowledge arrives in good conditions to the students, getting a quality education. These data will serve as a history to see the evolution of a determined teacher and as a supporting point to improve on the fields where he is failing. However, the fact of to include the data doesn't have too much influence on the attitude for visualizing them. For that reason, the best form for these data call the reader's attention (the teacher or anyone else) is to show them by mean of intuitive and easy graphs, understandable in a first look.

This kind of graphs will call the attention and will show the evaluations of the four main components of the previously treated surveys at the state of art.

V. Graphical representation

There exist different forms to display data graphically to the user. In this particular case we need to show a graph which information contains the four main facets related with the learning of a determined teacher. In addition, we must to take into account that for each of them there exist other aspects which constitute them. These aspects will be also represented.

Following the specifications described in the article [4] where the graphs of football games are taken as reference, we are going to use for this case the same form of representation but with the particularity of using a square rather than an octagon. Thus, the representation of the data would be displayed as follows at the figure 4.

Once observed the data referred to these four main elements which constitute the evaluation of a teacher, for the case of wanting to look deeper in each of them, we only need to pass over one of them to see the associated data. With it, we can watch the information related with the evaluation of a determined aspect of the teacher learning. At the figure 5 we can observe how that information is shown (theoretical part).

With all of these data added to the teacher's curricula, the information contained in it will be completed. Of this form

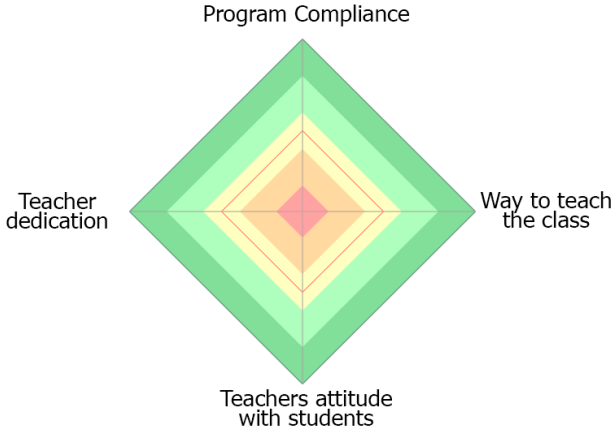

Fig. 4. Graphic representation of the teacher's attitudes.

there won't be only technical aspects but also aspects referred to the learning attitudes.

VI. Conclusions and future work

With the inclusion of the students' opinion into a teacher's curricula we achieve that the teacher pays more attention to his work of teaching because that information will be available for the educational institutions and students can see it when they want. Moreover, as that data is displayed graphically, the user who consults these data will have it easier and in one look he will know the attitudes of a determined teacher. But it is not only used as a consult method to external agents to the teacher but the teacher will be able to consult the data to see the areas which need a improvement for the efficiency in the educational labours was more productive. With it, the opinion of people who must receive the knowledge for the educational system, gets the deserved importance. In addition we foment the good practices and the self-criticism of the teachers to improve their learning capacities. All of this is resumed in the aspects previously commented:

- To foment the dedication of the teaching stuff to improve their learning skills.
- To guarantee that the students are agree with the learning and with the taught knowledge.

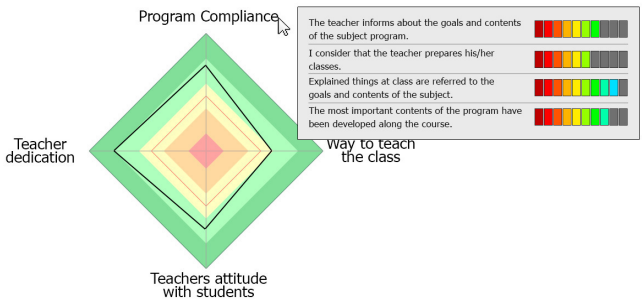

Fig. 5. Contained information inside of a specific aspect of the teacher's learning.

- To obtain a history for the teachers can see what facets to improve.
- To include in the teacher's curricula not only the technical skills but also the learning skills.
- A control by the educational institution of their employees, by checking if they reach the expected expectatives.

The following challenges that we have proposed to us are referred, among others, to foment that the participation in the surveys to be the more realistic as possible, trying to avoid that the external factors have influence on the students at the time of qualify the attitudes of a determined teacher and on a specific subject. This type of factors can be determined by comments of the teachers due to a fear to a negative evaluation or by the students trying to do wrong evaluations without take into account that this actions can have a negative influence into the curricula of the teacher to evaluate.

***Abstract*—The paper presents case study – Information Systems and Computer Science in Civil Engineering curricula. Introduction gives historical background of present role and position of IS, Information & Communication Technologies (ICT) and CS. Later details of the course of Information Technologies (IT) are presented in which elements of IS (ICT) and CS are combined. The use of spreadsheet and its Solver as well as Computer Algebra System (CAS) are stressed. Special attention is put on lectures which give necessary theoretical background for classes. Additionally there are presented some remarks about the subject Computing in Civil Engineering (CCE) which is natural successor of IT course. The paper is illustrated by the results of questionnaires performed in the beginning and in the end of semester. The main purpose of the article is to present changes and convergence between mentioned above subjects.**

I. Introduction

THE place and role of Information Systems (IS), which can be treated in narrow sense as a term referring mainly to ICT, and Computer Sciences (CS) in curricula of Civil Engineering (CE) studies changed a lot in last few decades. In ’70 and ’80 mainframe computers were used and students were taught Algol and FORTRAN as programming languages. In ’90 first PC laboratories were created so Algol and FORTRAN were replaced by Turbo Pascal. Students were also taught software like spreadsheets and text processors. Moreover for the purpose of Numerical Methods Computer Algebra System (CAS) MathCAD was introduced. In XXI century Windows environment and its applications dominates in curricula of studies. Additionally to these changes IS and CS are more separated than before. They are taught in different subjects namely Information Technologies and Informatics because Visual Basic for Applications (VBA) as sample programming language was in 2005 replaced by C++. The place and role of IS and CS in curricula of CE studies are subject of never ending discussions. The most orthodox engineers see no room for such subjects. In their opinion students’ knowledge gained from secondary school on the level of European Computer Driving License (ECDL) described in [1] is absolutely satisfactory for future civil engineers. Their opponents see growing role of IS and CS in all engineering fields. Existing curricula is to some extend a kind of compromise between these two opposite opinions. In the rest of the paper laboratories and lectures in the field of IT, curricula of CCE and attempts to flip the education will be presented.

II. Information Technologies: Laboratories

Because in common opinion C++ taught on 2nd semester of BSc studies in subject named Informatics is not the best idea curricula of the subject Information Technologies (IT) taught on 1st semester is a trial to make a reasonable combination of IS and CS. Curricula of IT subject is based on compromise between the level of students’ knowledge and foreseen needs of other subjects. While first point can be easily measured by questionnaires second one is hard to tackle with because of mentioned above conservative attitude of many teachers to the role of IS and CS in engineering.

A. Results of questionnaires

Questionnaires has been conducted regularly since 2011.

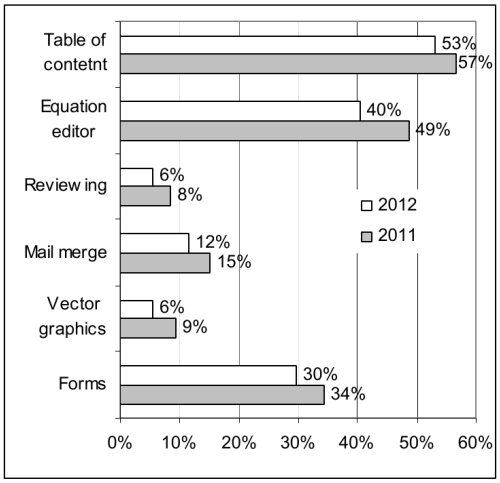

Fig. 1 Sample questions concerning text editor

This work was supported by Warsaw University of Technology

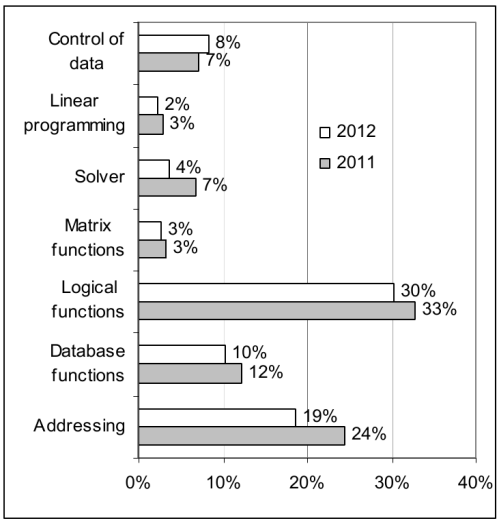

Fig. 2 Sample questions concerning spreadsheet

Their results are worse than expected. Students know how to run software like text editor or spreadsheet but they do not know how to use it in order to solve particular problem in effective way. Both Fig. 1 and Fig. 2 show that the knowledge of more advanced functions in text editor and in spreadsheet decreases. This means that material from IT on the level of ECDL stil should be present in curricula of studies.

B. Block 1: First things first…

First block consisting of three classes can be named first things first. Students are definitely very skilled mainly in dragging, dropping and tapping, so topics like file systems, file transfer and rights are quite new for some of them. Similar situation happens in the field of presentation graphics. Ten slides and 20 MB files are common problems because terms like resolution and appropriate graphic file format are in students' opinion not necessary for them. Last but not least text editors are also used in rather ineffective way. Styles, table of content, bibliography tools as well as mail merge are used very rarely. Last part of this short block consists of elements of Hyper Text Markup Language (HTML) and Cascade Style Sheet (CSS). People who are against this say that nowadays nobody creates web pages in pure HTML and CSS using only text editor. The purpose of these classes is different. First of all this is one of the simplest examples in which it is possible to presents to students how something from the field of IT works. Moreover in contradiction to clicking, dragging, dropping and tapping HTML and CSS require precise thinking which can be treated as an example of algorithmic thinking necessary in programming. Last on the list of pros is the fact that due to existence of numerous validators students can easily check results of their work.

C. Block 2: Spreadsheet - in between…

This block of classes is also three weeks long. There are three major points in this block: logical functions and conditional statements, database functions and their usage and Solver described precisely in [2]. Solving engineering problems especially during design process means using conditions. Simple spreadsheet IF function combined with OR, AND and NOT functions are excellent introduction to programming. Table databases are not real relative databases but they can at least give to students a flavor of database systems and give to them an opportunity to learn how to formulate queries using specialized database functions. Solver opens the opportunity to solve more complicated problems like optimization. Students are taught two things: how to solve linear and nonlinear maximization and minimization problems and how to create appropriate mathematical model of a given problem. Fig. 3 shows Solver window for linear programming problem.

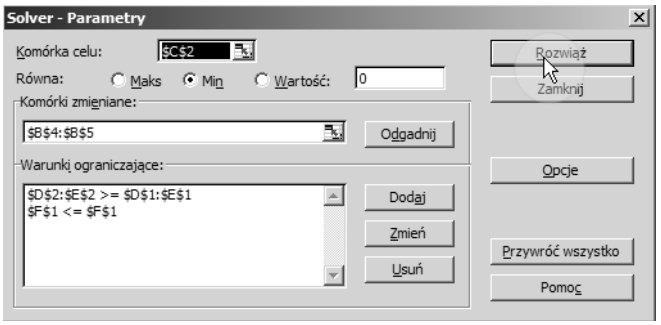

Fig. 3 Solver parameters for linear problem

D. Block 3: CAS – towards algorithmics and programming

The last and the biggest block of classes is devoted to CAS namely to MathCAD which is described in many books like: [3], [4] and [5]. Its presence in curricula of studies is a source of never ending discussions. In the opinion of many teachers students overuse MathCAD while preparing their design homework using it. It is enough that one person creates a file and all remaining can simply enter only data.

First part of MathCAD classes is devoted to solving classical mathematical problems:

- Symbolic calculations
- Definition of variables and functions
- Calculus: integrals, derivatives, limits.
- Matrix and vector operators and functions.
- Solving problems: linear and nonlinear equations, minimization and maximization.

Second part is devoted to programming. In the first part basic instructions (if, for, while) and control statements (return, continue, break) are introduced. The idea of this subject was inspired by the book [6]. List of algorithms is based on two Polish books from this field: [7] and [8]:

- Numerical algorithms (bisection, regula falsi, Newton method)
- Classical algorithms (Euclid's algorithm for greater common divider, Fibonacci numbers)
- Sorting algorithms (insertion, selection, bubble)

These algorithmic problems are solved together with classical programming problems including:

- Matrix and vector operations and
- Sums of series.

Fig. 4 presents sample MathCAD code of insertion sorting algorithm.

```
ins(w) := | n ← length(w)
          | for j ∈ n − 1, n − 2.. 1
          |     rob ← w_j
          |     i ← j + 1
          |     while i ≤ n ∧ rob > w_i
          |         w_{i−1} ← w_i
          |         i ← i + 1
          |     w_{i−1} ← rob
          | w
```

Fig. 4 Sample MathCAD code

III. Information Technologies: Lectures

Lectures are also very controversial part of the subject Information Technologies. There is quite common opinion that they are not necessary because in the second decade of XXI century everybody is a specialist in the field of IS and CS. Lectures are mainly based on four books: [9], [10], [11] and [12]. First one is accompanied by excellent web site enabling students to learn independently. Subjects of subsequent lectures are as follows:

- Introductory remarks: layers of computing system, the history of hardware and software.
- Binary values, number systems, conversions, floating point arithmetic.
- Data representation of text, graphics, audio and video; compression.
- Boole algebra, gates and circuits; von Neumann architecture;
- Elements and parameters of computing system.
- Algorithms and their representation: searching and sorting algorithms, recursive algorithms.
- Programming languages: translation, compilation, interpretation, basic programming structures, programming paradigms and languages.
- Types and data structures: stacks, queues, lists; subprograms.
- Operating system: role, memory and process management.
- File system and directories.
- Information systems and applications: spreadsheets and databases.
- Computer networks and their security: network addresses, cloud computing.
- Internet and the World Wide Web: HTTP, HTML.
- Introduction to artificial intelligence and expert systems.
- Limitations in the field of hardware and software; the untouched problems; questions and answers.

IV. Computing in CE

This subject plays supplementary role to IS and CS. Its curriculum consists of three blocks. First is devoted to Directs Stiffness Method (DSM) enabling students to solve trusses, beams and frames. Second part is devoted to stationary heat transfer problems – students learn how to solve set of Partial Differential Equations (PDE) using Finite Difference Method (FDE) or Finite Element Method (FEM). The last block devoted to optimal design is mainly based on the book [13]. Student learn from this block how to solve Operation Research (OR) problems as well as structural optimization problems. Tools used in curricula of this subject are mainly known from IT classes – this is spreadsheet and CAS software MathCAD. The stress is put on building appropriate mathematical model. In many cases for simple problems solution can be verified by hand calculations. Fig. 6 presents solver window for transportation problem.

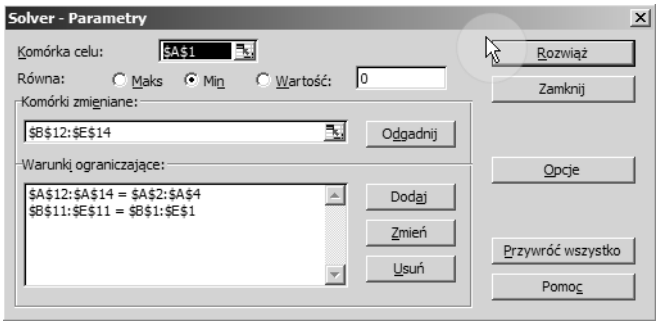

Fig. 5 Solver parameters for transportation problem

V. Towards Flipped Education

For ten years students have been provided with different multimedia materials in the form of podcasts – personal on demand broadcasts. First podcasts prepared in the Division of Information Technologies (DoIT) had the form of screencasts – "digital recordings of computer screen output often containing audio narration". Screencasts contain software animations helping students to learn how to use software. Second kind of podcasts are slidecasts – "audio podcasts combined with slideshow". Slidecasts have the form of knowledge clips – short explanatory presentations of particular problem and its solution. Last kind of multimedia materials prepared by DoIT are webcasts – "media presentations distributed over the Internet using streaming media technology to many simultaneous viewers". In fact webcasts were lecture captures which were recorded and later distributed as podcasts. Tenths of hours of different podcasts stored on ed-

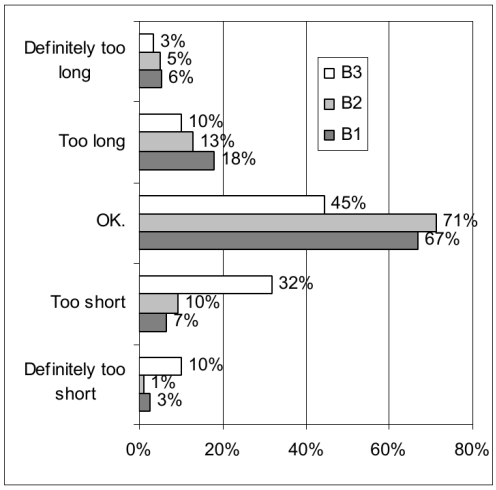

Fig. 6 Opinion about the length of blocks

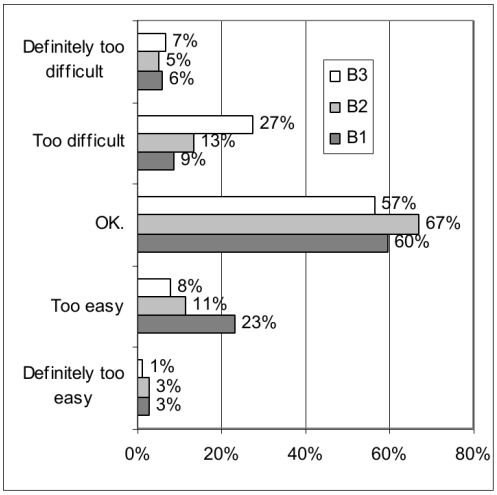

Fig. 7 Opinion about the difficulty of blocks

ucational portal helped a lot during classes but did not have expected impact on quality of learning process measured in terms of grades obtained by students.

Starting from academic year 2012-2013 in some of the groups podcasts are used in different way. Students are asked to watch podcasts at home. During classes they should be prepared to use software without any problems and to solve using it particular problems. This idea is known as flipped classroom and is described precisely in [14] and [15]. First results of this experiment are to some extend promising - students gain better scores in flipped mode. Students are not very keen to spend time at home watching podcasts. They do prefer to "be taught" during classes. This problem can be easily solved by adding simple point to subject regulations – students should be prepared to computer laboratories and this fact is checked by means of test before the class. According to European Credit Transfer System (ECTS) in fact the same amount of time as at the university average student should spend learning at home. It is much more effective to watch passive in nature screencasts at home and solve problems with tutor in class than the other way round.

VI. Conclusions

The question of the place and role of IS (ICT) and CS in engineering curricula belongs to the category of ill posed problems. From the point of view of majority of teachers the most important for engineers is their intuition, so they neglect the knowledge from the fields of IS (ICT) and CS. Results from all computational programs should be verified and this is out of the question. One can say that the role of computations is to prove hand calculations. But on the other hand IS and CS can make engineers work more efficient.

From students' perspective IS tools are treated as specific black box. In order to use these tools in proper way at least basic knowledge form CS area is required.

Results of questionnaires from the end of the course presented on Fig. 6 and Fig. 7 show that the idea of sustainable presence of IS and CS in curriculum of civil engineering studies is accepted by students.

Presented paper shows that further convergence between IS and CS in higher education is necessary, because tools used by engineers are more and more complicated. New and innovative teaching methods like podcasts and evaluation of teaching can help to merge from IS to CS and vice versa. Curricula of studies should be continuously improved by adding new elements like for example Geographic Information Systems (GIS) or Building Information Modeling (BIM) software and systems.

Testing the perception of time, state and causality to predict programming aptitude

José Paulo Leal
DCC/FCUP & CRACS/INESC-TEC
University of Porto, Portugal
Email: zp@dcc.fc.up.pt

***Abstract*—The aim of the research presented in this paper is the development of a novel approach to predict programming aptitude. The existing programming aptitude tests rely on the past academic performance of students, on their psychological features or on a combination of both. The novelty of the proposed approach is that it attempts to measure student capabilities to manipulate abstract concepts that are related with programming, namely time, state and causality. These concepts were captured in OhBalls - a physical simulation of the path taken by a sequence of balls through an apparatus of conveyor belts and levers. An engine for this kind of simulation was implemented and deployed as a web application, creating a self-contained test that was applied to a cohort of first-year undergraduate students to validate the proposed approach. This paper describes the proposed type of programming aptitude test, a software engine implementing it, a validation experiment, discusses the results obtained so far and points out future research.**

I. Introduction

PROGRAMMING is hard to learn for most people [9], [12]. Although some students seem to learn it without apparent difficulty, this is not the case of most of them, especially those majoring in subjects other than computer science or software engineering. Even students in those areas are not immune to these problems, as many educators feel that they do not acquire the necessary programming skills in introductory courses [10]. Probably some students are not cut out to be programmers and knowing it in advance would a great advantage [7].

Predicting which students are likely to succeed in learning programming is not easy, some even say it is unfeasible [9]. Nevertheless, this is precisely the goal of the research described in this paper: to create a programming aptitude test, and especially to explore new ways to predict programming aptitude.

Several studies suggest that the high school performance in mathematics is the best indicator of a programming aptitude in college [3], [6], although the correlation between both is usually small. The standard explanation is that both mathematics and programing require abstract reasoning, thus a student with a good performance in mathematics during high school is bound to succeed also in college programming courses.

It is indisputable that a connection exists between programming and mathematics, at least in a broad sense. Although it is much more difficult to define mathematics than programming, if we accept that the realm of mathematics is patterns of thought them clearly computer science in general, and computer programming in particular, are deeply connected to this discipline. However, the mathematical knowledge of a high school student is essentially algebra, calculus and basic logic, and these fields lack a number of abstract concepts that are essential in programming, namely time, state and causality.

The concept of *time* is central to computing. Computers have an internal clock that regulates how instructions are executed. Programs are sequences of instructions that are executed in a flow over a period of time. All the elements of a computer, or of a program, are in a certain *state* that evolves over time. The execution of instructions *causes* changes to these states, that are influenced by their previous states.

This type of reasoning, however abstract, is in general absent from mathematics, especially from the branches of mathematics taught in high school. Take calculus for instance. Although the variable of a function may be interpreted as time, the function itself exists beyond time; it always existed and never changes. A derivative may be seen as the amount of change of the function's value but it has no discernible causes or consequences. Or take Boolean logic as another instance, where A implies B that does not mean that A precedes B or caused by B. If A is true then it has always been true and will never change. This timelessness exists also in algebra where "variables" are actually "unknowns", values that can and eventually will be determined by a computation, not values that actually change over time.

It can be argued that some programming languages, namely declarative languages, are closer to mathematics and above these concepts of time, state and causality. Although this is true, these languages are not widely used and certainly not used as much as Java, C/C++ and Python in introductory programming courses [11]. Moreover, although the denotational semantics of these languages may be independent from time and state, their operational semantics depends on them and the programmer must understand them, if not for anything else, to be able to debug programs.

An algorithm is probably the mathematical concept learned before college that most closely resembles to a computer program. However, students learn specific algorithms that they execute, for instance the division algorithm, rather than study algorithms as a topic, without actually creating new algorithms. These differences between mathematics and programming are possibly the reason why a student may reveal

978-83-60810-53-8/$25.00

aptitude for maths but none for programming and vice versa, and why math grades are insufficient to predict proficiency in programming.

The motivation for this research comes from the intuition that there is a kind of reasoning that is specific to programming, that is different from the reasoning required in mathematics. Based on this insight, the goal of this research is to develop a new kind of test based on the concepts of time, state and causality. The test should be self-contained, in the sense that it should not require a person to administer it and should not require any previous knowledge of programming concepts.

The remainder of this paper is organized as follows. Section II reviews the related work on predicting programming aptitude. Section III presents the proposed type of aptitude test and describes a JavaScript engine implementing it. Section IV reports on an experiment to evaluate the proposed type of test. The final section summarizes the research conducted so far and identifies paths for future research.

II. Related work

Predicting programming aptitude is still a challenging task, although this topic is being studied for more than 40 years [1] and its relevance has been well establish for almost a quarter of a century [7].

Most of the recent research in the literature attempts to correlate programming aptitude with factors that are unrelated with programming, either the student academic record or psychological features. As part of the academic performance the most relevant factor is previous math grades [2], [3], [8] although science grades and even average grades have also been investigated. Other plausible factors were also investigated, such as creativity, problem solving aptitude, attitude toward computers, with even lower correlations [6]. None of these factors has yet provided a good predictor of programming aptitude.

The test recently proposed by Dehnadi [5] differs from the previous since it is actually related to programming; it is a sequence of questions on Java assignment statements. Dehnadi claims that *consistency* in the interpretation rather than its correctness is the main indicator of programming aptitude. The purpose of the test is not to discriminate students who answered correctly, which would assume prior knowledge of programming. The purpose is actually to determine those who answered consistently according to a single mental model. This would reveal the ability to create a meaningful rule to interpreter the assignment command, from which the aptitude to learn a programming language could be inferred. Unfortunately, this experiment was later repeated by Caspersen [4] and also by Wray [12] and none was able to reproduce the results of Dehnadi.

Wray [12] explored the known link between autism and descendants of mathematicians and scientists. He proposed an alternative method for predicting programming aptitude based on mild autistic-spectrum related questionnaires from the Autism Research Center. These questionnaires tests two facets of autism: the level of understanding of systems of objects (SQ) and the level of understanding of other people emotions (EQ). Individually these tests are moderately correlated, but combined they provide a good correlation (r=.67) with programming aptitude. However, the test was applied only to 17 students after they have completed an introductory programming course, and no subsequent results were published on the use of this method to predict programming aptitude.

III. Testing programming aptitude

The goal of this research is to develop a new kind of test to estimate programming aptitude. This kind of test intends to estimate the perception of time, state and causality, under the assumption that these concepts are present in programming reasoning and should reveal an aptitude to program. Also, the test must not require any programming knowledge and be self-contained, in the sense that anyone should be able to take it alone, without or with minimal supervision.

The test that is being developed is based on a set of physical simulations with a common scenario called *OhBalls*. This name comes both from the blue ball than moves on a screen, and the interjection that participants pronounce when it doest not behave exactly as expected. Since it is based on a simulation the test must taken on a computer, which nowadays is hardly a difficulty. In its current implementation the OhBalls test is deployed on the web hence it can be taken virtually anywhere.

A test with the OhBalls scenario is composed by a sequence of panels. Each panel presents a physical simulation set in a room where balls are dropped from a pipe on the ceiling, move through a system of conveyor belts and eventually fall in one of several buckets on the floor. The participant must predict the number of balls that will land on each bucket when the simulation is executed. Figure 1 depicts a example of those panels.

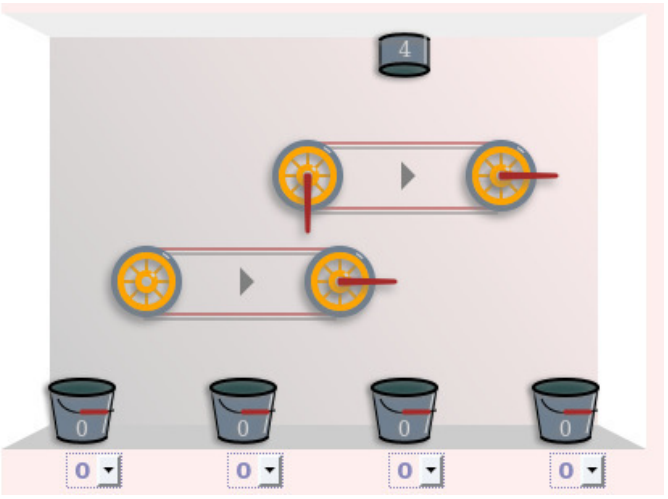

Fig. 1. Example of an OhBalls panel

Balls falling from the pipe land on a conveyor belt that carries them either to the left or to the right. The direction in which the upper side of the belt is moving and the ball would be carried is shown by the arrow head in the middle of the conveyor belt. This direction can be reversed by one of the levers connected to the wheels of the conveyor belt when a ball pushes it. For instance, the first ball falling from the pipe in Figure 1 will be carried to the right by the top conveyor belt and fall in the rightmost bucket. When falling to the bucket it will activate the right lever of the top conveyor belt, reversing its direction, and thus the second ball will go to the left.

The levers have always the same effect – reverse the conveyor belt to which they are connected – but are activated in different ways. For instance, the right lever on the top belt is activated when the ball falls out of the belt, while the left lever on the same belt is activated when the ball is carried to the right by the bottom belt. Hence, the second ball will fall on the second bucket from the right, and will reverses the direction of both belts.

The levers change the state of the system from one ball to the other. In the panel of Figure 1, when the third ball falls from the pipe the top belt will be moving again to the right, while the bottom one will be moving to the left. Hence, this ball will eventually land on the rightmost bucket, raising its count to 2, while reversing the top belt. At this moment both belts will be moving to the left. Thus, the fourth and last ball will be carried to the left, and is dropped on the leftmost bucket. Any subsequent ball would also end in the leftmost bucket but this simulation stops after 4 balls.

The number initially on the pipe indicates the number of balls that will fall during the simulation, and each bucket counts the number of balls that reached it. Under each bucket there is a selector where the participant predicts the number of balls that will reach it when the simulation is completed. The simulation is started by pressing a button (not shown in Figure 1) that is activated when the sum of these selectors equals the number in the pipe.

During the simulation balls fall from the pipe on the ceiling one after another. When a ball is dropped the counter in the pipe is decreased. When the ball reaches a bucket its counter is increased. Then a new ball is dropped from the pipe if this counter has not yet reached 0. When all balls reach a bucket the simulation stops and the number in each bucket is compared with the number in the selector beneath it. The participant is considered to have successfully predicted the outcome of the simulation if these figures match for all buckets. The participant may replay each simulation several times but will not be able to change the answer made before executing the simulation for the first time.

It should be noted that levers do not stop balls by themselves. They are activated by balls and change the direction of belts that carry them through the apparatus. For instance, the left lever on the top belt will be activated when a ball is moving to the right on the lower belt. The lever will not stop the ball in this belt but will reverse the direction of the top belt, affecting only the following balls. If this particular lever (in the left on the top belt) was pointing up instead of down then it would affect balls coming to the left in the top belt. It would not stop them but it would reverse the belt before they reach the point where they would fall.

In summary, the apparatus is composed of one or more conveyor belts that carry a ball falling from the pipe to the buckets on the floor. The motion of each belt is given by a pair of wheels. Levers are always bound to a belt, more precisely to one of its wheels, and can be in 4 possible directions (left, right, up and down).

It is obvious that many panels of this kind can be created with a different number of belt and lever settings. For instance, with a single belt there are 16 different combinations. On each side there are 4 possibilities for placing a lever: no lever at all, pointing up, pointing down, left or right, depending on the position of the wheel[1]. More than one lever per wheel would be possible but would also be too confusing. In a panel with 2 belts these must be arranged so that falling balls go either to another belt or to a bucket.

The easiest way to achieve this is to use a *grid* to place the center of the belts, the buckets and the pipe. The distance between the wheels of a belt must be set in a way that balls are dropped in alignment with the center of other belts and buckets positioned bellow them. Also, the distance between consecutive rows must take in consideration that a certain gap between belts, large enough for the ball to move between them, and small enough for the ball carried by the lower belt to activate a lever in upper belt. The pipe should be at the center and have a belt aligned bellow.

With this approach a setup with 2 belts in two different ways can be created, with the lower belt either to left or to the right, with a total of 512 possibilities. It would not make sense to place belts exactly over each other, or any relative position where balls would not go from one to the other.

An engine to execute this kind of simulation was implemented in JavaScript using the HTML 5 canvas element with a 2D context. This engine runs on a recent version of all major web browser. It can be parametrized with any number of panels following the approach described above. Currently the panels are limited to a grid of 5 rows by 7 columns, which is large enough to place 4 belts, a pipe and bottom row of buckets in each column of the grid.

The current version of engine supports only the prediction of the simulation outcome. In a future version it should allow the participant to place levers in order to achieve a certain configuration. Obviously, this is much closer to the reasoning involved in programming than the current implementation, which is comparable to tracing a program for debugging it. Implementing this feature is not difficult. The main reason for not having it in the first version was lack of knowledge on how the participants would react to this kind of test and the possibility that they would find it too complex as it is.

[1] a lever pointing inwards would be senseless

IV. EXPERIMENT

An experiment was designed to investigate how potential participants perceive the OhBalls type of test and its effectiveness in predicting programming aptitude. For this experiment a number of students enrolled in an introductory programming course took an OhBalls test and the outcome was compared with the grades of their middle term exam. This section presents the web application developed as the main instrument for this experiment, analyses the data collected with it and discusses the obtained results.

The web application developed for the experiment is based in the simulation engine described in section III. It allows a considerable number of participants to take the test simultaneously, while it collects data for later processing.

The interaction of each participant with the web application proceeds in four stages: identification, questionnaire, tutorial and test. The total time of each participation is about 20 minutes. To start the participation each student introduces his or her ID that is checked against a list previously loaded into the application, ensuring that each student participates only once. After being identified, the participant completes a small questionnaire with demographic data, mathematics and average grades from high-school, and former experience with computer and programming.

The OhBalls test is preceded by a tutorial that explains how it works. The tutorial runs on the same type of interface and highlights each important part while a text in a message box provides the necessary details. It explains how the balls are carried by belts in the simulation, how they activate levers and these change the direction of belts, how they reach buckets and new balls repeat the simulation until a predefined number of balls is processed trough the simulation. This tutorial explains also that the participant must predict the number of balls ending in each bucket before running the simulation, and how to activate it and proceed to the next panel. This tutorial runs in a loop until the participant decides to start the test. During the test the participant may rerun this tutorial, if needed.

The OhBalls type of test configured for this instrument consists of a sequence of 30 panels. Each panels is accompanied by a small text that emphasizes a particular point that was not present in the previous ones, such as “note that levers may by activated while balls are falling”.

The first set of panels has a single conveyor belt, and each panel is increasingly more complex than the previous ones. The following set of panels has two belts also with increasing complexity. Nevertheless, the first panels with two belts are less complex than the last ones with a single belt, since they have no levers or just a single lever. The following two sets, with three and four belts, are ordered in the same fashion: the first panels are fairly easy and the last are more difficult.

After the simulation is run the participant is informed if she succeeded in predicting the outcome of the simulation, the time she took to complete it (the number of seconds the panel was shown before pressing the button to start the simulation) and the percentage of correct answers.

When the participant proceeds to the next panel the application sends the data it collected to the server. The data collected for each panel includes the time the student took to complete it, the number of balls the student expected in each bucket and a Boolean indicating if the outcome of the simulation was predicted with success or not.

The participants were students enrolled for the first time in an introductory programming course. This course is common to the computer science and computer engineering programs offered by the computer science department of the faculty of sciences at the university of Porto. The course syllabus is problem solving oriented and uses C as programming language.

The experiment took place in September of 2012 during their first practical class and the participation was optional. Although no student refused to participate in the experiment, those that were unable to complete the test due to timetable constraints were excluded. The students received a brief explanation on the purpose of the experiment and were assured that their participation would not have any impact on their course grades.

The number of participants in the OhBalls test was 153 of which 115 where considered valid. Of these students a considerable number decided they were not ready to take the middle term exam. Only the data referring to the 57 students that took also the middle term exam was used in this experiment. Of these 57 students considered in the experiment the number of females was 10 (17.5%) and 18.16 was the average age.

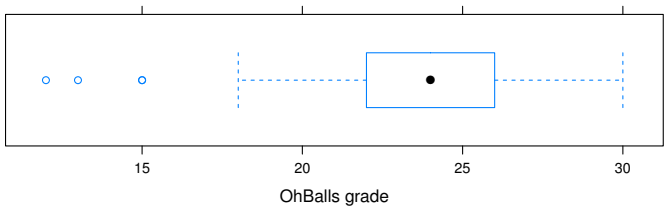

Fig. 2. Box plot of experiment grades

The time taken in each panel by the participants varied from 1 to 558 seconds, with a mean of 33.25 seconds. A possible inverse correlation between time spent analysing the panel and the a correct prediction was investigated, but it was not very high ($c = -0.24$).

To measure the outcome of each participant’s test a grade was computed by assigning 1 point to to each panel correctly answered and 0 otherwise. Thus, each participant had a grade with range 0 to 30 (the number of panels) assigned to her. Considering the series of test grades, the minimum grade was 12, the mean 23.3, the median 24 and the maximum 30. A 5 value summary of the ObBalls grades in the experiment is shown in Figure 2.

There was a good number of very simple panels, to make sure the participants understood the test, but most likely this difficulty was overestimated. In fact, taking 1 for a panel correctly answered and 0 otherwise, the overall median of was 1 and the mean 0.74; by panel, in 23 out 30 the median was 1. The data suggests that the OhBalls test used in the experiment is too simple and more complex panels are needed.

The correlation of the OhBalls grade with the middle term exam was not high ($c = 0.31$) and inferior to the correlation between the high school math grade reported by the students ($c = 0.39$). Nevertheless it was possible to identify a subset of 8 panels for which the correlation is comparatively high ($c = 0.54$). Figure IV is a plot of the the grade for this selected set of panels (as percentage) and the grade in the middle term exam (also as percentage).

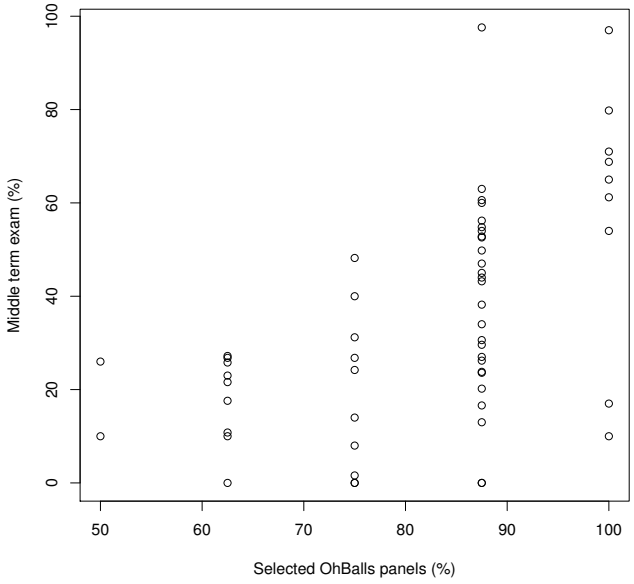

Fig. 3. Scatter Plot of selected panels and mid-term grades

Figure IV shows that the selected OhBalls panels predict the maximum grade the student will obtain, i.e. the student grade is almost always lower than the grade obtained in the selected panel of OhBalls.

The grade in the selected panels was also used in complement with other factors that are known to have influence in programming aptitude, namely math and other high school grades. The initial questionnaire collected the average grade used by Portuguese state universities to rank students applying to their programs. This average includes in equal parts the high school average grade and the national exams grades in particular subjects. In this case these subjects can be either math alone or math, physics and chemistry. A sum of equal parts of these 2 grades (selected OhBalls panels and average grade) reached a higher correlation (c=.64). By comparison, the average grade alone obtained a smaller correlation (c=0.57). The scattered plot of these combined grades with the mid-term grades, with the regression line in red, is presented in Figure 4.

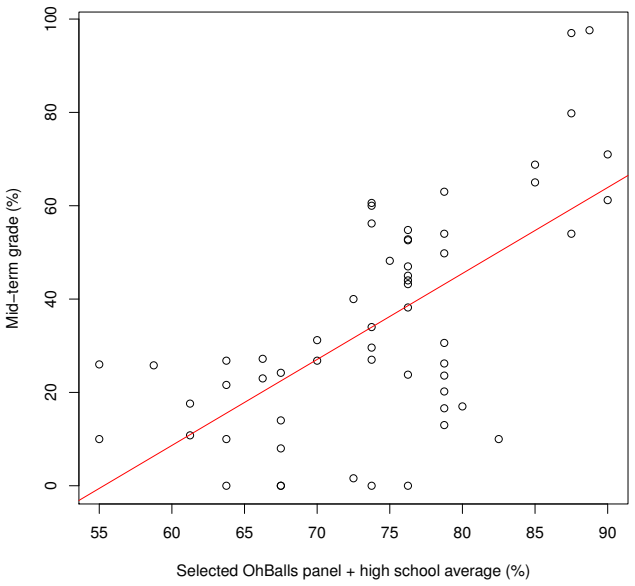

Fig. 4. Scatter plot of selected panels + average and mid-term grades

In any event, these are just preliminary results suggesting that there is room for improvement. The OhBalls panels used in this test were clearly too simple and more complex ones should be used. The capacity for the participants to understand the test seems to have been underestimated. With the current implementation of the OhBalls engine it is easy to create more complex panels. However, new types of panels where the participant must place levers in order to achieve a certain outcome (number of balls in each bucket) should also be used.

The experiment showed also that the OhBalls type of test is able to engage students. They were much more quiet and focused when they were taking the test than they were in the rest of the class. This kind of test has a game-like quality that motivates students to complete it, which is a requirement if students have to take the test on their own without supervision.

V. Conclusion and Future Work

This paper presents a novel approach to estimate programming aptitude based on the understanding of the concepts of time, state and causality. The proposed type of test is named OhBalls and does not require any prior knowledge of programming since it is based on physical simulations displayed on a a web application. The object of the simulation is the path of a sequence of balls trough an apparatus of conveyor belts and levers, until they reach a bucket, which is simple to understand by any undergraduate student. The test is self-applicable, in the sense that it does not require the presence of a person supervising its application.

An OhBalls test was applied to a cohort of computer science and software engineering undergraduate students. The initial results are promising but reveal that more work is still needed to fine tune the test. The average results are comparatively high, suggesting that larger number of panels, and more difficult panels ones, are necessary. Still, a subset of the panels from the current version has a reasonably high correlation with the student intermediary grades.

The main conclusion is that the OhBalls tests must have more panels and more difficult ones, in order to discriminate better the students with higher understanding of time, state and causality. Moreover a new class of panels will be added with a different type of challenge. Instead of simply predicting the number of balls reaching each bucket, considering the influence of the levers, the participant will have to position levers bound to the belts to achieve a certain configuration of balls in the buckets. The kind of reasoning involved will be closer to programming, since currently it can be considered closer to debugging.

In the continuation of this research the methodology of the experiments will have also to be changed. In the experiment presented in this paper only the students that took the middle term test were considered and the students that dropped out where ignored. This "negative" information will be taken in consideration when comparing with the final results.

The current results obtained with the OhBalls test used in the experiment need to be checked against not only the final course grades but also with other programming courses that these students are going to take in the following semesters. To prove the effectiveness of OhBalls test the kind of experiment presented in this paper must be repeated in computer science programs with different pedagogical approaches, in different universities and countries.

ACKNOWLEDGMENT

The author wishes to thank to the students that voluntarily participated in the test reported in this paper, as well as to the lecturer and teaching assistants of the introductory programming course where it took place. This work is in part funded by the ERDF/COMPETE Programme and by FCT within the FCOMP-01-0124-FEDER-022701 project.

***Abstract*—During the last decade there has been a shift in the way learning process is conducted. One of the main reasons is that technology is changing. Due to this fast movement, concepts like "class", "workgroup" and "learning process" are changing too. Learning processes are going beyond the boundaries of what was known as "class". Face-to-face models get mixed with online environments where students are remotely connected through the Internet. This new approach is called blended learning, and it is aimed at improving learning as well as bringing learning where it was impossible or complicated. Nevertheless, one of the main issues is that teachers need innovative tools that support these different learning models.**

As a consequence, this work is focused on the development of a tool for dealing with the main issues found in blended learning scenarios. It is divided in three phases. First, the blended learning experiences and models of the last decade are reviewed. In a second phase, a tool called Drawer, for supporting the main features of the design and use of blended learning experience is developed. In the last phase, an evaluation is made to assess the outcomes of the new tool.

I. Introduction

INFORMATION Systems are a widespread component of the current society. Computer science, multimedia technologies, telecommunications, Internet and other concepts of the "*digital age*" are essential in a wide range of fields. Information and communication technology allows the creation of tools and infrastructures for information management, data processing and communication with others, both individuals and groups. These tools can be used in almost every activity, including teaching and learning. But tools are only a part of the equation. How to use them and how to put in practice the related concepts may be firstly understood for a successful implementation of these activities. Therefore, experiences about their use are essential for the understanding of how and when to put them in practice.

In the case of education, the curricula are increasingly incorporating a combination of traditional face-to-face learning models and non-face-to-face models (mainly online through the Internet). Institutions and teachers are aware of the potential of using such approaches in the implementation of successful learning experiences. With the emergent technologies and the wide array of technological support at our disposal, there is no point in putting aside blended learning. But setting up blended learning environments is not a trivial task. There are a lot of things to take into account. All the involved stakeholders are crucial when setting up these learning experiences: teachers, students, institutions and academic staff, among others.

As a consequence, the first goal of this work, the study of the different perceptions of blended learning during the last decade, arises. In this period, technology has been leading the evolution of learning as well as teaching processes. But it is important to point out that technology is not the goal; it is only a tool to facilitate the connection between the different elements within the learning process. Pedagogical implications have to be always kept in mind.

When understanding how to use blended learning, teachers will have to choose and use the correct tools. But nowadays there is a gap between the perception of how these tools will look like and how they are built. This is why the understanding of blended learning is important in order to develop tools for helping teachers. And that is the second goal of this work: to gather the knowledge of the study of a decade of blended learning to develop a tool that combines the key elements for supporting blended learning environments. Finally, the third goal of this work is to make an evaluation to ensure that students get benefits through the use of the developed tool.

The paper is organized as follows: firstly, it is presented how blended learning has been understood and used during the last decade. Then, the lessons learned are highlighted. Next the developed tool is described. This tool follows the key elements previously found. Subsequently, a comparative evaluation of the developed tool is presented. And finally, the conclusions and the future work are presented.

II. A decade of Blended Learning

In this chapter different course experiences and models for the design of e-learning and blended learning in the last decade are reviewed. The main objective is to infer the key elements for the design of tools for supporting successful blended learning scenarios. Teachers, through this review, will know different experiences and approaches to apply in their education curricula. They also will be able to use exis-

tent tools in a different manner, by taking advantage of the depicted course models and experiences.

Valiathan in [1] categorized three different blended models. Skilldriven learning combines selfpaced learning with instructor support to develop specific knowledge and skills. Attitudedriven learning mixes various events and delivery media to develop specific behaviors. Competencydriven learning blends performance support tools with knowledge management resources and mentoring to develop workplace competencies.

Twigg presented new models for online learning improving learning and reducing costs [2]. Six characteristics were found when designing blended courses: 1) whole course redesign; 2)active learning: all of the redesign projects make the teaching-learning enterprise significantly more active and learner-centered; 3) computer-based learning resources; 4) rather than depending on class meetings, student pacing and progress are organized by the need to master specific learning objectives which are frequently in modular format; 5) on-demand help. Enhancing students feel that they are part of a learning community is critical in regard to persistence, learning, and satisfaction; 6) alternative staffing. Not all the tasks associated with a course require highly training and expertise. This work also identified five distinct approaches for course design: a) supplemental model: retains the basic structure of the traditional course, particularly the number of class meetings; b) replacement model: the key characteristic of the replacement model is a reduction in class-meeting time, substituting it with online, interactive learning activities for students; c) emporium model: the redesign model allows students to choose when to access course materials, eliminates all class meetings and replaces them with a learning resource center featuring online materials; d) fully online model: the instructor must be responsible for all interactions; e) buffet model: information technology in teaching and learning means that it can radically increase the array of learning possibilities presented to each individual student.

Aspden [3] asserted how a blended learning approach alters the dimensions of the relationships between the students and the other aspects of their learning experience. The findings reported indicate that the blend itself makes effective engagement in a range of possible situations, allowing students to fulfill their different activities together with more flexibility according to their particular circumstances.

Heinze [4] concluded that face-to-face, blended learning and e-learning are difficult to understand separately, mainly because there are overlaps between then, as depicted in Figure 1. So, the different learning strategies are represented in two axes: use of technology and time spent on online learning. Blended learning is located between face-to-face and online modalities.

Graham [5] described trends and future directions for blended learning systems. In Figure 2 it is depicted the progressive convergence of traditional face-to-face and distributed environments, by allowing the development of blended learning systems. Graham found six major issues relevant to designing blended learning systems: 1) the role of live interaction; 2) the role of learner choice and self-regulation; 3) models for support and training; 4) finding balance between innovation and production; 5) cultural adaptation; 6) dealing with the digital divide.

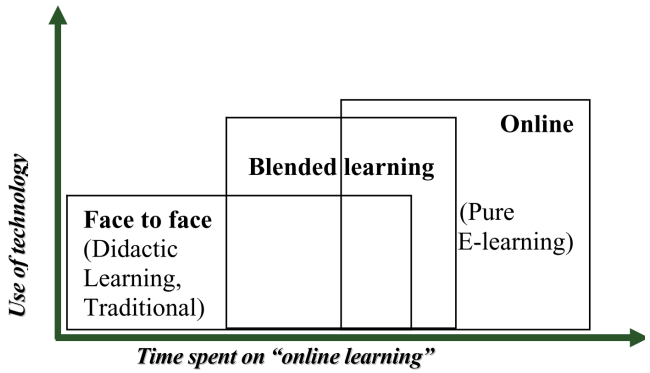

Fig. 1 Learning approaches

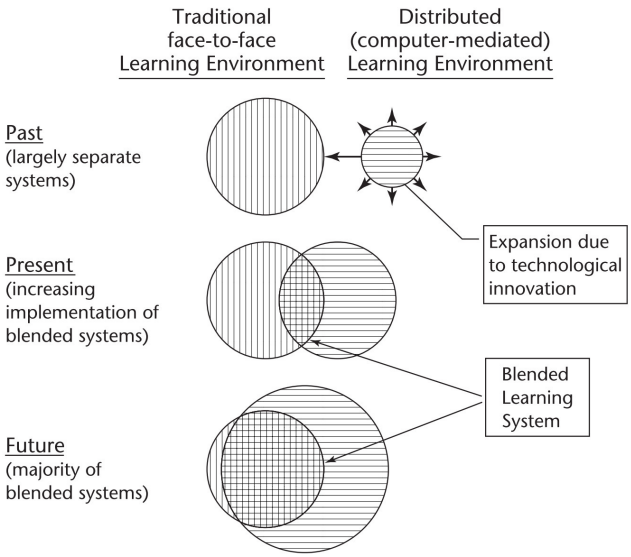

Fig. 2 Progressive convergence in blended learning systems

For Kulvietiene [6] the integration of a virtual classroom into learning managing systems has many advantages: a) opportunity is presented for provided blended learning; b) learning activities including both virtual classroom sessions and learning in a virtual classroom can be managed from a single location; c) information about learning activities is stored in a single location.

Draffan [7] identified the challenges for blended learning from two perspectives: the learner and the teacher. From the learners point of view, the main challenges are: skills, e-skills, preferences, content interaction and design, learning interactions and assistive technologies. From the teachers perspective, the main challenges are: the issue of context, learning design and to facilitate inclusive learning. It is needed to ensure that the students can interact successfully with the technologies, among themselves (through reflection), with their peers, with their teachers, with the support workers and with the learning materials.

Kim [8] presented a survey that found blended learning gained popularity in many organizations but also that several barriers exist in implementing it.

Wang [9] used asynchronous tools for online collaboration and offline interaction between students in blended learning. The offline atmosphere in carrying out the asynchronous computer media communication activities were sorted into five major categories: struggling with platform operations, handling technical problems, passive attitudes towards the procedure, tense atmosphere in class, and engagement in tasks. Blended learning does not automatically help students in their adoption of active learning strategies. The roles should be recognized to promote effective and efficient online/offline interaction.

Dziuban [10] reached a reasonable conclusion: students react generally to the course, the content, the instructor, the learning climate, and themselves. One remarkable and well-known conclusion is that the boundaries of what has been called the "class" are disappearing.

For Khan [11] assessment was, without any doubt, one of the major tools in the teaching and learning process. Assessment is considered an effective tool in determining student's knowledge gain in any particular course they enrolled. Traditional learning is more class oriented and less flexible in terms of class schedule, use of latest technology and learning methodology, while blended Learning is flexible and supports both classroom and online teaching.

Fleck [12] depicted the opportunities and challenges in blended learning communities. They presented the case of The Open University and its explicit social mission to provide educational access to those who were otherwise denied the opportunity for learning. To provide it, different models for blended learning arise throughout the time: a) correspondence and broadcast models: printed course materials sent by surface mail in a correspondence course style; b) purpose-designed quality distance education model: systematic consideration of pedagogic principles, professional editing, and explicit design for effective delivery over a variety of media; c) practice-based model: between learning materials and students; between tutors and students; between student peers; and above all between students and their work colleagues; d) learning community model: thanks largely to the web and readily accessible search procedures, raw information and data are available very easily and increasingly at little or no cost.

In his work, Fleck describes which features the next generation of learning models would have: a) the creation of a learning community; b) emphasis on process & activities, not content and assets; c) use of a wide range of existing & specially designed assets; d) focus on student-driven learning; e) use of Web 2.0 and mobile devices to support communication; f) design of face-to-face residential schools for business networking.

Moskal [13] proposed some questions for an initial blended learning: 1) Why should the institution engage in blended learning? What are our goals and what outcomes do we expect to achieve? 2) What student benefits do we seek? 3) What courses or programs will we offer in a blended format, and why? 4) How will we engage in and support our faculty in order to make them successful? 5) How will we roll out blended learning throughout the institution? 6) What levels of investments are we prepared to make and what returns do we expect?

Graham [14] presented six cases of institutional adoption of blended learning to examine the key issues that can guide university administrators interested in this endeavor. He describes three broad categories for the adoption of blended learning: strategy, structure, and support.

In [15] Bohle proposed four factors as crucial elements for a successful bottom-up change process in blended learning environments: the macro and the micro contexts, the project leader and the project members. He also revealed that bottom-up change process leads to three important outcomes: 1) the development of blended learning programs which match the needs of faculty and learner; 2) incentives for new task forces to solve institutional bottlenecks which only the faculty could have discovered; 3) new knowledge for the institutes.

Taylor [16] identified facilitators and barriers to systemic implementation of blended learning. It was found that, as teaching and learning environments are socially dynamic, strategic institutional change would only happen if there is a shared vision and energy that touches all parts of the organization.

Owston [17] examined the relationship between student perceptions in blended learning courses and their achievement. The overall conclusion of this study is that high achievers are very satisfied with the blended format. On the other hand, lower achievers may not be able to succeed in this learning environment as well.

Taplin [18] analyzed the monetary value students place on having access, via the Internet, to recorded lectures in a blended learning context. The principal results are that the average price students are willing to pay is approximately $30 per equivalent full time student.

III. Lessons Learned

The e-learning approach takes advantage of the benefits that information technologies provide to learning environments. They bring new opportunities in learning environments. But, contrary to the general believe of most teachers, distributing knowledge elements through electronic media is not always enough to take advantage of the e-Learning capabilities. It should not be only regarded as a cheap way of distributing resources to a big number of students. For understanding what blended learning is, how it has been used and how it be implemented in an effective way, next are presented blended learning definitions during the last decade:

- A solution that combines several different delivery methods, such as collaboration software, Webbased courses and knowledge management practices [1]
- Learning which combines online and face-to-face approaches [4]
- Learning that is facilitated by the effective combination of different modes of delivery, models of teaching and

styles of learning, and founded on transparent communication among all parties involved with a course [4] [7]
- Systems that combine face-to-face instruction with computer-mediated instruction [5]
- A combination of various networked technologies in a single learning package; a synthesis of various pedagogic methods that enables to achieve an optimal quality of learning process; a combination of various lecturing technologies (video cassettes, compact discs, internet material, etc.) together with direct lecturing by an instructor [6]
- An approach of combining face-to-face instruction with computer-mediated instruction is called blended learning [9]
- Blended approach studies how to join the best feature of face-to-face and online instruction [11]
- Instructional approach that substitutes online learning for a portion of the traditional face-to-face instructional time [17]
- A combination of online learning and face-to-face approaches to teaching [18]

Other lessons learned from the previous study are the main characteristics to keep in mind when designing blended learning approaches. These characteristics have been inferred from the review done in this research. They are intended to guide teachers, but they could be also interesting from other points of view, such us for measuring the quality and for evaluating courses based on blended learning scenarios. Main lessons learned are: a) Students learn by doing, not by listening to some one talk about doing. There is a wide range of learning approaches, from face-to-face to fully on-line. b) The "right way" to design a high-quality course depends entirely on the type of students involved. c) Students need to be treated like individuals, rather than homogenous groups. d) Effective blend of face-to-face and online learning opportunities have to take into account individual students' particular needs. e) Blended learning will be characterized on how they blend instead of whether. f) To guarantee inclusive learning is fundamental for creating successful blended learning. g) The term "class" goes beyond the boundaries of the physical location. h) One of the key issues is the role of technology. But technology is not an end in it itself, pedagogy must lead.

Through the review of the blended learning models and experiences, the weaknesses and the strengths have been also gathered.

The main weaknesses found in blended learning are:
- Need of effective guidance
- Technical issues
- Lack of communications
- Unsatisfactory use of the face-to-face session time
- Implementation
- Robust and reliable infrastructure is required
- Social interdependence among the participants, the tasks assigned, and the e-learning tools remain challenging for teachers

The main strengths found in blended learning are:
- Compatibility with working life
- Flexibility
- Good student support
- Improved pedagogy
- Increased access and flexibility
- Increased cost-effectiveness
- Information from the face-to-face activities to total online interactions is stored in a single place.
- Promotion of social interaction
- Quick feedback to learners which will help them in their learning process
- It provides collaborative activities among teacher and students
- It allows access to everyone who needs training by providing it in different ways

These characteristics produced a shift in teaching and learning from simple knowledge transmission in which "content" is transferred to the devising of processes and activities that enable deep learning following the "triple A" paradigm: Anytime, Anywhere, Anyone.

This change could be described by the Table I [11], where it is characterized the shift between traditional and blended learning from the point of view of the features of learning.

TABLE I.
SHIFTS BETWEEN TRADITIONAL AND BLENDED LEARNING

Characteristics of learning	**Traditional learning**	**BlendedLearning**
Place	Mainly in classrooms (Not flexible)	Combination of classroom / home, library (flexible)
Learning Methodology	Offline	Offline as well as Online Learning
Time of learning	Fixed as per the schedule (Not flexible)	Adjustable as per personal choice (Flexible)
Use of Technology	Not must up to the instructor to choose the teaching methodology	Latest use of technology is must

Creating scenarios that allow teachers in the process of setting blended environments is still challenging and complex. As a result of the aforementioned characteristics, collaboration and social factors are key aspects when designing these environments. In the Table II, Lambropoulos [19] describes social awareness requirements and propositions.

TABLE II.
SOCIAL AWARENESS REQUIREMENTS AND PROPOSITIONS

Social awareness requirements	Propositions
Embodied self & group presentation	Emoticons, avatars, group network representation
Visibility of social presence and connectedness, locality	Individual nodes, group ties and networks, online status
Social and cognitive awareness	Enhanced discussion forums, group network representation
Depiction of the individual and group locality to indicate the spatio-temporal relationship	Group network representation
Participation measurements	Participation graphs
Lightweightness & interoperability	PHP and JAVA programming languages
Simple to interpret and easy to use	User-centered design

IV. DRAWER

Drawer is a web application for helping teachers to design assessments. The main characteristics are the support for collaborative tasks, the sharing of information and the management of social interactions between users. Drawer has the advantage that all these functionalities are integrated in the same environment, making it easy to use. They are easily accessible, being easy to create learning experiences.

The application was made bearing in mind the findings made in the previous phases of the project. So, the key elements for developing successful blended learning experiences arise. To support them, the application manages the following elements: a) users and their relationships: user profiles, creation of groups, personalized shared workspaces; b) synchronous and asynchronous communication; c) information is stored in a single place: files, logs, conversations and other information.

The management of users and their relationships is made by the application. Drawer includes mechanisms for controlling the authentication and access to the application. Only registered users are allowed in the system. The main screen of the application is depicted in Figure 3. There, users are allowed to log in the system or to create a new account.

Once the user is logged in the system, the main screen for logged users is presented (Figure 4). There, there are two main areas. The main menu, that is located at the top of the screen, and the rest of the interface. The main menu has the following sections: start, alerts, mailbox, user information and search.

Fig. 3 Main screen of Drawer

The *"start"* section corresponds to the screen depicted in Figure 4. There, users view the available drawers. Drawers are stacked by categories for better organization or for grouping users. Users are allowed to create new drawers or stacks, simply by clicking the "plus" symbol located in the right side.

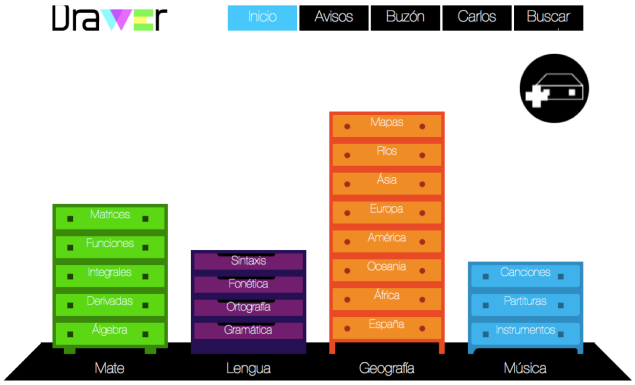

Fig. 4 Main screen for a logged user

One of the main characteristics of Drawer is the way it shares information among users. It follows the paradigm set in Drag&Share [20] allowing users to drag documents from his local devices to the shared workspace. As depicted in Figure 5, when users enter in a drawer, the shared workspace for that drawer is presented. There are allocated the resources and other users, as well as the synchronous communication means. All this in a single view, making it easy to follow others work and work in the tasks. Users are represented by their names over the shared workspace, showing their movements in real time. Each user has a representative color in the system for the chat and his cursor (the name over the shared workspace). Resources are represented in the shared workspace by the name and a representative icon. In the shared workspace, other users can be invited to perform collaborative tasks.

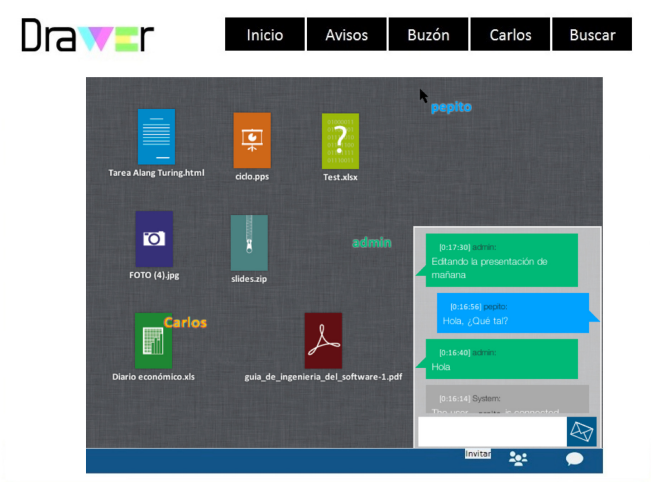

Fig. 5 Shared workspace

Users can perform actions over the resources by making right click or a double touch over them. These actions are depicted in the Figure 6. They can create new documents with the included rich text editor. The text editor allows the creation of documents with enriched text. Also images, videos and any multimedia resources can be inserted within these documents. The next option is to download documents from the shared workspace to the local device. The edit option allows users to edit existent documents in the shared workspace. The preview option shows the selected document. To delete documents, users only have to select the delete option. Finally, users can hide documents selecting the corresponding option, preventing other users to view the document in the shared workspace.

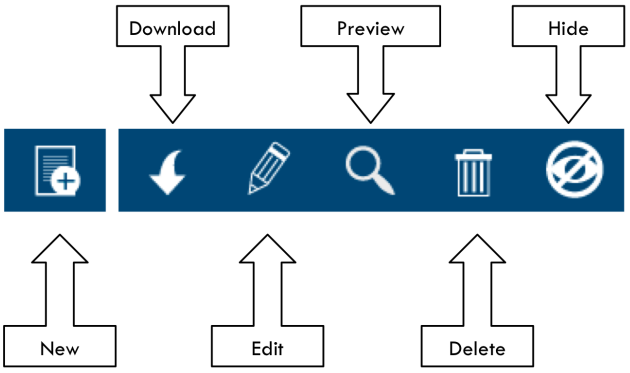

Fig. 6 Options in the shared workspace

The *"alerts"* section gives users information about the events produced in the system. There, they can see new friend requests, pending messages and request for resource sharing. The *"mailbox"* section, as depicted in Figure 7, allows the asynchronous communication between users. In this section, the active conversation between users or groups could be found. The section *"user"* contains personal information about the logged user. Also the information about the resources and interactions the user has made with the system is represented.

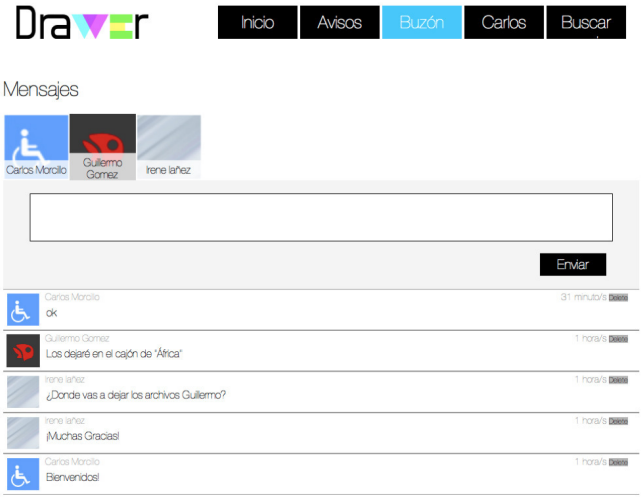

Fig. 7 Mailbox section

The section *"search"*, as depicted in Figure 8, allows searching for other users. This section is designed for viewing other users and to send them a friend request. This request may be accepted or rejected. Friends in Drawer are allowed to easily share information, send messages and perform collaborative tasks.

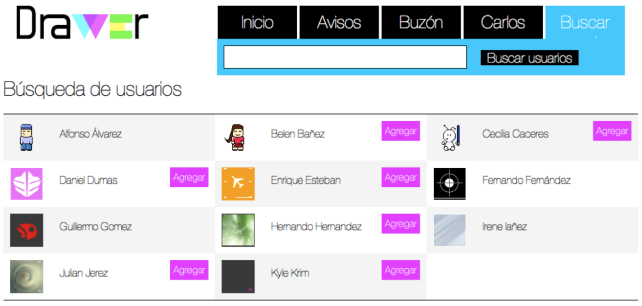

Fig. 8 Search users option and friendship management

V. Evaluation

Through this evaluation, we want to assess the impact in a blended learning activity when using Drawer. An activity is done by using the means provided by Moodle by default and using Drawer. The aspects to be assessed are how the proposal affects the productivity in the task, that is, how much time users expend to complete it, and how usability of the system is affected. Therefore, the evaluation is focused on the level of productivity and the user's satisfaction while using the system. Tasks time has been used to measure productivity and satisfaction has been measured using a questionnaire based on SUS (System Usability Scale) test [21]. Time, as productivity measure, has been selected because it provides a good insight on the impact when performing tasks using different systems. The SUS test has been chosen because it has proved to be a valuable evaluation tool, being robust and reliable.

The group of selected students to perform the evaluation has the following features. Seven students make up the

group. Four students are males and the other three are females. The participants are nearly 25 years old on average. The oldest and the youngest user are 28 and 22 years old, respectively.

To perform the evaluation it is selected a learning scenario where the teacher sends an assessment to a group of students in a blended learning scenario. Some of the students are in the same physical room, but other students aren't. They have to perform the task collaboratively. Students have a device for accessing the web application. The activity consists in an assessment where the students have to make a summary of a document provided by the teacher. Each student is responsible of making a part of the summary. They have to choose a leader responsible of joining the individual summaries. As a result, they will get the final summary. The task is divided into the following five subtasks: 1) the text is distributed, selecting the parts to be done by each student. At this time, the leader is selected among the students; 2) partial summaries are made and send to the leader; 3) the leader gathers the partial summaries into the final summary. It is send to all the members of the group; 4) the group reviews the final summary and decides if it is ended; 5) the leader sends the teacher the final summary.

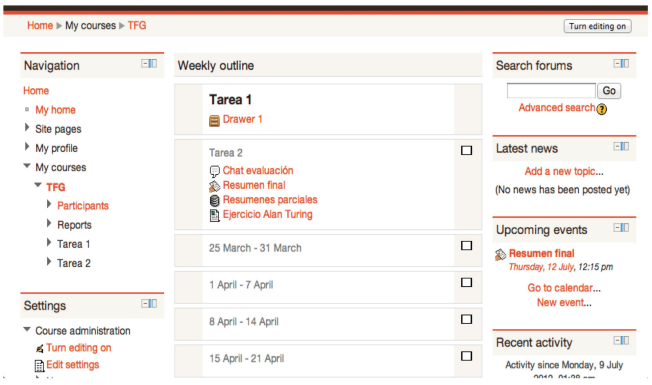

Fig. 9 Moodle setup to perform the task

The teacher is in charge of setting up the scenario for performing the activity. In Figure 9 it is depicted the scenario for performing the activity in Moodle. The scenario in Moodle is composed by the chat, a database for sharing partial summaries, and one link to upload the final summary. The scenario in Drawer is depicted in Figure 10. At a glance, this is simpler for users than the one used in Moodle.

The productivity of the system is analyzed based on the time spent to perform the collaborative task. This time is divided into the five tasks described above. The average time is shown in Figure 11 for the test developed in Moodle with default activities, and in the Figure 12 for the test developed in Drawer. The average time decreased drastically in four of the five measured tasks when Drawer was used.

Regarding student's satisfaction, the SUS satisfaction questionnaire has been used. In this test, users have to express their agreement with 10 sentences after performing the task. For each sentence, a score between 1 and 5 is given, meaning 1 strongly disagreement and 5 strongly agreement. Then, based on these values, the SUS satisfaction questionnaire final value is calculated. This value can be between 0 and 100. A final value near 100 indicates a complete satisfaction. In the performed test, the final value in Moodle with default activities was 33.10, which indicates that students were not satisfied with the system. The final value in Drawer was 84.2, which confirms that users were very satisfied when using it.

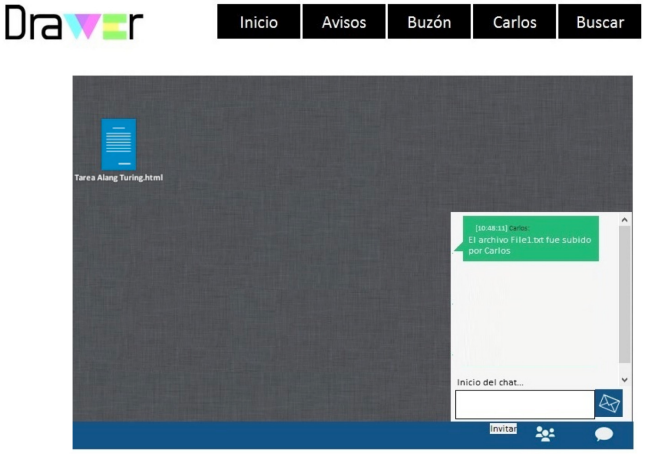

Fig. 10 Drawer setup to perform the task

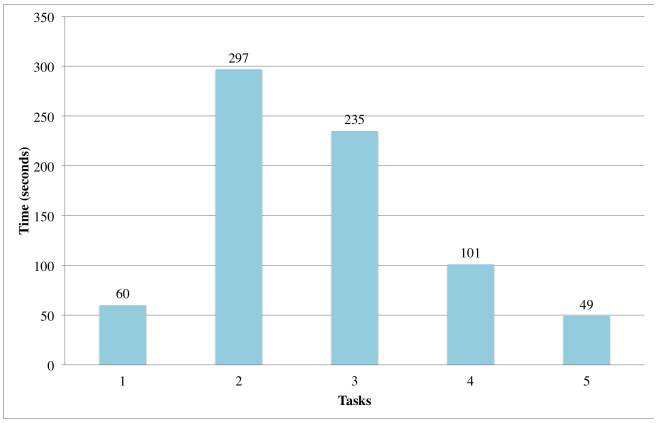

Fig. 11 Average times on each task with Moodle

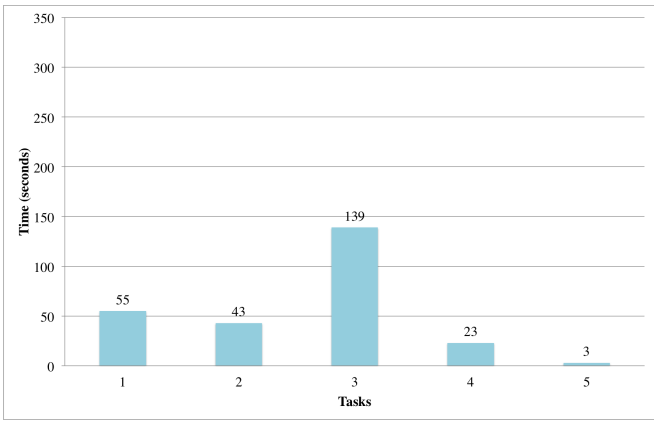

Fig. 12 Average times on each task with Drawer

At the end of the test, users were invited to write their personal impressions about the tools. Next, some of the comments made when using Moodle in the evaluation are included:

- "I don't know where I have to upload the file"
- "When I manage to upload the file, I don't know if I did it well. I have to search on the list where all the files were shown to see if mine were there"
- "It is tedious, you have to download the final file, search for it and then open it"
- "Because the chat was opened in other window, there was a moment when other users sent messages to me but I didn't realized it"
- "Workgroup was complicated"

In the other hand, comments made when using Drawer in the evaluation were:

- "This tool is very useful for workgroup"
- "Intuitive and easy to use"
- "You can open and edit files within the application"
- "You are always aware of what is going on"

VI. Conclusion

Teachers need innovative tools for supporting new learning experiences. There are many issues to bear in mind when designing applications for supporting the curricula. So, this work is intended to present the main characteristics of blended learning approaches as well as the weaknesses and strengths found in a review of blended learning experiences and models of the last decade. A new web application has been designed and implemented taking into account the lessons learned.

Through the review the main characteristics that blended learning systems shared during the last decade have been recollected. We can summarize that blended learning is a wide area between a face-to-face and a fully on-line environment where students need to be treated as individuals and each institution has to understand the right model for delivering blended learning. Moreover, the fact that learning is more productive when doing than when listening how to do is taken into account. Finally, it is important to understand that technology is important, but pedagogy must lead.

With Drawer we make a contribution for dealing with the weaknesses present in most of the studied blended learning experiences: need of effective guidance, lack of communications, unsatisfactory use of the face-to-face session time and social interactions. The evaluation shows that Drawer improves the selected activity performed in blended learning scenarios compared to Moodle. The productivity and the usability have been taken as indicator for measuring the outcomes in one of the main tool in learning scenarios: assessments. Both indicators reflect a drastic improvement when using Drawer instead of Moodle.

As a future work, we want to introduce Drawer within the curricula of educational centers in order to receive feedback for the improvement of blended learning support.

***Abstract*—E-learning is a contemporary teaching tool that has become popular and widely used in engineering education in recent years. This article presents the outcomes of a study on considering students` different learning styles in teaching information and communication technology using e-learning. Students were divided into two study groups. The reference group studied according to a provided learning model which including both theoretical educational material and practical assignments. Students of the test group were divided according to their learning styles using the Felder-Silverman model. Different relevant learning models, which included the same theoretical material and practical assignments, were designed for students of the test group based on the learning styles. The results of the study proved that the learning materials which were designed taking into account students` different learning styles considerably improved the achievement of the learning outcomes. A detailed description and analysis of the study is presented in the article.**

I. Introduction

ENGINEERING education is a large system and it is almost impossible to predict its behaviour over far too distant future since the system parameters show a high rate of change. All knowledge is changing so fast that we cannot give students what they will need to know tomorrow. Instead, we should be helping them develop their learning skills so that they will be able to learn whatever they need to. If we can achieve that, we will have world-class engineers, people who are innovative and resourceful.

Learning styles are characteristic cognitive, affective, and psychological behaviours that serve as relatively stable indicators of how learners perceive, interact with, and respond to the learning environment. Students learn best when instruction and learning context match their learning style.

Understanding students' different learning styles is one of the midpoints of effective education. The aim of the research described in the article was to abolish mismatches between students' common learning styles and teaching styles in e-learning and make teaching in engineering more effective.

According to Felder and Brent [1], students learn in many ways – by seeing and hearing; reflecting and acting; reasoning logically and intuitively; memorising and visualising; drawing analogies and building mathematical models.

Classroom activities of teachers and students take place in mutual communication. Therefore, the guidance and the formative role of the teacher should be realized in the creation and review of theoretical material and the material in practical classes. However, most of the learning processes are individual learning activities and here self-regulation of the student is realised. The task of the teacher in this case is to provide students with a supportive learning environment: motivate, guide and support. It should be noted that learning should be based on individual personality traits. This ensures successful acquisition of knowledge.

II. Methodology

Since 2010, we have applied a flexible, adaptive approach to teaching computer science in Tallinn University of Technology. The main idea of this method was students division into groups according to their prior subject knowledge. The tasks were also of different level and it has given visible results – the level of knowledge has increased [6]. In teaching we have been focused our attention on activating an individual student's learning.

Students learn in different ways: some like to listen to and talk, while the others prefer to read texts or study by investigating the charts, diagrams and drawings. Any learning style can give good results if it is timely identified and a right approach is chosen and applied.

Teaching must transfer knowledge and support learning, but it must also be cooperative and directed toward students' reflection and development. Helping students in finding and forming their own style of learning – should customize the learning process aimed at creating the conditions for each student for the maximum development of his/her abilities, aptitudes, satisfaction of cognitive needs and interests.

Since the beginning of the fall semester 2012, we have conducted experiments in which we have tried to identify the most suitable learning activities for students, based on an individual test on learning styles. 300 students of economics, social and technical disciplines have been involved in the experiment. In the e-environment Moodle (https://moodle.e-ope.ee/) students were divided into two equal groups of 150 participants: a reference group and a test group.

978-83-60810-53-8/$25.00

Students of both groups were taught the informatics courses depending on their prior knowledge: a test was carried out dividing them into beginners, advanced, and experts users. For beginners – the test result was 0% – 60%; for advanced – the test result was 61% – 80%, for experts – it was 81% – 100%. The test contained a different number of computer science related tasks with different difficulty levels.

The system and its effectiveness have been described in the article about a flexible approach to learning [6].

In addition, for the students of the test group all course materials and the whole learning process was designed to match their learning style preferences identified in the test [7].

Felder divides students based on their perception of the material and work with it into the following groups [2]:

active (ACT) and reflective (REF)
sensing (SEN) and intuitive (INT)
visual (VIS) and verbal (VRB)
sequential (SEQ) and global (GLO)

Active learners acquire new knowledge best by doing, discussing and explaining it to others in a group. At the same time reflective learners first think about it alone.

Sensing learners like learning facts and solving problems by well-known methods. Intuitive learners prefer discovering new possibilities and relationships and they are more innovative.

Visual learners remember pictures, diagrams, charts and video best. Verbal learners prefer written and spoken explanations.

Sequential learners like step by step studying, where each step follows logically from the previous one. Global learners prefer to get information by large portions and randomly.

The preferences of students, based on tests carried out among the students of the test group, are shown in Table I. The total for each student is 400% as each student could account for four different forms of information acquisition.

Data from Table I is shown in the following diagrams.

Tests carried out have shown that the majority of students do not have any preferences in the selection of learning materials and that they use a combination of different learning styles– they are well balanced (Fig. 1).

Figure 2 shows the types of students who acquire material better if their learning style has been taken into account. So, this group of students learns better if they are given possibilities to participate in group work, discuss, solve real tasks based on facts, etc.

However, some students have very strong preferences in learning. As presented in Figure 3, according to the tests active learners, sensing learners and visual learners fall into this group [4].

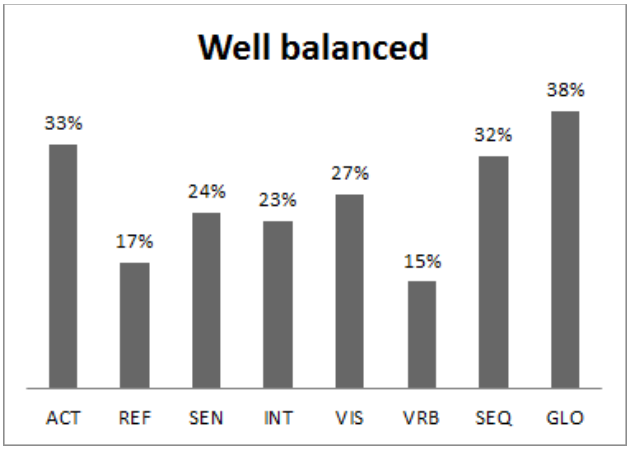

Fig. 1. Well balanced students

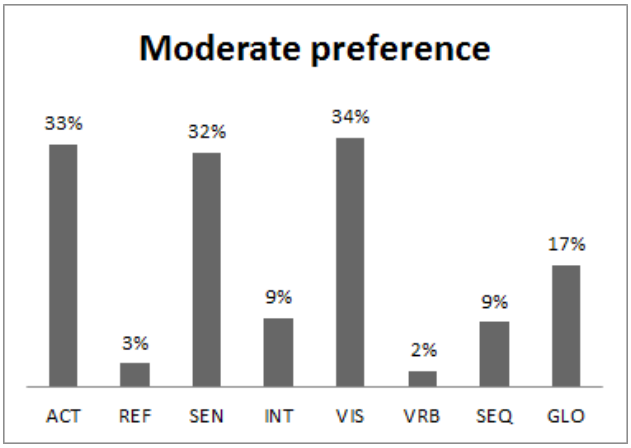

Fig. 2. Moderate preference

This way it was possible to find out the main preferences of students in the test group.

Based on the recommendations for the selection of educational material [3], [2], we designed and offered students assignments and theoretical materials according to their learning styles in the Moodle e-environment.

For example, to active learners we proposed group work assignments, to sensing learners – exercises, which were connected with solving real problems, and to visual learners – visual representation of course material, the same principles as have been used in the Khan Academy [5].

TABLE I.
THE PREFERENCES OF STUDENTS, OF THE TEST GROUP

	ACT	REF	SEN	INT	VIS	VRB
Well balanced	33%	17%	24%	23%	27%	15%
Moderate preference	33%	3%	32%	9%	34%	2%
Strong preference	13%	1%	10%	2%	22%	0%

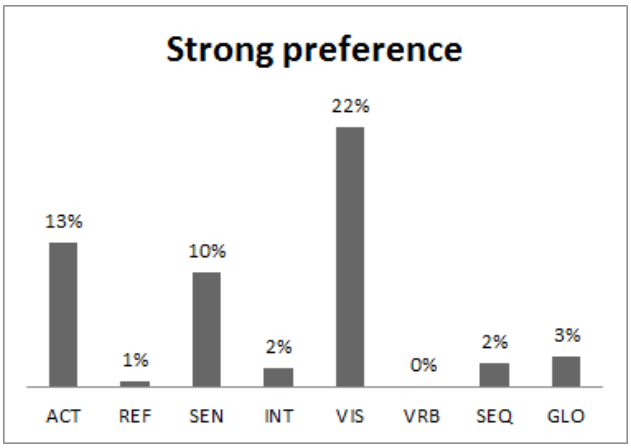

Fig. 3. Strong preference

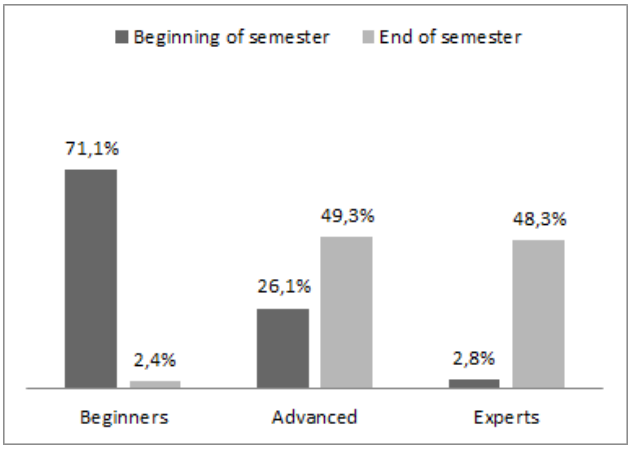

Fig. 4. Division of students into groups by test results in the reference group

All things considered, we managed to make the learning process more flexible by using e-environment opportunities: the students themselves chose the learning tempo, types of educational materials, and direction of individual and group work.

III. Results of the Experiment

The first results of our work showed a positive trend in the acquisition of knowledge. To divide students into groups by prior knowledge all of them were tested at the beginning of fall semester 2012. The same test was held at the end of fall semester. The test results confirm that students of the test group had mastered the learning material better than the students of the reference group (Fig 4 and 5).

Students of the test group coped better with their final exam due to the adopted learning material. Growth of knowledge has had a positive effect on their academic achievement (Fig 6).

Students' feedback in the test group also indicated that the material selected according to their learning styles motivated and helped them to learn.

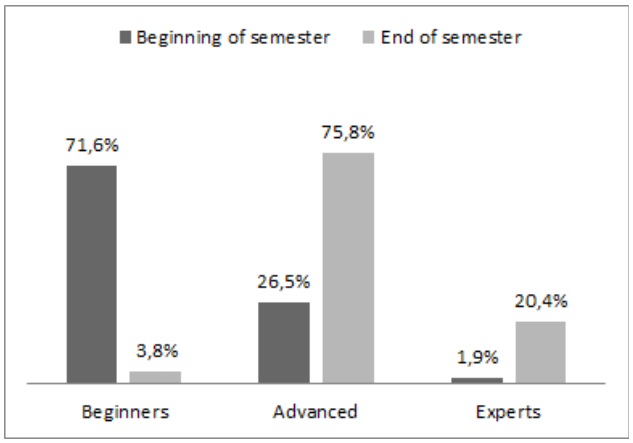

Fig. 5. Division of students into groups by test results in the test group

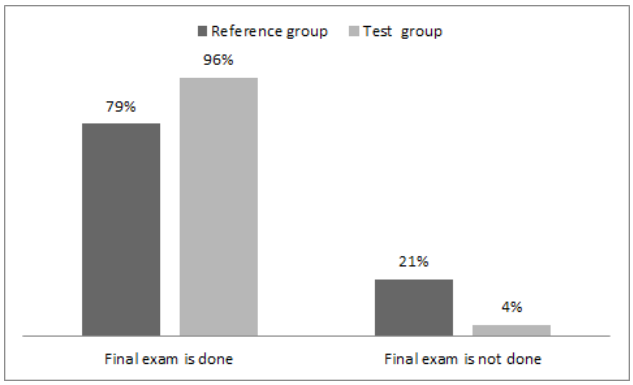

Fig. 6. Academic achievements. End of fall semester 2012

IV. Conclusions and Further Development

Students have different levels of motivation, different attitudes about teaching and learning, and different responses to specific classroom environments and e-learning. The more thoroughly teachers understand the differences, the better chance they have of meeting the diverse learning needs of all of their students. Teachers should attempt to improve the quality and efficiency of their teaching, which in turn requires understanding of the learning styles of students and designing instruction to meet these preferences.

Our selected flexible adaptive learning approach improved the quality of educational material and enhanced the educational effect of the use of innovative methods. The approach also provided us with additional opportunities to build individual educational paths for students, and in addition, apply the approach on students with different levels of readiness to learn.

Thus, we gave students the opportunity to choose their own way of learning the course. Students themselves felt the need for further studies, and did not feel the pressure from the teacher. They had the opportunity to work with educational materials in the manner and volume that was appropriate for them directly.

In conclusion, we would like to emphasize again that the content of the material adapted for each learning style should also cater for individualization of learning. It is important to remember that any learning style works well with the right approach.

Our chosen direction is a deeper study and analysis of students' data which could give us a better overview of why and how students learn. Additionally, there is the need for the curricula adaptation and teaching materials composition in accordance.

amadbouly@kau.edu.sa

***Abstract*–This paper presents a developed higher education quality assessment model (HEQAM) at King Abdulaziz University (KAU). This is because of; there is no universal unified quality standard model that can be used to assess the quality criteria of higher education. Besides, there are shortcomings in the coverage of some current educational quality standards. A Developed questionnaire to examine the quality criteria at KAU is investigated. The analytically hierarchy process is used to identify the priority and weights of the criteria and their alternatives. The model is constructed of three levels including eight main objectives and 53 alternatives. It included e-services criteria which is one of the recent university components, in addition to new sub-criteria for enhancing the model. It produces important recommendations to KAU higher authorities for achieving demanded quality services. Also, it helps KAU to achieve one of its strategic objectives to be a paperless virtual university.**

I. Introduction

UNIVERSITIES all over the world face big challenges to meet the growing number of students, supporting life-long learning for larger and larger parts of the population and of dealing with growing student heterogeneity. Beside these challenges universities are required to provide and maintain a high education quality learning environment based on a standard High Education Quality Criteria (HEQC).The high education service quality has gained tremendous attention from managers and academics due to its importance on business performance, cost reduction, and student satisfaction [1-4]. So, most of the universities are struggling to enhance the professional experience and skills of their personnel in order to utilize the new technologies in their teaching activities in an efficient way [5]. This is to gain a competitive advantage among other universities. Therefore, Saudi universities seek to examine their strategic positions by evaluating existing quality services, and adapting to students' perceptions to enhance their leadership position. On the other hand, higher education plays a significant role in advancing society toward sustainable development [6].

Having an acceptable level of quality services have to be the main concerns of any higher education university system, for guiding the country toward sustainable development. The kingdom of Saudi Arabia (KSA) government spends a lot of efforts to achieve a highly recognized education level by maintaining and improving the HEQC for all universities in the kingdom. Also, KAU has taken significant steps towards the improvement of education quality to facilitate the academic and managerial process, and to support policy making within the university. Due to the rapidly growing concerns about higher education quality in both international and local contexts, this paper proposes a developed model for evaluating higher education quality standards, and applying it at KAU as a case study. The next sections of this paper explain the related work, model construction, model evaluation, model results and discussion, then the conclusion and references.

II. Importance of the Study

Quality assessment of higher education institutions can contribute to the process of standardization of academic degrees. In fact, because of the changing landscape and increased call for accountability, higher education is now being challenged to re-conceptualize methods and processes used to indicate quality and excellence, including those used for assessing and evaluating quality of education programs. The quality of higher education services, especially in developing countries must be viewed as a strategic issue for social and technological development and economic growth [7]. Another issue that shows the importance of evaluating the quality of higher education programs and the need to have HEQC, is the fact that the world has become an open space were people circulates freely throughout all countries; this circumstance requires the establishment of quality standards so that a qualification obtained in the different institutions can be accepted all over the world, simply we can say that applying these HEQC will lead to and help in achieving the goal of accreditation of KAU education programs. Also, this is a major requirement to enhance the academic rank of Saudi universities among other worldwide universities.

III. Literature Review

Nowadays, service quality assessment is an issue that cannot be neglected by any university, even in the higher education in developing countries. In order to tackle this problem, it is necessary to invest in quality systems and tools for improvement. Universities are usually driven to engage in reforms by a variety of forces, which mostly come from globalization, supply and demand issues, competition, accountability, and technology. Their survival and development are determined by improving service quality those satisfying students' needs, since it is a vital significance to higher education services. Earlier researchers studied higher education quality services emphasized academic issues more than managerial issues [8,9], concentrated on effective course delivery

mechanisms and the quality of courses and teaching. Table 1 shows a brief of recent quality models that are used to evaluate higher education in some well-known universities. In this paper, a new service quality assessment model will be explained in section (4).

TABLE 1
HIGHER EDUCATION SERVICE QUALITY MODELS.

This paper	2013	King Abdulaziz University, Jeddah, S.A.	A developer model for assessment of higher education quality Standards, case study KAU.

The assessment of the quality of human resources, physical, technological, financial and information resources at KAU could be appropriate, sufficient and accessible to realize its mission. Also KAU works effectively to plan, provide, evaluate, assure, and improve the academic quality and integrity of its academic programs, curricula, credits and degrees awarded. However, identifying all HEQC within KAU is an important issue. In this paper, a new effective quality model for evaluating HEQC at KAU is presented. To achieve the research objectives, a questionnaire that is used to examine the HEQC at KAU was developed. In addition to that, the e-services criteria are added to the quality model. There is no doubt that e-Services are one of the most recent required components for KAU. They will help in achieving the virtual university strategic goals, among which are the distance learning education. In addition, they are required to implement a successful paperless university [16-19]. They include: interactivity, mobility, flexibility, accessibility, portability, and social process. It is also aimed to achieve, highly demanded HEQC model that helps KAU to become a model to be followed as a paperless university, as well as achieving one of the KAU strategic objectives to be a virtual university.

IV. PROPOSED HIGHER EDUCATION QUALITY ASSESMENT MODEL

Fig.1 shows the proposed higher education quality model. It is based on the development of the model explained in [9]. This proposed model is constructed of three hierarchy levels, including eight main objectives (criteria), and 53 sub-objectives (i.e. alternatives). The eight main objectives include the following:

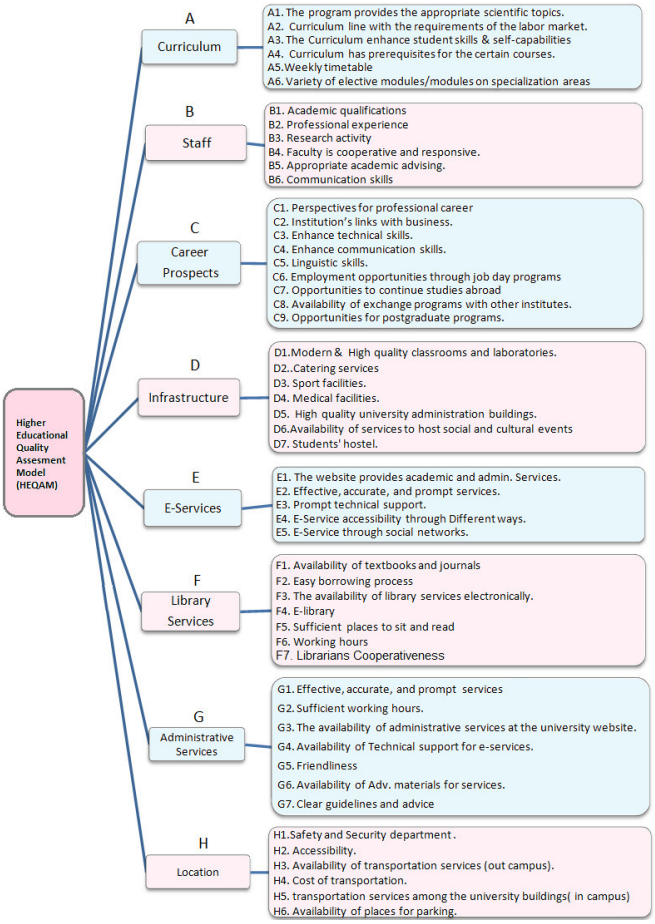

Fig.1 the Proposed HEQAM Model.

A. *Curriculum*

It is one of the main criteria that affect the higher education quality. It includes six sub-objectives (alternatives) named A1 to A6 and defined as shown in Fig.1. It plays an important rule for establishing the KAU university quality. The curriculum is an "organized program of study for a given degree, certificate award, incorporating all matters such as academic staff requirements, duration of academic program, admission requirements, content requirements and assessment process requirements" [20]. Also, all university curricula have to include [21]: enrolment requirements, objectives, scope, specific courses and content, duration, mode of assessment, standard references, and academic award. To achieve and maintain quality in curriculum development and delivery, university has to encourage academic excellence in research that enables departments to have professors, senior lecturers and several lecturers who participate in developing and reviewing curricula. The curriculum change imposed on higher education institutions through policies and strategies is required in order to develop graduations, enhance employability, widen access and improve retention. It sets out skills and employability curriculum framework for programs, including practical examples, and considers some of the challenges facing this holistic approach to a potentially fragmented area of policy development.

B. *Staff*

It includes six sub-objectives named B1 to B6 and defined as shown in Fig.1. The university that "holds essential educational facilities with affective staff of teaching and training will make students be more motivated, loyal and good performers"[22]. Good performance of teachers inside and outside the class is a significant feature for enhancing students' impartiality, motivation and satisfaction. Course instructors' teaching methodology is also a prime indicator considered by students, when they rate their teachers in their educational development and successful completion of their studies. Higher the intellectual ability of the instructor, the better will be the students' evaluation [23, 24] and consequently more will be the reliability on the teaching staff. The teachers who teach with punctuality, accuracy, reasonability and logical approach in a student friendly manner are more popular [25, 26]. Students level of satisfaction increases by working with those course instructors and lecturers who properly handle the assignments, projects, exams and facilitate students' logical reasoning and aptitude development.

C. *Career Prospects*

It includes nine sub-objectives named C1 to C9 and defined as shown in Fig.1. The quality of university education, allows students that get graduated an excellent career opportunities. Also taking into account the higher education to the needs of the labor market from diverse disciplines, provides job opportunities for graduates of eligible students.

D. *Infrastructure*

It includes seven sub-objectives named D1 to D7 and defined as shown in Fig.1. The infrastructure in higher education can include: facilities, researches, and faculties. In order to have a functional institution, all the aforementioned elements, have to be evaluated, improved and updated. University strategic planning has to include adequate infrastructure components into consideration, since good infrastructure enhances the quality of education and services provided. For examples, classrooms could be equipped with overhead projectors, internet connection, proper lighting and suitable cool system, to facilitate communications between instructors and students. In addition; for applied science; up-to-date laboratories and language labs are needed for experiments and projects of the fields, such facilities can increase learning quality and enhance the sense of research among students and faculty in the fields pursued.

It is necessary to have a healthy students and faculty body, by providing proper playgrounds, swimming pools and gym equipments. In addition, parking lots, which fulfill the needs of all university community, will ease the work conditions. Also, maintaining existing equipments and buying new ones are continuous tasks that require expertise and financial resources. There are needs for effective communication, cooperation, team-work among all the components inside university campus.

E. *E-Services*

It includes five sub-objectives named E1 to E5 and defined as shown in Fig.1. Using e-Services facilities, such as the integration of information and communication technologies, and internet in higher education, achieve imparting easily accessible, affordable and quality higher education leading to the uplift of Saudi Arabian universities. The benefits of e-services in education can provide, right from breaking time and distance barriers to facilitating collaboration and knowledge sharing among geographically distributed students. It increases the flexibility of delivery of education so that learners can access knowledge anytime and anywhere. It can influence the way students are taught and how they learn as now the processes are learner driven and not by teachers. This in turn would better prepare the learners for lifelong learning as well as to contribute to the industry. E-Services also play an important role for establishing the virtual university applying eLearning and also using necessary electronic resources capable for establishing the paperless university.

F. *Library Services*

It includes seven sub-objectives named F1 to F7 and defined as shown in Fig.1. The evolution of information technology has made students' needs for information services to change. This inevitably puts pressure on academic libraries, to work towards improving service quality and student satisfaction. This is necessary to face competition in global higher education industry whilst meeting the specific information needs of students. Students who constitute major users of academic libraries in universities often consider library's service quality based its ability to meet their expectations prior to enrolment. Thus, influencing their overall perceptions of the overall service quality of the institution necessitating a review of quality issues associated with services of academic libraries in universities. Adding electronic resources such as internet play important roles with research in the libraries. Journals and magazines library subscription also facilitate the students task of the faculty. Virtual libraries subscribing, also save time, money, and human resources.

G. *Administrative Services*

It includes seven sub-objectives named G1 to G7 and defined as shown in Fig.1. Administrative services managers plan, coordinate, and direct a broad range of services that allow universities to operate efficiently. A university may have several managers who oversee activities that meet the needs of multiple departments, such as mail, recordkeeping, security, building maintenance, and recycling.

The work of administrative services managers can make a difference in employees' productivity and satisfaction; for example; they might be responsible for making sure that the university has the supplies and services it needs. Administrative services managers also ensure that the university honors its contracts and follows government regulations and safety standards. Administrative services managers may examine energy consumption patterns, technology usage, and office equipment; for example; they may recommend plan for maintenance equipment or buying new ones.

H. Location

It includes six sub-objectives named H1 to H6 and defined as shown in Fig.1. University location security, safety and ease accessibility are important criteria from the student's point of view. They achieve a significant correlation between the quality of education and the distance of a college from the nearest town centre. Also, transportation services play an important role in the assessment of university location. They may include several alternatives among which are availability of transportation services in campus and out of campus, as well as cost of transportation.

V. Model Evaluation

Survey questionnaires are developed to collect information about current situation of higher education quality criteria at KAU. These questionnaires are adapted from a work explained in [9]. It is based on Servqual model aspects [8], although it does not use its defined dimensions. Two questionnaire are designed, one for students and the other for faculty members and expertise. The two questionnaires are developed, reviewed and updated with the assistance of KAU education expert consultants. Based on the results from these surveys, the main criteria for the main objectives and their related alternatives of the proposed model are identified. Then, the AHP method [27] is used as a tool for assessment of the weights of the model criteria and their priority. Table 2 shows the pairwise comparisons matrix among the main eight objectives of the higher educational quality model proposed, using the data collected from the developed questionnaires. Another additional eight pairwise comparison matrices are constructed to calculate the ranked weights for the sub-objectives, using AHP-Expert Choice [28].

VI. Results and Discussion

Based on the data collected from section (V) above, a group of eight main criteria with a total of 53 alternatives as shown in Table 2 are identified, in order to design the higher education quality model for enhancing service quality at KAU. Results in Table2 showed that the main eight criteria, including: Curriculum (A), Staff (B), Career Prospects (C), Infrastructure (D), e-Services (E), Library Services (F), Administrative Services (G), and Location (H) are ranked with 19.7%, 17.3%, 15.9%, 12.7%, 11.7%, 9.8%, 7.2% and 5.9% due to importance levels, respectively. The analyses of these criteria are explained in details next sections.

TABLE 2
PAIRWISE COMPARISON MATRIX.

	Curriculum	Staff	Career Prosp.	Infrastructure	E-Services	Lib.Services	Adm. Serv.	Location	Weights
Curriculum	1.00	1.00	1.00	2.00	2.00	2.00	3.00	3.00	19.7%
Staff	1.00	1.00	1.00	1.00	2.00	2.00	2.00	3.00	17.3%
Career Prospects	1.00	1.00	1.00	1.00	1.00	2.00	2.00	3.00	15.9%
Infrastructure	0.50	1.00	1.00	1.00	1.00	1.00	2.00	2.00	12.7%
E-Services	0.50	0.50	1.00	1.00	1.00	1.00	2.00	2.00	11.7%
Library Services	0.50	0.50	0.50	1.00	1.00	1.00	1.00	2.00	9.8%
Admin. Services	0.33	0.50	0.50	0.50	0.50	1.00	1.00	1.00	7.2%
Location	0.33	0.33	0.33	0.50	0.50	0.50	1.00	1.00	5.9%

A. Curriculum Quality

Six criteria are used to characterize the curriculum. Both faculty members and students were asked to give the importance rating these criteria. Results are shown in Fig.2; where appropriate scientific topics were the most important criteria. It can affect Curriculum with a 22.2% importance level. The second important criterion for this criterion is requirements of the labor market, with 20.1% importance level. Enhances student skills & self-capabilities is the third important criterion that can affect Curriculum in the model with 16.3% importance level. Prerequisites come in the fourth rank with 15.1% importance level. Weekly timetable and Elective modules have 13.4, and 12.8% importance level, respectively. Details of these ratings in relation to the model design are shown in column (A) in the Fig.2.

B. Staff Quality

Students and faculty member's questionnaire surveys reported that Staff within the university plays an important role in affecting the education quality. They have reported that Academic qualifications and Professional experience is the top of most importance level of this criterion. The applied AHP is used to assess quality determinants, to measure their weights to discover those that influence students' satisfaction most. Academic qualifications and Professional experience get 20.6% and 18.6% with respect to the staff criterion, respectively.

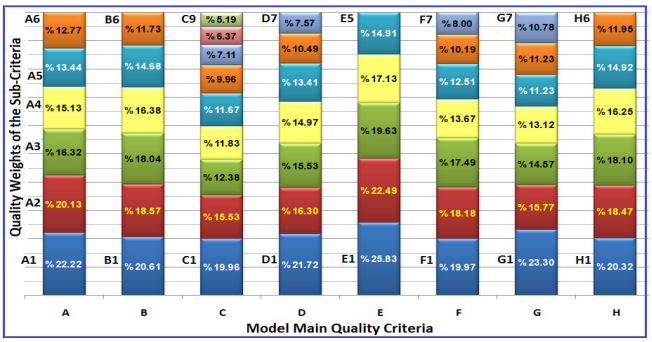

Fig. 2: Weight of alternatives to the HEQAM Model.

The third source of Staff quality criteria is the Research activity with an importance level of 18%. Cooperative, Academic advising, and Communication skills affect Staff quality criteria with 16.4%, 14.7%, and 11.7% importance level. Column (B) in the Fig.2 represents the Staff sub-criteria weights in percentage.

C. Career Prospects Quality

Another important factor that affects the higher education quality is Career Prospects. Students and faculty member's surveys reported the sub-criteria that affect this factor. Perspectives for professional career were the most frequently reported factor with an importance level of 20%. The other important factors that affect Career Prospects Quality are Institution's links with business, technical skills, communication skills, Linguistic skills, job day programs, studies abroad, exchange programs, and postgraduate programs.

Column (C) in the Fig.2 represents the Career Prospects sub-criteria weights in percentage.

D. *Infrastructure Quality*

This is one of the key criteria found and has been highlighted by both students and faculty members in the survey. Results showed that Modern & High quality classrooms and laboratories have 21.7% importance level with respect to Infrastructure Quality. The other related important level weights of the Infrastructure Quality sub-criteria is shown in column (D) of Fig.2.

E. *e-Services Quality*

In the survey faculty members and students rated the criteria of providing Academic and Admin-website Services as the most important criterion that may affect the E-Services with a 25.8% importance level. The other related important level weights for E-Services sub-criteria is shown in column (E) of Fig.2.

F. *Library Services Quality*

Results show that, the criteria of Availability of textbooks and journals were the most important criterion that may affect the Library Services Quality with 20% importance level. The other related important level weights of for these Library Services Quality sub-criteria is shown in the column (F) of Fig.2.

G. *Administrative Services Quality*

Results show that, the criteria of Effective, accurate, and prompt services were the most important criterion that can affect the Administrative Services Quality with a 23.3% importance level. The other related important level weights of for these sub-criteria is shown in the Fig.2, column (G).

H. *Location Quality*

Results show that the Safety and Security is the most important criterion that may affect the Location with a 20.3% importance level. The other related important level weights of these sub-criteria are shown in Fig.2, column (H).

VII. Model Quality Weights Comparison and Recommendations

All quality of model weights related to each criterion is shown in Fig.3. Comparison between different criteria's weights related to the criteria with the overall ranking for criteria's weights related to the HEQAM Model is shown in Table 3. The column of the total quality criteria (TQC) is computed by multiplying of weights related to criterion by the weight of the quality of the sub-criteria. For example, 19.7 X 22.2 = 4.4, 19.7 X 20.1 = 4, and 19.7 X 16.3 = 3.2, etc, hence the column of the TQC is computed as shown in Table 3. This table indicates the alternatives quality percentage alternatives quality weights arranged in ascending order. For example, the appropriate scientific topics (A1) have the first priority in the Curriculum, while the Academic qualifications (B1) have the first priority in the Staff quality. Table 4 shows the relation between the qualities of the sub-criteria alternatives and their weights related to the total quality of the model (TQM). The sub-criteria alternatives that occupied the first ten positions are:

(1) The appropriate scientific topics for a student's scientific path (A1).
(2) Curriculum line with the requirements of the labor market (A2).
(3) Academic qualifications (B1).
(4) Modern & High quality classrooms and laboratories (D1).
(5) Professional experience (B2).
(6) The Curriculum enhances student skills & self-capabilities (A3).
(7) Perspectives for professional career (C1).
(8) Curriculum has prerequisites for the certain courses (A4).
(9) The website provides academic and administrative services (E1).
(10) Research activity (B3).

These results have to be taken care of by the higher authorities at KAU. And be taken as recommendations to follow up in order to achieve high quality education.

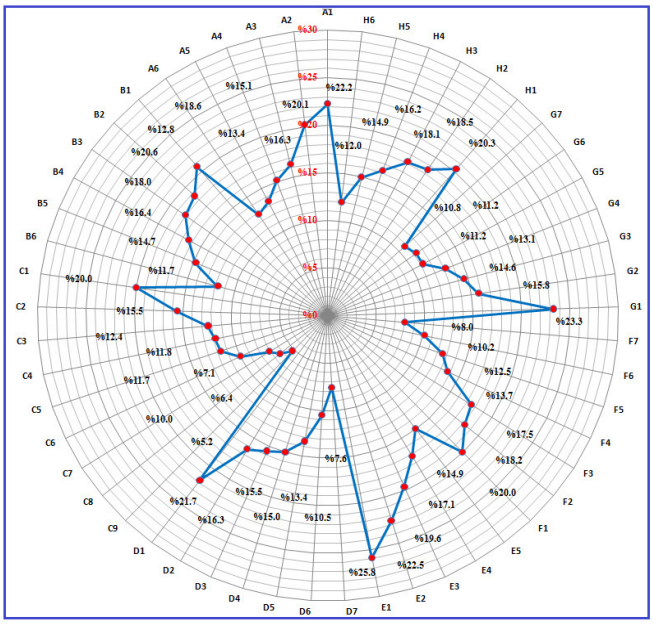

Fig.3: Ranking of all alternatives' weight to the HEQAM Model

TABLE 3
CRITERIA AND ALTERNATIVES OF HEQAM MODEL.

#	Main Quality Sub-Criteria	Alternatives	Weights related to Criterion	Weights related to TQC	Average Weights
A	Curriculum 19.7%	A1. The program provides the appropriate scientific topics	22.2%	4.4%	3.3%
		A2. Curriculum line with the requirements of the labor market.	20.1%	4.0%	
		A3. The Curriculum enhance student skills & self-capabilities	16.3%	3.2%	
		A4. Curriculum has prerequisites for the certain courses.	15.1%	3.0%	
		A5.Weekly timetable	13.4%	2.6%	
		A6. Variety of elective modules/modules on specialization areas	12.8%	2.5%	
B	Staff 17.3%	B1. Academic qualifications	20.6%	3.6%	2.9%
		B2. Professional experience	18.6%	3.2%	
		B3. Research activity	18.0%	3.1%	
		B4. Faculty is cooperative and responsive.	16.4%	2.8%	
		B5. Appropriate academic advising.	14.7%	2.5%	
		B6. Communication skills	11.7%	2.0%	
C	Career Prospects 15.9%	C1. Perspectives for professional career	20.0%	3.2%	1.8%
		C2. Institution's links with business.	15.5%	2.5%	
		C3. Enhance technical skills.	12.4%	2.0%	
		C4. Enhance communication skills.	11.8%	1.9%	
		C5. Linguistic skills.	11.7%	1.9%	
		C6. Employment opportunities through job day programs.	10.0%	1.6%	
		C7. Opportunities to continue studies abroad	7.1%	1.1%	
		C8. Availability of exchange programs with other institutes.	6.4%	1.0%	
		C9. Opportunities for postgraduate programs.	5.2%	0.8%	
D	Infrastructure 12.7%	D1.Modern & High quality classrooms and laboratories.	21.7%	2.8%	1.8%
		D2..Catering services	16.3%	2.1%	
		D3. Sport facilities.	15.5%	2.0%	
		D4. Medical facilities.	15.0%	1.9%	
		D5. High quality university administration buildings.	13.4%	1.7%	
		D6.Availability of services to host social and cultural events	10.5%	1.3%	
		D7. Students' hostel .	7.6%	1.0%	
E	E-Services 11.7%	E1. The website provides academic and admin. Services.	25.8%	3.0%	2.3%
		E2. Effective, accurate, and prompt services .	22.5%	2.6%	
		E3. Prompt technical support.	19.6%	2.3%	
		E4. E-Service accessibility through Different ways.	17.1%	2.0%	
		E5. E-Service through social networks.	14.9%	1.7%	
F	Library Services 9.8%	F1. Availability of textbooks and journals	20.0%	2.0%	1.4%
		F2. Easy borrowing process	18.2%	1.8%	
		F3. The availability of library services electronically.	17.5%	1.7%	
		F4. E-library	13.7%	1.3%	
		F5. Sufficient places to sit and read	12.5%	1.2%	
		F6. Working hours	10.2%	1.0%	
		F7. Librarian Cooperativeness	8.0%	0.8%	
G	Adminstrative Services 7.3%	G1. Effective, accurate, and prompt services	23.3%	1.7%	1.0%
		G2. Sufficient working hours.	15.8%	1.1%	
		G3. The availability of administrative services at the university website.	14.6%	1.0%	
		G4. Availability of Technical support for e-services.	13.1%	0.9%	
		G5. Friendliness	11.2%	0.8%	
		G6. Availability of Adv. materials for services.	11.2%	0.8%	
		G7. Clear guidelines and advice	10.8%	0.8%	
H	Location 5.9%	H1. Safety and Security department .	20.3%	1.2%	1.0%
		H2. Accessibility	18.5%	1.1%	
		H3. Availability of transportation services (out campus).	18.1%	1.1%	
		H4. Cost of transportation	16.2%	1.0%	
		H5. transportation services among the university buildings(in campus)	14.9%	0.9%	
		H6. Availability of places for parking.	12.0%	0.7%	

VIII. Conclusion

This paper proposed a higher education quality assessment model (HEQAM). It consists of eight sub-criteria, including 53 alternatives. The main criteria include Curriculum, Staff, Career Prospects, Infrastructure, E-Services, Library Services, Administrative Services, and Location Quality. The model is applied in KAU, for evaluating the education quality. The issue of main quality criteria and sub-criteria has been addressed to define determinates and their respective weight in the overall quality. The assessment of the university education quality from both students and expert's perspective are achieved using developed questionnaires. The work also provided recommendations on quality improvement of the institution based on its findings. The multi-criteria decision making AHP method was applied for qualitative and quantitative the model criteria. Results proved that the quality criteria that occupied the first five position included: the appropriate scientific topics for a student's scientific path (A1), Curriculum line with the requirements of the labor market (A2), Academic qualifications (B1), Modern & High quality classrooms and laboratories (D1), and Staff Professional experience (B2). The model quality weights obtained for the overall criteria have to be considered highly recommended factors to be followed for improving university education quality in the Kingdom of Saudi Arabia universities.

***Abstract*—Brief description of the author's results of development of cognitive processes (CP) computer modelling concept on the basis of improving the methodology and expanding the area of using computer-based testing technology in education is suggested. The fundamental heuristics for formalizing: the concept of degree of difficulty of test tasks (TT); the degree of confidence of individual's CP concept; the concept of stability modes of individual's CP and CP phases during the working time; the concept of the target level of the test session are presented.**

The heuristic algorithms of intellectual express and expanded analysis of the TT quality are developed. The algorithm of obtaining the cognitive individual's profile for formation and adequate interpretation of individual intellectual characteristics is offered. The concept of technical implementation of the CP computer model into the informational learning environment is formulated.

I. Introduction

BEGINNING of the XXI century represents a crucial stage in the development of education. In intellectually intense and fast-paced high-tech environment, with an excess of information, which has already exceeded the capacity of individual's perception of it, new approaches in teaching and educational technologies are necessary.

Due to the emergence of new trends in science up-to-date conceptual framework was born. Thus, the term "cognitive" (from the Latin word "cognition" – knowledge, perception), meaning "informative", "pertaining to knowledge," appeared in the sixties of the last century as a result of existence of a new paradigm in psychological research (cognitive psychology, cognitive science). In this paradigm special attention is paid to traditional cognitive processes (CP): perception, attention, memory, imagination and thinking etc. However, the cognitive approach is fundamentally different in a way that all of these processes are considered as components of the overall process of information exchange between the individuals during the learning.

Under the new conditions new learning technologies must be created – cognitive, i.e. ways, techniques, methods to ensure effective understanding by the individuals of information on the bases of unique indicators and characteristics of their CP. The task of great importance is to develop the modern methodologies of organizing individuals' learning and continuous monitoring and assessing of individuals' CP indicators, as well as of forming individual productive paths in the cognitive processes by means of introducing effective feedback systems via using the computer testing controlling methodology.

Recent scholarly research in the field of creating computer learning technologies can be divided into several categories:

Intelligent Tutoring Systems: information-reference systems; consultative type systems; intellectual training (expert-type tutoring) systems; accompanying type systems (e.g., ELM-ART-II, AST, ADI, ART-Web, ACE, KBS-Hyperbook, ILESA, DCG, SIETTE) [1].

E-Learning Management Systems elaborated the following SCORM standards, the specifications of the IMS Global Learning Consortium, and the Aviation Industry Computer-Based Training Committee (AICC) that regulate certain aspects of their development and use: the system's architecture and the system's interaction with outside systems; the ways of the learning system's interaction with learning resources; the presentation of courses' contents; the models of learning control; the testing algorithms and ways of presenting testing results (e.g., BaumanTraining, eLearning 3000, WebTutor) [2,3].

Diagnostic and Planning Expert Teaching Systems based on using the methodological tools of computer testing [4-7].

Despite the wide range of scholarly achievements and market offers in the field of computer learning technologies, all of them have a number of similar specifications:

a) The use of testing technology mostly for measuring students' learning individual achievements and the lack of methods for obtaining the specific characters of their individual intellectual activity and features of CP.

b) The necessity of development of the methods of intellectual diagnostics of test materials for increasing the quality of CP assessment.

c) The inflexible demands in most Ukrainian higher schools (HS) to the software required for their functioning and to the technical characteristics (in particular, the capacity characteristics) of computers, as well as to the speed and time of Internet resources use.

978-83-60810-53-8/$25.00

The purpose of this paper is brief description of the author's results of development of CP computer modelling concept on the basis of innovative approaches to improving the methodology and expanding the area of using the computer-based testing systems (CBTS) technology. The paper is also aimed at the presenting the key aspects of developing the use of author's modelling propositions as an instrument for receiving and adequate interpretation of the set of quantitative and qualitative identifiers of individual intellectual characteristics of individuals.

II. Cognitive Process Computer Modeling Concept

The CP computer modelling concept suggested by the author is based on implementing the following functional components: the database, the expert system of integrated diagnostics and cognitive process control (the latter comprising the logical conclusion mechanism, the working memory, the knowledge base, as well as the explanation subsystem and the dialogue subsystem), control systems, and CBTS.

A. The Database Structure

The database of the computer model is designed for storing:

– the structured learning content (LC), presented in the following systemically coordinated forms: brief textual notes of lectures for individuals' self-studying before the actual in-class teaching/learning starts Teach[1] (contain the basic notions, definitions, laws, examples, and algorithms of situational knowledge use from the course); slide-notes of the lecture materials for demonstrating and discussing directly in the in-class teaching/learning process – Teach[2]; laboratory assignments – Teach[3]; testing materials for assessing the degree of individuals' CP – Teach[4].

– reference and factual information about the syllabus, the number of individuals, the distribution of academic hours and learning units between in-class and out-of-class (independent) individuals' work;

B. Knowledge Base Structure

The core of the expert system of integrated diagnostics and cognitive process control is the knowledge base designed for storing: expert knowledge and the acquired analytically knowledge.

The foundations of expert knowledge are the author' research results in the area of computer testing methodology improvement and the development of intellectual instruments for supporting decision-making in what concerns the CP analysis. There are the following heuristics:

a) Reference time T_{ni} is the objective tool of complex quantitative formalization (scaling) of the degree of difficulty: the statement and visual representation of TT; the TT itself causes the timetable for task processing; the technology of entering the results of CP.

b) The degree of mismatching in factual and reference time for solving the TT – dynamic coefficient $D^f_{i=}t^f_i/t^n$, – demonstrates the objectivity of determined indicator of degree of difficulty of the TT – R_i.

c) The complex indicator of the degree of confidence of CP and the probability of guessing the correct solution is the correlation coefficient K_i between series of factual T_{fi} and reference time T_{ni} spent on correct result of cognitive processing of TT. The value of T_{ni} is determined after check testing of a group of experts [8].

d) The interpretation of the normalized K_i ranges may be the following: an individual with high level of the confidence solves the TT at steady pace ($K(t^*, t^f) \geq 0{,}5$); in the behavior of an individual, who has middle level of CP confidence, there are "gaps" in the problem domain's assimilation and uncoordinated pace of solving the tasks ($0{,}3 \leq K(t^*, t^f) < 0{,}5$); the individual, whose CP level is low, may try to guess the correct decision ($K(t^*, t^f) < 0{,}3$).

e) The concept of modes of stability of CP is a consequence of entering the concept of interpretation of the CBTS and individuals as a dynamic system. In this regard, the interpretation of equilibrium (EM) and periodic (PM) modes of the individual's CP may be the following [9]: EM corresponds to the situation, which is characterized by in-time constancy CP during the testing session; the PM is characterized by fluctuations in the CP individual's entropy as a result of changes in the level of complexity of TT.

f) In the author's interpretation the EM of CP is quantitatively identified by $K(t^*, t^f) \geq 0{,}5$ and PM – by $K(t^*, t^f) < 0{,}5$.

g) The concept of the CP phases is defined as a set of functional states of an individual during the test session: the primary reaction – short-term of reduction of the actual level of confidence and precision of CP; overcompensation and compensation – gradual improvement and stabilization of indicators of confidence and precision of CP; subcompensation and decompensation – reduction of actual level of confidence and accuracy of CP.

h) The concept of the informativeness level is considered on the basis of quantification of the effectiveness of test performance.

i) The concept of the target level $TL_i = f(U_j, P_j, Z_i)$ is considered on the basis of scaling the TT by: TT forms U_j (from lowest to highest: with only one correct answer; closed form of TT with multiple choice; matching TT; open form of TT with sequence-setting); boundary probability (P_j) of guessing the correct solution of TT; cognitive process difficulty levels Z_i (from lowest to highest: recognition and presentation; reproductive replay; productive replay).

j) The efficiency of CP testing is increased due to determining the consecutive order of giving TT in accordance with the decrease of their target level [10].

The Expert Block of the Knowledge Base includes the knowledge about subject area and the control knowledge:

a) The Algorithms of TT Quality Analysis:

– Heuristic Algorithm of the TT Quality Q_i Express Analysis. Presupposes the methodology of stage-by-stage guaranteed acquisition of a complete testing results' matrix from two incomplete matrices – the results of preliminary and final testing in the framework of one class period [10];

– Heuristic Algorithm of Expanded Analysis and of Improving the TT Quality Q_i. Includes possibility of establishing the fact (1) and assuming the ways of eliminating the "problematic" character of TT. This algorithm is based on entering the indicator of dynamic coefficient D^f_i in accordance with the following rule [11]:

$$\begin{aligned} &\text{if } Low_F \le Low_R \text{ and } High_F \ge High_R, \text{then } PROBLEM_v = -1 \\ &\text{if } High_F \le Low_R \text{ and } Low_F \ge High_R, \text{then } PROBLEM_v = +1 \\ &\text{else } PROBLEM_v = 0 \end{aligned} \quad ,(1)$$

where $D_{Ri} = \{Low_R, High_R\}$ is the boundary percentage of individuals, whose factual time of TT completion does not meet the reference one ($D^f_i \neq 1$).

b) The Algorithms of Adaptive Sequence of Distributing TT in order of decreasing the target level TL_i. This algorithm determines the necessity of transition λ to the next TL (2) in the conditions of surpassing the value of the boundary percentage G_{gi} of correct answers to TT as compared to the factual G_{fi} percentage. In the opposite case, this algorithm determines the necessity of terminating the testing procedure [12]:

$$\chi = \begin{cases} 0, \text{if } G^f_i < G^n_i \Rightarrow R_i = R_i - 1 \\ 1, \text{if } G^f_i \ge G^n_i \Rightarrow \text{Stop} \end{cases} \quad (2)$$

c) The Algorithm of Cognitive Individual's Profile (CP_PROFILE) obtaining:

– in the author's interpretation CP _PROFILE is a set of specific specifications describing: modes (MODES) and phase (PHAZES) stability of CP ; informativeness level (IL) of problem-oriented knowledge of individuals:

$$\text{CP\_PROFILE= <MODES> \& <PHAZES> \& <IL>} \quad (3)$$

– via using a statistical series of reference and actual time of CP of TT: processing transfer function charts for groups of individuals with a stable EM and PM of cognitive processes and individual "pictures" – structure of the time distribution (TD) during the test session and the intensity (high, middle or low frequency of correct answers) within the phase – of phases can be obtained (Table I). It helps to identify differences between individual's behaviour concerning the specificity of CP.

TABLE I.
SPECIFICATIONS OF THE INDIVIDUAL INTELLECTUAL PROFILE OF CERTIFIED INDIVIDUALS

MODES	Equilibrium mode of CP					Periodic modes of CP									
PHASES	High confidence level of CP					Middle confidence level of CP					Low confidence level of CP				
	1	2	3	4	5	1	2	3	4	5	1	2	3	4	5
TD (%)	5	87		8		20	60		20		10	70			20
Intensity	h	h	h	h	h	h	n	m	h	h	m	l	l	l	m
Explorations	Steady CP. Stable behavior within the fixed working time					Periodic state of CP. Insufficiently stable behavior within the fixed working time					Unstable state of CP. Insufficient level of knowledge				

– in accordance with algorithm of adaptive identification of the IL the formation of a quantitative assessment test perfomance (effectiveness) is carried out taking into account minimization of the impact of guessing on the objectivity of test results interpretation [8, 13] (Table II).

TABLE II.
THE ALGORITHM OF ADAPTIVE IDENTIFICATION OF IL

Levels of CP Confidence	Expert Conclusion	Algorithm of Identifying the IL
Low	Short time spent for solving difficult TT and long time spent for solving simple TT	$IL_k = \sum_{i=1}^{n} \left(S_i * \frac{t^f_i}{t^n_i} \right)$
Moderate	Only exceedingly prompt responses entail a "penalty"	$IL_k = \sum_{i=1}^{n} S_i * \frac{\sum_{i=1}^{n} t^f_i}{\sum_{i=1}^{n} t^n_i}$
Medium or High	Rational distribution of time for solving between difficult and simple TT	$IL_k = \sum_{i=1}^{n} S_i$

The Block of Knowledge Acquired by the Expert System in an analytical way comprises:

1. Knowledge about the current state of the CP: the individual's indications of CP, obtained on the bases of CP_PROFILE; the indications of learning content quality Q_k; the information about individual learning paths Din_k.
2. Actualized knowledge about the subject area – the dynamic boundaries.
3. Control knowledge which is a collection of algorithms for processing the database statistics and of control knowledge of the expert part of knowledge base that is launched by the mechanism of logical conclusion for acquiring new knowledge.

C. The Concept of Technical Implementation of the CBTS

The CBTS presupposes the implementation of a number of technological and methodological solutions. The first of them is the most effective integration into the informational learning environment of the majority of Ukrainian HS by means of using MS Office as an instrumental base for creating a unified up-to-date system of controlling the teaching/learning process.

The second one is placing the repository of the LC on a powerful (possibly distant) server in the Internet network with the aim of eliminating the limitations of technical characteristics in those computers that most HS in the country are equipped with.

The third is the use of such regimes as short-time deliveries of LC from the server; e-mailing by using wireless connections or the internal network; mobile (distant) regime

of system's work. These regimes are used for ensuring economy and efficiency of network resources [14].

D. Cognitive Model Control Algorithm

The developed methodology of CP computer modelling presupposes completion of the following principal control iteration stages [15]:

1. The Teacher, in advance of the next class, uses the control system for:

a) Formulating a request to the LC repository on the distant server as to compiling a set of learning units $Teach_z$.

b) Fine-tuning of the CBTS by indicating: the maximum number of points to be scored for every testing session (TS); the number of TL to be used in the TS; the modes of user's actions limitations: the possibilities for an individual to choose the order of TT and of returning the TT within test session.

c) Tuning the short-term connection with the Internet via a radio modem for transmitting the required LC $Teach_z$ to individuals.

2. Before coming to their class, individuals need: to get acquainted with the LC of the first form $Teach^1_z$; to take preliminary testing with using $Teach^4_z$; by means of tuning the short-term connection with the Internet – to transmit results of their testing to the control system.

3. On the basis of the Adaptive Methodology of Learning Process Individualization the following steps are implemented: multi-aspect diagnostics of the CP level with taking into account the quantitative and qualitative learners' intellectual characteristics; intellectual support of decision-making as to adaptive regulation of the structure and content of class work in accordance with the expert recommendations formulated in the knowledge base. Those recommendations allow:

a) Determining the most efficient conditions forms (group, individual autonomous, creative, calculative, research, or team learners' work) for individual cognitive processes.

b) Determining the learning elements requiring specific forms of cognitive processes (generalization, recapitulation, practical examples).

c) Automated tuning of $Teach^2_z$ or $Teach^3_z$ with recommendations as to mandatory consideration, possible consideration, or lack of necessity for consideration of qualitative results of students' acquisition of certain LC.

4. At the end of the class students have the final testing. As a result, information is collected and transmitted into the intellectual knowledge base.

III. Conclusion

Scientific novelty and practical value of the suggested CP computer modelling concepts, which allow to improve the CBTS-methodology and develop indicators of individual's intellectual activity and features of CP, are attested to and confirmed by the patents of Ukraine [8, 10-12, 14, 15]. The model has been introduced into the teaching practice of the Department of Economic Cybernetics and Mathematical Methods in Economics at Alfred Nobel University, Dnipropetrovs'k, Ukraine.

***Abstract*—EDUCache simulator [1] is developed as a learning tool for undergraduate students enrolled the Computer Architecture and Organization course. It gives the explanations and details of the processor and exploitation of its cache memory. This paper shows a set of laboratory exercises and several case studies with examples on how to use the EDUCache simulator in the learning process. These hands-on laboratory exercises can be also used in learning software performance engineering and to increase the student willingness to learn more hardware based courses in their further studying.**

***Index Terms*—Education; HPC; CPU Cache; Multiprocessor.**

I. Introduction

THE Computer Architecture and Organization course is devoted to help the students to understand how the computers work. This course is usually in the first study year and the teaching material is almost always totally new for the students. Computer architecture is acknowledged as a significant part of the body of knowledge and an important area in undergraduate computer science curricula [2], [3]. Learning the course requires huge efforts by the students, especially in case of computer science students. Instead of wanting to know how the hardware (computer) works, they just want to use it as a necessary tool to execute their software programs. While developing programs by using some high-level programming language, the students do not get a clear picture of how they are executed by the computer. This decreases the students' interest and deeper understanding in learning of the Computer Architecture and Organization course. Therefore, it makes the teaching even more difficult requiring a lot of effort from both instructors and students [4]. Teachers must not only cover a body of knowledge, but they must motivate students and make the course exciting by selecting appropriate topics, such as which processor should be learned [5].

Today's modern multi-processors consist of multilayer cache memory system [6] to speedup data access balancing the gap between CPU and main memory. This complicates the learning process even more since the students must learn the organization inside the multi-processor, and not only the architecture. We have developed EDUCache simulator [1] that visually presents cache hits and misses, cache line fulfillment, cache associativity problem [7], for both sequential and parallel algorithm execution. In this paper we present several hands-on exercises for EDUCache simulator that will improve the teaching and alleviate the students' learning process. Several predefined examples for special memory patterns that cover data locality and cache set associativity are also presented.

The rest of the paper is organized as follows. In Section II we discuss the related work about improving the teaching and learning of computer architecture and other hardware courses for computer science students. Section III briefly describes the Computer Architecture and Organization course. The EDUCache architecture, user interface and different working modes are described in Section IV. The newly proposed hands-on laboratory exercises and some predefined examples are presented in Section V. The final Section VI is devoted on conclusion and future work.

II. Related Work

This section presents the existing similar visual simulators that cover the area of computer architecture and organization. We also present the proposed methodologies and laboratory exercises in order to lighten the learning and teaching of the course.

A. Hands-on Exercises: Simulation or Real Hardware

Introducing appropriate hands-on exercises, homework assignments and projects besides the lectures will make the course more interesting and will provoke the students to dive more deeply to learn how the computer works. Liang [8] performed a nice survey of hands-on assignments and projects.

Two approaches exist in organizing the laboratory exercises, i.e., either with visual simulators or working on real hardware. Using appropriate visual simulators on hands-on exercises lightens the teaching process and can significantly improve the students' interest in hardware generally [9], [10]. The simulators or web online tools share the laboratory equipment, thus removing the obstacles of cost, time-inefficient use of facilities, inadequate technical support and limited access to design and laboratory resources [11].

Practical work on real hardware is also very important [12], [13], [14]. Wang [15] and Lee [16] proposed FPGA-based configurable processors to be used in laboratory exercises.

978-83-60810-53-8/$25.00

The students can develop, implement and monitoring both hardware and software of multi-core processor systems on real hardware.

B. Teaching Methodologies

Several methodologies are developed to teach the hardware courses in general for computer science students. Reinbrecht et al. [17] present a methodology that integrates functionally verified ASIC (Application-Specific Integrated Circuit) soft cores into a FPGA in order to allow the students to learn the fundamentals of hardware and its designs challenges, not only development, but also verification and physical implications.

Ackovska and Ristov [18] improved the hands-on laboratory exercises and introduced a new teaching methodology. They divided the exercises in tutorials and tasks. The former are published a week before the exercises as students can prepare for the exercise, while the latter are given to the students during the laboratory exercises. These changes improved students' grades without making the course exams easier. Hatfield and Jin [19] designed and developed many laboratory exercises to design and implementation of an operating model of a pipelined processor.

Da [20] elaborated the common methods of classroom teaching and experimental teaching and some efficient methods for classroom and laboratory teaching. He [21] addressed five problems related to computer architecture education in multi-core era and suggested a possible solution.

C. Visual Simulators

We have found many visual simulators that cover a particular fundamental part of computer architecture and organization. Nikolic et al. [9] evaluated many simulators and concluded that some simulators are designed for teaching, some for data profiling, and none of them covers all topics in computer architecture and organization. We [1] have presented a very comprehensive overview of several visual simulators:

- EduMIPS64 [22] for instruction pipelining, hazard detection and resolution, exception handling, interrupts, and memory hierarchies;
- Dinero IV [23] for memory hierarchy with various caches on single core systems;
- CMP$im [24] - based on the Pin binary instrumentation tool;
- HC-Sim [25] generates traces during runtime and simulates multiple cache configurations in one run;
- Herruzo's [26] simulator for understanding the cache look up process and writing elements in the cache memory.
- Misev's [27] visual simulator for ILP dynamic out-of-order executions;
- Valgrind [28] (with its module Cachegrind) profiler for cache behavior;

All these simulators were not primarily developed for teaching the cache memory although most of them are visual. They lack educational features since they are built to complete the simulation as fast as possible rather than to present the architecture and organization of cache memory system in a modern multi-processor. Our EDUCache simulator [1] offers step by step simulation allowing the students to pause the simulation and analyze the cache hits and misses in each cache level. Its power increases with appropriate hands-on exercises.

SimpleScalar [29] and SMPCache [30] are additional simulators selected by William Stallings as a simulation tool for the implementation of student projects [31].

SimpleScalar is used for program performance analysis, detailed microarchitectural modeling, and hardware-software co-verification. It supports non-blocking caches, speculative execution, and branch prediction.

SMPCache is a widely used simulator in more than 100 universities and research centers. It is a trace-driven simulator for the analysis and teaching of cache memory systems on symmetric multiprocessors, analyzing program locality; influence of the number of processors, cache coherence protocols, schemes for bus arbitration, mapping, replacement policies, cache size (blocks in cache), number of cache sets (for set associative caches), number of words by block (memory block size).

Although SMPCache is primary developed as a learning tool for the Computer Architecture and Organization course, it should be redeveloped since it has an option for one cache level and symmetric processor only, while our EDUCache simulator offers simulation of heterogeneous multiprocessor with three cache levels. Our hands-on laboratory exercises proposed in this paper supplements its value.

III. The Computer Architecture and Organization Course

This section briefly describes the Computer Architecture and Organization Course.

The course's main objective is to offer the students a clear understanding of the main computer architectures, performance of the computer parts and the whole computer system. It also covers the topics of today's modern multi-chip and multicore multiprocessors, as well as the digital logic circuits.

A. Course Organization

The teaching of the course is organized in three parts: theoretical lectures with 2 classes per week, theoretical exercises with 2 classes per week and practical exercises with 1 class per week in laboratory. Lectures and theoretical exercises are organized in larger groups of around 100 students, while practical exercises are carried out in computer laboratories in groups of up to 20 students, with each student working on its own workstation. Prerequisites for enrolling in the course are previously completed course in Discrete Mathematics.

Theoretical lectures cover the computer abstractions and technology, the computer language (MIPS), computer arithmetic, the processor, memory, storage, and multichip multicore multiprocessors [32].

Theoretical exercises are divided in two parts. The first midterm covers the topics: computer arithmetic, codes and performance parameters, while the second part deals with

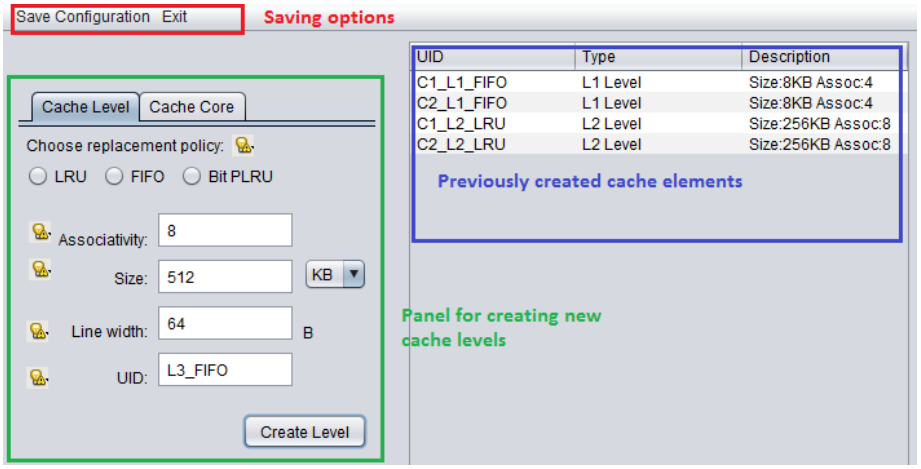

Fig. 1: Overview of design mode of EDUCache simulator - Creating L3 cache instance

digital logic. Hands-on laboratory exercises follow the topics of theoretical exercises.

The course can be passed in two ways, i.e., through midterms or final exam. The students must take the theoretical lecture part and exercise part (plus logic circuits) in either way.

B. Course Obstacles

The previous section briefly describes the course organization. We have analyzed the student results and determined that they had more problems with the topics of theoretical lectures compared to the exercises, and more precisely, the material of the second midterm, i.e., the processor, memory, I/O and parallelization. Our analysis show that although these subjects are covered during the theoretical lectures, neither theoretical nor practical exercises are provided for these topics, since the exercises cover to the design of logic circuits. Even more, IEEE Computer Society and ACM stated that more attention should be given to the multi-core processors architecture and organization, instead of the logic design level [33].

Therefore, we developed the EDUCache simulator that covers these topics. In this paper, we present the hands-on laboratory exercises that will make it even more appropriate in the teaching process, mainly focused on multiprocessor, cache and main memory.

IV. EDUCache Simulator

This section briefly describes the main features, interfaces and user interface of the EDUCache simulator. More details about the EDUCache simulator are presented in [1].

The EDUCache simulator is a platform independent simulator developed in JAVA whoose main simulation is described by a set of Java classes, each for a different CPU cache parameter. It allows the students to design a multi-layer cache system with different multi-core multi-cache hierarchy and to analyze sequential and parallel execution of user algorithm. Each chip can have one or several homogeneous cores. Each core has access to some cache of different cache level (generally L1 to L3). Particular cache can be owned by one, several or all cores of the chip. In general, L1 and L2 caches are private per core in modern multi-processors, while L3 cache is shared among several or all cores.

The particular cache level parameters can vary. Cache is determined by cache memory size, cache line size, cache associativity and replacement policy. EDUCache simulator allows the students to configure all these cache parameters and cache levels.

A. User Interface

The EDUCache simulator user interface is visual and user friendly. It uses the Multiple Document Inteface (MDI) paradigm. The EDUCache simulator works in two modes: *Design* and *Simulation*.

1) Design Mode: The students can configure various cache parameters and levels to create instances of cache levels and share them among chip cores.

The students create the cache levels with unique ID (UID). Figure 1 depicts an overview of EDUCache simulator user interface in design mode and an example on how a student can very easily create a particular cache level instance, select a replacement policy, set associativity, cache line size, cache size and select unique cache level UID.

After creating cache level instances, the students can create a core, selecting cache instances from the list of previously created ones (visible in the table in the right frame) for each cache level. Figure 2 depicts a user interface to create a core with unique Core UID, using previously created cache level instances.

Finally, the students can save the created configuration that represents a CPU chip. They configure the core instances, which they prefer to include on the chip and they are prompted where to save the configuration file.

After completing a multi-core chip with different caches in the design mode, the students can move to the simulation mode in order to simulate some memory accesses and analyze which of them will generate hit or miss in particular cache level of particular core.

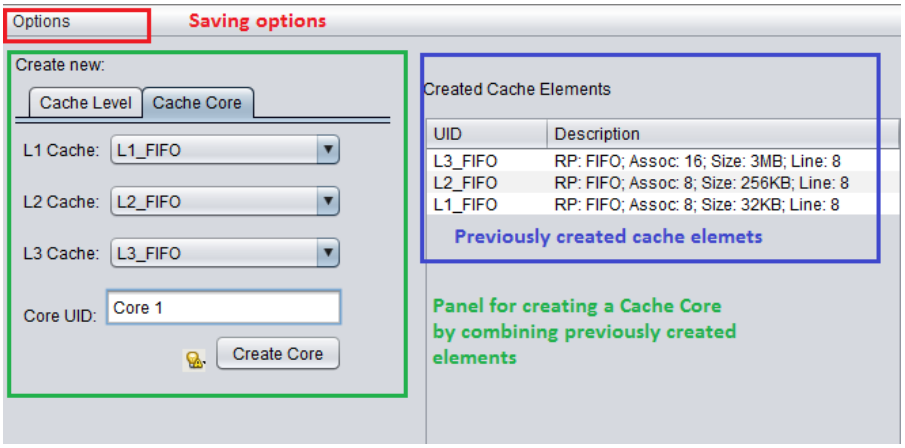

Fig. 2: Overview of design mode of EDUCache simulator - Creating a CPU core

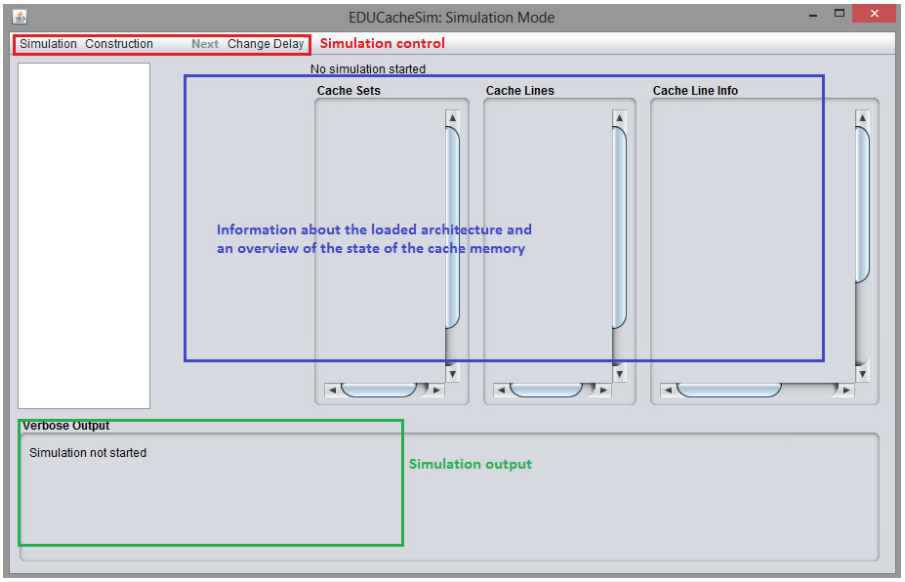

Fig. 3: Overview of Simulation mode - hit in L1 level of core C2, set #8, line #1, address 123416

2) Simulation Mode: After a configuration of the CPU chip with multiple cores per chip and multiple cache levels per each core, the students should load the memory addresses and run the simulation.

Figure 3 depicts the Simulation mode. Its main window consists of:

- *Simulation Control Menu Bar* - is the central control hub for the simulation process. It contains 2 menus, i.e., *Simulation* and *Construction*. The latter creates new or loads the existing configuration file for a core. The former loads a study case file, trace file, and operates the simulations (start, pause, stop, or step by step working mode);
- *Loaded Address Trace Frame* - shows the contents of the trace file, i.e., which core should read the address and the physical address that is loaded.
- *Verbose Output Frame* - shows the addresses that are read by cores, the search in L1 cache and selecting the set in which the address is supposed to map, the result, i.e. cache hit or miss, the cache line number if it is hit and the evicted line if the chosen set was full and read miss is generated; and
- *Visual Representation Frame* - is the main feature of simulation mode which gives a visual representation to the lookup process. It represents different levels of the cache level architecture: Core Pane, Cache Sets Pane, Cache Lines Pane, and Cache Line Info Pane.

V. Hands-on Exercises for EDUCache Simulator

This section presents how the EduCache simulator can be used as a tool in the laboratory exercises to introduce the students with the basic concepts of processor and its cache memory.

A. General Terms

All hands-on laboratory exercises follow the same concept. Each hands-on exercise starts with an explanation of the goal and objectives. Next, a brief coverage of the required topics is presented. This will remind the student of the topics that need to be learned or revised in order to be able to prepare for the exercise and complete it. The exercises should be given to the students a week before the exercise [18].

The objectives are step by step guides on what the student is supposed to do, e.g., configure the simulator, create a certain architecture, execute a simulation or analyze the results from an executed simulation. The guidelines are posed as simple instructions or as learning objectives. Questions are placed between the guidelines alerting the students which areas require more attention. In the end, the students must answer all questions, create the configuration file of the simulator and the simulation result file.

B. The Hands-on Exercises

This section presents the hands-on laboratory exercises for the EDUCache simulator. We present several exercises, some of which can be gathered or divided according to the available time for the hands-on laboratory exercises.

1) Exercise 1: Intro to EDUCache Environment: The first laboratory exercise is designed to introduce the EDUCache simulator to the students. The exercise goes over the different types of files that the simulator uses. The basic commands require the students to go through a simulation and to analyze the results. Learning objectives include: EDUCache design and simulating modes, loading a cache configuration file, and basic cache memory elements. The exercise concludes with running a simulation on a loaded trace file, creating a new trace file and running the simulation again, finishing with an analysis of the statistics that the simulator presents after the simulation is finished.

Although this exercise does not require a lot of students' effort, it should be graded. Otherwise, the students may not pay enough attention on learning the elementary controls of the simulator, which will cause them to have trouble with later exercises.

2) Exercise 2: Different Cache Parameters: The second laboratory exercise aims to present the basic parameters of cache memory to the students. That is, the size, associativity and the principles of multiple cache levels. The learning objective of this exercise is for the students to understand how these parameters impact on specific program execution. The principles of time and data locality are covered. The simulator is used to create multiple configurations with different parameters regarding to the cache size. Simulation is realized on a single memory trace. The students must observe into the results of the simulation and compare to find how the different sizes effect the program execution.

The final part of the exercise is to determine the smallest size for a cache level that gives the same performance as an infinite cache size. The grading should include optional questions for extra credit to inspire the students to show interest in the exercises since this exercise contains a significant number of tasks (and objectives) that the students must complete.

3) Exercise 3: Overview of Cache Set Associativity and Replacement Policies: The third laboratory exercise goes over the concepts of cache set associativity and replacement policies as one of the more complex cache memory parameters. The exercise shows the impact of these parameters on a specific program execution. The students must create configurations and use them to execute and analyze multiple simulations.

A set of address traces is given and the students' task is to observe and conclude the optimal replacement policy for each address trace. The exercise also offers the possibility to create experimental configurations which do not usually appear in real systems, such as certain cache levels with certain replacement policy. Another set of objectives takes a look at the influence of the set associativity.

TABLE I: Example 1 that generates cache misses

Parameter	L1	L2	L3
Size	32B	64B	128B
Associativity	2	2	4
Replacement	FIFO	FIFO	FIFO
Cache line	8B	8B	8B

TABLE II: Results of the simulation of the Example 1

Parameter	L1	L2	L3
Total reads	50	50	50
Cache hits	0	0	0
Cache misses	50	50	50

C. The Demo Examples

In this section we present several demo examples for characteristic memory access patterns in order to lighten the learning and understanding of the processor and its cache memory architecture and organization.

1) Example 1: Cache Miss due to "Loosely" Data: This example demonstrates the continuous cache misses for the loosely data. Table I presents the example of cache parameters. The trace file forces the access of the elements with 8B offset since we want to force a cache miss for each memory read (each read accesses the element of different cache line). Total 50 reads are realized and the results of the simulation are presented in Table II.

2) Example 2: Each Second Access is Cache Hit due to Data Locality: This example accesses pairs of elements such that each pair is placed in the unique cache line. The cache parameters are presented in Table III. Total 10 reads are realized. The results of the simulation are presented in Table IV. That is, we forced 5 pairs of miss and hit in L1 cache.

3) Example 3: Always Cache Hit due to Data Locality: This example demonstrates how the set associative cache memory generates cache hits for "tightly" data (data locality) of a single cache line. The cache parameters are the same

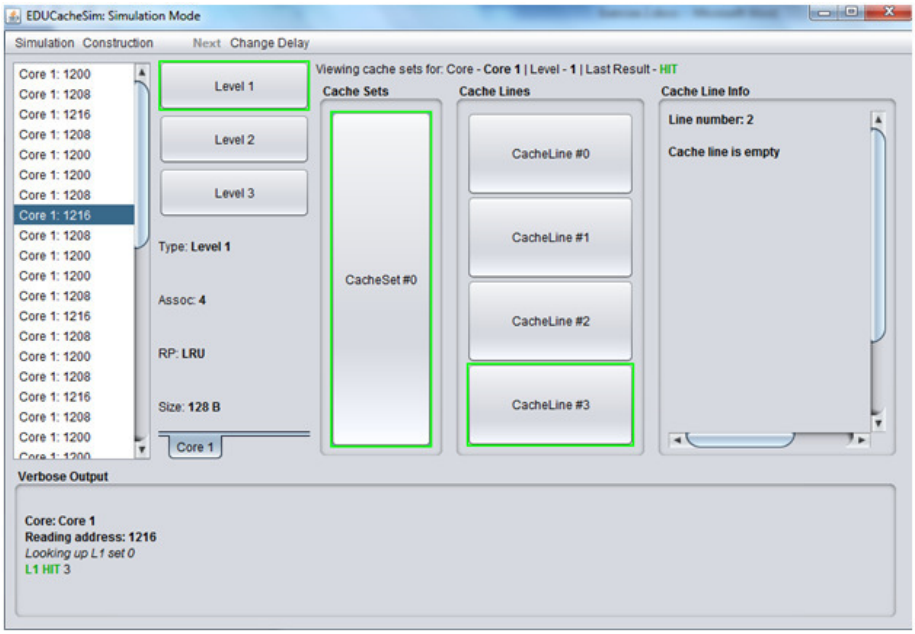

Fig. 4: Simulation of Example 3

TABLE III: Example 2 that generates cache hits for the second access

Parameter	L1	L2	L3
Size	128B	192B	256B
Associativity	4	4	8
Replacement	LRU	LRU	LRU
Cache line	32B	32B	32B

TABLE IV: Results of the simulation of the Example 2

Parameter	L1	L2	L3
Total reads	10	5	5
Cache hits	5	0	0
Cache misses	5	5	5

as the Example 2 presented in Table III. Since we want to generate a cache hit for each memory access, all addresses in the memory trace are in the range of a single cache line. Total 42 reads are realized. The results of the simulation are presented in Table V. That is, 1 cache miss is generated by the first access, and 41 cache hits by all others.

Figure 4 depicts a hit occurring on L1 cache always in the same cache line, as the rightmost pane shows the other cache

TABLE V: Results of the simulation of the Example 3

Parameter	L1	L2	L3
Total reads	42	1	1
Cache hits	41	0	0
Cache misses	1	1	1

TABLE VI: Configuration for Example 4

Parameter	L1	L2	L3
Size	16B	32B	64B
Associativity	2	2	4
Replacement	FIFO	FIFO	FIFO
Cache line	8B	8B	8B

lines are empty because all the required elements have been loaded into a single cache line Line #3.

4) Example 4: Cache Associativity Problem: This example demonstrates how the set associative cache memory can generate continuous cache misses if the data access are always in the same cache set, i.e., cache associativity problem [7]. The cache parameters are presented in Table VI. Total of 15 reads are realized, but only 3 different addresses are accessed. The results of the simulation are presented in Table VII.

This example results in constant L1 cache misses because of constant eviction of cache lines in the same set. Because we want to generate a cache miss by looking up the same cache set (in our case $CacheSet\#0$) for each memory read, all addresses in the memory trace must satisfy $Block\_address = X \cdot Number\_of\_cache\_sets$.

For our configuration, the cache line is 4 bytes, which yields that if the address in main memory is N bytes long, the block address will be the first $N - 2$ bits [6].

Figure 5 depicts a step in the simulation of this exercise. Reading the element stored in address 0 generates a cache miss on the Level 1 cache, because the previous read replaced it from the cache set.

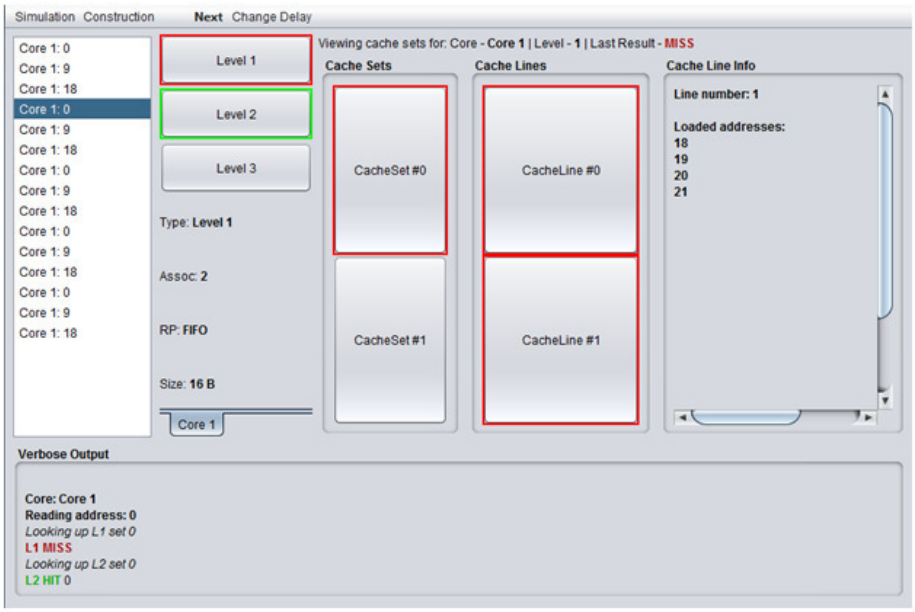

Fig. 5: Simulation of Example 4

TABLE VII: Results of the simulation of the Example 4

Parameter	L1	L2	L3
Total reads	15	15	3
Cache hits	0	12	0
Cache misses	15	3	3

Reading the element will generate cache hit in the Level 2. The rightmost panel shows the loaded addresses in $CacheLine\#0$ in $CacheSet\#0$.

VI. Conclusion and Future Work

EDUCache visual simulator offers the students a tool to design their own CPU core with multi level cache memories. It simulates cache misses and hits in particular cache set and memory location for sequential and parallel execution of an algorithm. The students can interactively learn about the cache hierarchy, architecture and organization of private cache level per core or shared cache level among all or a group of cores, the cache capacity and associativity problem, cache line, cache replacement policy, data locality etc.

This paper presents several hands-on laboratory exercises to support the students for the Computer Architecture and Organization course, i.e., using the EDUCache simulator they will better understand the architecture and organization of the modern processor and its cache memory. Several predefined examples are also presented to lighten the learning process and increase the students' willingness for the Computer Architecture and Organization course. This will help the students to develop their algorithms to achieve maximum performance using the same hardware resources.

We will introduce the EDUCache simulator and the hands-on exercises to this semester in courses Computer Architecture and Organization and Parallel and Distributed Processing, and survey the students about the impact to their willingness for learning the processor and its cache memory. Additional analysis will be realized after finishing the course this year to determine the results of the exams for the topics that cover the EDUCache simulator and the proposed hands-on exercises and examples.

***Abstract*—This article regards analysing the literature of processing competence in education, as well as competence management systems (CMS) and their role in developing competencies for students of higher education cycle. The Bologna Process and its results are described later in the text, explaining the need for National Qualification Frameworks and the benefits that they can produce when implemented correctly. We focuses on creating the basis for competence management system for Polish National Qualification Framework in Computer Science area, how it should work and how it should be implemented.**

I. Introduction

TECHNOLOGICAL market for jobs related with IT is constantly changing. The reasons for this are constant changes in technology and innovative products that affect the workings of certain services and sites. This results in constant changes in competences required by the IT market [23]. New competencies show up, they have new names and contents. Competencies that are already in existence, change their contents due to technological advancement.

The proposed system got two main roles: to be the Personal Competence Manager (PCM) for each student and to be the Organisational Competence Manager (OCM) for the given faculty. The system is based on competence development lifecycle [18] which includes elements like: creation of a reference competence description, the assessment of existing competences at individual or/and group level, the gap analysis, the definition of competence development programmes, continuous performance monitoring and assessment. Based on the PCM, users can choose their own competence development plans and follow them to built the desired competences. [20]. Based on OCM, the faculty can implement the following scenarios:

1. Knowledge analysis of a student that is trying to begin his second education cycle.
2. Market analysis to estimate how much student's competencies differ from those required by the market.
3. Reporting the level of students' summary competences, for example for accreditation committee.
4. Substantive evaluation of a given curriculum.

The definition of competence can be found in many scientific works [4], [8], [16]. Let us focus on those related with accepted standards. ISO 9000:2005 defines competence as the "demonstrated ability to apply knowledge and skills". ISO 19011 defines competence as "demonstrated personal attributes and demonstrated ability to apply knowledge and skills". ISO/IEC 17021:2011 defines competence as "ability to apply knowledge and skills to achieve intended results".IEEE Standard 1484.20.1-2007 [12] describes competency as "any aspect of competence, such as knowledge, skill, attitude, ability, or learning objective". In addition, there is a running discussion about difference between competence and competency term [8]. The IEEE Standard 1484.20.1-2007 interpreted the competency in the broadest sense to include learningobjectives (those things that are sought) as well as competencies (those things that are achieved).

The discussed competence management system (CMS) is being prepared for faculties related with computer science. Main goal of this system is to help to map the competences of a learner - which will be stored in some kind of a learner profile -with the competences that result from the competence development program[13]. In every higher education curriculum there are many types of different competencies [22]. While designing the concept of our Competence Management System we focused on key competences which we interpreted as Core Qualifications.

IT market is assessed for competencies in many research projects. The [15] is a good example of this practice where the standardisation of ICT job profiles was done and ICT job profiles model was defined. It is based on ontologies principle to describe "Knowledge Objects", "Skills", "Competences" and relations between them.

II. Problem Statement

Analysing main characteristics of a typical curriculum gives us the following mechanisms that develop competencies. Each curriculum consists of courses (subjects) realized in every next semester. On figure 1., an exemplary implementation of a given curriculum is shown, each circle represents a course. Some of them are extended for periods longer than 1 semester (for example 1.1, 2.1 and 2.3, 3.3. 4.3). In the course of studies, elective subjects start to appear from which student got to choose one (for example 4.6, 4.7, 4.8). Another matter are internships that student got to do (4.5). The curriculum ends with an implementation of specialisation courses (5.2-5.6, 6.2, 6.3), which affect the

[1] This work was supported by Project „Platforma Informatyczna TEWI", nr POIG.02.03.00-00-028/09,

overall profile of the student. It must be mentioned that the completion of each course means passing the course with a positive grade. Analysing the above educational path we can distinguish the following mechanisms that develop competencies:

- Competency is developed after completing the given course (e.g. after completing 1.2 or 3.2).
- Competency is developed after completing a certain set of related courses (e.g. 2.3, 3.3, 4.3) which can represent one bigger course divided into many stages (semesters).
- Competency is developed after finishing the internship (4.5).
- Competency is developed after completing a certain group of courses related to a certain technological or scientific aspect (3.1, 3.2, 4.1).
- Competency is developed after completing a specialisation (5.2-5.6, 6.2, 6.3).
- Competency is developed after completing the whole curriculum.

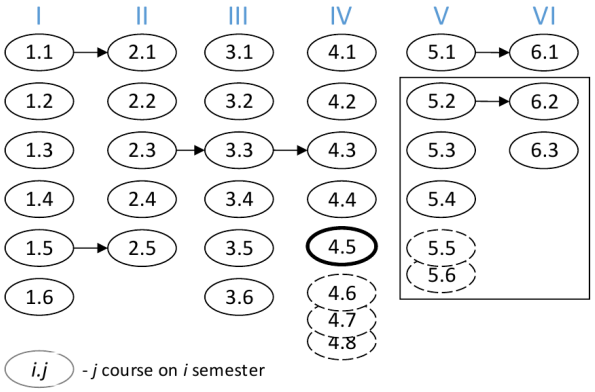

Fig. 1 Schematic representation of university curriculum

III. COMPETENCE MODELING IN IT EDUCATION

For every learning system Bloom's taxonomy is the basis for competencies description. In case of engineering sciences it can be expanded to two dimensions represented by cognitive and knowledge dimensions (Table I). Basic skills and features must be adjusted to the realities of IT's technical field. It seems that expanding skills' base with competencies related with mathematics and system analysis is a must. Typical mathematic-based competencies are[19]: thinking and reasoning, communication, argumentation, representation, modeling, problem posing and solving, symbolic and technical language.

Basing on literature we can define the target set of computer science student's competencies as a total set of knowledge, technology, skills and attitudes which function as action characteristics of an organizational member who can do his or her tasks outstandingly and efficiently in the computing environment [24]. Generally speaking student's computing competency consists of four components [24]:

- The computing mindset (driven from self-concepts and traits).
- The knowledge of computing technology (based on knowledge).
- The capability of computing application (determined from cognitive and behaviour skills).
- The potential of computing capability (driven from personal motives).

Each student upon completion of a given curriculum should posses a set of Core Competencies which are the basis for typical problem solving in the field of IT. The core competence in the literature on education defines a set of learning outcomes (skills or competencies) which each individual should acquire during or demonstrate at the end of a period of learning. It is one of a number of associated con-

TABLE .I
BLOOM TAXONOMY (based on [11])

Cognitive dimension		**Knowledge dimension**	
Remember	Exhibit the memory of previous-learned materials by recognizing or recalling facts, terms, basic concepts and answers.	*Factual Knowledge*	Knowledge about terminology and specification details.
Understand	Understanding of facts and ideas by interpreting, exemplifying, classifying, summarizing, inferring, comparing, and explaining main ideas.	*Conceptual Knowledge*	Knowledge about generation, classification, and structural modelling of certain concept.
Apply	Using the available knowledge to execute and implement solutions in different ways.	*Procedural Knowledge*	Knowledge about workflows, algorithms, methods, procedures, and events.
Analyze	Differentiating, organizing, and attributing knowledge by manipulating information using certain criteria.	*Meta-Cognitive Knowledge*	Knowledge about strategies and decisional conditions.
Evaluate	Checking and Judgments about information, validity of proposed ideas, or quality of work by certain criteria.		
Create	Generating, planning, and producing information or knowledge together and proposing new solutions.		

cepts, including core skills, core competency, generic skills and key qualifications [10]. According to [21] the core competence applied to education as a whole could be defined as facilitating the empowerment of people, through learning how to acquire information (data), turn it into knowledge and apply that knowledge to solve problems. The example of core competence for network building can be found in [9].

IV. National Qualifications Framework: an overview

A. Bologna Process and Lifelong Learning

Proposed in 1999 by Education Ministers from 29 European Countries, Bologna Process was started to create the European Higher Education Area (EHEA) [16]. After a series of ministerial meetings (Prague 2001, Berlin 2003, Bergen 2003, London 2007, Leuven 2009) and by the year 2013 there are now 47 participating countries in the Bologna Process. The main purpose of it was to create the Qualifications Framework of the EHEA which were greatly influenced by the UK's National Qualifications Framework (NQF) [2]and its later version, the Qualifications and Credit Framework (QCF) [7]. During this process the European Qualifications Framework which acts as a medium to translate national qualifications across European countries, was created. This way, workers and students in European Union gain more mobility between countries allowing them to study or work abroad without the difficulties of complicated analysis of their current competencies, knowledge and skills. Many other countries took prime example of UK and also implemented 8-level NQFs into their education systems. Those national qualifications can be easily translated to EQF and people who moved from one European country to another would not have to repeat what they already learned. The Bologna Process moved on to create the "Bologna qualifications framework".

Another accomplishment of the Bologna Process was creating the idea of Lifelong Learning. Pursuing knowledge for either personal or professional reasons for the individual's entire life rather than only learning "in the classroom". Lifelong Learning focuses on teaching outside schools and universities, using methods like home schooling, education for adults (for individuals that want to develop themselves), continued education (usually extended courses offered by higher education institutions), working with knowledge (using obtained knowledge in professional work) and personal learning (individuals learning using for example online sources of distance education).

B. How NQF works

EQF just like British NQF/QCF is divided into 8 levels, each of them describing what the learner knows, understand and is able to do (where 8th level is the most advanced and 1st level is the most basic). We can already see the similarity to British NQF/QCF which also had 8 levels and the last one was the most advanced[European Communities 2008]. The Bologna qualifications framework states that there are 3 cycles/levels of qualifications framework:

- Cycle 1 - usually correlated to qualifications of bachelor's degree
- Cycle 2 - usually correlated to qualifications of master's degree
- Cycle 3 - usually correlated to qualifications of doctoral degree

Those levels correspond naturally with NQF and thus EQF last 3 levels (6th, 7th and 8th) as they describe the same levels of education cycle. In Bergen 2005 all higher education ministers agreed on EQF levels 6-8 descriptors (as in Table II) to be also the descriptors for the three education cycles of qualification frameworks within European Higher Education Area

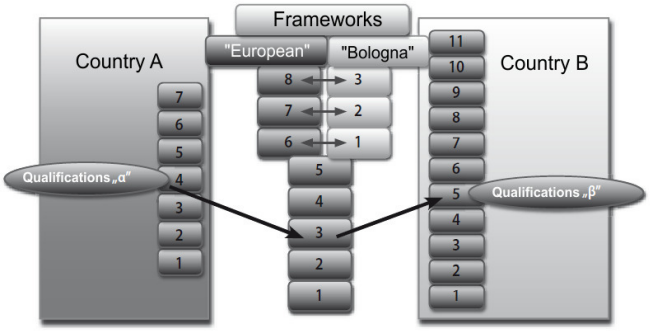

Fig. 2. EQF to NQF translation(based on [3])

Not every NQF easily translates to EQF on a 1:1 level. Different countries have adopted NQF system adjusted to their needs and modified it greatly. Figure 3. is an example of NQFs of France and England compared to EQF.

For example, the last three levels of EQF directly correspond with English and French NQFs but fifth level is different for both countries. This situation is similar with other countries' NQFs. That is one of the reasons Bologna Process focused on the last free cycles of education: bachelor's, master's and doctoral degree (the names for each degree can differ in various countries).

Introduction to European Credit Transfer and Accumulation System (ECTS) was necessary to make the 'translations' between different countries possible. Thus, each cycle referred to certain amount of ECTS credits/points:

- Level 1 - typically 180-240 ECTS credits
- Level 2 - typically 90-120 ECTS credits
- Level 3 - no ECTS

Usually 60 ECTS credits corresponds with 1 academic year which is equivalent to around 1500-1800 hours of study (during classes).

TABLE .II
DESCRIPTORS DEFINING LEVELS IN THE EUROPEAN QUALIFICATIONS FRAMEWORK (based on[8])

Level	Knowledge	Skill	Competence
1	Basic general knowledge	basic skills required to carry out simple tasks	work or study under direct supervision in a structured context
2	Basic factual knowledge of a field of work or study	basic cognitive and practical skills required to use relevant information in order to carry out tasks and to solve routine problems using simple rules and tools	work or study under supervision with some autonomy
3	Knowledge of facts, principles, processes and general concepts, in a field of work or study	a range of cognitive and practical skills required to accomplish tasks and solve problems by selecting and applying basic methods, tools, materials and information	take responsibility for completion of tasks in work or study; adapt own behaviour to circumstances in solving problems
4	Factual and theoretical knowledge in broad contexts within a field of work or study	a range of cognitive and practical skills required to generate solutions to specific problems in a field of work or study	exercise self-management within the guidelines of work or study contexts that are usually predictable, but are subject to change; supervise the routine work of others, taking some responsibility for the evaluation and improvement of work or study activities
5	Comprehensive, specialised, factual and theoretical knowledge within a field of work or study and an awareness of the boundaries of that knowledge	a comprehensive range of cognitive and practical skills required to develop creative solutions to abstract problems	exercise management and supervision in contexts of work or study activities where there is unpredictable change; review and develop performance of self and others
6* Cycle 1	Advanced knowledge of a field of work or study, involving a critical understanding of theories and principles	advanced skills, demonstrating mastery and innovation, required to solve complex and unpredictable problems in a specialised field of work or study	manage complex technical or professional activities or projects, taking responsibility for decision-making in unpredictable work or study contexts; take responsibility for managing professional development of individuals and groups
7* Cycle 2	Highly specialised knowledge, some of which is at the forefront of knowledge in a field of work or study, as the basis for original thinking and/or research Critical awareness of knowledge issues in a field and at the interface between different fields	specialised problem-solving skills required in research and/or innovation in order to develop new knowledge and procedures and to integrate knowledge from different fields	manage and transform work or study contexts that are complex, unpredictable and require new strategic approaches; take responsibility for contributing to professional knowledge and practice and/or for reviewing the strategic performance of teams
8* Cycle 3	Knowledge at the most advanced frontier of a field of work or study and at the interface between fields	the most advanced and specialised skills and techniques, including synthesis and evaluation, required to solve critical problems in research and/or innovation and to extend and redefine existing knowledge or professional practice	demonstrate substantial authority, innovation, autonomy, scholarly and professional integrity and sustained commitment to the development of new ideas or processes at the forefront of work or study contexts including research

C. Learning outcomes

Obtaining given knowledge, skill and competency means that student has reached the 'learning outcomes' planned to achieve after completing his education [1]. Whether we refer to only one lesson, learning module or the whole education cycle it does not matter, learning outcomes can correspond to all of these.

Learning outcomes can be divided into three groups: generic (outcomes that are general for a certain cycle of education, e.g. for outcomes for each bachelor's degree studies), field (outcomes that are specific for a certain type of studies, e.g. technical university), specific (outcomes that are specific for a certain learning module curriculum, major etc.). The general learning outcomes defined by NQF Work Group are also defined and incorporated into the first group. They can be defined by both Ministry of Education and the university as well, though they are distinguished which are which.

V. COMPETENCE (QUALIFICATION) MANAGEMENT SYSTEM

Student while completing the courses on studies achieve learning outcomes defined for the course, thus achieving learning outcomes for his/her major, and those learning outcomes correspond with learning outcomes by the Ministry of Higher Education. Achieving learning outcomes for a specific course means that the student posses a set of knowledge, skills and competencies. Each of those three can corre-

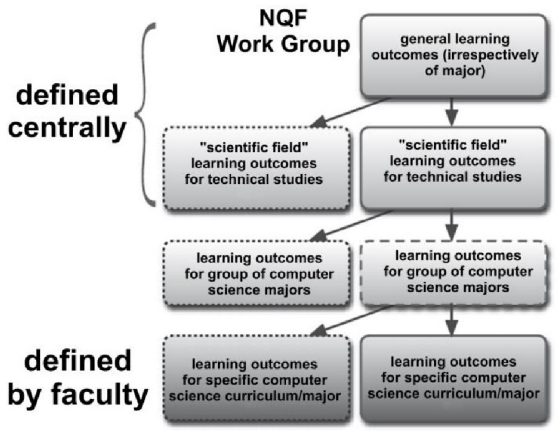

Fig.3 Defining learning outcomes in Poland (based on [3])

spond to a different learning outcome. The problem lies in finding an easy method to name and manage the key competencies we want to use in our management system, it is also essential for processing those sets in the system. That is when Core Qualifications (to correspond with the NQF name) term come in. Core Qualifications are combinations of knowledge, skills and competence, all of them contributing in the European Qualifications Framework. Using the same set of learning outcomes (knowledge, skill competence) as in the EQF makes it possible to easily process and compare Polish NQF with EQF but to make it even more adaptable Core Qualification (QF) must be implemented. In the future this system will be able compute the CQs of students from different Universities based exactly on learning outcomes and this knowledge, skill, competence sets.

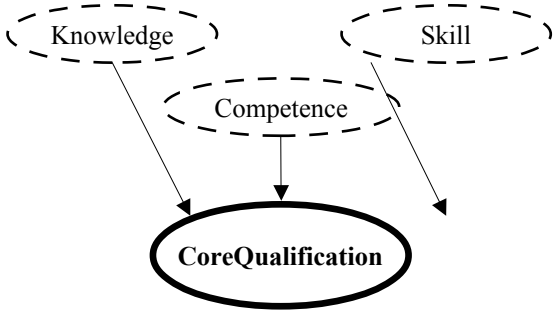

Fig. 4 Core Qualification components

Figure 6. presents the class diagram of NQF based on Computer Science Faculty at West Pomeranian University of Technology in Szczecin. The courses are created accordingly to EQF standards designed by the Bologna Process. The diagram clearly shows 3 distinctive learning outcomes groups like mentioned before. Although the 'specific learning outcomes' in the system are shown to more correspond with the specialisation instead of major, they mostly refer to the same learning outcomes designed for the major (or rather scientific field). The difference between this diagram relations and the learning outcomes mentioned before comes from the University-specific preferences. Sets of Knowledge, Skills and Competence visible from learning outcomes for specialisation and course will be the basis to create the Core Qualification.

The proposed system is using the Competence Object Library (COL) [17] for competence modelling. The COL based on the TENCompetence Domain Model (TCDM) for competence structure modelling and the competence set theory for fuzzy competence set expansion cost analysis [14]. The COL on one hand enables to model different kind of competence content, on the other hand the system can perform quantitative analysis of competence. The COL defines following classes [17]:

- Competency : any form of knowledge, skill, attitude, ability or learning objective that can be described in a context of learning, education, training or any specific business context.
- Competence: effective performance of a person within a context at a specific level of proficiency.
- Context: circumstances and conditions surrounding actions performed by a person.
- Category: indicates the relative level in a taxonomic hierarchy.
- Proficiency Level: indicates the level at which the activity of a person is considered.
- Relation: arbitrary association of competencies within a context and at specific proficiency level.
- Element of Competence: entity derived from competence that can form a set.
- Competence Set: collection of elements of competence. The system has to support the function CompetenceSet.CompareSet() with quantity outcome.
- Competence Profile: collection of competence sets. There is a relented function Competence-Profile.CompareProfile() for different profiles comparison.
- Required Competence Profile: requirements in terms of competence to be fulfilled by a person.
- Acquired Competence Profile : description of competencies possessed by a person.
- Learning outcomes: activity, job, skill, attitude, ability or learning objective for which competence requirements can be specified.
- Person (Student): competent actor performing activities.

VI. CONCLUSION

In this article, we focused on showing the complexity of the issue of competence management in university. The main area of study was computer science, because it is possible to use multiple reference models showing areas of expertise in the field (e.g. 2012 ACM Computing Classification System). Such knowledge-base enables in the future to decide on the level of student's competence and knowledge using the automatic ontology processing methods.

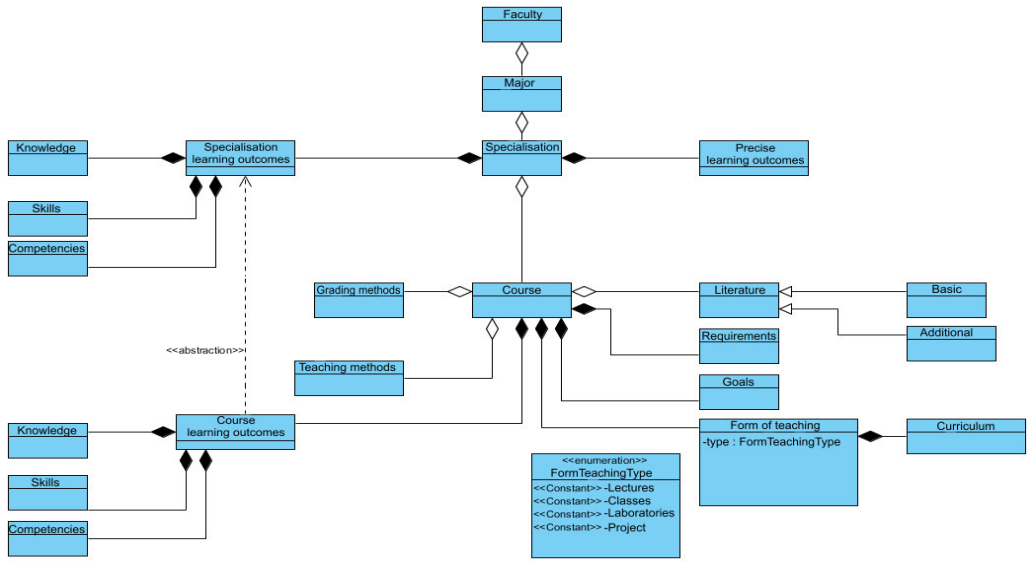

Fig. 5 Class diagram of the NQF at West Pomeranian University of Technology

The Bologna Process is a social and organizational program that includes a set of activities. Among them the qualification framework is one of the most important. The competence management system increasing the possibility of changing qualifications of the student depending on the market requirements.

Frontiers in Network Applications, Network Systems and Web Services

SYMPOSIUM SoFAST-WS focuses on modern challenges and solutions in network systems, applications and service computing. The Symposium builds upon the success of Frontiers in Network Applications and Network Systems (FINANS'2012) and 4th International Symposium on Web Services (WSS' 2012) held in 2012 in Wroclaw, Poland. These two events are now integrated into one event to fully exploit the synergy of topics and cooperation of research groups.

The topics discussed during the symposium include different aspects of network systems, applications and service computing. The primary objective of the symposium is to bring together researchers and practitioners analyzing, developing and administering network systems, with particular emphasis on Internet systems. Authors are invited to submit their papers in English, presenting the results of original research or innovative practical applications in the field.

Topics

Topics include (but are not limited to):

- Architecture, scalability and security of Open API solutions,
- Technical and social aspects of Open API and open data,
- Service delivery platforms - architecture and applications,
- Telecommunication operators API exposition in Telco 2.0 model,
- The applications of intelligent techniques in network systems,
- Mobile applications,
- Network-based computing systems,
- Network and mobile GIS platforms and applications,
- Computer forensic,
- Network security,
- Anomaly and intrusion detection,
- Traffic classification algorithms and techniques,
- Network traffic engineering,
- High-speed network traffic processing,
- Heterogeneous cellular networks,
- Wireless communications,
- Security issues in Cloud Computing,
- Network aspects of Cloud Computing,
- Control of networks,
- Standards for Web services,
- Semantic Web services,
- Context-aware Web services,
- Composition approaches for Web services,
- Security of Web services,
- Software agents for Web services composition,
- Supporting SWS Deployment,
- Architectures for SWS Deployment,
- Applications of SWS to E-business and E-government,
- Supporting Enterprise Application Integration with SWS,
- SWS Conversational Protocols and Choreography,
- Ontologies and Languages for Service Description,
- Ontologies and Languages for Process Modeling,
- Foundations of Reasoning about Services and/or Processes,
- Composition of Semantic Web Services,
- Innovative network applications, systems and services.

***Abstract*—Intrusion detection systems have been around for quite some time, to protect systems from inside ad outside threats. Researchers and scientists are concerned on how to enhance the intrusion detection performance, to be able to deal with real-time attacks and detect them fast from quick response. One way to improve performance is to use minimal number of features to define a model in a way that it can be used to accurately discriminate normal from anomalous behaviour. Many feature selection techniques are out there to reduce feature sets or extract new features out of them. In this paper, we propose an anomaly detectors generation approach using genetic algorithm in conjunction with several features selection techniques, including principle components analysis, sequential floating, and correlation-based feature selection. A Genetic algorithm was applied with deterministic crowding niching technique, to generate a set of detectors from a single run. The results show that sequential-floating techniques with the genetic algorithm have the best results, compared to others tested, especially the sequential floating forward selection with detection accuracy 92.86% on the train set and 85.38% on the test set.**

***Index Terms*—Anomaly detectors generation, genetic algorithms, feature selection**

I. Introduction

WITH the expanding and increasing use of networks, and accumulating number of internet users, network throughput has become massive and threats are more diverse and sophisticated. Network and information security are of high importance, and research is continuous in these fields to keep up with the development of attacks. Intrusion Detection is a major research area that aims to identify suspicious activities in a monitored system, from authorized and unauthorized users. An Intrusion Detection System (IDS) could be host-based or network-based. In Network IDSs (NIDS), network administrators are not able to keep up with the increase in network attacks number and complexity, for both known and unknown attacks. So, there is an urgent and pressing need for replacing them by automated systems for constant monitoring and quick responses [1]. Machine Learning techniques are used to create rules for an IDS by enhancing the domain knowledge. They improve performance by helping to automate the knowledge acquisition process by using training data to find and exploit regularities. They learn how to estimate knowledge from the training data sets. Because one of the biggest challenges of IDS is the massive amount of data collected from the system, learning algorithms are used to discover models that are appropriate to classify normal and anomalous behaviors [2][3].

Different machine learning (ML) techniques are used in the development of anomaly intrusion detection. They could be pattern classifiers, single classifiers, hybrid classifiers, or ensemble classifiers. Such techniques include Support Vector Machine (SVM), Artificial Neural Networks (ANN), Self-Organizing Maps (SOM), Decision Trees (DT), Genetic Algorithms (GA), and many others. In this paper, a genetic algorithm is used to generate detectors for an anomaly intrusion detection system. Some feature selection techniques are applied for feature reduction, before applying the GA.

The paper is organized as follows: Section II gives a background for different components of the system. Section III introduces the proposed anomaly detectors generation algorithm. Section IV describes the experiment steps and the involved data sets. Section V shows the experiment result. Conclusions and future work are discussed in Section VI.

II. Background

A. Anomaly Intrusion Detection

Intrusion Detection Systems can be classified - based on methodology - into misuse-based and anomaly-based. Misuse-based IDS builds a database of attacks signatures and use them to detect anomalies. It's accurate and definitive concerning detecting unknown that do not match the stored patterns. This is where the anomaly-based IDS acts better. Anomaly IDS builds a model that represents the normal behaviour of a system and assume that deviations from such model are attacks or suspicious activity. So, it detect unknown attacks but it may have a high false alarm rate, based on its adjustments. A model in anomaly IDS can be statistical, knowledge-based, or machine learning. A learning technique could be embedded too, to update and adjust the normal model from time to time,

978-83-60810-53-8/$25.00

to represent the actual system behaviour that may change from time to time [4][5].

B. Feature Selection

For each problem with some sample, there is a maximum number of features where performance degrades instead of improves – which is called the curse of dimensionality. An accurate mapping of lower-dimensional space of features is needed so no information is lost by discarding important and basic features. Two issues one should pay attention to while doing this: (1) How dimensionality can affect classification accuracy and (2) How dimensionality affects a classifier complexity. A feature is good when it is relevant but not redundant to the other relevant features. There are two techniques to follow for this: feature extraction and feature selection. Feature extraction algorithms tend to create a new subset of features by combining existing features. Feature selection (FS) algorithms tend to limit the features to only those which would improve a task performance. The FS [6][7][8] is an essential machine learning technique that is important and efficient in building classification systems. When used to reduce features, it results in lower computation costs and better classification performance. Feature selection algorithms are composed of three components: search algorithm, evaluation function, and performance function. The search algorithm could be: exponential – which is expensive to use as they have exponential complexity in number of features, sequential where it adds and subtracts features, so they have polynomial complexity; or randomized – where it require biases to yield small subsets, and they usually achieve high accuracies. An objective function is a function to evaluate the candidate features for feature selection.

Based on evaluation criteria, FS techniques can be divided into filter methods and wrapper methods. Filters evaluate feature subsets by their information content, using distance measures, correlation measures...etc. Wrappers use a classifier for features subset evaluation by their predictive accuracy. Filter techniques discards feature upon their evaluation based on data general characteristics or using some kind of statistical analysis, without any learning mechanism involved. Wrapper techniques use a learning algorithm to find the features subset with the best performance. They are more expensive computation-based, and slower due to the repeating process, but they give more accurate results than filter techniques. This might be a drawback for high dimensional data but it could be defeated by using a fast learning algorithm.

1) Correlation-based Feature Selection: Correlation Feature Selection (CFS) is a heuristic approach that evaluates the worthiness of a features subset. So, based on correlation concept, a feature is considered good if it is highly correlated to the class but not to the other features [9]. So, a suitable measure of correlation between features needs to be defined in which it represents the important and highly effective features. A function that evaluates the best individual feature is:

$$M = \frac{k * r_{fc}}{\sqrt{k + k * (k-1) * r_{ff}}} \tag{1}$$

Where: M is the heuristic merit of a features subset S containing K features, $r_{fc}$is the average feature-class correlation, and $r_{ff}$is the average feature-feature inter-correlation.

The numerator indicates how predictive a group of features are; and the denominator indicates how much redundancy there is among those features.

2) Sequential Floating Selection: Sequential-floating selection is a flexible extension of sequential forward and backward selection (SFS and SBS respectively), with backtracking capabilities [10][11]. Sequential selection methods find optimal group of features by applying step-optimal method where in each step the best/worst feature is always added/discarded. No additional steps are taken to evaluate the selected features in each iteration to refine the subset. An improvement to the methodology is to apply the plus l-take away r method, where additional forward/backward steps are applied after each iteration to correct the selection decision in order to find the optimal final subset of features. If $l > r$ then is Sequential-floating forward selection, if $l < r$ then it is sequential-floating backward selection [12]. Sequential-Floating Forward Selection (SFFS) basically starts with an empty set, then at each iteration it adds sequentially the next best feature. Then, it tests if it maximizes the objective function when combined with the features already selected – and this is how SFS works. In addition to that, after each forward step, SFFS performs a backward step that discards the worst feature of the subset after a new feature is added. The backward steps are performed as long as the objective function is increasing.

In a similar manner but in an opposite direction, Sequential-Floating Backward Selection (SFBS) starts with the full set of features, then it sequentially removes the feature that least reduces the objective function value. This is how the SBS works. So, SFBS performs forward steps after each backward step, as long as the objective function increases.

3) Principle Components Analysis: Principal Components Analysis (PCA) is a way to find and highlight similarities and differences between data by identifying the existing patterns [13][14]. PCA is based in the idea that most information about classes are within the directions with the largest variations. It works in terms of standardized linear projection that maximizes the variance in the projected space. It is a powerful tool in the case of high-dimensional data. It calculates the eigenvectors of the covariance matrix to find the independent axes of the data. The main problem with PCA is that it does not take into consideration the class label of the feature vector, hence it does not consider class separability.

4) Information Gain: Information Gain (IG) help us to determine which feature is most useful for classification, using its entropy value. Entropy indicates the information content of a feature or how much information it is giving us. The higher the entropy, the more the information content. IG value is calculated as:

$$IG(T,a) = H(T) - H(T|a) \tag{2}$$

where H is the information entropy, T is a training example, and a ia a variable value. This equation calculates the IG

that a training example T obtains from an observation that a random variable A takes some value a. IG in machine learning is used to define a sequence of attributes to investigate, which leads to the building of a decision tree. A decision tree can be constructed top-down using the IG by first beginning at the root node, and use the attribute with the highest IG as an ancestor node. Then child nodes are added for each possible value of that attribute. All examples are attached to suitable child nodes where the examples values are identical to the node's attached value. If the all examples attached to a child node can be labelled with a unique class label, then this node is marked as a leaf and that classification is added to the node. These steps are repeated until all classifications are added to the child nodes [15][16][17].

5) Rough Sets: Rough Set Theory (RST) [18][19] can be used to discover dependencies in data for features reduction, using the data alone without additional information required. RST results in the most informative feature set, which would be the most predictive of the class label. The concepts are used to define necessity of features, which is calculated by functions of lower and upper approximations. The measures of necessity are employed as heuristics to guide the feature selection process. An information table is defined for the objects and the attributes as a tuple:

$$T = (U, A) \tag{3}$$

where U is a finite non-empty set of the primitive objects, and A is a finite non-empty set of the attributes. Each feature is associated with a set of its values V. The attribute set would be divided into 2 subsets C and D, which are the condition and decision subsets, respectively. If P is a subset of A, the in-discernibility relation is defined as:

$$IND(P) = \{(x,y) \in UxU : \forall a \in P, a(x) = a(y)\} \tag{4}$$

where $a(x)$ is a feature value a of object x. x and y are said to be in-discernible with respect to P, if $(x,y) \in IND(P)$

C. Genetic Algorithms

As mentioned before, ML techniques are used to create rules for the intrusion detection systems, and genetic algorithms is a common algorithm that is been used for such purpose. Genetic Algorithms (GA) are search algorithms inspired by evolution and natural selection, and they can be used to solve different and diverse types of problems. The algorithm starts with a group of individuals (chromosomes) called a population. Each chromosome is composed of a sequence of genes that would be bits, characters, or numbers. Reproduction is achieved using crossover (2 parents are used to produce 1 or children) and mutation (alteration of a gene or more). Each chromosome is evaluated using a fitness function, which defines which chromosomes are highly-fitted in the environment. The process is iterated for multiple times for a number of generations until optimal solution is reached. The reached solution could be a single individual or a group of individuals obtained by repeating the GA process for many runs [20][21].

D. Negative Selection Approach

Negative Selection Approach (NSA) as an artificial immune system (AIS) technique that is based on the self/non-self discrimination. It first builds a database of normal profiles, and then trains the detectors on that profile to be able to detect anomalous behaviour (that is not normal), when they are later released in the system. The detectors do this discrimination process by being able to recognize normal patterns, then any pattern that is not recognized as normal is considered anomalous. For its similarity to the anomaly detection concept, NSA has been widely applied in different anomaly intrusion detection and fault detection systems in different areas. NSA is very common and easy to implement, and it gives very good results specially when it is combined with classification techniques. Detectors generated and used are simply rules, that define low and high limits, or specific values, of the features used for the intrusion detection [22][23].

III. The Proposed Anomaly Detectors Generation Approach

In this paper, a genetic algorithms is applied with deterministic crowding niching technique, to generate a set of detectors in a single run. The detectors are generated following the NSA concept – as mentioned before – using the self samples from the training set. The original algorithm was originally implemented in [24] using only real-valued features. Then it was applied in [25] using a predefined set of features of different data types. Equal-width binning is applied on the features values as a preprocessing step to first create homogeneity between features, and second to discretize the values so that there would be no extreme values in the experiment. The number of bins for each feature was defined using the following formula.

$$k = max(1, 2 * \log l) \tag{5}$$

where l is the number of observed values. Then each value is replaced with the enclosing bin (the bin that includes this value). Algorithm 1 shows the detailed steps of the detectors generation approach.

A set S of normal connections (self particles) is defined in the beginning, to start generating the detectors that will be able to match normal connections in the future. The self space S is filled with randomly selected individuals from the normal connections in the training set. An individual is composed of a set of values representing the selected features for the IDS. Going through the GA process, crossover and mutation are applied where crossover provides exploitation and mutation provides exploration. The final result is a set of detectors (individuals) with features values that most represent normal connections.

The fitness of an individual is measured by calculating the matching percentage between an individual and the normal samples, as follows:

$$fitness(x) = \frac{a}{A} \tag{6}$$

Algorithm 1 GADG

Fill S Space with normal individuals from training set.
Run equal-width binning algorithm on continuous features.
Initialize population by selecting random individuals from the space S.
for The specified number of generations **do**
  for The size of the population **do**
    Select two individuals (with uniform probability) as $parent_1$ and $parent_2$.
    Apply crossover to produce a new individual (*child*).
    Apply mutation to child.
    Calculate the distance between *child* and $parent_1$ as d_1, and the distance between *child* and $parent_2$ as d_2.
    Calculate the fitness of *child*, $parent_1$, and $parent_2$ as f, f_1, and f_2 respectively.
    if $(d_1 < d_2)$ and $(f > f_1)$ **then**
      replace $parent_1$ with *child*
    else
      if $(d_2 <= d_1)$ and $(f > f_2)$ **then**
        Replace $parent_2$ with *child*.
      end if
    end if
  end for
end for
Extract the best (highly-fitted) individuals as your final solution.

where a is the number of samples matching the individual by 100% , and A is the total number of normal samples. where a is the number of samples matching the individual, and A is the total number of normal samples.

Both the Euclidean and Minkowski distance measures were tested in the GA – each in a separate trial – to calculate the distance between a child and a parent. The Euclidean distance is also used in the discrimination function to detect anomalies. The Euclidean distance between two individuals is calculated as follow:

$$d(X,Y) = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 \ldots (x_n - y_n)^2} \quad (7)$$

The Minkowski distance, which uses the p-norm dimension as the power value, between two individuals is calculated as:

$$d(X,Y) = (\sum_{i=0}^{n} (|x_i - y_i|^p))^{1/p} \quad (8)$$

IV. Experimental results and discussion

A. Data Set

The NSL-KDD [26] data set was used in the experiment, as it is more refined and less biased than the original KDD Cup99 data set [27]. In addition to that, it contains much less number of records, so the whole training and test sets can be used in the experiments. Table I shows the distributions of normal and attacks records in the NSL-KDD data set.

TABLE I
DISTRIBUTIONS OF NSL-KDD RECORDS

	Total Records	Normal	DoS	Probe	U2R	R2L
Train_20%	25192	13449	9234	2289	11	209
		53.39%	36.65%	9.09%	0.04%	0.83%
Train_All	125973	67343	45927	11656	52	995
		53.46%	36.456%	9.25%	0.04%	0.79%
Test+	22544	9711	7458	2421	200	2754
		43.08%	33.08%	10.74%	0.89%	12.22%

B. Feature Selection

Each one of the feature selection – that were mentioned earlier – was applied to the NSL-KDD data set, and each came up with a set of feature, shown in table II. In addition to the FS techniques applied in this paper, other two sets of features selected in [3][28] using Information Gain (IG) and Rough Set (RS) for degree of dependency respectively, were used.

TABLE II
SELECTED FEATURES

FS Technique	Selected features
CFS	3, 4, 8, 12, 29, 33, 39
SFBS	2, 3, 6, 29, 34, 35, 36, 37, 38, 39, 40, 41
SFFS	1, 2, 3, 4, 6, 7, 10, 12, 17, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 40, 41
PCA	1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 13, 14, 17, 18, 22, 27, 28, 29, 31, 32, 35, 37
IG	1, 6, 12, 15, 16, 17, 18, 19, 31, 32, 37
RS	3, 6, 12, 23, 25, 26, 29, 30, 33, 34, 35, 36, 37, 38, 39

The suggested approach was executed for each set of features, then the generated detectors were tested against the Train Set and the Test Set to investigate the detection accuracy and which set of features gave the best results. The values used for the algorithm parameters are shown in table III.

TABLE III
PARAMETERS VALUES

Population size	200, 400, 600
Number of generations	200, 500, 1000, 2000
Mutation rate	2/L, where L is the number of features
Crossover rate	1.0
p	0.5

A mutation rate is a measure of the likeness that random elements of your chromosome (individual) will be mutated, which is dependent on the number of features in our experiment. A crossover rate defines the percentage of chromosomes used in reproduction, in this case all selected chromosomes are used. The p norm set for the Minkowski distance measurement is selected as a small value between 0.0 and 1.0 to detect similarity more than difference.

V. Results and Discussion

The algorithm was applied twice for each features group, with the two previously mentioned distance measurements.

Then, the resulted groups of detectors were tested against the whole Train Set and the Test Set. The performance measurements used are accuracy, sensitivity, and specificity, and they are calculated as:

$$Accuracy = \frac{TP+TN}{TP+FN+TN+FP} \tag{9}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{10}$$

$$Specificity = \frac{TN}{TN+FP} \tag{11}$$

Where:

- TP is the True Positives, when an attack is detected successfully and raises an alarm.
- TN is the True Negatives, when a normal connection does not raise an alarm.
- FP is the False Positives, when a normal connection is wrongfully detected as an attack and raises an alarm (false alarm).
- FN is the False Negatives, when an attack is not detected and does not raise an alarm.

Accuracy mean how much accurate the system is to define anomalous and normal activities. Sensitivity expresses the ability of an IDS to correctly classify a connection as an attack. Specificity expresses the ability of an IDS to correctly classify a connection as normal. The average and maximum rates are shown in figures 10, 11, and 12 respectively.

	CFS	SFBS	SFFS	PCA	IG	RS
Train (Euclidean)	92.46%	90.67%	92.86%	92.40%	54.04%	89.65%
Train (Minkowski)	92.04%	90.67%	92.68%	92.36%	53.77%	89.81%
Test (Euclidean)	82.02%	71.94%	85.21%	81.76%	44.57%	79.96%
Test (Minkowski)	81.22%	72.53%	85.38%	81.27%	43.39%	79.43%

Fig. 1. Average Accuracy for Train and Test Sets

	CFS	SFBS	SFFS	PCA	IG	RS
Train (Euclidean)	90.54%	84.08%	91.87%	85.91%	3.26%	87.81%
Train (Minkowski)	89.24%	84.08%	92.15%	87.76%	1.04%	88.64%
Test (Euclidean)	71.71%	55.03%	89.70%	72.02%	3.25%	73.56%
Test (Minkowski)	69.98%	54.96%	90.21%	71.15%	0.61%	73.02%

Fig. 2. Average Sensitivity for Train and Test Sets

	CFS	SFBS	SFFS	PCA	IG	RS
Train (Euclidean)	94.13%	96.41%	93.72%	98.05%	98.26%	91.25%
Train (Minkowski)	94.48%	96.41%	93.14%	96.37%	99.67%	90.82%
Test (Euclidean)	95.64%	94.29%	79.28%	94.64%	99.18%	88.42%
Test (Minkowski)	96.07%	95.74%	78.99%	94.65%	99.93%	87.90%

Fig. 3. Average Specificity for Train and Test Sets

We can realize from the charts that CFS, SFFS, and PCA give the best results in general – figure 10. They give close results for the train set, but SFFS has the best results for the test set. Looking into the details, the SFFS selected features result in the best sensitivity rates (figure 11), which means the detectors can successfully detect anomalies in higher rates (91.87% and 92.15% for the train set, 89.7% and 90.21% for the test set). Although SFFS gives lower specificity rates (figure 12) than other algorithms, but as an overall no other algorithm resulted in such high true positive rates. We can realize too that although IG resulted in the highest specificity rates, it almost totally fails to classify anomalous activities in the data.

VI. Conclusion

In this paper, an anomaly-based, NSA inspired, network intrusion detection system was implemented, where GA was used to generate anomaly detectors for the system. In order to decide which features subset should be used, multiple feature selection approaches were used, and the results were compared to see which algorithm gave the best results. As shown above, although the SFFS gave the biggest features subset, it also gave the best accuracy and the best sensitivity rates - which is

most obvious on the Test set which includes unknown attacks. Checking the features selected by each algorithm, one can realize that:

- Feature 3 — service — is very important in the detection process, it was not selected among the effective features using the IG technique and it shows poor performance in anomalies detection.
- Feature 1 — duration – is also very important, it was selected by the techniques that resulted in better accuracy and detection rates.
- Features that are concerned with the connection rates counts — 22, 29, 30, 31,...,41 — affects the performance too in a better way, they help improve detection accuracy.

In the future, a classification technique should be used to classify the detected anomalies and refine the results more.

How to Develop a Biometric System with Claimed Assurance

Andrzej Bialas
Institute of Innovative Technologies EMAG,
ul. Leopolda 31, 40-189 Katowice, Poland
Email: a.bialas@emag.pl

***Abstract*—The article concerns the process of developing biometric devices with a view to submit them for certification in compliance with ISO/IEC 15408 Common Criteria. The author points at the assurance paradigm which shows that the source of assurance is a rigorous process of the product development along with methodical and independent evaluation in an accredited laboratory. The state of the art of certified biometric devices was discussed. There was some focus put on the issue of insufficient support that the developers get in this respect. Basic processes related to the Common Criteria methodology were described (IT security development, IT product development, IT product evaluation). These processes were illustrated by the elements of security specifications of certified biometric devices. The author proposes that development patterns can be used to prepare evidence material, while specialized devices supporting development processes – to deal with basic difficulties encountered by the developers of biometric devices.**

I. Introduction

TODAY'S IT applications, especially those used in the large businesses, banking, e-government and e-health sectors require dependable identification and authentication. One of the possible group of solutions used in these applications is provided by biometrics.

Biometric authentication concerns the automatic identification of humans by their intrinsic physiological characteristics (finger images, hand/facial geometry, vascular patterns, iris, retina, etc.) or behavioural characteristics (hand writing, keystroke dynamics, etc.).

Biometrics can be used for:

- identification of a person's identity; the captured biometric sample is compared with enrolled templates contained in the database to find the matching one;
- verification of a person's identity; the captured biometric sample of the person claiming the given identity is compared with the enrolled template associated with the claimed identity and stored in the database.

Both processes, identification and verification, should be supported by the enrolment process, responsible for capturing biometric samples and storing them in a secure way. Providing mechanisms to associate an identity with a person, biometric devices are often used when quick, secure and positive authentication is needed.

Biometric devices implement the best matching technologies for the given application domains. These devices encompass hardware and software parts. The implementation of these parts is important, as it is always critical for the entire security system in which these devices work.

IT users require trustworthy biometric devices because these devices usually secure their critical applications in high risk environments. The Common Criteria (CC) [1] methodology can be used to develop trustworthy biometric devices.

The developers of biometric devices should be familiar with the Common Criteria methodology because they should be able to perform different CC-related security analyses and tests in order to prepare biometric IT products for evaluation, to elaborate evaluation evidences and to assist the evaluation process. Most of IT developers, not only biometric technology developers, have difficulties to successfully perform these tasks. For this reason some Common Criteria supporting documents and guidances (e.g. [2]) have been elaborated and consulting services are offered. One of the Common Criteria-based methodologies supporting the IT security developers in their works will be presented in this paper. It was elaborated during the CCMODE (Common Criteria compliant, Modular, Open IT security Development Environment) R&D project [3], co-financed by the EU within the European Fund of Regional Development. The objective of this project was to elaborate a CC-compliant methodology and tools to develop and manage development environments of IT security-enhanced products and systems for the purposes of their future certification. The CCMODE project resulted in the following products: knowledge, patterns (including documentation, procedures, evidences, specification means, etc.), methodology and tools which can be used by different organizations to create and manage IT development environments [4]–[5]. The contribution of this paper is to provide developers of biometric devices with the new patterns-based and software-supported assurance methodology to make this development process easier. The paper shows how the general purpose patterns and tools elaborated in the CCMODE project can be adopted for biometric devices. The paper also discusses the state of the art of the certified biometric devices pointing out sources of knowledge useful for developers.

The paper presents a short primer for the CC methodology, a range of the CC-related support offered for biometric technology developers, a review of the development process of biometric devices in the CCMODE development environment, and conclusions.

II. Common Criteria methodology – a primer

The ISO/IEC 15408 standard Common Criteria [1] assumes that the reliability of security measures depends on how much accuracy and rigour is put into the development, testing, verification, documenting etc. of IT products. The more rigorous is this process, the more precise are the used good engineering practices, the better is the organization of the development /production /maintenance environment – the more reliable, trustworthy is the IT product. In the nomenclature of the standard, the commonly understood reliability was replaced by a more precise term – assurance. The assurance can be measured by means of Evaluation Assurance Levels (EAL) in the range from EAL1 (minimal value) to EAL7 (maximal value). The applied degree of rigour affects the cost of the product development, manufacturing and maintenance, therefore when the EAL is declared, the developer has to compromise between the product costs and the assurance level. In practice, among already evaluated 1,200 IT products, the biggest number are those on levels EAL3 and EAL4 [6]. An IT product in the CC nomenclature is called TOE – Target of Evaluation.

The Common Criteria methodology comprises three basic processes:

- IT security development based on different types of security analyses; a special document is worked out, called Security Target (ST), which is a set of security requirements – functional requirements describing how security measures should work and assurance requirements describing how reliable the developed products are;
- TOE development, including its documentation; this documentation, being an extension to the above mentioned ST, is evidence material prepared for the sake of the third process – security evaluation;
- IT security evaluation, carried out in an independent, accredited laboratory [6].

The standard has a wide application range as it is difficult to find an IT product without any security measures of its functions. Rigorous regulations related to the product development, along with independent evaluation, are the source of assurance for such a product.

Biometric products are security-related products requiring assurance.

III. Common Criteria Support for the Biometric Devices Developers

The developers of biometric devices can use the BSI guide [2] which is about the preparation of evidence material. The guide has a general character (concerns any IT products) and does not give any patterns to prepare the material. Therefore the developers have to use consulting services in this respect. There are few software tools which support the development of evidence material. One of them was described in [7]. The tool allows to generate a Security Target pattern which is one of over a dozen documents needed in the whole process. Some valuable practical hints about the evidence preparation and the certification itself are available in [8].

The developers of biometric devices can get some assistance from the so called Protection Profiles. These are evaluated sets of requirements for a certain class of IT products. For biometric devices only two Protection Profiles have been developed so far.

The [9] profile presents a biometric verification system in terms of [1] and defines functional and assurance requirements for such a system. Two other biometric systems, i.e. enrollment- and identification systems, are not considered in this profile. The profile focuses on the stand-alone version of the biometric device. Moreover, it does not discuss the biometric modality and related hardware. For this reason, the [9] focuses only on a software solution. This PP has EAL2 claimed. Testing is not considered (thresholds). This profile is of basic significance for the developers of biometric devices. The second PP [10] provides fingerprint spoof detection.

Up until now only three biometric devices have successfully passed the certification process [6]. The Security Target [11] presents the functionality of the Palm Secure biometric verification system, based on the structure of the veins in the palm as a unique characteristic of a human body. The Security Target [12] specifies a system that provides fingerprint spoof detection as part of a biometric system for fingerprint recognition. The ST [13] (EAL2+) specifies a distributed (server-based) authentication system based on biometric data.

IV. Development Process of Biometric Devices in the CCMODE Development Environment

In order to obtain a certificate for an IT product, including a biometric product, it is necessary to carry out the three basic processes mentioned in section 2.

4.1 IT security development process

This process encompasses activities aiming at the elaboration of the TOE security functions (TSF) meeting security functional requirements (SFR), to be implemented at the claimed EAL during the next process – TOE development. The IT security development process includes (key parts):

1. Preparation of the ST introduction.

The developer should assign the TOE type (i.e. biometric device) and provide a concise but precise description of the TOE, which can be an entire biometric device or its part only. The TOE can encompass software, hardware or both. It should be described in the ST introduction what the TOE is and what the TOE operational environment is, including the required non-TOE hardware/software/firmware in this environment. In the TOE description physical and logical scope of the TOE should be specified. The ST introduction should present the TOE usage and its major security features.

2. Conformance claims.

They specify conformance with the used CC standard version (e.g. v.3.1), with protection profiles (if applied) and with assurance packages expressing the EAL level.

3. Security problem definition (SPD).

The security problem can be expressed as the assets protection against threats (this method is recommended to apply

more reliable technical measures) or as OSP (Organizational Security Policy) rules to be fulfilled to avoid incidents (organizational measures are less appreciated than the technical ones). A good practice is to start with the identification of the TOE protected assets (they can be inside or outside the biometric TOE) and external entities interacting with the TOE (sometimes called subjects). The biometric TOE protects usually the users' assets placed outside the TOE (e.g. on servers), called primary assets. To protect these assets, it is vital to protect the TOE internal assets, e.g.: biometric reference and life records, claimed identity, configuration data, etc., (sometimes called secondary assets). The external entities can be authorized or not, can be humans or processes. Usually, the main "actors" are: administrator, user, attacker. Specifying threats, OSPs or both, some assumptions for the operational environment concerning connectivity-, personal- or organizational aspects can be added. Examples of threats are: "Using the identity of another user, an attacker may perform a brute force attack to be positively verified by the TOE.", "An attacker modifies biometric references or other security-relevant system configuration data.". An example of OSP is: "The TOE shall meet recognized national and/or international criteria for its security relevant error rates like: False Accept Rate (FAR) and False Rejection Rate (FRR)." More examples are included in [9]. The elementary items of the SPD (as well as SO, TSF) are specified by mnemonic names called generics.

4. Solution of this problem by setting the security objectives (SO) – for the TOE and its operational environment.

The security objectives are concise statements of the intended solution to the given SPD problem (i.e. threat, OSP, assumption solutions). The security problem can be solved partially by the TOE (specifying the TOE security objectives countering threats or enforcing OSPs) and partially by its environment (specifying the security objectives for the operational environment countering threats, enforcing OSPs or satisfying assumptions). The first case expresses the elementary TOE responsibility for security, e.g.: "The TOE shall ensure that all users can be held accountable for their security relevant actions." [9]. The second one expresses the elementary TOE operational environment responsibility for security, e.g.: "The TOE operating equipment and adequate infrastructure shall be available (e.g.: operating system, database, LAN, public telephone, and guardian)." [9]. The developer should provide a rationale that security objectives really solve the problem and are necessary. Security objectives represent an elementary security measure.

5. Working out the security requirements.

The security functional requirements specification (SFRs) is elaborated on the basis of TOE security objectives, while the security assurance requirements specification (SARs) is derived mainly from the declared EAL (please note: EALs are predefined packages of SARs). The SFRs are expressed with the use of the functional components from Part 2 of the standard [1], while the SARs are expressed by the assurance components from Part 3. Both kinds of components are grouped in families and the families – in classes representing ordered security issues. The components can be considered the semiformal specification language of Common Criteria. The informally expressed TOE security objectives are translated to the SFR components and they will be implemented in the TOE security functions. For example, the "FAU_GEN.1 Audit data generation." component presents requirements how the audit records should be created and what they should contain. The security objectives for the TOE operational environment are not translated to the components and will be expressed in technical and operational documentation of the biometric system. The set of SARs implied by the claimed EAL can be modified by adding extra components or replacing components existing in the EAL by more rigorous ones (this is expressed by EAL+). The SARs will determine the range and details of the TOE development and the TOE evaluation processes. The security requirements elaboration is finalized by their rationale. An example of SAR is "ADV_TDS.3 Basic modular design." describing the TOE decomposition into subsystems and modules.

6. Preparation of the TOE summary specification (TSS).

The TSS contains the TOE security functions (TSF) derived from the SFRs, functions which should be implemented in the considered IT product or system during the next step – the TOE development process. The best practice is to group the SFRs around the specific security functionality and assign them to the defined TSF which implements this group. The TOE summary specification provides potential consumers of the TOE with a description how the TOE satisfies all the SFRs (presenting details concerning the SFRs implementation). Examples of TSFs expressed by generics (short mnemonics) [12] are: "TSF_FFD Detecting if a finger presented on the sensor is a fake or not.", the "TSF_AUDIT Producing an audit record for every use of the security functions of the TOE.".

The IT security development process provides a set of TOE security functions, which should be implemented, at the claimed EAL. This process can be facilitated by the use of the ST pattern elaborated in the CCMODE project.

Fig. 1 presents the CCMODE Tools – documents generator window with the security target pattern. On the left side the pattern structure is shown, while the right side presents some fields to be filled in by the IT product related data. Some fields are automatically filled in by data from the project knowledge base. On the bottom part some users functions and knowledge access points are available.

Using patterns the developer focuses on the TOE security issues only, not on composing the evidence documentation compliant with Common Criteria. During this work he/she is guided by the advanced help system.

4.2 TOE development process

The TOE development process encompasses the elaboration of the evidences documentation implied by SAR components of the claimed EAL (please note Table 1 placed on page 31 in the third part of the standard [1]).

The evidence material can have different forms:

- documentation, for example: configuration management plan, manuals for the maintenance personnel or for the administrator, security policy of an institution that develops the product, configuration list, procedure of the system installation, delivery procedure, testing documentation, plan of penetration tests, and many other documents of that type which, with respect to their contents, always resulting from proper SAR requirements;
- documented results of independent research or observations conducted by the evaluators, e.g. a report concerning the analysis of the TOE vulnerability and TOE development environment, report from independent testing of the TOE, report from the inspection of the TOE development environment, or a ranking list of risk cases identified in the development environment;
- behaviour or activities of people who play certain roles in the TOE life cycle, for example the roles resulting from a certain procedure (accepting the product of system before it is delivered to the client, etc.); an example of such evidence can be a protocol, note or the so called records, i.e. traces of different operations (activity reports, logs – either electronic or not) recorded in the management system.
- security target or protection profile.

This process of the TOE development includes:

1. Preparation of the ADV (Development) assurance class evidences (architecture, interfaces, design, implementation).
2. Preparation of the ALC (Life cycle support) assurance class evidences (configuration management, product delivery, development process security, used tools).
3. Working out the test documentation (ATE class), including tests specification, their depth and coverage.
4. Working out the TOE guidance documents (AGD class), i.e. manuals and procedures.
5. Vulnerability analysis support (AVA class).

The result of this process are evaluation evidences for the given IT product and the EAL claimed for it.

4.3 IT security evaluation process

The IT security evaluation is performed by an independent security lab accredited according to the existing national evaluation scheme. The basic tool is the security evaluation methodology CEM [14]. The certificates are published in the Common Criteria portal [6].

IT security development and TOE development processes can be conducted in a traditional way – from the basics with the help of consultants, or they can be carried out on the basis of patterns and supporting tools. The developed evidence material prepared with the use of tools is more coherent – thanks to that there are fewer problems during the evaluation.

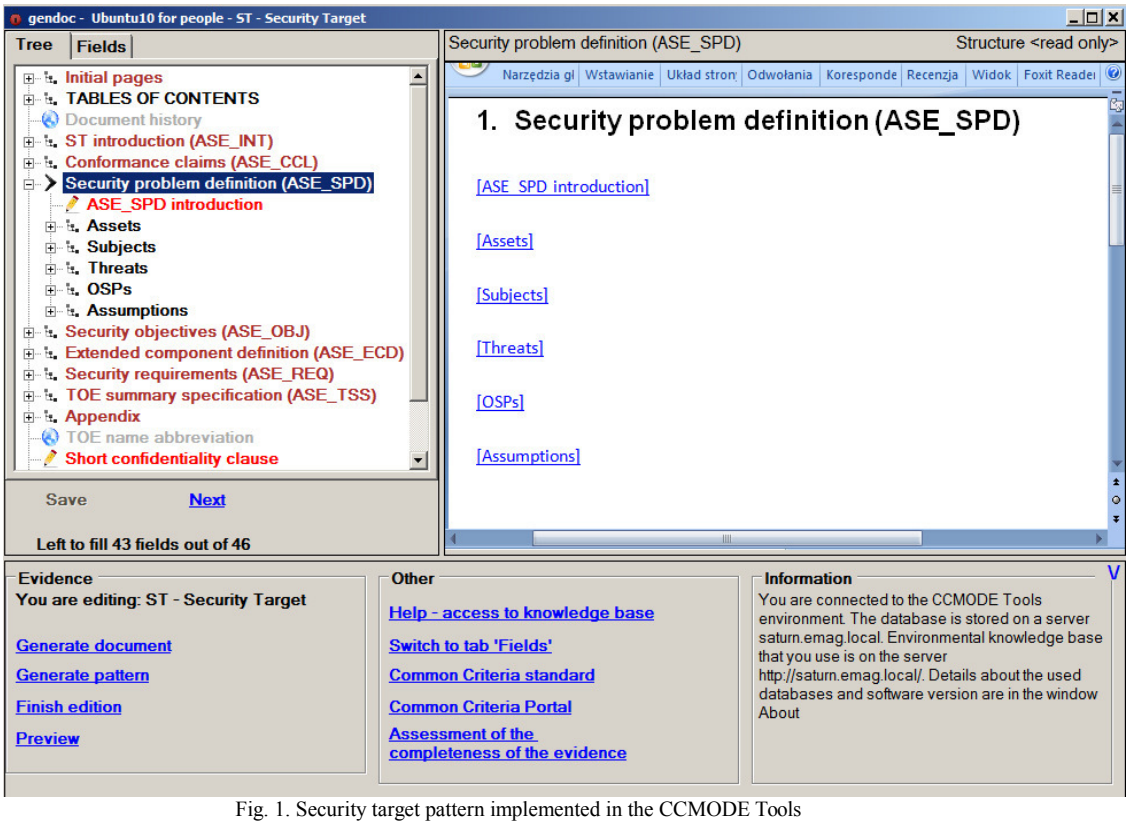

Fig. 1. Security target pattern implemented in the CCMODE Tools

V. Computer aided development of IT products

IT developers, including biometric devices developers, are focused on their products, use technology-specific language and have difficulties to express the results of their work in the Common Criteria specific terms. This standard specifies a set of detailed requirements (SARs) and the developers have troubles how to produce evidences meeting these SARs. They expect assistance by experts or patterns of evidences. Thanks to these patterns they focus only on the product-related issues, not on composing the evidences. Within the CCMODE project such patterns were elaborated as Microsoft Word templates for all assurance components [3]–[4], [15]–[16]. Additional advantages were achieved thanks to the software support of the Common Criteria related processes. The CCMODE Tools for developers [5] was elaborated as a result of the CCMODE project. The Tools encompass:

- project manager module, responsible for initialization of projects and their management in the life-cycle models,
- configuration management module, responsible for the configuration management according to the CC requirements on different EALs,
- Microsoft Word-based GENDOC module designed to work out evidences,
- Sparx System Enterprise Architect (EA)-based module for security analyses and the ST/PP elaboration,
- Subversion (SV)-based module responsible for versioning the project artifacts (including evidences),
- Redmine-based module for TOE design bug tracking and the ALC_FLR implementation,
- Testlink-based module for test development and management (ATE),
- project self-assessment module (CEM compatible),
- auditing module allowing to assess the conformance with different standards,
- knowledge base module for the project management,
- standard-related knowledge.

CCMODE Tools support traditional CC-related projects as well as the site certification concept [17].

VI. Conclusions

The paper presents general guidance for the biometric technology developers with respect to the Common Criteria standard requirements. This standard allows to develop biometric devices with the claimed measurable assurance. The assurance is based on the rigorous methodical development and independent evaluation by an accredited body. The paper provides biometric technology developers with concise information about three basic Common Criteria processes.

The paper draws the readers' attention to certain barriers in the dissemination of certified products, including biometric products. The major barriers are the lack of knowledge and skills among the developers in the use of the Common Criteria standard, high costs of the products development, lack of supporting tools and patterns that would facilitate the use of the CC methodology. The barriers result in the fact that in some IT domains the number of certified products is low. This concerns biometric technologies too.

In the huge number of certified IT products (more than 1,200) only 3 are biometric devices and only 2 protection profiles of biometric products were elaborated and evaluated. The developers point at difficulties in the preparation of evidence material [8]. To help IT developers in this activity, a set of evidence patterns was elaborated and all CC-related development and evaluation processes were computer supported (CCMODE Tools). It is extremely important to have access to knowledge which enables to carry out projects. Therefore the set of tools is supported by an extensive knowledge base.

The CCMODE project focused on the computer support of the CC-related projects management, CC-related security analyses, and pattern-based development of the evaluation evidences. More information about using this tool is placed in [5], [18]. The developers of biometric products who are free from going deep into the nuances of the Common Criteria standard and do not have to prepare the structure and layout of their evidence material from the basics, would be certain to say that their work is easier.

Computer support of the security development process according to the Common Criteria standard is the value provided by the CCMODE project. This is particularly due to the following:

- central management of the project with respect to: roles, development tools (UML, SDK, calibration tools, personalization tools, CAE/CAD, etc.), life cycle models,
- providing CCMODE Tools with the tools to manage the versions and configuration of the product, documentation, faults, tests, security measures of the development environment, and with the tools to conduct analyses, make security models, and carry out audits for compliance and security evaluation,
- providing the developers with proper-structure patterns supported by precise guidelines from the data base about what kind of information should be put in particular fields; these fields are partially filled in automatically with data from the project knowledge base.

These activities are undertaken to facilitiate the developers' work, lower the cost and shorten the time of new products development. This is particularly important in niche-market domains of the standard application, where there are not many products developed. Biometric technology is such a domain.

CCMODE Tools and the accompanying patterns were validated on the basis of several projects concerning software systems and intelligent sensors [4]–[5], [19]–[22]. The paper is an encouragement to take up validation in the field of biometrics. This work should start with the extension of the data base with a subset of generics describing assets, subjects, threats, OSPs, assumptions, security objectives, and

functions that would allow to make and analyze security models of biometric devices.

Abstract—Many carpool and ride-sharing solutions have been proposed and even developed in the previous decades, but rarely have they been able to attain a global user base, at least not up until recently. That was mostly because many of them were not initially designed as scalable, leaving their users with a sub-par user experiences as their user base grew, and often their mobile or desktop client reach was not ubiquitous enough, leaving them available only to a small portion of mobile client devices and/or desktop browsers. This paper describes the design concepts, distribution and cloud computing strategies the authors feel any future global carpool and ride-sharing solution could follow, making it very scalable and ubiquitous enough to successfully reach and serve a global user base.

I. Introduction

THE carpooling, thus also the ride-sharing industry, has only recently started becoming globally interesting. However, carpooling formally appeared in the US in the mid-1970s, after the 1973 oil crisis [1]. At that time the rising costs of using a personal vehicle for transportation of only one passenger made it prudent to drive more than one passenger, usually co-workers commuting daily to and from the same workplace, splitting transportation costs. However, the reduction of oil and gas costs in the 1980s and the breakdown of a typical 9AM to 5PM workday in the 1990s led to a spiral down trend in carpooling popularity. Federal government in the US tried to counter such a trend by giving incentives to carpooling drivers, growing the number of no-toll carpool lanes–the so called, High Occupancy Vehicle (HOV) lanes–across many highways. Those lanes were also allowing for relief from ever growing traffic jams and gridlocks, as the number of vehicles on the roads was ever increasing, which in 2000 exceeded 740 million globally [2] and was projected to be over 2 billion motorized vehicles by 2030 [3]. The sheer number of vehicles alone will create many well-documented problems for urban areas, such as increased traffic, increased pollution, parking congestion, and the need for expensive infrastructure maintenance. To reduce those and also personal transportation costs why not make a global real-time carpool and ride-sharing solution?

This work was not supported by any organization

A. Problems

As said, the expenses, both environmental and fiscal, of single occupancy vehicles could be reduced by utilizing the empty seats in personal transportation vehicles. Carpooling and ride-sharing target those empty seats: taking additional vehicles off the road reducing traffic and pollution, whilst providing opportunities for social interaction. However, historically carpool scheduling often limited users to consistent schedules and fixed rider groups–carpooling to the same place at the same time with a set person or a group of people. To make that problem worse, the leading problem concerns, given in a 2009 survey about why people don't carpool, were difficulty to organize carpools and inconvenience of organization [4]. We feel both of those can be addressed by employing some novel web technologies and modern day available data stores which hold social and location based individual user's data. Besides having to solve the aforementioned problems for making a carpooling and ride-sharing solution that users will want to use, to make it usable on a global scale the ubiquity problem should also be addressed. By ubiquity we mean the problem of having to make it available across both various mobile and desktop platforms, current and future ones, so our proposed solution also utilizes few other rather novel web technologies.

This paper attempts to propose concepts, distribution and cloud strategies that we feel will bring best value for any future global carpool and ride-sharing solution. The rest of the paper is organized as follows: Section II overviews some related work. Section III gives overall design concepts and our objective. Section IV elaborates on our proof-of-concept prototype system implementation choices, with subsections focusing on several specifics. Section V discusses our future work, plans and intentions and finally Section VI concludes this paper.

II. Related Work

As noted, this section deals with existing carpool related work. Subsection A reviews carpool and ride-sharing related solutions currently available and subsection B surveys some of the literature and papers on the subject.

A. Current carpool and ride-sharing solutions

Entering carpool and ride sharing search terms in some of the largest mobile app store and internet search engines returns a great deal of mobile apps and internet websites offering either classic or dynamic carpooling and ride-sharing. Classic carpool mobile app or website indicates that its users effectively schedule and advertise their plans for a trip well in advance, effectively via a searchable electronic bulletin board, seeking other users travelling in the same direction at the same time either in part or fully. Although some of those apps and websites, such as carpooling.com [6] and its mobile client apps have their uses and large user bases, the static routing problems they help solve makes those uses fairly limited.

The inconvenience of having to search though large carpools or even smaller but fixed choice driver groups, hoping to amongst them find a pre-scheduled and advertised trip adequately consistent with one owns schedule, makes such apps or websites non-practical for relatively short and near-immediate on-the-go carpool and ride sharing trip plans. It is for that reason that even [6] and its large network of European subsidiary websites, added advanced time constrained search features to “find a lift”, which to a certain extent alleviate some of the inconveniences for their on-the-go passenger users. However, the added hourly time-constrained advanced searching still inconveniences their vehicle driving users to be mindful of their advertised pre-trip given schedules, even though that may not always be objectively possible, due to unforeseen events such as: road accidents, gridlocks, etc.

Thus, a new form of dynamic carpool and ride-sharing mobile apps and websites is emerging, indicated by their use of real-time passenger requests along with real-time vehicle driving users’ location data, foregoing the need for well in advance pre-scheduled and advertised trips. Amongst some of the most known and pioneering mobile apps and websites offering dynamic carpooling and ride-sharing are Lyft [21] and SideCar [22], screenshots of their mobile apps are given in Fig. 1.

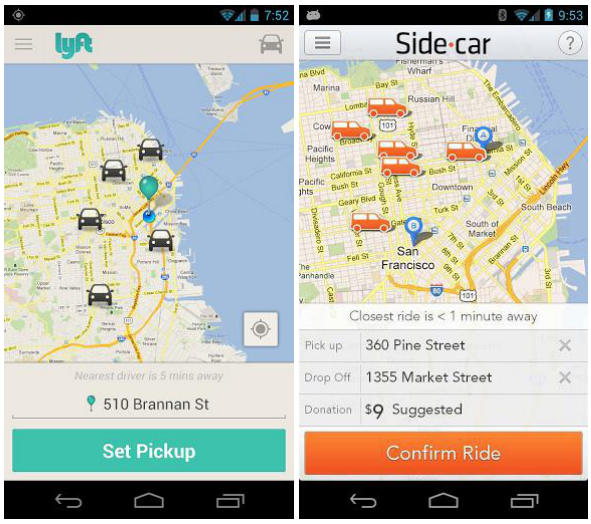

Fig. 1 - Screenshots of mobile applications from lyft.me and side.cr

Both of the listed mobile apps are available for iOS as well as for Android mobile platform, from which screenshots are taken, but neither currently present a web browser user interface. This is probably intentional since both mobile apps are natively written, and by our observations both use TCP sockets to communicate with their respective backend services, so they would both need some changes to make them web-friendly. Unfortunately, those code changes could include some rather tedious transformations because native TCP socket traffic has not been well suited for consumption in web browsers relying dominantly on HTTP, until recently. Another popular application and website named Waze [7], which isn’t predominantly used for carpool and ride-sharing, but for gridlock traffic reporting and avoidance, seems to have however taken another approach. Although their mobile apps are currently natively written, the website does present a "live map" user interface which maps events reported by their users. Such events include pickup requests and replies of passenger and vehicle driving Waze users who are otherwise linked in a popular social network. Unfortunately, access to those real-time events is currently only provided to its iOS app users and not through backend GeoRSS feed via HTTPS. The original GeoRSS XML format is transformed to JSON for easier web browser JavaScript consumption, and presumably for traffic overhead reduction, but is still limited in update interval time. To our knowledge, there are no other globally popular websites and mobile apps that currently allow for carpool and ride-sharing uses using any other drastically different approaches.

B. Current carpool and ride-sharing papers

Because static variety carpool still represents the majority of existing solutions, almost all of the available papers and literature on carpool and ride-sharing mainly tackle the static ridesharing issues, whereby users must pre-schedule their trips, neglecting the dynamic aspect. Despite much of the progress experimented on dynamic carpooling and ride-sharing concepts thanks to the current solutions, it still remains in the early stages regarding publicly available works and literature that deal with its real-time automation. In order to make up for that shortfall, some of the papers which mention carpooling and ride-sharing, and even some that did considered the dynamic aspect [8], in majority also considered other issues beside the static and dynamic carpooling and ride-sharing problems at the same time. Some papers are especially involved in the concepts of traceability, communication and security services, which their authors feel that none of the current solutions evoked, identifying the security issues as one of the main reasons hindering their success [9]. All cited current papers admittedly still provided us with a lot of beneficial ideas and food for thought transferred onto this paper, its findings and conclusions, and out of that still quite disorganized literature which tackles a lot of issues, we have identified some yet non-tackled, laid out in the following sections. Mainly, we take issue with web browser user interfaces and standardized web technologies which seem to be the unifying way forward, putting ubiquity in the grasp of every hybrid web and mobile application.

III. DESIGN

In the previous section we cited some of the current solutions, ideas and issues tackled in carpooling and ride-sharing recently. In this section we are building up on those solutions and ideas, proposing some of our own design concepts for a global dynamic real-time carpooling and ride-sharing solution. Subsection A describes some of design concepts we feel are suitable for a real-time dynamic carpooling and ride-sharing solution. Subsection B further extends on A, allowing for the proposed real-time solution to tackle the problem of being able to serve up to a global user base, adding cloud and distribution design concepts. Finally, subsection C tries to deal with the ubiquity problem, considering the client user interface technology we feel will be future-proof and available on almost all new mobile and desktop platforms.

A. Real-time dynamic solution design concepts

As it was noted in section II, real-time dynamic carpooling and ride-sharing solutions are becoming more common amongst the current carpooling and ride-sharing solutions, although it takes more designing effort to achieve real-time dynamic capabilities than for mere static carpooling and ride-sharing. The reason for the recent increase is obviously because real-time dynamic solutions are more convenient, and thus more likely to be used in greater numbers by end users, but also because some technologies previously used for seemingly real-time communication on the web, have only recently matured and have been standardized.

In the begging of the so called Web 2.0, at the time when real-time updating websites were only just starting to appear, most of those websites used Asynchronous JavaScript and XML (AJAX) [10], which is a group of interrelated web development techniques used on the client-side to create asynchronous, seemingly real-time web applications. Most of those techniques relied upon regular HTTP, a simple request-response and stateless protocol. Having to achieve what was usually two-way communication took some effort for websites and web applications, using various workarounds, techniques involving the use of the browser XmlHttpRequest object or some other web browser plugins.

The first workarounds developed into techniques known as: frequent polling, long-polling and the so called forever-frames. Although all of those techniques were, and still are, very much usable for seemingly real-time web page updates without requiring full page refreshes, they had drawbacks. Their primary drawback was, notwithstanding client-side implementation difficulties, the amount of server-side and network resources they consume. The server is either forced to respond to a large number of frequent requests, or it opens up a number of long running responses, which additionally occupy its hardware resources. On the other hand, using workarounds such as various browser plugins, although less network and server-side resource demanding, turned out to be non-practical, because of the lack of plugin support on current mobile devices. For such reasons, new techniques were developed, and recently standardized by the W3C. As part of the HTML5 specification Server-Sent DOM Events (SSE) were standardized in 2011 [11], but have not yet been implemented by all desktop browsers, namely, Internet Explorer. However, Web Sockets API [12], drafted a protocol back in 2009 currently supported by all major web browsers. Web Sockets provide a full-duplex communication channel over a single TCP connection, thus allowing for a lower network latency time due to less traffic overhead compared to HTTP. Compared to SSE and other polling techniques Web Sockets provide the best option for building real-time communication on the web, and that is why such a protocol is part of our proposed design concept.

B. Distribution and cloud design concepts

Having chosen Web Sockets (WS) as a preferred means of communication, although helping solve latency issues which can lead to a great number of performance problems in building real-time solutions, left another issue unsolved. WS based communication, as all others, still has a limit on the maximum number of simultaneous clients connected to a single server node. Even though that number may be greater when using WS, it still depends on available server hardware resources. Since vertical scaling of server hardware resources can be expensive and still limiting, the solution to the problem is horizontal distribution, across multiple server nodes. Ideally, any global real-time solution would be best served in one's own server farm, but given hardware and its maintenance costs, renting cloud resources works as well. However, for horizontal scaling, one needs to be able to scale data also. Since traditional, i.e. relational data scaling is much harder [13], we have turned to non-relational data (NoSQL). NoSQL databases besides easier scaling, offer better performance in data writes, as well as a possibility of scaling reads onto multiple database nodes, combining sharding and some parallelism approaches. Utilizing the two in a document oriented NoSQL data store that supports geospatial data indexing would make it a perfect fit for our proposed solution and storing our users' location based data. Also, a key-value memory caching NoSQL data store could be used as a messaging backplane for communication between our individual server nodes, but that use is trivial.

C. User interface architecture design concepts

To make a website or mobile app truly ubiquitous, one needs to support as many different desktop and mobile platforms as possible, ideally all of them. Although client applications can be natively written for each platform, there are some unifying user interface technologies for almost all current desktop and smartphone mobile platforms today.

So, to achieve ubiquity, we propose the use of combined HTML5/CSS3 for user interface (UI) rendering. Building the UI around streamed real-time data flows of state changes created by passenger and vehicle driving user events (users requesting rides, user driving busy, user driving free, etc.) is why the paradigm of reactive programming seems to be the perfect choice. Reactive programming is not to be confused with responsive web design, which is also utilized, for same UI reuse across various device screen resolution sizes.

Any changes in state registered by user client applications are asynchronously transferred via WS to distributed load balanced cloud server nodes which are displayed in Fig. 2.

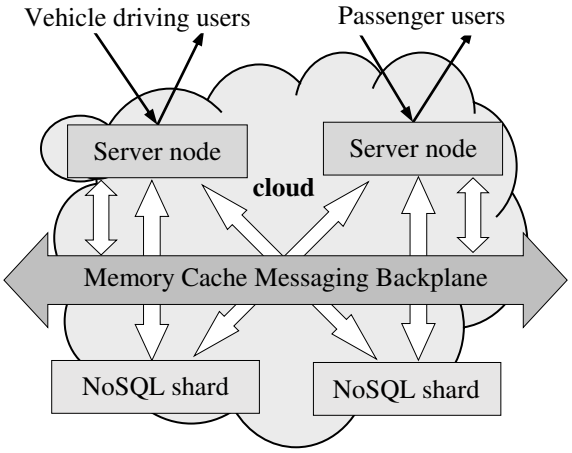

Fig. 2 - Basic design diagram

IV. Prototype Implementation

This section describes in more detail some of the implementation choices we used to build the prototype of our distributable cloud-based dynamic real-time carpooling and ride-sharing solution. Subsection A describes our prototype's real-time communication transport library choice. Subsection B deals with our use of NoSQL data stores for geospatial indexed data and fast memory caching messaging backplane implementation, along with our choices of NoSQL technology and products used. Subsection C goes into some of our UI implementation details.

A. Real-time communication

Having helped develop the first online taxi dispatching solution in Serbia, realized in .NET and being cloud-hosted on Microsoft Azure [14], influenced a lot of our primary technology choices for the prototype of a real-time dynamic carpooling and ride-sharing solution to be described here.

As noted in the design section, the need to have a real-time dynamic carpooling and ride-sharing solution is imperative, since those solutions are what most users currently wish to use. To make our prototype solution real-time capable, the choice to implement it using a library capable of WS protocol communication in .NET came down to a library named SignalR [15]. SignalR is an open-source library for ASP.NET to add real-time web functionality to .NET applications, adding the ability for server-side code to push content to the connected clients as it happens, in real-time. SignalR server is capable of supporting clients written in .NET, JavaScript and some other programming languages. The server-side code can push content to those connected clients via a number of transport techniques, most suitable being bi-directional WS, if available. For a server-side the WS transport requirements are either a self-hosted ASP.NET 4.0 application or one hosted within Internet Information Services (IIS) 8. Server-side hosted on earlier versions of IIS fallbacks to other means of message transports. For clients, WS requirement issue is a bit lengthier to describe, so it is listed in better detail in the client UI subsection.

B. NoSQL implementation

Since IIS 8 was our prototype's hosting platform of choice, it should be noted that the server node could then only have been hosted within the Windows 8 / Server 2012 OS platforms. Fortunately, Windows Server 2012 was made available to end-users on the Windows Azure cloud platform as a virtual machine operating system choice since late 2012, and it is deployable onto an Extra Small machine instance. Extra Small Windows Azure instance, which entails a shared core processor with only 768MB RAM, may not be the first choice from a performance standpoint. However, it is sufficient for proof-of-concept deployments and for limiting cloud-hosting costs.

Deploying SignalR server-side code alongside a NoSQL key-value memory cache data store named Redis [16], with the minimum amount of RAM allocated to Redis, produced a fully functioning server node capable of serving a test number of simultaneous users. Since a new server node can be cloned, and any cloned node's Redis instance can then be easily subscribed to a Redis instance of an existing node, we can easily increase the number of new server nodes to meet all of our scaling needs. Scale out is so easily achieved in part due to SignalR's in-built scaling mechanisms, which uses Redis pub/sub features for a messaging backplane. Each SignalR server node could then, through its Redis instance, be notified of any new WS communication channel needed in real-time. The load balancer of connected computing cloud instances, which is built into Windows Azure, takes care of diverting traffic to a SignalR server node best able (least busy) to process any incoming new or reoccurring real-time request. But since each node has then been notified, by its Redis instance, that such communication has taken place each channel should be reusable by any other SignalR node, so each node is capable of replying to any real-time request.

Beside Redis NoSQL, our prototype incorporated another NoSQL document-oriented geospatial indexing data store for ease of scaling, named MongoDB [17]. MongoDB allows for rapid storing of user current locations by extensions to the stored location data, incorporating another key value used for sharding of that data across multiple MongoDB store instances. Data sharding approach allows for quicker reads since our shard key represents a geographical area within which our users are seeking or soliciting ride request during their relatively short trips. Thus, sharding increases read performance by reducing the amount of indexed data being queried in each MongoDB instance, because that data gets spread out across multiple data store instances. By adding MongoDB's built-in MapReduce (MR) to our queries the tasks of searching through sharded data execute in parallel.

Also, MongoDB by itself incorporates some replication set mechanisms, giving it a highly-available aspect as well, which bodes well with the SignalR's ability to distribute via Redis as a messaging backplane, reducing single points of failure.

C. User interface

Finally, for ubiquity reasons, our choice of prototype client UI rendering technology incorporated HTML5/CSS3. Having previously built a fully functional HTML5/CSS3 client for a commercial online taxi dispatcher, which was wrapped as an app using a mobile development platform named PhoneGap [18] runnable across various mobile platforms, we felt confident that HTML5/CSS3 was also a right choice. Both desktop and mobile web clients shared the same JavaScript logic codebase which offered unified access to geolocation [19] features of the devices they all ran on, a must for a dynamic carpooling and ride-sharing applications. The look and feel across smaller resolutions changes accordingly, but not drastically, by utilizing responsive CSS3 design incorporated in jQuery mobile [20] as of version 1.3.

All the clients also use a reactive programming paradigm, connecting to the backend via code using the Reactive extensions for JavaScript (RxJS) library [21]. This means the user interface responds asynchronously to user actions and events which they result as, either events which are streamed from the server-side generated by other users and fed via WS to all supporting clients, or user's own events. If, per chance, the mobile device's web browser does not support WS transport, SignalR client in JavaScript will gracefully fall back to other means of seemingly real-time transports, which RxJS will still continue to process as asynchronous events.

Support for WS as a mean of communication transport, depends primarily on a platform web browser's capabilities which is for current desktop and mobile web browsers given in Table I.

TABLE I.
WEB BROWSER SUPPORT FOR WEBSOCKETS

Web browser	**Supported since version**	**Supported**
Internet Explorer	10.0 (fully)	Yes
Firefox	4.0 (partially) 6.0 (fully)	Yes
Chrome	4.0 (partially) 14.0 (fully)	Yes
Safari	5.0 (partially) 6.0 (fully)	Yes

V. Future Work

Having described some our prototype's implementation details (Fig. 3) our future work and plans envision for it to be deployed and tested in the real-world. Since the prototype clients were based on previous work done for a commercial online taxi dispatcher, it will be initially tested and deployed as part of that solution in limited numbers. Early adopters of the online taxi dispatching service will get the benefit of being able to track a few assigned taxis in real-time. Drivers of those taxis will be either issued mobile devices with pre-installed HTML5/CSS3 web clients and/or those client apps will be installed on their own devices. Such real-world tests will hopefully lead to identifying problems not yet foreseen. Once a stable solution is reached the prototype could and will become a standalone service, open for public use and not just for taxi dispatching and the cost of its operational maintenance could then also be better estimated. If deemed low enough to be offset by ad support according to [20], its use could be completely free for end users unlike [21, 22].

To reach that point however, some other issues, such as security and privacy, will also need to be tackled. In [5] the solution for the security and privacy issue was implied by use of a 3rd party location based service (LBS), which used OAuth protocol to authenticate and subsequently authorize which exact set of users would be allowed access to the authorizing user's location. Unfortunately, come February 2013 the 3rd party LBS was shut down, and an alternative solution should either be found or developed prior to prototype's launch as a standalone service. Trying to avoid the repeat of having to find alternatives to a 3rd party components not being operational any more, the focus could be on building up own LBS features respective of privacy, but relying on information which can be provided from popular social networks. To aid us in that endeavor, instrumental part of the puzzle could be Windows Azure built-in Access Control Service (ACS), allowing for users to single sign-on to the proposed carpool and ride-sharing service just as if they were signing into the aforementioned social networks. If those users comply, their location data could then only be made accessible to a subset of their social network friends, a widely acceptable solution from a current privacy standpoint.

VI. Conclusion

This paper tried to underscore the need for developing dynamic real-time carpool and ride-sharing solutions, instead of already outdated static ones, by employing some novel web technologies and approaches. Since a prototype has been successfully developed following the outlined design concepts, distribution and cloud strategies, it is obviously possible to build other such solutions using the same approaches. Especially interesting is the possibility to develop a web platform application that runs across multiple devices and their web browsers, be they mobile or desktop. Using an open-source jQuery mobile library and Apache Cordova [23] mobile developer platform, which was derived from PhoneGap, is what interests us the most and we feel could be the unifying tools for any future service supposedly usable across multiple operating systems, current and future. Combining those with some other frameworks which use the HTML5 UI elements such as the canvas tag thus adding the ability to render graphical data such as street level maps for carpool should, by our position, be the leading way forward.[i]

***Abstract*—Advances in web services and open network interfaces enable development of new user-oriented applications in different areas of digital life. Among them, digital entertainment is one of fastest growing networked application domains. Technologies like CDNs (Content Delivery Networks) and HTTP streaming opened the way for new models of TV and video consumption over the Internet. Thanks to emergence of new networking technologies and cooperation paradigms the distinction between traditional TV and the Web is slowly blurring, creating new category of TV entertainment which is more interactive, delivered over multiple screens and inviting users to participate and collaborate.**

This paper presents research on selected social and interactive TV services, focusing on innovations related with incorporation of network interfaces and web protocols. Two use-case scenarios are investigated: one of them explores telco 2.0 interfaces for interactive videos, and the other allows users for social exchanges while watching live sports events. The evaluation results by qualitative user study are presented for the second use-case. A technical architecture is introduced, focused on seamless integration into a typical WebTV platform of telco operator. As important contribution of the paper, some new emerging network protocols and features (like telco 2.0, WebRTC, WebSockets, HTML5 video) are evaluated as potential enabling technologies for future social and interactive TV.

I. Introduction

With the proliferation of IPTV and WebTV content delivery, the TV viewing experience is changing from predominant "lean-back" (passive) viewing habit into the new era of "lean-forward" behavior. People demand more interaction, participation, and social features in addition to just watching the TV. The actors on TV services market (content providers, service aggregators, telco and cable operators) are facing a number of challenges, from the point of view of usage, business and technology, how to integrate the new social and interactive experience into their established service platforms. This paper aims to study selected scenarios for future evolution of social and interactive TV programs, focusing on opportunities brought by new telco network interfaces and web services technologies.

A technical architecture for proposed use-cases is studied from the point of view of telco operator, aiming to integrate new features by leveraging and extending existing TV distribution systems. Special focus is put on OTT (Over-The-Top) content delivery model. The OTT model usually refers to content providers and 3rd party companies who directly access their customers over open Internet. For telecommunication network providers, OTT model starts to be considered as a viable alternative, allowing for addressing additional customers and complementary to the managed IPTV solutions that are still predominant [1]. The OTT content delivery architectures typically use HTTP streaming protocol (e.g. MS Smoothstreaming or Apple HLS) and a CDN (Content Delivery Network) for video distribution over unmanaged Internet with optimal QoE (Quality of Experience).

This paper aims to answer the following research questions:

- From service point of view: what are the realistic and compelling usage scenarios for social and interactive TV?
- From architecture and technology point of view: what are the opportunities brought by new emerging web protocols and network interfaces?

These questions are addressed through analysis of two use-case scenarios, namely:

- Scenario#1: interactive immersive video,
- Scenario#2: social exchanges between spectators of live sports events.

II. Interactive content

The first concept presented in this paper belongs to the category of interactive videos. With interactive video, the movie becomes a kind of immersive game where different story variants may be displayed depending on previous decisions of a viewer. Although interactive videos will probably not enter the mainstream movie industry in the short term at least, they could be appealing for selected types of video production like short artistic movies, instructional scenes, or video games.

The interactive video concept has been known for some years and it has been used for example in DVD interactive games. More recently, it has become quite popular with YouTube service, which offers tools for creating interactive videos. The user may control the video by clicking buttons displayed after the end of particular clip and leading to different variants of the story (see e.g. semi-amateur video [9]). The work presented in article [10] follows the same concept, although removing some of its limitations. The transitions

978-83-60810-53-8/$25.00

between video clips are seamless and more deeply embedded into narrative of the movie. The authors of [10] provide some guidelines for scriptwriting and shooting interactive videos and identify interaction goals for the viewer: to influence the story, to change the perspective, or to see additional material.

The related works mentioned above have a common limitation: the interaction tool and interface for a user is basically a computer mouse. The viewer has to click a button or an area on the screen to make his decision regarding the storyline. This is not very natural, and feeling of immersion is broken at the time of interaction. On the contrary, interesting video referenced in [11] presents an experiment, where mobile phone has been used as interaction tool. A natural conversation has been imitated between the viewer and the character on screen. The outcome of this conversation has been taken into account in the movie storyline. Interrogated user has been selected among the cinema theater audience. A computer system has called his or her mobile phone and conducted a simple dialog using voice recognition technology.

The approach taken in our project is similar to [11], but not limited to the audience of cinema theater. We propose integration of interactive video system into the WebTV content distribution architecture. Any client located in the Internet could watch and control the interactive video. Like in [11] we use the mobile phone (which is a natural tool for inter-personal communication) to imitate a conversation between the viewer and character on the screen, preserving the feeling of immersion into the fictional story.

A. Usage scenario

Fig 1. exhibits our Interactive Video prototype in use. We have produced a short example movie, not targeted for wide distribution, just for demonstrating the potential of proposed system. The movie protagonist consults the viewer before taking crucial decisions for the storyline. For that, in certain moment the system calls the viewer's mobile phone number, previously entered on a web page. The viewer can hear character's voice on his mobile phone (e.g. a phrase "*tell me if I should take the elevator or use the stairs*"). Then he may answer "*yes*" or "*no*" and in the next video scene the protagonist follows the viewer's advice. All actions are synchronized between the video and real life, i.e. the viewer's phone rings at the exact moment when movie character makes a call; the protagonist starts speaking when the user picks up the call, and during conversation the same voice can be heard on the phone and in the video. The movie character interrogates viewer for his advice in several crucial moments in the story, and the movie has three different endings depending on user's answers.

Thanks to our system the user can feel an illusion of real communication with fictional character while watching the video and is empowered with possibility to influence the story.

B. Architecture and enabling Technologies

A prototype has been developed to demonstrate service concept and serve as playground for evaluation of some new

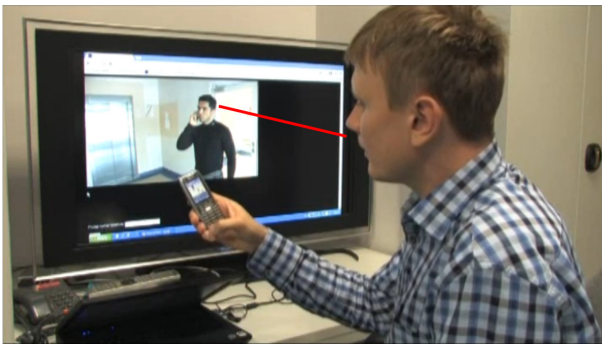

Fig. 1. Interactive video prototype

interesting technologies that may impact future interactive TV. The prototype schema is presented in Fig 2.

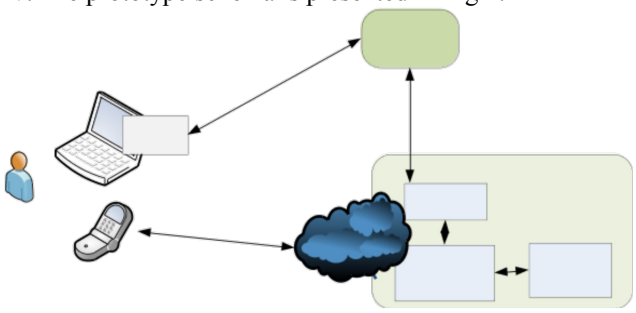

Fig. 2. Architecture of interactive video system

WebSocket and HTML5 video

As design goal, the Interactive Video service should be available for any Internet user equipped with PC computer with a standard web browser, without need of additional software or plugins. Thus, in our architecture the server side hosts logic of interactive movie and controls the sequence of videos that should be played to particular user, depending on his individual interactions with the system. So, the server must be able to send some kind of commands to user's video player (which is embedded in his web browser). This command has to be sent in asynchronous way, i.e. without preceding request from the client. Asynchronous communication is not a usual mode in the client-server world of Internet. There are some techniques to overcome this limitation, e.g. by frequent polling of server by the client, but they can be very inefficient in terms of traffic and processing overhead if one wishes to achieve a timely response. In addition, popular technologies for implementing video player plugins, e.g. Adobe Flash or MS Silverlight, do not allow easily (or not at all) for server-side control of the video player. The player can be controlled from the user-side by mouse clicking on displayed buttons, but the external program has no possibility to change the video that is played, in arbitrary moment.

HTML5 framework [7] comprises some prospecting technologies for solving the limitations mentioned above. The HTML5 video tag enables playing the video natively by a browser. In addition, the video player can be externally controlled by JavaScript code, which in fact facilitates implementing interactive videos over the web. Another HTML5

feature we have investigated is WebSocket [12], an asynchronous protocol allowing the server for sending messages to the client in arbitrary moment. To establish a WebSocket connection, client browser sends a WebSocket handshake request (special HTTP GET message) to the server. Once the WebSocket connection is established, data frames can be sent back and forth between the client and the server in full-duplex mode. Thanks to HTML5 and WebSocket we could implement interactive video scenario as a standard web application, not requiring installing any additional software on the client machine.

For watching an interactive movie, user opens a web page hosted on Interaction Controller server (see Fig. 2). A form for entering a phone number is displayed, as well as "Start" button for launching the video. When a user clicks it, the browser opens WebSocket connection with the Interaction Controller server. A timer process is started for the new user, to control video playback. The timer process will trigger a sequence of user interactions (phone calls at specific times) and video clips, according to pre-programmed scenario.

To play certain video, the Interaction Controller has to send a command to the client browser to open appropriate video file. For that, the server uses WebSocket connection opened at the beginning of the process. The command is interpreted by JavaScript function run by the browser, and it tells browser to stop playing current video and start a new one, available under specified link. The video file is retrieved and played either until it ends, or until next command from Interaction Controller server is received.

Telco2.0 API

The server triggers interaction with a user by invoking advanced Telco 2.0 API functions. Telco 2.0 is a concept of exposing telecommunication services (SMS, call control, location, etc.) through open APIs to external developers. HTTP REST or SOAP is usually used as invocation protocol. Telco 2.0 interfaces are implemented by many network operators and API standardization efforts are recently taken by GSMA organization [13].

Advanced voice API service that we have used allows for establishing a voice call between user's phone and IVR (Interactive Voice Response) machine. IVR is a telecommunication system which controls automatic dialogs with the user. It is typically used by customer relation systems, e.g. when you call a hotline and hear a recorded message *"press 1 to reach customer service, or 2 to report technical problem…"*. In our case, the IVR system has been programmed to play an audio file with recorded voice of the movie character. A user may answer to question asked by the character with almost natural language (in practice, for the purpose of the prototype just simple phrases were used like *"yes/no"*). The ASR (Automatic Speech Recognition) system is then engaged for voice analysis and matching the answer with pre-configured phrases. Finally, the Interaction Controller server is notified about the user's answer to the interaction question. The server, knowing the user's response, chooses appropriate variant of the story and accordingly commands playback of a video file using HTML5 features as described previously. The interaction process is executed in real-time, i.e. there is no perceived delay between the decision expressed in phone conversation, and effect observed in the video.

Evaluation

The concept has not been tested by real users, as we recognized that user's perception and perceived usage benefit depends a lot on a story that is being told by the interactive video. As we only had possibility to produce a simple amateur video as a proof of concept, the user tests would be too much biased by assessing the video (narrative and artistic quality) instead of potential offered by new technology. However, internal tests done with the prototype gave us some interesting insights on the technical and usage aspects.

On the technical side, new web-oriented technologies and protocols like HTML5, WebSockets, Telco2.0 API, have proved their merits for supporting interactive video scenarios. The proposed server-based architecture correctly manages execution of interactive video and allows for providing it as a service to WebTV users. The voice API has been confirmed as powerful tool for carrying out automated voice-based dialogs with users.

Some usage tests have been performed, however only by project members and thus the trustfulness of results is limited. Anyway, based on the feedback of this limited experiments we can confirm that the interactivity is fluid and switching between consecutive videos is almost seamless. Feeling of immersion in the story is genuine and experiment participants could admit that conversation with fictional character was really funny and enjoyable for them. As a drawback we can mention that the automated dialog and voice recognition technology is still not perfect when user says a phrase or sentence that is not understandable or unexpected. As a hint for future work, such situation should be covered in the interactive video scenario, e.g. the movie character should keep on asking viewer for repeating his answer in the case it had not been properly recognized by the system.

III. Social Interactions Around Sports Events

Social TV is recently an often discussed trend in media industry. In fact, this term covers a wide range of scenarios and applications. As a general consensus, Social TV refers to services where TV watching experience is augmented with some forms of inter-personal and inter-audience communication.

The scenarios where content (i.e. a TV show or a movie) is a trigger for social communication, have been studied in numerous related works. For example, paper [2] distinguishes two types of communication around content: synchronous (while watching TV, e.g. through text or voice chat) and asynchronous (after watching, e.g. by leaving notes or recommendations for people who will watch the same content at another time). The authors of [2] have analyzed impact of TV genres (like movies, news, sports, soap operas) on social activities of people. Apparently, sports is one of the genres that is the most "talked about" while

watching, i.e. is a good candidate for social TV system supporting communication in synchronous mode. Intuitively, we can expect that watching sports triggers intensive emotions, and it is natural for us to share these emotions with others, especially friends and relatives. In addition, contrary to films or documentaries, sports do not have strict plot-oriented structure and do not require full viewer's attention all the time. There are usually some breaks and low-activity periods when the action on screen is not so absorbing and the social exchanges at that time would not interrupt watching experience so much.

The social communication aspect can be realized through (1) existing social networking services like Facebook or Twitter, (2) a dedicated application, or (3) enhanced TV service delivery platform. As an example of the first approach, paper [3] presents exhaustive report on how Twitter has been used by producers of popular TV reality show X-Factor for enabling inter-audience communication during and after the show. Interaction with the audience by interactive communication channels and 2nd screen has become an intrinsic part of TV show format. The example of second approach is GetGlue [4], a popular application for sharing and exchanging comments while watching TV shows.

In our approach, the communication features are even more closely integrated into the TV viewing experience thanks to implementing them as part of live TV content distribution architecture. We propose a Social TV system that is specially designed for sports programs and adapted for using during live TV transmissions. Our solution enables social exchanges among friends and fan communities.

A. Usage scenario

In our scenario, social communication around sports events has two "dimensions". The first one concerns exchange of messages, photos and user-generated videos between people who are physically present on the tribunes (e.g. of a football stadium), and those who stay at home and watch live transmission on their TV set or PC computer. Using special mobile application, spectators at the stadium may share emotions and comments with viewers at home. After launching the application, user may select the "event" he attends to. The "event" is configured by service provider and it corresponds to particular match or concert. Then, the application role is twofold. First, it allows for browsing and watching the messages, photos and videos sent by other spectators of the same event. Each message may be commented (by adding text) and ranked by clicking on an icon of a thumb. Second, most important, the application allows for quick upload of your own content after clinking on "send message", "send photo" , or "send video" icons.

Uploaded messages are displayed in real-time on top of the video watched by users of WebTV service. Special video player has been developed using MS Silverlight framework. It displays incoming messages as a scrolled list on the right side of the screen, with preview of picture or video content appended to the message. Viewer may enlarge each message to see its rank and associated comments. He may also add his comment and rank the message in the same way as users of mobile application. Thanks to our system people at home may have a glimpse of stadium atmosphere, which is shaped by fans supporting their players. Example screenshot of WebTV player, displaying a gallery of photos provided by fans at the stadium, is presented in Fig 3.

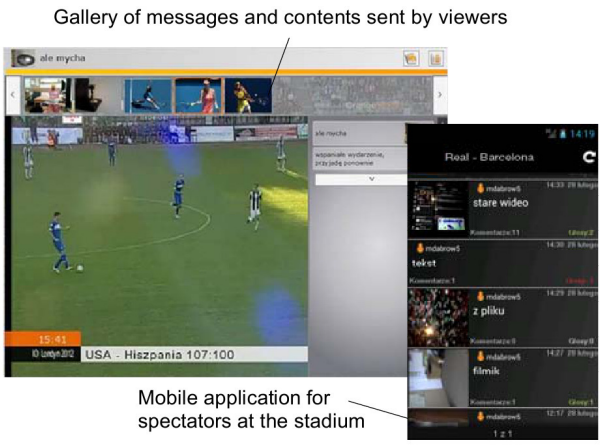

Fig. 3. Sharing photos/videos between spectators at the stadium and viewers at home

Remark that our service concept is a bit similar to FanFeeds, described in article [5]. FanFeeds is a system for aggregation and presentation of additional content-related media on 2nd screen while watching the program. This supplemental information can be contributed by people (from our social group, or strangers) who are watching the same content. The authors of [5] present the prototype concept and results of field trial, which thoroughly investigated people's motivations and incentives to communicate over content. The need to exchange comments during watching the content has been confirmed through trial results. Basically, we enable sharing comments between viewers of a live event in similar way as FanFeeds. However, in our approach we specifically focus on connecting two groups of people: spectators physically present at the stadium, and TV viewers at home. In this way, a fan community can be created by spectators of a sports event, regardless if they attend it physically or at home on TV.

Another dimension of social exchanges around sports events, that we consider in our system, is real-time interpersonal communication. With our service, friends or relatives can watch the televised event together despite being apart in their homes. Real-time communication by text chatting while watching TV has been often mentioned in literature and for example article [6] presents an advanced social TV system based on chat. Real-time voice and video communication is less popular, as it is more challenging from the usability and also technical point of view (a user device equipped with camera is certainly required). The experience of videoconference while watching TV may be replicated by using external application, like e.g. Skype, launched on a PC computer. We take a different approach, by integrating videoconference into the TV content delivery system, providing user with a single interface to access TV service together with the social features. PC and camera is currently required to run the service, while in the future an STB

equipped with camera could also be envisioned. Thanks to group management and presence service a user may see that his friend is watching the same sports program, and invite him to watch together. Fig. 4 presents exemplary screen layout with two participants watching together a tennis match.

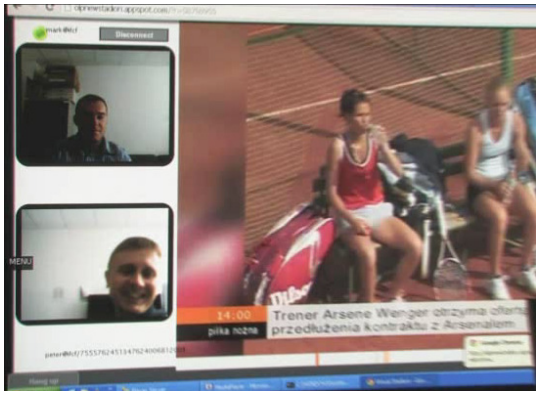

Fig. 4. User-to-user communication while watching TV show

We can say that people who have joined the service are gathered on a "virtual stadium" and constitute a kind of social circle of virtual supporters. They may communicate by voice an they can see each other. In addition, they may take part in quizzes or small games. In our developed prototype, the quiz questions are moderated by service operator and sent to all participants at the same time.

B. Architecture and enabling Technologies

A proof-of-concept prototype has been developed to verify viability of the use-case (concerning both dimensions of communication as described above) and maturity of enabling technologies. It extends typical OTT-based content delivery system with components for managing social exchanges and inter-personal communication. The prototype schema is presented in Fig. 5. On the server-side we distinguish the WebTV platform, which groups content preparation and distribution functions (encoding using H.264 standard, and streaming with adaptive protocol MS Smooth-streaming). The streams are delivered over CDN (Content Delivery Network). The social TV features are provided by two servers. The "Virtual Stadium" server provides clients with a main service web page and manages real-time communication: users identification and presence, as well as groups and videoconference participants matching. The videoconference media is exchanged in peer-to-peer mode between communicating clients by WebRTC technology. The "UGC server" handles functions related with non-real time communication mode. It aggregates messages submitted by user's smartphones (an Android application) and stores associated contents as JPG and H.264/MP4 files. For enabling unified display of UGC messages overlaid on TV content, a special video player has been developed with Microsoft Silverlight.

Although most of the technologies used for the prototype are standard and widely known, the WebRTC merits some attention as it is relatively new and can be considered as very promising for communication services over the Internet.

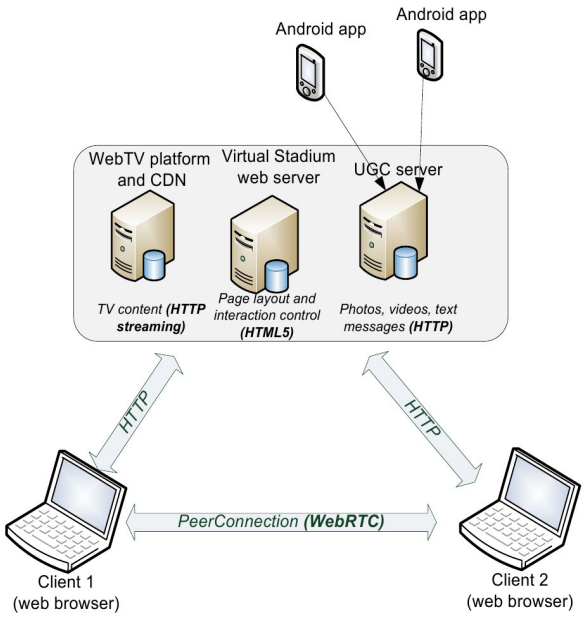

Fig. 5. SocialTV prototype architecture

WebRTC

WebRTC is part of HTML5 framework [7] and it enables embedding real-time communication component within a web page. The communication session is handled directly by web browser, without need of any software plugin. WebRTC [8] defines a standardized browser API that can be invoked using JavaScript by web applications for services such as voice and video calls. WebRTC is subject of ongoing standardization works in IETF and W3C.

The client (see Fig. 5.) opens a "Virtual Stadium" web page on his PC computer. A Silverlight player downloaded from the web page provides access to live TV content through connection with WebTV platform and CDN (Content Delivery Network). When a user decides to connect with his friend, Virtual Stadium server is invoked to generate a session token that is shared by web browsers of communicating parties. A WebRTC peer-to-peer connection is then established between them, for direct exchange of videoconference media (audio and video), all displayed on the same web page as TV stream.

Thanks to WebRTC technology the videoconference service could be seamlessly and easily integrated into the WebTV content distribution architecture.

C. Evaluation

Apart from assessing technical maturity, important goal of research work was to evaluate potential market adoption of the Social TV service. Qualitative tests with real users were conducted for this purpose, using methodology of Focus Groups Interviews (FGI). Four sessions were carried out, each with 6 participants recruited by external agency with regard to typical Social TV user profile that is: age 21-40, people watching matches, concerts, etc. either live or via

web TV, active users of social networking, video-chat applications, internet chat rooms and discussion forums. The goal of the test was to survey reaction of potential users to the Social TV service concept, determine factors which encourage people to use the services and identify any usage barriers. During interviews, service concept and demo videos were shown to participants, followed by a guided discussion on perceived benefits and flaws of the presented concept.

We can conclude from the interviews that users positively perceive the service as meeting their need of sharing comments and emotions while watching live events on TV. The opinions gathered during experiments confirm findings of [2], saying that sport is one of the TV genres that especially trigger social exchanges. Watching live sports is related with strong emotions, which are best experienced in a group. We may quote of the test participants: "*When you're alone, you don't feel the thrill. You have no one to experience it with.*".

Referring to possibility of sharing messages and photos between spectators at the stadium and viewers at home, interviewed persons appreciated the feeling of being a part of live event, thanks to access to additional content sent by participants in real time. Moreover, they liked the possibility of seeing more than is shown by the camera in a typical broadcast: "*At such an event, you cannot be everywhere at once. And we all know that everybody pays attention to slightly different things.*"

The aspect of sharing emotions and experiences has been appreciated by test participants. The impression of watching the event in the company of others, being in connection with the fan community, is important.

The respondents pointed also to some limitations of the concept. A bias has been detected between the benefit perceived by viewer at home, who enjoys additional supplemental content, and benefit of people at the stadium, who may not have sufficient motivation to use our service. We think that possible ways to increase the perceived benefit for users at the stadium are: a competition for spectators (win a prize for best photo from the tribunes), or adding a gamification scheme (collect points and rewards for sharing). Test participants advocated also for possibility of creating user groups and sharing comments within a closed social circle instead of general population of TV viewers. Comments collected during the tests certainly give us interesting hints for future development of the service. A field trial is planned in spring 2013, where the prototype will be evaluated during a real football match event.

As main benefit of Virtual Stadium use-case people mentioned possibility to share opinions and comments with friends immediately during live TV broadcast. The interviewees emphasized the difference between exchanging comments on the event while it was still on, with sharing them after the event is over. The respondents agreed that they saw a greater need to share emotions during the event than after it was over.

Although some concern has been raised that interactivity may disturb perception of the event, participants noticed that while watching sports there are usually some less exciting moments, when conversation with friends would be hardly disturbing for the viewing experience.

Some test participants have previously used other tools for communicating with friends while watching TV: ("*I once watched a match over Skype with a friend who was in South Africa then.*"). Nevertheless, the idea of all-in-one service, integrating several currently used tools has been appreciated as making the experience easier to use. The respondents liked also the fact that it would be available simply in a web browser, without need to install additional software.

Quizzes and games during the match have been judged rather controversial. People find it annoying if the quiz question pops up suddenly on the screen, covering the broadcast. The quiz component has to be designed with great care, being less intrusive and providing sufficient benefit for the users to participate (rewards, competition, possibility to show-off your knowledge in the area, etc.).

Another critical comment concerned current limitation of videoconference to only two participants. Sometimes there is a need to comment or discuss in a larger group. In future works the videoconferencing system should be extended for multiple users.

IV. Conclusion

The paper has discussed several exemplary realistic scenarios for TV services of the future, focusing on opportunities brought by new advances in network interfaces and web protocols. The interactive video use-case assumes imitating a voice dialog between the viewer and fictional character of the movie. Social TV for sport programs allows for two types of inter-audience communication: sharing of comments and photos between spectators at the stadium and viewers at home; and videoconference connection between friends while watching live sports event. The scenario has been evaluated, with positive feedback, by small scale user test.

For all presented use-cases a technical architecture has been designed and prototyped, assuming full integration with OTT-type content delivery architecture of a telco operator. The service logic is implemented by dedicated server components, and standard web browser is used as unified client device for content consumption as well as for social features. In the case of interactive video, mobile phone is employed as second device, using its most natural function, that is a voice call.

Several emerging technologies have been evaluated considering their potential for enabling interactive TV. Among them, HTML5 and WebSocket overcome limitations of traditional web architecture for interactive videos controlled from the server side. Advanced Telco 2.0 interfaces can be used to engage with the viewer through his phone. Mobile applications and open web services interfaces allow for quick and easy upload of user-generated text and contents. Finally, WebRTC is a promising framework for integration of content delivery and inter-personal communication within a web page.

***Abstract*—This paper describes principles of the data communication in the distributed database system AD-DB developed by paper authors. The database system is designed to function properly in such a complex and dynamic network as the VANET is. That way, vehicles connected to the VANET could distribute traffic related data to others.**

I. Introduction

VANET (Vehicular Ad-hoc NETwork) is the field of important research nowadays. Many are trying to develop new principles to make it possible to distribute information through this network. Applications for VANET could be divided into two categories: safety applications and comfort applications. Safety applications are more important ones. They are focusing on distributing information about traffic accidents, obstacles and other safety hazards to as many vehicles as possible [13][14].

VANET is defined to be a special case of MANET (Mobile Ad-hoc NETwork) where network nodes are represented by vehicles in a road traffic. But problems with distributing data in VANET are completely different from the MANET ones. MANET nodes as computers with limited power source and limited computing resources have to communicate in small time frames to preserve as much power as possible. All research of the MANET communication is about minimizing communication and computing time and about conserving node power.

On the other hand, almost all of VANET nodes (vehicles in road traffic, road infrastructure) have good power source. So research in this area is focusing on the best way to distribute information for all nodes that are interested in it.

II. State Of the Art

A. Classic Architecture of Distributed Database System

Architecture of DDBS from data organization point of view is shown at the figure 1. It is simple layered model with four layers. Each one of them represents some view on data itself.

There are four layers of distributed database system, each modeling one kind of view on distributed database [1]:

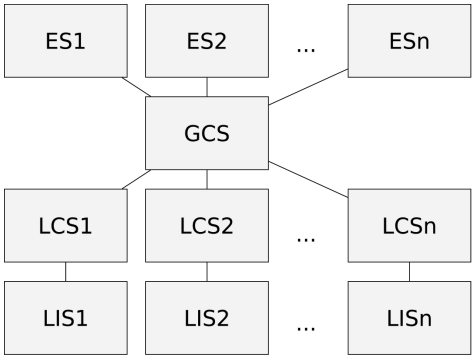

Fig 1: DDBS reference architecture [1]

1. *LIS (Local Internal Schema)* represents physical representation of data stored at one node. It is analogy of internal schema from centralized databases.
2. *LCS (Local Conceptual Schema)* describes logical organization of data at one node. It is used to handle data fragmentation and replication.
3. *GCS (Global Conceptual Schema)* represents logical organization of data in whole distributed database system. This layer is abstracting from the fact that the database system is distributed.
4. *ES (External Schema)* represents user view into distributed database. Each external schema defines which parts of database is user interested in.

The fact that the user is using only global conceptual schema through views defined in external schema, assures that the user can manipulate with the data regardless of its position in the distributed database system. Therefore it is necessary to have a mapping from every local to the global conceptual schema. This mapping, named GD/D (Global Directory/Dictionary), is defined as part of the distributed database system.

The main role of GD/D is to provide access to mapping between local conceptual schemas and the global conceptual schema. So it has to be accessible from every node sending queries to the system. There are several ways to ensure it [4] [5]:

978-83-60810-53-8/$25.00

1. *Centralized directory* – Whole GD/D is stored centrally at one node. The advantage of this solution is that it makes GD/D manipulation simpler. However, one central node represents single point of failure for the whole distributed system and can be bottleneck as well.
2. *Fully redundant directory* – Replication of the whole GD/D is stored on every node. That way it can be quickly accessed whenever needed. But its modifications are more complicated due to its multiple occurrences in the system.
3. *Local directory* – Every node stores only its own part of the GD/D, so its management is very simple. On the other hand, global query requires communication with other nodes to make possible to create the query plan.
4. *Multiple catalog* – In the clustered distributed database system it is possible to assign whole GD/D replication to one node in each cluster. It is combination of first two ways.
5. *Combination of 1. and 3.* – Every node has its own GD/D replication and there is one global replication as well. Each of this possibilities has its pros and cons. But they have all something in common: the system needs to recognize all of its parts.

Whether the GD/D is stored at one node or somewhat distributed through the system, there needs to be some way how to access it as a whole. This is not possible in VANET as there is no way to ensure communication between all of the nodes. In this situation, GD/D cannot be used to locate requested data.

As of the present time there is not solution designed specifically for VANET known to the authors. But there are few solutions for MANET, so we will describe them in next sections of the article.

B. TriM protocol

The TriM protocol is the one of first attempts for solving the problem of data distribution in MANET environment the generic way. It was designed as a part of PhD thesis at the University of Oklahoma [6]. The main focus of the protocol is to minimize power consumption and to utilize all three modes of communication [7]:

- *Data Push* represents data distribution using broadcast messages.
- *Data Pull* represents on demand data distribution.
- *Peer-to-peer communication* for querying data.

The main disadvantage of the TriM protocol is its requirement to have same data on all nodes. This requirement makes it practically unusable in the VANET environment.

C. HDD3M protocol

HDD3M protocol tries to solve TriM protocol problems. As in the original protocol, HDD3M aims to use all three modes of communication and to conserve as much power as possible. The main difference from the TriM protocol is possibility to manage database fragments and to modify distributed database in transactions.

HDD3M divides nodes into 3 categories:

- *Requesting node (RN)* is sending queries to distributed database system.
- *Database node (DBN)* is containing database fragments.
- *Database directory (DD)* stores GD/D for distributed database.

This protocol must solve problems with distribution GD/D. There is no guarantee that all of database directory nodes receive the GD/D update request. Some of the nodes could be inaccessible through MANET or shut down due to lack of energy. When the network is fragmented, keeping the data accurate and actual might be impossible.

The biggest problem for deployment of distributed databases in the VANET environment is the necessity of the knowledge of all the nodes in the system. This problem persists in this solution as well because the GD/D is still used.

III. Principles of Proposed Solution

So the only way to make sure it is possible to use the distributed database system in the VANET environment is to remove the GD/D from the system and replace it with a different principle. As it has been said already, the GD/D describes the mapping between the local and global conceptual schemes. Without the mapping the system does not know where the data are located and how to query them.

Using the GD/D in the VANET environment is impossible because it requires knowledge of the whole system (*global* directory). In a VANET every node knows its immediate surroundings only. So querying of a distributed database is fairly limited in such environment. The only nodes which can be addressed to using queries are those in the immediate surroundings in the network. So the system naturally creates virtual clusters of nodes that can communicate with each other. The clusters might overlap, so each of the nodes of the cluster can communicate with another set of nodes.

The only possibility to introduce principles of distributed database systems into VANET environment lies in allowing to query data only from clusters containing the query node. That way we can replace GD/D with another principle – CD/D (Cluster Directory/Dictionary). But there is still question, how to store CD/D and how to distribute it throughout the database system. The possibilities are same as they were for storing GD/D. They were described in the subsection A. in section I of this paper.

Best possibility for VANET seems to be to store they own part of CD/D at each of network nodes. Other possibilities would be complicated to implement due to highly dynamic nature of VANET.

This is the way distributed database management system AD-DB is working. AD-DB was created as the result of PhD thesis at University of Žilina [2] by one of authors.

IV. Query Processing in AD-DB

As we already said, it is impossible to keep CD/D as a whole and distribute it throughout the VANET. Instead of that, AD-DB is using broadcast messages for data communication and lets each data node to decide whether it has requested data or not by looking to its own part of CD/D.

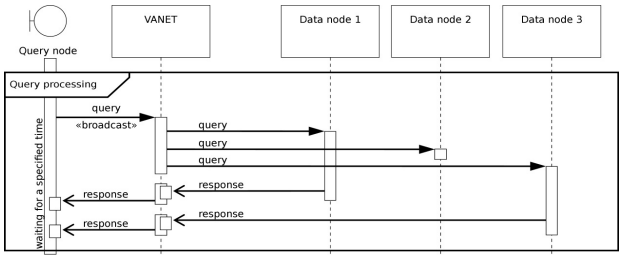

Fig 2: Query processing using the pull method [2][3]

AD-DB supports two methods of communication each based on slightly different principle:

- *Pull method* is application of pull mode of data communication into AD-DB database. It allows each node to query data from cluster.
- *Push method* is application of push mode of data communication into AD-DB database. It allows to share own data to other nodes without any prior query.

A. Pull method

Pull method represents the standard method of query processing in classic distributed database systems. One of nodes sends query to the system and waits for the results.

The method could be used in such situation where a client does not have to update data periodically and it needs to query it once instead. One time search for nearby cinemas could be taken as an example of such a situation.

It is also possible to use the pull method as a mean for data replication but it is much more ineffective than using the push method [15].

The query principle is shown on Fig. 2. Communication is done in the following steps:

1. *Global query optimization*. It is important to optimize a query to minimize the size of resulting data.
2. *Sending a query*. Query node sends optimized query using broadcast message. That way all of the data nodes in cluster receive the query. The query node waits for the specified time.
3. *Query fragmentation*. Every data node which received the query fragments the query and searches for subqueries the node is able to execute.
4. *Local subquery optimization*. Data node optimizes each of found subqueries and prepares it for execution.
5. *Subquery execution*. Data node executes each of subqueries.
6. *Sending the result*. Data node sends back the resulting data together with identification of executed subquery using unicast message.
7. *Results evaluation*. After the specified time runs out, the query node evaluate all results received from data nodes and merges them to one complete result.

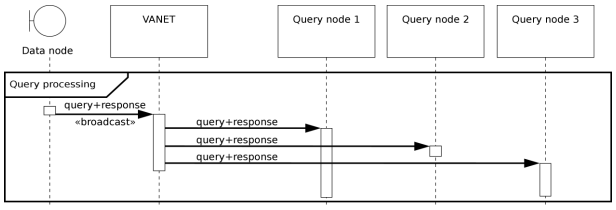

Fig 3: Schematic illustration for push method [3]

B. Push method

Taken that organization of the network structure is changing rapidly in VANET, it is clear that sometimes there is need for querying the same data repeatedly. Possibility of using push method of data communication in AD-DB can be handy in such situation.

That is also the reason why the push method is more effective to be used in data replication algorithms than the pull method [15].

Schematic principle of push method is shown on Fig. 3.Communication is done in the following steps:

1. *Local query optimization*. Data node optimizes query and prepares it for execution.
2. *Query execution*. Data node executes the optimized query.
3. *Sending the data*. Data node sends resulting data packed with the query through VANET as broadcast message.
4. *Results evaluation*. When query node receive the data, it analyzes attached query to determine whether it needs the data or not. If it needs the data, it forwards the data to user application to process it.

V. High Level Communication Protocol for AD-DB

Schematic representation of the communication protocol used in AD-DB is shown on Fig. 4. Data node can process message processQuery. That is sent by a query node in form of broadcast message in the pull method of communication.

The query message has following structure [2]:

- *Schema uuid* is a unique identifier of the current database schema. It is important to include this for data node to be able to determine whether it should process the query or not.
- *Serialized query* represents the query itself. The best way to transfer the query is in a form of serialized abstract syntax tree of it, as it is easy to process by data node.

There is no need to transfer session identifier of any kind, because query and uuid could be used as a unique identifier of the request.

The response message structure is as follows [2]:

- *Schema uuid* as a part of response unique identifier.

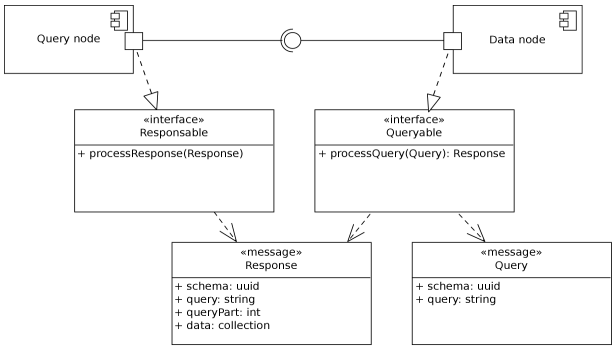

Fig 4: Schematic representation of communication protocol used by AD-DB [2]

- *Serialized query* as a part of response unique identifier. It is possible to use query as a part of unique identifier, because query processed by the database system is expected to be simple and short. If this assumption was not true, it is still possible to use value computed from a query by some hash function instead.
- *Query part* is the identifier of processed subquery.
- *Data* as a collection of the resulting objects.

Using the schema uuid and query pair as a unique identifier of a request has one advantage over using surrogate identification number. This way the response message format can by the same for the pull and the push methods of communication.

Important part of a response message is the query part identification. It represents a unique identifier of query part processed by a data node as a subquery. This identifier is needed by a query node to be able to merge all responses from all responding data nodes.

There are two possibilities how to use the same system of numbering for all query parts by the both query and data node:

- Inserting the identifier directly into serialized query. Process of identifier inserting is done directly by the query node after the global optimization.
  Example of query with identifiers (syntax of the query language used by AD-DB is published in multiple publications by authors [2][3][8]):

  $$^{(1)}\bowtie(^{(2)}projects//(\lambda x|x\triangleleft name{=}\text{KANGO}),^{(3)}employees)$$

  where $^{(1)}$ identifies the whole query as one part, $^{(2)}$ identifies collection of all projects with the name KANGO, and $^{(3)}$ identifies collection of all employees.
- Automatic numbering of all operations by theirs priority. Priority of an operation can not change as it is defined by the query language, so the numbering will be same on both query and data node. This system is preferred and it is used by AD-DB as it does transfer slightly smaller quantity of data between the query and data node.

Push method is using the processResponse message. It is sent by the data node in a form of broadcast message.

VI. The OSACP Protocol

OSACP (Object Structure Aware Communication Protocol) is an application protocol designed specifically to transfer structured data through VANET. It is designed as a part of PhD thesis at University of Žilina [9]. OSACP is using UDP transport protocol on top of IPv6 network protocol. Its design allows it to transfer any structured data through VANET and reconstruct it on the other side even if part of data was not transferred correctly [10][3].

Missing parts of the structure are replaced by special object UNKNOWN to indicate incomplete message. It is up to the user of the distributed database (person, or another application) to decide whether it can process the message or not.

VII. Conclusion

There is no known distributed database systems, that would be possible to operate in the VANET environment. There are few attempts to do so for MANET, but they are unusable for VANET.

The paper presented the communication system of the distributed database system AD-DB. The database system is designed to be used in VANET environment and so its basic principles had to be altered for such usage.

In the nearest future we would like to focus on enhancing query optimization algorithms, but there are many other areas which would be interesting to explore. For example, many of data in VANET are of highly temporal character, e.g. current weather, traffic flow speed, traffic obstacles, etc. It would be interesting to have possibility to query current state of those temporal data.

We have some accomplishments in this area even now. We have designed system to query visual objects recognized by vehicle cameras through VANET [11][12]. So the next logical step would be to integrate this system into distributed database system AD-DB.

***Abstract*—This article presents results of designing a Content Delivery Network monitoring system for resource limited applications. CDN monitoring is important both for content providers (media companies) and administrators (Internet Service Providers). It is a challenging task since network traffic may generate huge volume of data which must be parsed and analysed in real-time. This paper describes the design of a prototype system that uses a small resource footprint, scalable Big Data solution, which is motivated by real world use cases.**

I. Introduction

DISTRIBUTED internet systems monitoring is already an important branch of industrial computer systems. Network data transfer, hardware state and many other aspects of distributed systems need to be constantly tracked in order to detect anomalies, prevent failures and measure hardware and software load. In this field Content Delivery Network (CDN) monitoring becomes a fast developing branch of telecommunication. Network caching is used in a variety of different contexts to provide cost savings due to decreased bandwidth consumption, but also to reduce network latency. Due to the techniques described in [1] that makes RAM/HDD resources ratio important especially for use cases in developing regions of the world.

CDN Monitoring requires detailed information, both statistical and sensor-reported to be available real-time and cover any given period of time while not loosing any detail. For example, if a malfunction is detected one may need to track it back behaviour up to the unlimited time point in order to find possible coincidences with other events. Therefore all relevant data concerning CDN operation must be stored in exact shape.

There are several highly efficient systems able to collect and store raw logs. Flume [2] for example is able to collect log lines, send them to a HDFS storage and generate reports on them. Hive [3] can evaluate SQL-like queries over large data volumes collected in Hadoop HDFS [4]. All these classical Big Data technologies require large hardware configurations while storing data inefficiently from the time series point of view. Much better approach is applied in OpenTSDB [5], a dedicated time series database running on Hbase [6]. Its data model can be effectively tuned to achieve both very fast querying and limited hardware. This paper describes optimizations for a CDN monitoring system based on experiences of its deployment in one of the biggest telecommunication companies in Poland which operates commercial CDN services.

A. Limitations of Network Traffic Monitoring

The CDN monitoring becomes especially challenging in developing regions where storage footprint for monitoring is very limited. The situation at those regions is especially unfortunate since the transmission of data logs into public clouds or third party services cannot be performed for the reasons like cost, security and privacy.

This type of monitoring system may be useful in environments where the link bandwidth is a constrained resource e.g. the CDN nodes deployed at libraries, schools, remote communities, etc., basically all locatlizations where uplink bandwidth is limitted.

Also, the security and privacy constraints are general in this scope e.g., most of ISPs are reluctant to deploy subset of CDN systemts called Transparent Caching solutions primarily because of logging concerns in third party services.

The goal of this research was to develop CDN monitoring tool for usage in developing regions with limited resources. We present the system which provides the same level of flexibility of traditional heavy weight monitoring tools.

II. Time Series Database

From a theoretical point of view the system needs to store time series understood as a collection of observations made sequentially in time [7]. These discrete observations T are represented by pairs of a *timestamp* and a *numerical value* (t_i, v_i) with the following assumptions:

- number of data points (timestamps and their values) in one time series is not limited,
- each time series is identified by a name which is often called a *metric name*,
- each time series can be additionally marked with a set of *tags* describing measurement details,
- observations may not be done in constant time intervals,
- storage should not limit time series to be piecewise constant or linear (see Fig.1).

978-83-60810-53-8/$25.00

A. Architecture

The general architecture of the system is composed of three components: data collection, data storage and querying engine.

As in many other systems data are inserted by distributed *data collectors*, which may work directly on data sources and push data into the data storage. Usually data collection is a result of the ongoing measurement or monitoring processes (the operating system, databases and web servers or network devices: see OpenTSDB monitoring tools [8]). The system does not limit possible data which can be inserted and analysed. The only requirement is that it must have a form of *time series*.

According to the existing taxonomies (like in FAME system [9]) measured values are of two types [10]:

- level values stay the same from one period to the next in the absence of activity. For example, inventory is a level value, because inventory stays the same if you neither buy nor sell.
- flow values are zero in the absence of activity. For example, energy expenses go to zero if there is no consumption.

This distinction turns out to be important when interpolating missing values and for time scale conversion. Our system is open for both solutions by inserting zeros when necessary during data collection time.

As we described in [11] our CDN monitoring system is built on OpenTSDB which uses HBase and HDFS as a data storage. OpenTSDB is responsible for storing data in two HBase tables: the first one contains main data compacted into one hour blocks, the second one keeps time series and tag IDs. OpenTSDB is also evaluating queries by getting proper data blocks from HBase and aggregating them into a time series according to the query semantics. Performance of all the system is influenced by all the three components: HDFS, HBase and OpenTSDB.

B. CDN Metrics and Metrics Querying

For the purposes of CDN monitoring the most important metrics from an operational point of view are:

- bandwidth – average number of bits per second transferred from the platform within a given time period [kbps, Mbps, Gbps]
- traffic – sum of bytes transferred in a given time period [kB, MB, GB]
- sessions – number of active sessions in a given time period

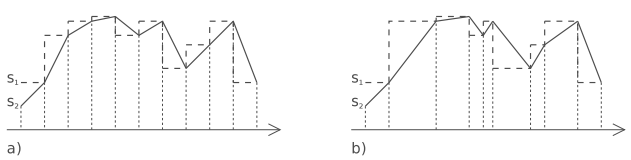

Fig. 1. Time series with constant (a) and variable (b) sampling, piecewise constant (S_1) and piecewise linear (S_2).

- unique clients – number of unique IP addresses
- url hits – number of content download events content from given URL addresses
- byte cache hit ratio – percent of data volume sent from the cache [%]

Additionally, all metrics must be further divided into the following dimensions:

- node name – CDN node name or IP which sends data to a client
- cluster group name – group of nodes logically grouped together
- http response code – HTTP code sent in response to a client request
- country ISO code – client's geographical location
- AS code – Autonomous System code of a client's Internet Service Provider
- CDN instance name – a logical grouping of nodes working in one or multiple CDNs
- provider name – name of a content provider
- origin server name – name of an origin server which contains the original data cached by a CDN
- url – url which is tracked by the system

We use the following metric naming schema:
`[infrastructure].[measurement].[aggregation]`
where:
`infrastructure` indicates a system which is measured (in our case CDN instance, but could also be CPU),
`measurement` indicates a name and type of the measurement being done (for example Mbps, MB, requests, etc.),
`aggregation` describes the type of aggregation done during the data collection which results in one data point for a given time interval.

For example, one of the clients' requests in Poland downloading the content from a hypothetical disco-tv could be stored as (a metric name, timestamp and value followed by a list of tags):

```
cdn.mbps.avg5min 2013-02-20-21:04:20 2.50
node=node01.waw.cdn-lab.pl group=waw02 httpcode=200
country=pl as=AS5617 cdn=lab provider=disco-tv
origin=share.disco.pl url=clip463421-doda
```

which means that within 5 minutes period the collector calculated average value of Mbps to be 2.5 for server named **`node01.waw.cdn-lab.pl`** being in cluster group **`waw02`** for a client located in Poland in **`AS5617`** downloading content from a provider named **`disco-tv`** originating from a server **`share.disco.pl`** with the use of CDN instance named **`lab`** and referencing url **`clip463421-doda`**.

This approach, characterized by defining all possible dimensions for each metric, enables very flexible querying of collected data. For example, one could ask for an average Mbps for given provider in Germany in a given time period or number of error codes returned for a given provider's network (identified by AS number) when accessing certain CDN node by given URL. Please note, that all tag values combination defines one time series. Total number of time series stored for

tag name	min values	real-life
node	10	100
group	5	10
httpcode	5	12
country	1	90
as	1	30
cdn	1	5
provider	1	5
origin	1	20
url	10	50
total time series	2500	$810 \cdot 10^9$

TABLE I
APPROXIMATION OF POSSIBLE NUMBER OF TIME SERIES FOR ONE METRIC IN MINIMAL AND REAL-LIFE SCENARIOS.

one metric is then given by $v_1 \cdot v_2 \cdot \ldots \cdot v_i,\ i = 1 \ldots l$ where l stands for the number of tags attached for a metric and v_i is maximal number of distinct values possible for tag i. Let us analyse how many time series can be generated by an average metric and tags set. An approximation of minimal and real-life scenarios are given in Table I.

The real-life approximation was done using production data from one of the working average CDN systems. It assumes it is possible that accessing all URLs will be tracked with possibly all http response codes and hitting all possible nodes from each country. Since there might be some dependencies between the dimensions the real observed values may be smaller, however, the database must be prepared for the worst scenario which may appear for example during malfunction. Actually, anomalies are the most important from the analytical point of view. Therefore the system should be able to present data including all possible dimensions, and tag values ranges.

C. Data Volumes

Another aspect of CDN monitoring is the estimation of data volumes which must be processed by the system in real-time. CDN traffic monitoring may be based on at least three information sources: CDN proprietary logs, Apache http logs and Syslog events. Due to the latest IETF standarization efforts [12] and [13] we may expect fourth information source of the logs from CDN interconected systems. One request for content generates one line in the log entry (about 0.2 kB). One Smooth Streaming video generates up to 300 entries per 5 minutes (about 60 kB) 10k users watching 90 minutes smooth streaming video generates about 10GB of log data. In some cases log coalescing funciton may be used, however that techniques may reduce size of log by a factor of 10 in average. Another example is 100k users downloading a 1GB game with 5Mbps connection may generate up to 1GB of log data. These data need to be downloaded and analysed and cannot wait for batch processing at night or weekend days. CDN systems offering content worldwide may be equally loaded all the time in which case a monitoring system must collect and process data in real-time.

III. OPTIMIZATIONS

It is a typical HBase performance design pattern to build clusters of at least 11 nodes. In more demanding environments 50 nodes is an average number. This approach would lead to building a monitoring infrastructure more expensive than the monitored CDN itself. Therefore the time series database must be deployed on a single node cluster with a pseudo-distributed configuration on one hand allowing for possible quick extensions in the future and generating sensible running costs on the other hand.

A. Single Node Configuration Performance

Let us now analyse the performance of a single node configuration. We executed two types of queries:

- Aggregating all available time series for a given metric into a one time series in a given time window. For example[1]: `select sum:cdn.bandwidth.15min from 01.01.2012 to 31.12.2013`
- Performing a selection of time series using tags before the aggregation and within a given time window. For example: `select sum:cdn.bandwidth.15min from 01.01.2012 to 31.12.2013 where provider=disco-tv and country=de`

Due to the CDN logs behaviour we used an equal sampling with 5 minutes time period therefore each day is described by $24 \times 12 = 288$ time points. Please note that the time series may not be continuous and therefore their number may vary throughout a queried time window. In Table. II we can see that an average time series processing speed for a query which is scanning all time series in given a time window is about 660k points per second. Since we scan all data, the number of points and time series is constantly increasing. The processing of 4 days data takes almost 40 seconds. Queries for the periods longer than 4 days failed due to an out of memory error. Similar situation appears for the filtered time series querying presented in Table III but we may observe that processing speed is much worse due to more complex data selection from the database. However, the number of processed points is much smaller allowing for better response times. Although it was possible to run queries covering even 16 days, the response time took 108 seconds, which is totally unacceptable from a user's points of view.

B. Reduction of data complexity

One of the conclusions from the previous section is a need to reduce the number of time points and time series in the database. This can be achieved in two ways:

- by aggregating the points in time with downsampling, which can be called *horizontal compaction*
- by aggregating time series with grouping the tags for one metric, which can be called *vertical compaction*

Both solutions lead to a reduction of available information but may be acceptable if consulted with the user queries. For example, in a most typical example a user wants to get brief information about the system and would like to drill down if needed. Therefore both the detailed and coarse information

[1]In this paper we use an abstract query language with obvious semantics to express platform independent queries.

TABLE II
QUERYING AGGREGATING ALL TIME SERIES, DAYS: 1...4.

queried days	proc. time	data points	periods	series	pts/sec.
1	2.9	2,225,293	288	7,726	767,342
2	13.2	9,497,624	576	16,488	719,516
3	28.5	17,137,873	864	19,835	601,328
4	38.1	25,099,032	1,152	21,787	658,767

TABLE III
QUERYING FILTERED TIME SERIES, DAYS: 1...16.

queried days	proc. time	data points	periods	series	pts/sec.
1	6	793,907	288	2,756	132,317
2	8.4	1,295,810	576	2,249	154,263
3	14.1	2,284,509	864	2,644	162,021
4	20.6	3,250,740	1,152	2,821	157,802
16	108.9	12,479,745	4,608	2,708	114,598

should be kept in the system. In case of short time periods a user is interested in a detailed information, for the longer ones the details would not be visible anyway, therefore the coarse plots are just fine.

1) Downsampling Collectors: There are two possible ways to calculate the downsampled time series. The first one, the easiest, is to perform downsampling right during the data collection process. However, this would require to store aggregates for a long time according to the downsampling period (even one week or more). Keeping a collector's state for a longer time may be dangerous in case of a server malfunction. In industrial prototype we prefer solutions which are stateless, run frequently and returning results as quickly as possible. Therefore, we propose another way by implementing additional collectors which process data already stored in the database and send it back into another metrics after aggregation. The basic architecture of this solution is visible in Fig. 2 where the new collector is in gray colour. Obviously there should be one downsampling collector running for each downsampling time period. It is not working continuously but rather started every given time interval. For flexible querying it produces several metrics containing four different aggregations if sensible: *minimum*, *maximum*, *sum* and *average* of values for the sampled time period. Additionally to enable further average calculation it also counts a number of processed points and put the result into another metric called *count*. For some metrics (like Mbps) the summation downsampling does not make any sense and should be omitted.

2) Tags Grouping During Data Collection: During the prototype evaluation phase, we have observed that although a client could run queries containing any combination of tag values he is usually interested only in a subset of two or three tags. The queries concerned: geographical location; traffic per AS, http response code, origin server; and download speed. All time series need to be further divided per content providers. Therefore, instead of one metric with 9 tags, as it was described in II-B, we propose five metrics with six tags. In case of bandwidth metric (cdn.mbps) it could be:

- **`cdn.mbps-country`** with tags:
  `node, group, cdn, provider, origin, country`

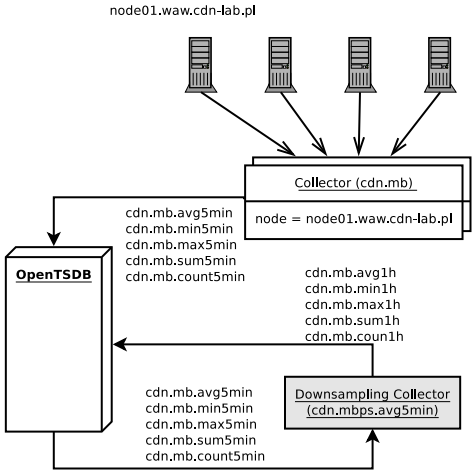

Fig. 2. The basic architecture of a downsampling collector.

- **`cdn.mbps-group`** with tags:
  `node, group, cdn, provider, origin, group`
- **`cdn.mbps-network`** with tags:
  `node, group, cdn, provider, origin, network`
- **`cdn.mbps-speed`** with tags:
  `node, group, cdn, provider, origin, speed-group`
- **`cdn.mbps-httpcode`** with tags:
  `node, group, cdn, provider, origin, httpcode`

Obviously, a user cannot display for example http codes for given AS or country with the above metrics and tags. However, these detailed queries can be processed with the original unoptimized metrics since selecting many tags greatly reduces the number of queried time series. Furthermore the query gets sensible number of data points. The optimized metrics should be used for general queries aggregating many time series. This optimization is a kind of a pre-aggregation done for certain query types.

This vertical aggregation can be run as a post-processor alike in downsampling or during the data collection process. Due to the architecture presented in our previous publication [11] it is much simpler to build it as a MOLAP cube with a reduced number of dimensions.

IV. RESULTS

Adding the vertical compaction optimization by aggregating time series during the data collection time has increased the log processing time for one CDN log covering data transfer for 5 minutes period from a single node by a factor of 3 from about 10 to 30 seconds. The log rotates every 5 minutes (300 seconds) so the time left can be used for processing log files even 10 times larger which will not be the case of a small or medium system.

The horizontal time compaction by the downsampling of the existing data and putting it back into the database as a new time series does not introduce any additional cost in an on-line log processing and does not need to be further studied here.

TABLE IV
SPEED-UP FOR QUERIES ON OPTIMIZED TIME SERIES.

days	1	2	3	4	16
speed-up total	3.2	11	17.8	16.5	
speed-up filtered	12	12	11.75	15.8	13.4

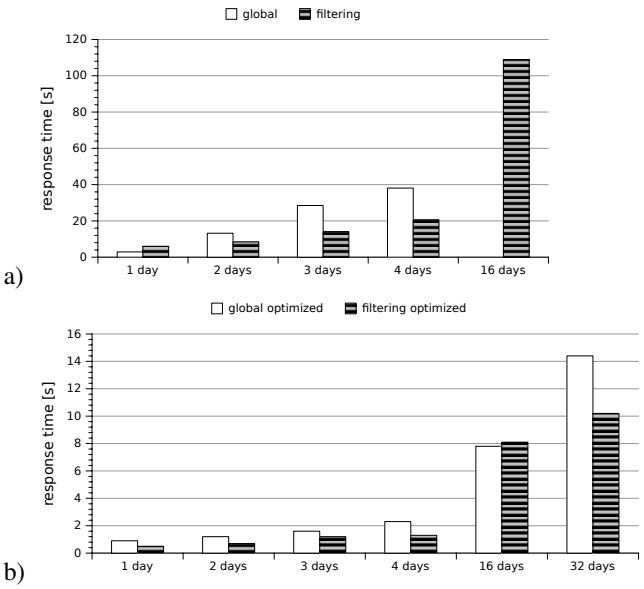

Fig. 3. Response times for initial unoptimized system (a) and final optimized version (b). The charts present two types of queries: global aggregating all time series and filtering performing selection before aggregation. For unoptimized system global query for more than 4 days could not be run due to out of memory error. The queries were run on time series without downsampling.

The reduction of time series and tags describing one metric resulted in an outstanding improvement of the database querying performance (see Table IV and Figure 3). This effect was possible first by the reduction of Hbase tables lookups. When processing queries, OpenTSDB first looks for IDs of the time series in a meta table. The more time series and tags, the more expensive this initial query can be. Then, the second great speed up is achieved by reducing the complexity of the time series needed to be grouped and interpolated in order to get the final time series which answers the query.

The response times for the same queries, but working on remodelled time series, are around 15 times faster for the longer time periods. This optimization decreased the amount of memory necessary to process the time series during the aggregation and therefore allowed for the processing of the times ranges longer than 4 days, which is obviously important for the real-life monitoring platforms.

V. CONCLUSIONS

We presented the problem of a small and medium scale CDN monitoring system in a case of limited resources which does not allow for real Big Data storage cluster. The initial state could not be accepted by the industrial requirements since the short term queries were processed too slowly and longer term queries could not be evaluated at all. Adding more resources by inserting computational nodes or increasing size of memory was not possible due to budget constraints. A significant improvement was achieved by introducing optimizations of the time series stored in the system. All initial properties of the system including the real-time processing and a fine grained data store allowed for detailed queries.

As the next step we plan to study the number of time series reduction allowing for arbitrary queries on an optimized series. This could be achieved by adding more metrics with reduced tag sets.

VI. ACKNOWLEDGMENTS

We appreciate many valuable comments from the anonymous reviewers of Federated Conference on Computer Science and Information Systems 2013. We thank Sara Oueslati, Paris, France for her great support with setting up the logging environment in the ISP CDN networks, and Marc Fiuczynski, New Jersey, USA for additional technical feedback.

***Abstract*—One of the more important stages in the development of wireless networks was developing protocols, procedures and systems providing packet data transmission. Packet data transmission enables sending sets of measurement data and other information over long distances, and thus integrating with other available networks, for example the Internet. The aim of this article is to demonstrate the implementation of communication algorithms of the above networks as exemplified by communication with an automobile on-board network. The part of the article which deals specifically with the functionality of the discussed transmission types addresses the issues of remote control as exemplified by low-power executable devices**

I. Introduction

THE first automotive microcontroller built by the Bosch company in 1979 was a 4-bit microprocessor microcontroller implemented in BMW 732 and BMW 633 Csi cars. Its function was solely to control ignition and fuel injection systems. From the time perspective it can be said that it was the first ECU system (Engine Control Unit) in the world –computer controlling and monitoring of engine operation.

Constant development of Information Technology (IT) and microprocessor evolution enabled further development of controlling and monitoring of automotive subsystems by introducing information buses. Fast and error-free data transmission to main controllers is possible thanks to digital communication buses installed in cars which on the basis of this information make further control decisions , (e.g. correcting engine operation, ABS or EPS systems.). At present, the most popular bus used in the car industry is the Control Area Network (CAN). Its standard was made public in 1986 by Bosch and the first CAN controller (made by Intel) was made available in 1987.

The first implementation of the system took place in the mass-produced Model S of Mercedes-Benz.

Continuous efforts of designers to increase passenger safety and comfort have resulted in installation of several buses managing the work of on-board microcontrollers in modern cars, which control both operation and measurement systems. These buses create on-board information networks, such as LIN, K-Line, Flex-Ray or MOST (Fig.1)

Each of the aforementioned networks and buses controls different executable systems both while the vehicle is in motion and when it is stationary – for diagnostic purposes. (Fig.2)

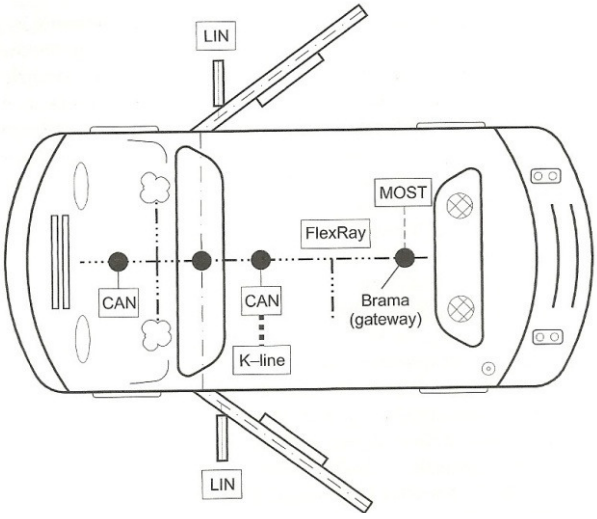

Fig. 1 On-board computer network [1]

II. Remote Control of an Object Over TCP/IP and GPRS Network

Information technology tools available at present, as well as wireless telecommunications networks, allow for easy remote monitoring and controlling of various vehicle functions [4]. Such control is made possible, i.a., by the development of the GPRS network concept, which enabled

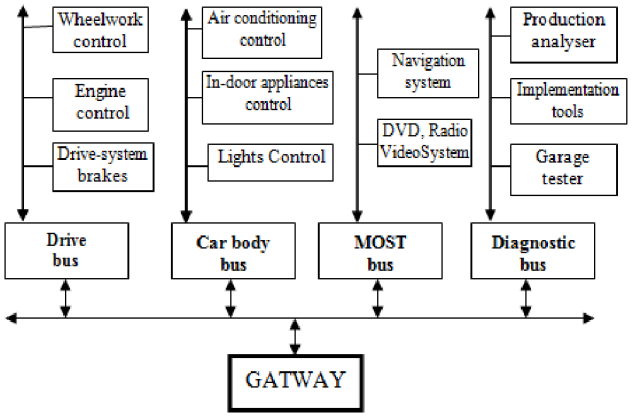

Fig. 2 Digital bus networks controlling run-time systems (according to [2])

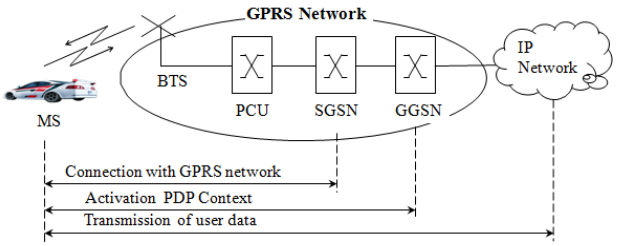
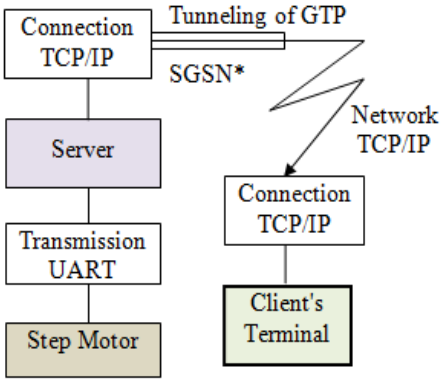
packet data transmission.[3] Figure 3 illustrates establishing connection between a MS (Mobile Station) and the Internet.



MS - Mobile Station, **BTS** - Base Transceiver Station; **PCU** - Packet Control Unit;**SGSN** - Serving GPRS Support Node; **GGSN** - GPRS Gateway Support Node;**GPRS** - General Packet Radio Service

Fig. 3 Packet data transmission over GPRS between a mobile station (MS) and the Internet [1a]

The sequence of establishing a connection involves activating and connecting an MS to the GPRS network and then defining the MS's PDP Context, including the assignment of an IP number. Then packets may be mutually exchanged, which enables the assignation of the sender's and the receiver's addresses to each connected user , , both in the IP and the GPRS network. How the GSM/GPRS network operates is described in [3]. The model of remote controlling of a selected object over TCP/IP is shown in Fig.4.



* SGSN - controller Serving GPRS Support Node, GTP - GPRS Tunnelling Protocol

Fig. 4 Model of remote control over the TCP/IP protocol

The end user (Client) controls the object via the GTP protocol (GPRS Tunneling Protocol) tunelled by TCP/IP protocol. Data exchange between the controlled object and the Central Computer (Server) uses UART.

(Tunneling means establishing a connection between two different protocols by encapsulating one protocol in another. By means of tunneling a connection between distant hosts can be established, giving the impression of direct connection.)

III. AN EXAMPLE OF SELECTED OBJECT CONTROL

Figure 5 illustrates an example of object controlling over TCP/IP. This method of controlling was developed for purposes of laboratory teaching during lectures in Wireless Data Transmission Systems delivered by this paper's author to the Computer Science students.[5]

The object of control is a stepper motor (EDS 10) linked to a computer by means of a microcontroller 8051. The executable system is remotely controlled by over a dozen methods. Parameters of controlling are entered from the keyboard of a remote computer. (Client)

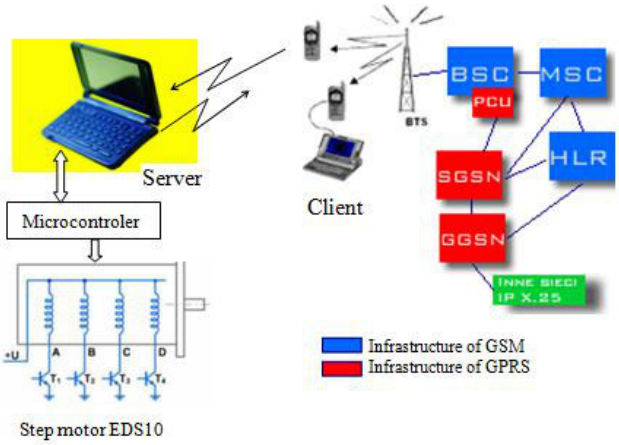


Fig. 5 Diagram of a remotely controlled step motor

Providing software for the above system involved the following stages:

- programming TCP/IP interface between a remote computer, the so-called Client Computer and the Central Control Computer - Server (initialized by the Client)
- designing and programming an interactive user interface, enabling the introduction of selected values of control parameters.
- developing programs in the microcontroller's language for controlling a given object (i.e. the step motor).

The user's (Client's) interface is shown in Fig.6.

The remote control program is run in two modes:

- Client mode and
- Server mode

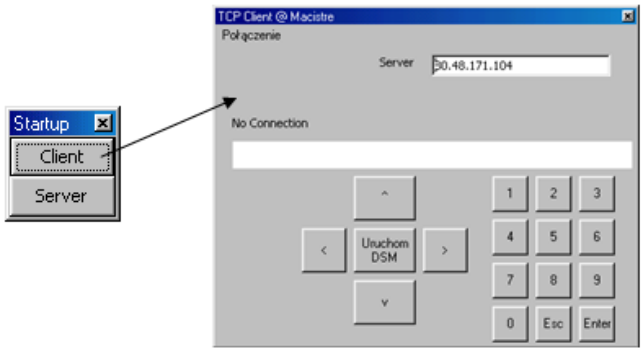

Fig. 6 User interface in the remote control system in Client mode

Client runtime mode

There are two stages in this mode:

- establishing connection with the remote server by entering its IP number in the text field of the form (the top right corner of the interface) and choosing the option "Connect" from the system menu

- handling the interactive form by means of which the user enters control parameters (keys 0-9, direction arrows, key ESC and Enter.)

The system was designed so that messages from the microcontroller 8051 could be displayed on the client's desktop. These messages show both the state of the running control program and the parameters required for control purposes. They are displayed in the white field of the interface. (They also appear on the remote LCD of the microcontroller.)

Server runtime mode.

The Server's aim is to handle communication between the Client and the microcontroller and concerns the transformation of the controller's Assembler language to messages shown on the screen of the Client's remote interface.

Handling the Server requires defining the connection between the Server and the Client as well as the Server and the microcontroller.

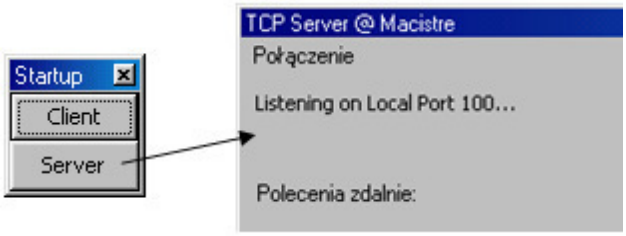

Fig. 7 User interface in the remote control system - Server mode

Client – Server Communication

The above communication was carried on the basis of one of the available controllers working in the TCP/IP standard. Port no 100 was selected. (Cf. Fig.7)

Server - Controller DSM8051 communication

Communication between devices was set up to use the following control (counting from the Server). Transmission parameters were set to 1200 bauds (Theoretically - even for 57 600 bauds)

Microcontroller DSM8051

The DSM8051system [6] employs a Micromade 8-bit microcontroller . It is a programmable training controller equipped with both analogue and digital input/output ports, for connecting and handling peripheral devices.

, The stepper motor controlling software, which controls the step motor in different ways, was developed on the basis of available systems . (about 10 various programs) (Fig.8) . The software coded in microcontroller's assembler may be launched from the Client's remote desktop. User Interface for Client/Server mode was written in Microsoft Visual Studio 2010 Software.

Description of control program operation

There are three stages in the program:

- establishing connection between individual devices (Client, Server, Microcontroller)
- providing parameters to control the step motor from a remote control desktop
- carrying out the motor movement according to a preset set of characteristics.

Below there are examples of characteristics controlling the EDS 10 system.

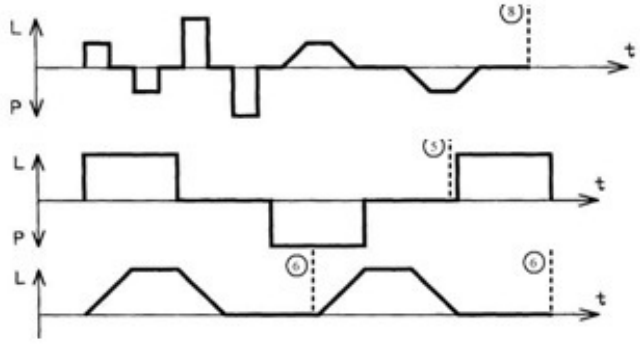

Fig. 8 Selected control characteristics of a step motor

System software has been presented as a UML diagram (use cases) below. (Fig. 9).

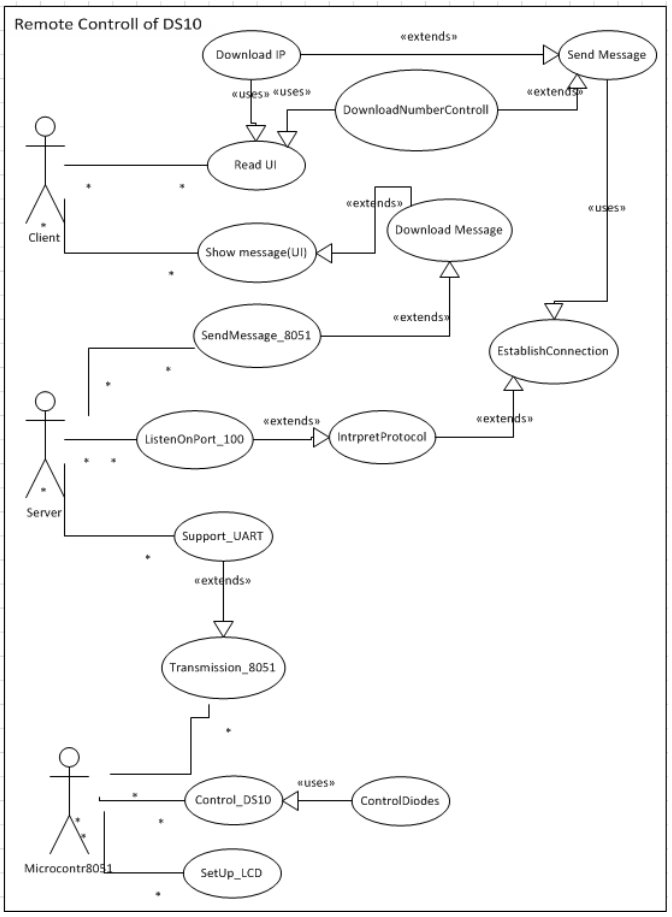

Fig. 9 Use cases for operating software

IV. CONCLUSIONS

The presented solution of remotely controlled communication with an executable system allows for:

- remote monitoring of an executable device – both continuous and on demand
- remote read-out of the system parameters - both continuous and on demand
- remote (e.g. cyclic) recording of measurement data in the microcontroller's memory, from where the data can be read out at any moment (periodically or on operator's demand).

Assuming that the server (Fig.5) symbolizes the on-board computer, there are many ways in which the described system can be used in a motor vehicle and they depend only on the designer's creative imagination and automation systems (microcontroller's) installed in the motor vehicle.

Connecting the Gateway (Fig.2), handling interbus communication to the on-board Computer (Server-Fig.5) instead of the executable device/EDS 10 enables the implementation of many telematic services in vehicles. Some of them are: BMW Assist or BMW Tracking ([3], [4]) and similar. Telematic BMW services are currently available in Austria, France, Germany, Great Britain and the United Arab Emirates.

Summing up, it should be stated that the main objective of the presented solution is long distance data transmition , which can be used in all fields of technology, e.g. telemetry, positioning or remote control.

***Abstract*—This document describes how to use the Trusted Platform Module (TPM) in the method of secure transmission of data stored on the Flash RAM through insecure transport channel. In this method the sender of the file specifies the recipient and the recipient knows who is the sender of the file. The idea of a solution that uses symmetric and asymmetric encryption is described. The TPM is used to safely generate symmetric and asymmetric keys, and theirs the safe collection, storage and management in order to protect files during transfer. The way of organizing data in a cryptographic keystore for users authorized to use the system for the secure transmission of files stored in Flash RAM is described.**

I. Introduction

IN THE era of widespread use of the Internet moving data from one location to another is a natural phenomenon. Data may be transferred with the use, for example, of HTTP protocol (files describing the presentation of Websites in HTML) FTP protocol or others. Transferring a non-confidential data over the Internet is not born of trouble. The problem occurs when the transferred data are sensitive and can be made available only for selected recipients. Then securing the data transferred on the route between the sender and the recipient is necessary. For this purpose, in Internet TLS protocol (Transport Layer Security) at the application layer or IPSec protocol (Internet Protocol Security) at the network layer are commonly used. The applied solutions in this area use symmetric and asymmetric cryptography. In both approaches from the point of view of security, the most important task is authentication both sides communicating against each other. This can be achieved by using one of the following methods:

- password known for both sides (shared secret);
- manually exchange of public keys of both sides;
- using public key certificate (X.509).

Normally is used the last solution, which is most comfortable, but requires the access to the Certification Authority.

Transfer data in the data processing systems of different classification levels is much more complicated problem [4]. In such systems, it is important not just who is the data recipient, but also whether the data recipient has adequate security clearance certification. Due to the legislation regarding of classified data processing very often it is not possible using a computer network to data transfer and building a mechanism for user authentication [12]. Then the transfer of sensitive data over insecure transport channels becomes a necessity. In such systems, the only way to safe data transfers is secured a removable media (i.e. Flash RAM or removable disk) connected to the system by USB interface [3].

This paper presents a solution to such preparation the data stored in Flash RAM so that storage medium can be used for secure transmission of the data [3]. In this solution a sender of the data (ie, the creator of the protected media content) can be sure that the data will only be available for a designated recipient, and the recipient can be sure that the received data originates from the expected sender. The described mechanism uses both symmetric encryption algorithms and asymmetric. The presented solution uses a *filter driver* [1][5][6][9]. In this solution, it is assumed that in terms of operating system the data can be processed in two directions: from plain text form stored on your hard disk, to protected form on removable media (e.g. Flash RAM, hard drive) connected to the system via the USB bus and, conversely, from protected form on removable media to plain text form on the hard drive.

The process of securing exchange of data is transparent for the user except for moment at which the system will recognize new storage media Flash RAM connected to the station. Then, the user is forced to specify his preference of data encryption algorithms, origin of cryptographic keys and location of protected files. For this reason to implement the process securing data it is necessary using separate operating system modules (drivers) running on the system kernel mode [5][9][10]. Schematic diagram of developed solution is shown in Fig 1.

User have access to the described solution through the Control Applications (***CApp***). The basic elements of constructed system are cooperating with each other drivers: encryption driver [1][2][3] and driver supporting, which are compatible to the Windows Driver Model [5][9]. Both

This work was supported by The National Center for Research and Development, Project OR00014011

978-83-60810-53-8/$25.00

elements work in operating system kernel mode and communicate with each other using the internal mechanisms of the operating system (in the figure these mechanisms are labeled as IRP (Input-Output Request Packet) [5][7][9][10]. The purpose of the encryption driver **(EnD)** is realization of the process of encryption / decryption data and determination a value of hash function for these data. The tasks of the Driver Supporting **(DSu)** are among other things, creation of signatures for protected data and intermediation in transmitting messages / commands between **DSu** and **CApp**. Both drivers cooperate with the Trusted Platform Module (TPM). The purpose of the TPM are a secure cryptographic key generation, storing them and sharing, and supporting cryptographic procedures. Management Console for Cryptographic Module (MCCM) is used to management of TPM and cryptographic keystore management. An important element of the system is a DLL library that provides the encryption functions.

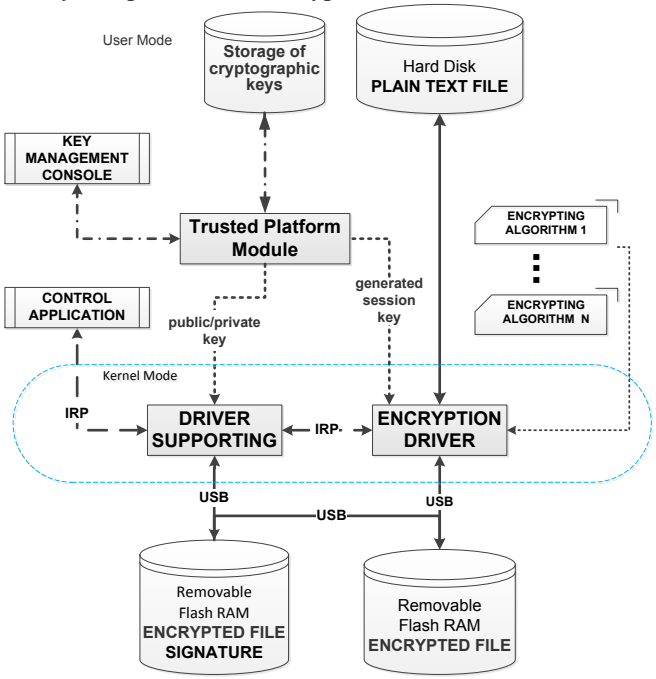

Fig. 1 Schematic diagram of securing data stored on removable media

The products of the process of securing data are two files: a file with encrypted data and signature of that file describing the file containing the encrypted data. The both files can be saved on one medium, or each file on different medium. Choosing a storage location of the signature file is defined by the user through **CApp**. It should be noted that saving the encrypted file and the signature file on separate media increases the security of stored data, but it is cumbersome to use. In the next sections of the paper is presented the process of creating and reading a protected file and the concept of using the capabilities of TPM to management of the cryptographic keys for procedures of protecting the file on a removable Flash RAM.

II. THE PROCESS OF CREATING AND READING A PROTECTED FILE

In the process of creating a protected file on removable flash memory (that is a creating an encrypted file and the signature of this file) and reading (decrypting) the file from the removable flash memory are necessary attributes of the user who created the protected file (this user will be called the sender) and user for whom the protected file was created (this user will be called the recipient). When a protected file is created the user logged into the system is the sender, and he specifies the file recipient using the **CApp**. When reading a protected file with using the **CApp** logged user plays the recipient role, a sender's attributes are read after successful decryption of signature of this file, using a private key of the logged on user. Permissible is a situation in which the logged user is simultaneously sender and the recipient of data.

The process of creating a protected file includes the step of encryption, and then creating a signature for that file. However during the process of reading a protected file in a first step the attributes needed for decrypting this file are obtained from the signature. In the second step the file is decrypted.

A. Creating a protected file

The process of writing the file, including file encryption and hash generation, is performed by the **EnD**. Operation of **EnD** has been presented in [1]. The diagram describing the process of writing the file is shown in Fig. 2. Dashed line in Fig. 2 indicates operations implemented by the **EnD**. During the process of file encryption is determined the value of the hash function to ensure the integrity of the file.

Determined value of the hash function, and the generated session key after completion of record are transferred to the **DSu** in order to generate a signature for the stored data. The process transferring the hash function value and the session key transferring is implemented using the system mechanisms marked in Fig. 2, as the IRP.

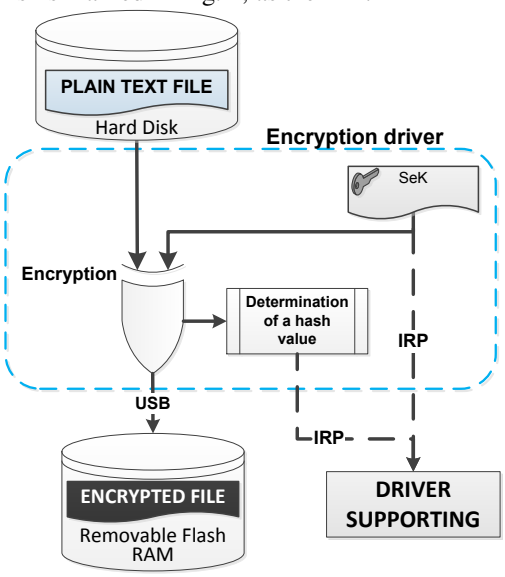

Fig. 2 The process of writing data to removable flash memory

B. Determining the signature

For each of the protected file the signature is generated which containing the information needed to read of this file. Signature of the file contains the following fields:

SeK - random key to encrypt / decrypt the secure file;
HASH - value of hash function which is determined based on the content of protected file after encrypting this file;
H_ID - identifier of the algorithm used to generate the hash;
En_ID - identifier of the algorithm used to encrypting;
O_ID - identifier of the logged user (the sender) who initiated the operation of data write - this identifier is required to determine the public key of sender when the file is read;
TMS - time stamp of file creation - this value corresponds to the date of file creation.

The structure of signature is shown in Fig. 4, and process of signature creation proceeds according to the diagram is shown in Fig. 3.

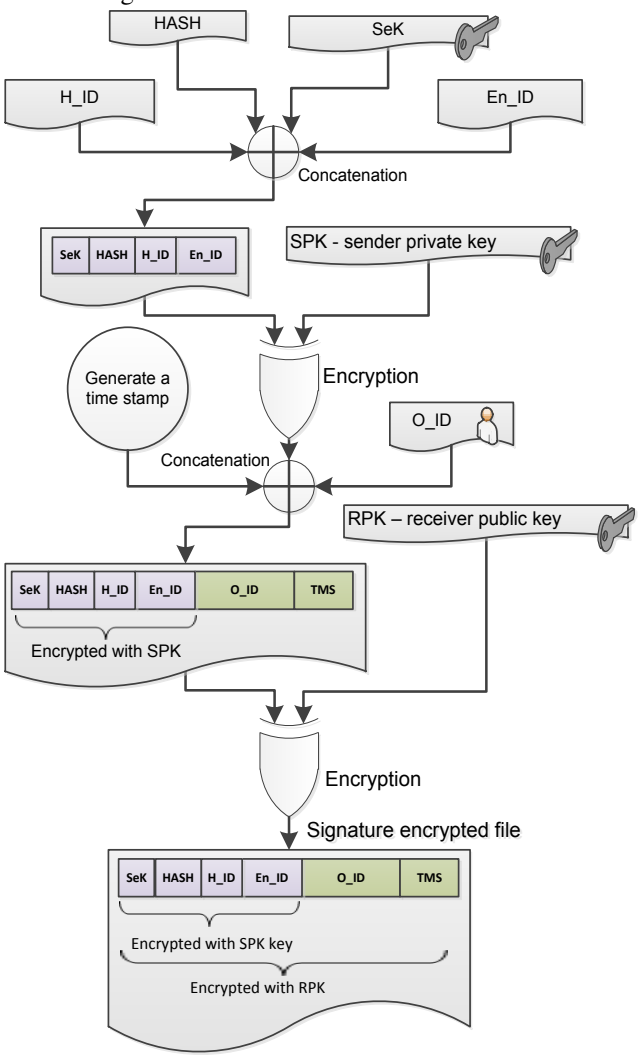

Fig. 3 The algorithm of signature generation for protected file

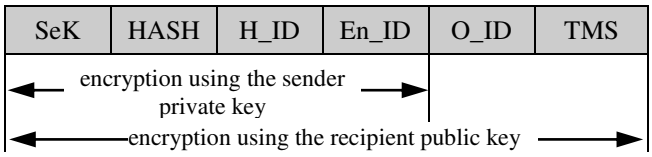

Fig. 4 The structure of signature secure file

C. Reading a protected file

The process of reading the file requires that the signature was read before and then decrypted. These activities are performed by the logged user (recipient of file) using **CApp**. The process starts with decrypting the signature file using the private key of the logged user, then reading time stamp and user identifier (O_ID) which assumed the role the sender creating a protected file. The time stamp protects the an encrypted file before moving it to another medium than that on which was originally written. Incompatibility of date and time stored in the time stamp and date and time, when the file was created, causes displaying the message and terminating the procedure of file reading. With compatibility of the parameters the next part of the signature is decrypted using the user public key which identifier (O_ID) has been read. The next steps of file decoding are schematically shown in Fig. 5.

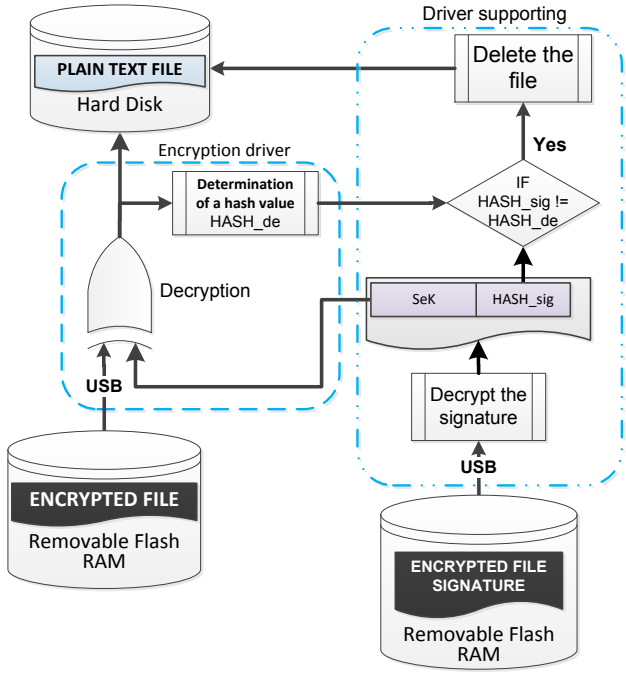

Fig. 5 The process of data reading from an external file

On the Fig. 5 operations performed by the **EnD** are marked using thick dashed line, and the operations performed by the **DSu** are marked using the thinner line (two dots dash).

During the read data the value of hash function (HASH_de) is determined. If the value HASH_de is different from the values obtained from the signature (HASH_sig) a message is displayed and the decrypted file, which was saved on hard disk, is being deleted [7].

III. THE CONCEPT OF USING TPM

Trusted Platform Module (TPM) is an implementation of a standard developed by the Trusted Computing Group [11]. This module is designed to support the cryptographic procedures and protocols that can be used for securing data [12]. Trusted Paltform Module, software TrouSerSwin consistent with TSS[1] and OpenSSL[2] library is a full-featured encryption system that provides the following functions:

- generating an asymmetric key pair;
- secure storage of keys;
- generating an electronic signatures;
- encryption and decryption;
- implementation of an operation defined by the standard PKCS # 11 cryptographic.

The TPM uses the mechanism of Root of Trust (RT) of secure data transmission in a computer system and is the basis to perform trusted cryptographic operations. This mechanism consists of the following components [8]:

- Root of Trust for Measurement (RTM) – uses Platform Configuration Registers (PCR) to record the state of a system;
- Root of Trust for Reporting (RTR) – uses PCR and RSA signatures to report the platform state to external parties in an unforgettable way;
- Root of Trust for Storage (RTS) – Uses PCR and RSA encryption to protect data and ensure that data can only be accessed if platform is in a known state.

The following algorithms are typically implemented in TPM: RSA, SHA-1, HMAC and AES[3]. In addition, each TPM chip stores a unique serial number and your RSA private key that is never available to read. TPM components are shown in Fig. 6.

The most important element of TPM is the cryptographic coprocessor. It performs the following actions:

- generating keys for asymmetric and symmetric cryptography using a Random Numbers Generator;
- encryption/decryption of data using the RSA algorithm;
- supporting of the integrity protection (SHA-1 Engine) and authentication (HMAC Engine).

The non-volatile memory of the module stores the asymmetric keys[4]: Endorsement Key (EK), Storage Root Key (SRK) and symmetric key NV_KEY. The EK key is usually generated during the production of the TPM and is used to decrypt the certificates for the other keys generated by the TPM. The SRK key is generated during the initialization of the TPM and is used as a master key to secure store of users' keys. In the key store are stored a keys of users who can create protected files (file sender) and users who will be recipients of protected files. The RK key is used to import the public key of recipients protected files. The NV_KEY key is designed to encrypt a data resource of users.

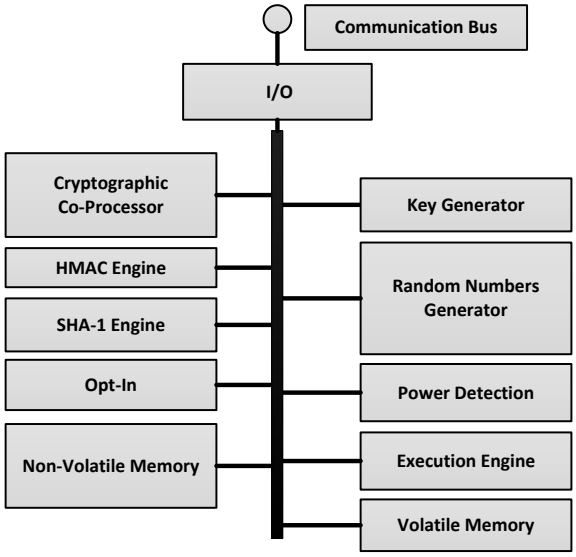

Fig. 6 TPM Component Architecture (based on [11])

For secure storage of user data involved in the exchange of protected files, especially cryptographic keys for that users, in the system created two protected resources: cryptographic keystore and TPM users' table.

A. Cryptographic keystore

The cryptographic keystore is designed to securely store, manage and share keys of all users involved in the exchange of protected files. These users include:

- local users who are on the station will be acted as the sender of uploaded files or recipient of received files;
- external users who are adequately recipient uploaded files and sender received files.

Keys for local users is generated by the TPM. The private key and public key of local users are stored in the cryptographic keystore. For each external user is kept only the public part of the key. The keys of external users are imported from other stations. Each key in the cryptographic keystore is identified by Universally Unique Identifier (UUID)[5].

Cryptographic keystore has a hierarchical structure (Fig. 7). At the top of the hierarchy is placed Storage Root Key (SRK). That key is generated by the TPM during the initialization of the module and is always stored in the non-volatile memory of TPM. Public part of the SRK key is used to encrypt the keys present in the hierarchy below the SRK key. The SRK key is the predecessor of the following keys:

[1] TSS – Trusted Computing Group Software Stack – specification of the software that allows the implementation of applications based on the TPM. For Windows OS, it is a project "TrouSerSwin", and in the case of Linux systems, it is possible to use the project "TrouSerS".

[2] OpenSSL – OpenSource cross-platform library that contains the implementation of protocols and general-purpose cryptographic algorithms.

[3] TPM uses a symmetric algorithm AES to protect the confidentiality of the session in which it participates following the recommendations of the TCG. However, symmetric encryption functions are not normally accessible outside the TPM.

[4] The Endorsement Key (EK) and the Storage Root Key (SRK) are mandatory for TPM while the Roaming Key (RK) and NV_KEY are necessary for the implementation of security procedures for files on Flash RAM.

[5] In the present solution as the UUID is used Globally Unique Identifier (GUID) of objects in Windows which is assigned to individual users.

- Roaming Key (RK) - used in the procedure to import the public keys of external users;
- Storage Key (SK) of local or external user - is used to encrypt the encryption keys used by individual users.

The safest place for storing cryptographic keys is non-volatile memory of the TPM, but due to the small size of the memory only the most important keys are stored there. Other keys are placed on your hard disk. The arrangement of keys is show in Fig. 7 to cryptographic keystore management is used the TrouSerSwin library with service TCSD[6] which works according to recommendations of the Trusted Computing Group.

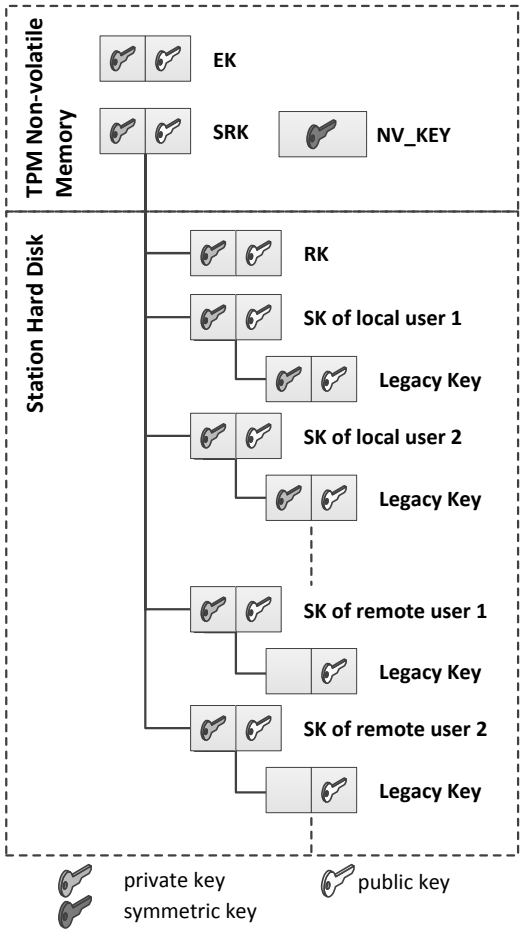

Fig. 7 Hierarchy of cryptographic keys supported by TPM

B. TPM users' table

The TPM users' table stores users data involved in the exchange of protected files. These refers to local and external users. A user with an access account to resources of the station may be considered as the local user. Otherwise an external user is the user with an access account to another station and whose data were imported from that station. The following record is combined with each TPM user:

- name of access account;
- display name of user;
- user Security Identifier (SID) on the local station - identifier used in Windows systems to determine access rights - USER_SID;
- Globally Unique Identifier of User - is used to identify the SK key of user – USER_GUID;
- identifier of user Legacy Key - this key is used to encrypt data intended for that user – USER_LEG_GUID.

The data of TPM users are encrypted with a symmetric key NV_KEY stored in non-volatile memory of TPM.

C. Cryptographic module

The cryptographic module is used to manage TPM users. This module consists of the following components:

- TPM;
- cryptographic keystore and a table of TPM users;
- TrouSerSwin library with service TCSD and Open SSL library;
- Management Console for Cryptographic Module (MCCM).

Architecture of cryptographic module is shown in Fig. 8.

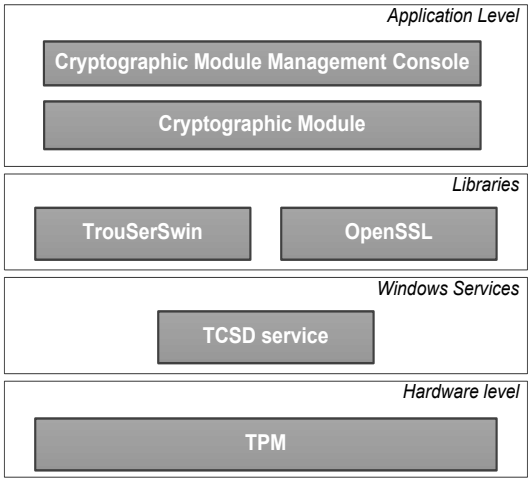

Fig. 8 Architecture of cryptographic module

The management console can be operated in a cryptographic module configuration mode and in TPM user management mode. The following functions are available in cryptographic module configuration mode:

- **login/logout** – opening / closing session of the cryptographic module configuration (entering the password for the owner of the TPM is necessary to opening the session);
- **reset TPM** – cleaning of TPM, i.e. delete all data from the cryptographic keystore and from TPM users' table;
- **initiate TPM** – creation of data structures for cryptographic keystore and for TPM users' table, and in particular the following keys: SRK, RK and NV_KEY.

A screenshot of the management console in configuration mode is shown on Fig. 9.

The following functions are available in user management mode:

- **Add user** – add a local user;
- **Remove user** – remove the user together with his keys stored in the cryptographic keystore;

[6] TCSD – software for management of TPM resources and support of local and remote requests. The software is part of TrouSerSwin software or TrouSerS software.

- **Generate keys** – generating the cryptographic keys for a local user;
- **Remove keys** – removal of previously generated cryptographic keys for the user;
- **Initiate import** – preparation of removable media to import external users data;
- **Import users** – import external users data;
- **Export users** – save the data of local user on previously prepared USB stick to transfer the data to another station.

A screenshot of the management console in user management mode is shown on Fig. 10.

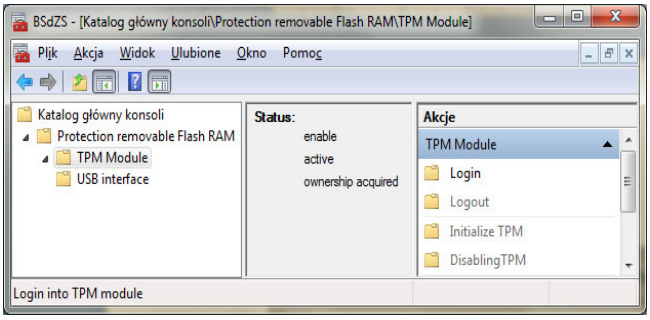

Fig. 9 A screenshot of the management console in Configuration Mode

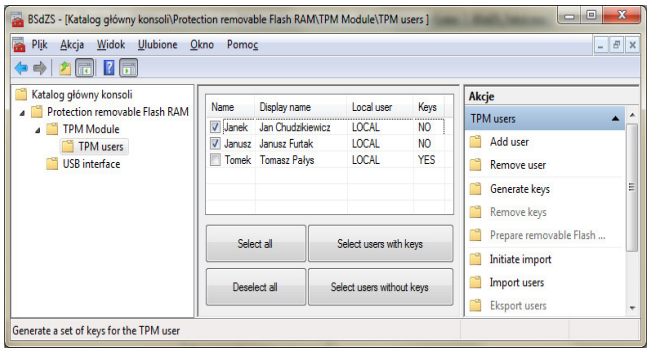

Fig. 10 A screenshot of the management console in User Management Mode

The "Add user" is designed to select from among the users defined in the system users who will be able to transfer protected files. For each selected user the GUID is generated. Data for these users are placed in TPM users' table.

The "Generate keys" is designed to generate the SK key and Legacy Key for local TPM user and put the keys in the keystore.

D. Export / import of user data

The procedure for preparing a protected file requires public key of the external user (file recipient) The source from which the keys are obtained, are stations where target user is a local user. The procedure for transfer of selected data about the local users of station ST2 to station ST1 includes the following activities (Fig. 11):

- transfer the public part of the RK key of ST1 station (e.g. via Flash RAM) - preparing a Flash RAM using the action "initiate import";
- providing media to the station ST2;
- preparation of a protected file that contains data about the local users of station ST2 using the action "Export users";
- providing the file and signature to the station ST1;
- decrypt user data, adding data these users (as an external users) to TPM users' table, and keys of that users to the keystore using the action "Import users".

Transfered protected file contains data of only selected local users of station ST2. The data of each user include:

- display name of user;
- Globally Unique Identifier of User – USER_GUID;
- identifier of the user Legacy Key - USER_LEG_GUID;
- public part of the user Legacy Key.

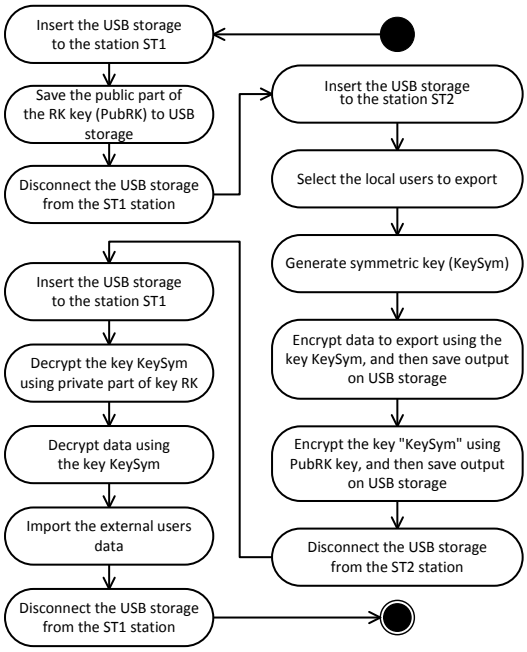

Fig. 11 Import data of users from station ST2 to station ST1

The file containing the user data is encrypted using a symmetric key generated at the station ST2. For that file is prepared other file (signature) containing symmetric key used to encrypt that file and value of SHA1 hash function for that file. The file (signature) is encrypted using the previously supplied public part of the key RK ST1 station.

At the station ST1 the received file containing signature is decrypted using the private key RK of the station ST1. In the next step the integrity of the file is checked up, then the file is decrypted using the symmetric key contained in the signature file.

The new records are created in TPM users' table basing on contents of received file. For each new external user in cryptographic keystore creates a hierarchy of keys containing the key SK and Legacy Key. The key SK is generated and will be identified by the sent user identifier USER_GUID. Lower in the hierarchy will be placed sent the Legacy Key.

IV. HANDLING FOR CREATING AND READING A SECURE FILE

The process of creating protected file requires first of all connection one or two (depending on where the file with the signature will be stored) removable Flash RAM memories to a computer through USB interface. The devices are automatically detected by **EnD**, which transmits information about them via the **DSu** to **CApp**.

Logged user (file sender) configures the parameters of the process of creating a protected file using **CApp**. These parameters are as the following:

- location of public key data recipient file ("Location of Public Key" field) – TPM is default (see Fig. 12), but it is possible provide the recipient public key from a disk (see Fig. 13);
- identifier for user (receiver) encrypted data ("Data Recipient" field) – one of the users whose keys are stored in the assets managed by the TPM;
- drive in which will be stored the protected file ("Data Drive" field);
- drive and path to the directory in which will be stored the file with the signature ("Signature Drive" field);
- identifier for the algorithm used to encrypt ("The encryption algorithm" field);
- identifier for the algorithm used to generate hash value for the protected file ("The Hash function algorithm" field).

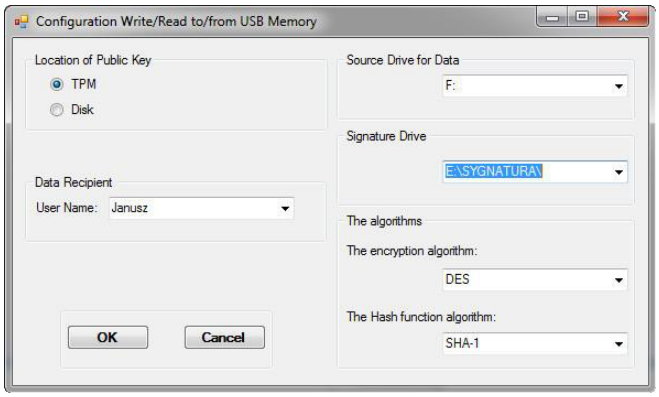

Fig. 12 The window of control application CApp for write data - recipient's public key is derived from the TPM

Identifier (O_ID) and the private key of the sender (the elements required to generate the signature) are automatically retrieved from the cryptographic keys storage managed by TPM. After determining the data configuration logged user can begin the process of copy the file using , e.g. Windows Explorer. The name of file which stores the signature will be concatenation of the name of protected file and string "SIG". The process of creating a file with the signature is started after the encryption process is finished and is, just as the encryption process, invisible to the user. When next file for the same recipient is being encrypted it does not need to change the configuration data unless the other parameters (that is the identifier of encryption algorithm or identifier of algorithm generating of hash value) will be changed. Always for the next file a new session key will be automatically generated.

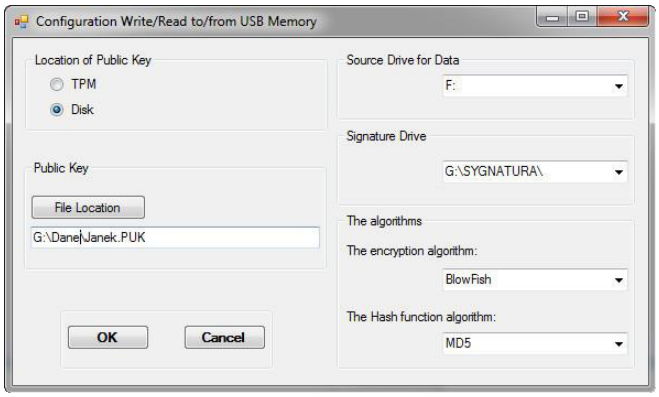

Fig. 13 The window of control application CApp for write data - recipient's public key is derived from disk

The process of reading protected file requires connection to a computer through USB interface one or two (depending on where is stored the file with the signature) removable Flash RAM memories. The devices are automatically detected by **EnD**, which transmit information about them via the **DSu** to **CApp**. The logged user (recipient of the data) using **CApp** has to specify the drive on which is stored encrypted file and indicate the file with the signature corresponding to the encrypted file. He accomplishes this by selecting (see the Fig. 14):

- drive on which is stored the protected file ("Data Drive" field);
- drive and path to the directory on which is stored the file with the signature ("Signature Drive" field).

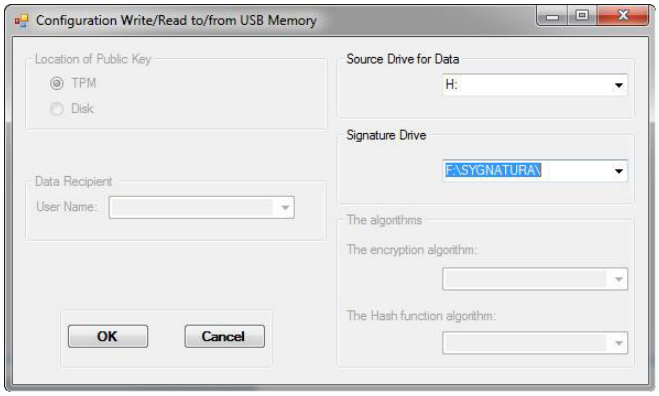

Fig. 14 The window of control application CApp for read data

Other parameters required to decrypt the file are determined based on the signature. After initializing by the logged user the process of copying a file **EnD** sends to the **DSu** the name of the copied file and pauses the copy process to the moment when receives data required to decrypt the file (that is the identifier of encryption algorithm, session key and identifier of algorithm generating of hash value). Based on submitted by the **EnD** the name of encrypted file, **DSu** identifies a file containing the signature and performs

the process of signature decryption and reading the configuration data. Then performs the verification process read out TMS with the date and time of the creation of an encrypted file. In the case of inequality of these values message is displayed and the file reading process is interrupted. In the case of equality of those values other configuration data read from the signature are passed to ***EnD***, which resumes the process of decryption. During the process of decrypting the file the ***EnD*** determines the value of a hash function for that file. After completion the process of copy ***EnD*** transmit to ***DSu*** determined value of the hash function for verification. If the designated hash value is not equal to the value read from the signature a message is displayed and the ***DSu*** deletes the file which has just been decrypted.

II. Conclusion

This paper presents a method for securing data on removable Flash RAM used to transfer sensitive data over insecure channels of transmission, such as a courier, traditional mail system and so on.

The developed method ensures the integrity and confidentiality of protected file. File sender (i.e., the creator of the protected content) is to ensure that the data will be available only to the specified recipient. The recipient can be sure that the resulting data are derived from the appropriate sender. Protecting the original file consists in preparing two files. The first one contains the encrypted contents of the original file (symmetric algorithm is here used). The second file is the signature for the encrypted file and contains the encryption key and the hash function value for encrypted file. The second file is encrypted using asymmetric cryptography. This approach ensures the safe transfer of the encryption key between stakeholders.

Both parties involved in transferring such protected data are forced to safely generate asymmetric keys and the safe theirs collection, storage and management. Particularly important is the proper procedure to generate symmetric key. For this purpose, the TPM has been used. This module supports (by using the hardware) many activities related to securing data on removable media and provides secure management of cryptographic keys.

From the safety point of view the most sensitive point of presented system for protecting the files transferred using removable Flash RAM is the procedure for export / import keys of external users. Particularly sensitive operation is "manual" transfer of a public key of station to which the data of users should be imported. The presented method is intended for use in an environment where it is not possible to use a computer network for data transfer. Such restrictions may apply in case of data transferring between systems, which belong to different security domains (i.e. with different levels of classification)[2][4] [12]. For this reason, it is not possible to use public key infrastructure (PKI) and Certificate Authority (CA). On the other hand organizational requirements for how to process data in such systems and how to use the removable media give a guarantee for safe transfer of the public key by the described procedure of export/import data. It should be noted that in cases where there are no obstacles to the use of computer networks in the presented procedure of export / import data is possible to use PKI and CA.

***Abstract*—The aim of this paper is to present a prototype LocNet API programming interface for indoor positioning systems and a prototype LocFusion API interface enabling joint use of terminal positioning data from mobile operator's GMLC and the LocNet API. The use of data from complementary information sources can improve the accuracy of user terminal positioning in large buildings, where coverage of satellite systems is weak.**

***Index Terms*—Location Services (LCS), Application Programming Interface (API), Open Middleware, Mash-Up Services**

I. Introduction

THE ABILITY to determine the geographical position of a wireless terminal allows telecom operators to implement new Location Based Services (LBS) [1], [2], [3], [4]. Mobile operators can provide their subscribers with a variety of information related to their actual geographic location, e.g. the nearby points of interest such as ATMs, hotels, restaurants, gas stations, traffic information, etc.

Terminal localization techniques used in contemporary mobile communications networks vary in accuracy offered, implementation complexity and cost. The simplest positioning methods, such as Cell-ID or received signal strength (RSS) based, are usually easy to implement in existing networks and do not require any modifications to the user terminals. The accuracy offered by these methods strongly depends on the size of the cells as well as on radio wave propagation conditions. In typical scenarios, the positioning accuracy varies from a few hundreds to tens of meters. Much better positioning accuracy may be achieved with the use of satellite positioning systems, such as the popular GPS. Satellite systems allow to determine user location with an accuracy of up to a few meters. However, the use of satellite receivers for accurate positioning of mobile terminals in indoor environment or in densely built up city centers is difficult or impossible. Thus, due to the weak coverage, satellite systems are not useful in areas with a large concentration of users (i.e. where such services are needed) [5]. These limitations of contemporary positioning systems contribute to the search for alternative high accuracy and availability methods suitable for complex environments.

One of the possibilities to increase accuracy of positioning in indoor areas is to use dedicated local positioning systems [6] along with contemporary Gateway Mobile Location Centre (GMLC) service. An attempt to integrate local indoor positioning systems with UMTS network architecture was described in [7]. The authors proposed integration of local indoor positioning networks (Assistant Location Networks) directly into core network.

In this paper we present a prototype LocFusion API. This programming interface allows joint use of information obtained from the GMLC of the network operator and from an indoor positioning system. In the prototype implementation, the access to the GMLC data is provided by Orange Labs Poland with the use of TerminalLocation API Telco 2.0 interface [8]. The information from local positioning systems is available through the proposed LocNet API interface.

The remainder of this article is organized as follows:

- Section II presents the basic concept and principles of operation of LocNet API prototype. LocNet API allows to access the results returned by local indoor positioning systems extending the range of satellite based localization services.
- The architecture, the operation, and the implementation of LocFusion API prototype are described in section III. LocFusion API allows joint use of location information from the operator's GMLC and the LocNet API.
- Section IV provides possible usage scenarios for LocFusion API.
- Section V summarizes the paper.

II. LocNet API

LocNet API is a universal programming interface used to communicate with compatible local indoor positioning systems. The interface retrieves the coordinates (x, y, z) describing the user's location inside the building along with supplementary position related information, e.g. description of the zone of the building, floor number etc. The interface specifies only communication protocol and does not impose implementation of any particular positioning methods and algorithms. Thus, the LocNet API can be used with many different classes of positioning systems.

The prototype implementations of LocNet API described in the paper were tested with two different positioning systems: LocNet indoor positioning and tracking system developed and maintained by Lodz University of Technology [9], [10], and LocNet-PW terminal positioning system developed by Warsaw

978-83-60810-53-8/$25.00

University of Technology and Orange Labs Poland. Both systems used throughout the tests employ GSM and/or Wi-Fi received signal strength (RSS) measurements [11] to estimate the actual position of the terminal [12]. However, the two systems employ various classes of positioning algorithms and are implemented with the use of different server technologies.

To enable interaction between local positioning servers and LocNet API, the servers should be capable to accept LocNet API compatible requests and return positioning results in LocNet API compatible data format.

LocNet API application server is responsible for registration and management of local positioning servers providing terminal location information. This is achieved with the use of a database storing information on LocNet locations (i.e. sites where local positioning systems are available) and corresponding configuration parameters.

LocNet API application servers also triggers GSM/Wi-Fi RSS measurements required to estimate actual terminal position. To achieve that, the server communicates with user terminals. To support the RSS measurements, a dedicated LocNet Android application was developed. The application designed for Android based mobile devices performs GSM/UMTS/Wi-Fi signal strength measurements and passes the results back to the server. After successful initialization, LocNet Android application runs in the background. The application can be activated with the use of SMS message sent by LocNet API. After activation, the application starts the measurement procedure and sends the results back to the LocNet API. RSSI measurement results are sent in JSON format.

III. LocFusion API

The main goal of the LocFusion API interface is to allow joint use of terminal location data from different, complementary sources [13]. LocFusion API permits co-operation with local indoor positioning systems through LocNet API and with the GSM/UMTS network Gateway Mobile Location Centre (GMLC) via RESTful API exposed by PLMN operator. The possibility of common use of the location information from different sources makes it possible to determine more accurate information on the probable location of the user terminal.

LocFusion API enables to determine the user's location information in one of the two modes. Basic operation mode involves determining the user's location based on the results of the received signal strength measurements collected at a single point of the building. The other mode involves the possibility of determining the position of the terminal based on a sequence of signal strength measurements collected along the path describing the movement of the user [14].

LocFusion API interface makes it possible to easily incorporate additional sources of positioning information, such as RFID, dedicated WLAN systems using other communication protocols (ZigBee, 6LoWPAN), inertial sensors, etc.

A. API Architecture

The system is composed of three main modules: local positioning networks coupled with local positioning server, dedicated application server that manages all local positioning networks and exposes their features via web-based API, and main application server that manages all of the elements and communicates with the user. A database of sites where wireless local positioning networks are deployed is managed and supervised by LocNet API application server. The server also provides indoor positioning data for the API. An important part of the prototype system is Telco 2.0 Web Gateway that is used to incorporate external GMLC into the system. The architecture of the proposed solution is presented in Fig. 1.

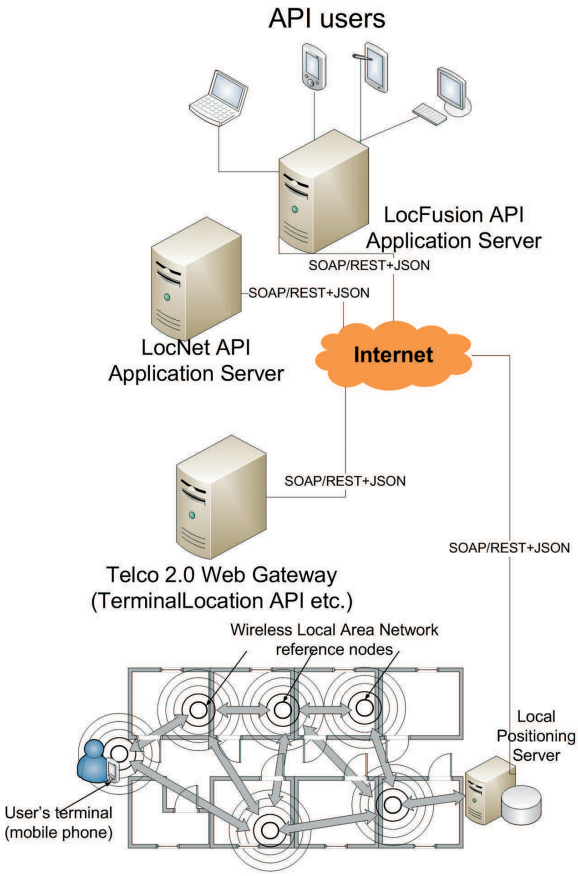

Fig. 1. LocFusion architecture.

Main application server is also responsible for managing security policy of the LocFusion system, especially for user authorization and maintaining legal affairs of estimating user's position in PLMN.

B. Software Architecture

LocFusion API has a modular software architecture. Every module can be developed separately and independently of each other until interfaces interoperability is kept. Moreover, at functional level LocFusion software is layer-organized as shown in Fig. 2.

Modular software architecture permits to expose certain positioning modes over the northbound interface. For prototype implementation three different API modes have been

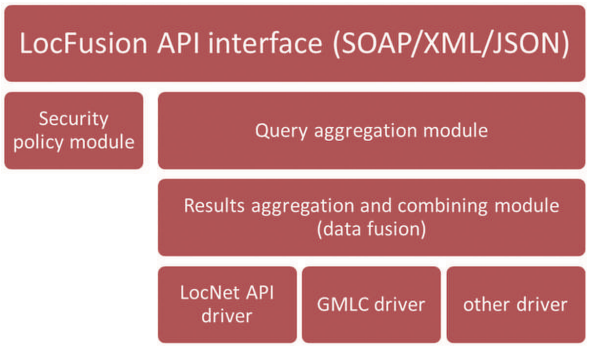

Fig. 2. LocFusion Software Architecture Functional Diagram.

implemented:

1) Single position estimation:
   - With remote call address (callback) – in this mode request identifier is returned immediately while entire terminal position is passed to provided callback address as soon as it is available,
   - At single HTTP transaction – in this mode HTTP response is sent to the user directly with estimated position. Server response contains only position estimator, request identifier is not passed to the end-user.
2) Multiple position estimation:
   - With remote call address (callback) – in this mode request identifier is returned immediately while entire terminal position is passed to provided callback address as soon as it is available. Terminal position is estimated periodically, the period between each two estimations is provided within request along with the total number of position estimations.

In each mode at least two parameters have to be provided in order to perform user positioning: valid authorization key (API-key) and phone number. Each API-key is then verified in Security Policy Module against phone number to verify whether positioning permission has been granted by the user. In particular, terminal can be localized only if user granted permission for MSISDN to be localized.

C. LocFusion Query Processing And Aggregation Algorithm

In many positioning system applications developers and designers focus on accurate positioning in means of estimating absolute geographical location of the end user. This approach is the most convenient way to mark position in outdoor scenarios, hence it is easy to integrate with GIS systems.

On the other hand, indoor positioning does not rely on absolute location identifiers since in-building descriptors (e.g. “office room 312” or “conference room”) can be more convenient to utilize. Moreover, when 3D positioning is considered accurate and reliable altitude identification is necessary. When considering outdoor positioning absolute altitude above the sea level is the most popular. For indoor positioning the most applicable altitude identification could be floor index

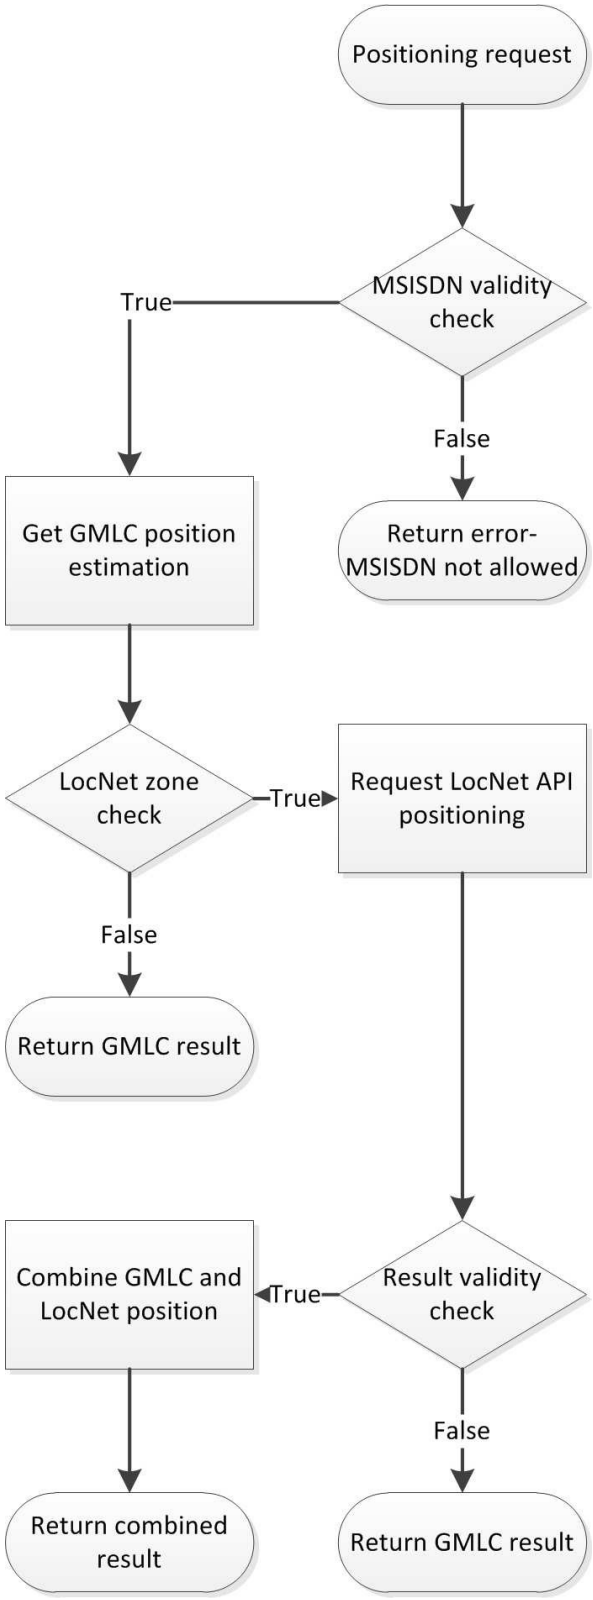

Fig. 3. Query processing algorithm.

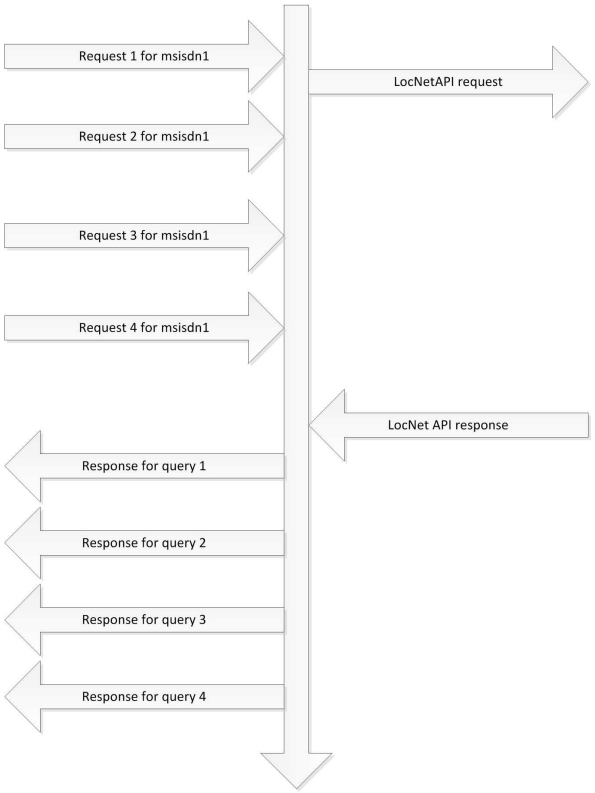

Fig. 4. Query aggregation flow diagram.

(e.g. ground floor, 1st floor etc.), hence it is more convenient building altitude identification rather than absolute values above the ground or sea level.

Therefore, LocFusion API is designed to provide additional descriptors for indoor position including floor index or name, zone within a building (e.g. "north wing"), room or office number or its name (e.g. "kitchen" or "office room 312") and site-related information (if available), including site features etc.

Moreover, contemporary absolute geographical position is calculated and returned for API backward compatibility. Absolute coordinates are also be the only result if no additional indoor positioning could be invoked.

Therefore every valid positioning request is internally processed with the use of an algorithm presented in Fig. 3. In order to increase API efficiency and to minimize LocNet API calls internal API request aggregation module has been implemented. Main feature of this module is to collect all valid positioning request for certain mobile subscriber and satisfy all the requests with single LocNet API call and thus single terminal call. Aggregation module operation idea is presented in Fig. 4.

IV. Usage Scenarios

LocFusion API might be seamlessly incorporated in a number of Location Based Services (LBS) but it is primarily designed to increase positioning accuracy inside the buildings. Therefore, possible use scenarios include but are not limited to monitoring and navigating the elderly or disabled people indoor, services allowing parents to localize their child, monitoring the trace of the employees (e.g. couriers or security guards).

The ability to determine reliable user position inside building makes it possible to aid elderly or visually impaired people in navigating inside public buildings like offices, hospitals or shopping centers. In this case LocFusion API might serve as reliable and accurate network-based user location source. Moreover provided context- related information might be used directly to inform users on their current location.

There are already developed applications that use positioning capabilities of the mobile network (offered by GMLC) to help parents in finding their child. These services offer rough location estimation and thus do not make possible to find a child for example inside big shopping center. In this case LocFusion API might provide both: rough location outside building (as accurate as the one offered by GMLC) and accurate context-related position inside the building. It is worth to mention that returned results include description of the building area (like "left wing corridor", "3rd floor") which makes them easy to use in finding people indoor.

LocFusion API makes it possible to send periodic position updates to the remote service and thus allows to implement a variety of tracking and monitoring LBS directly on the basis of the API. Possible use of the API includes monitoring and tracking of the employees that should follow a desired trace like couriers, security guards etc. It is also possible to use LocFusion API for Machine-To-Machine (M2M) applications, mainly for tracking of important and precious equipment (machines, electronic devices etc.) coupled with GSM module.

V. Summary

This article presented the prototype Application Programming interfaces that allows joint use of the dedicated indoor positioning system and GMLC in order to improve accuracy and usability of the location information. Modular system architecture and detailed description of the key components has been provided as well as detailed summary of developed query processing algorithms. The article also provides description of the possible use of LocFusion API.

Future works on the API includes evaluation of API performance in both computing and network usage aspects. It is also planned to undertake experiments to analyze positioning error when LocFusion API is used for tracking services.

***Abstract*—The paper presents a set of mobile applications aiding the visually impaired in using the public transport. A user equipped with a modern smartphone with mobile data transmission and positioning capabilities can access location related context information. Keeping up the connection with dedicated system servers gives the user access to additional services, e.g. enables the use of passenger information system and provides access to services facilitating the navigation in urban areas. The paper describes an overall architecture of the system for guidance and public transport assistance of the visually impaired. Then, the details of the applications developed for Android based smartphones are presented. The applications are mainly focused on aiding in urban navigation and provide various ways of accessing data from public transport passenger information system.**

***Index Terms*—Context-aware services, mobile computing, personal communication networks, pervasive computing, radio navigation**

I. Introduction

ACCORDING to the World Health Organization there were more than 285 million visually impaired living in the world in 2012 [1]. Even moderate vision impairment may strongly affect their everyday activities and often leads to social exclusion. Inability to sense the surrounding environment, poor orientation and navigation capabilities, difficulties in accessing textual information result in a limited mobility of the blind and the visually impaired [2]. Travelling becomes especially challenging in urban areas. Lack of good spatial orientation makes difficult to find a safe path among obstacles, and to locate and identify points of interest (POI) like bus stops or pedestrian crossings. Inability to access textual information like street name, public transport timetables, numbers of vehicles gives rise to additional difficulties. Recently, a number of electronic travel aids (ETA) addressing the needs of the visually impaired have been developed. The devices are used to overcome difficulties associated with everyday activities, i.e. problems with spatial and geographical orientation, navigation, accessing visual information. Electronic systems aid the visually impaired in mobility and in accessing various public services. One of the applications of the electronic aids is to facilitate access to public transport services. Precise information on user location can be used to retrieve position related data from public transport passenger information systems, e.g. bus or tram arrival times, information on routes, temporary changes to the timetables, etc. A number of electronic systems aiding the visually impaired in urban travelling involve various beaconing techniques to identify landmarks like bus or tram stops, entrances to public buildings, etc. [3][4][5][6][7]. Transmitters installed in the landmarks send signals uniquely identifying the place. System information can then be decoded with the use of a dedicated handheld receiver and presented to the user as voice messages. Another approach to guidance of the blind involves the use of dedicated user terminals equipped with GPS receiver, GSM transceiver and inertial sensors [8][9]. With the growth of popularity of advanced mobile phone terminals, more and more smartphone applications aiding the visually impaired in navigation and travelling appear on the market [10][11][12]. Some of them, like OnTheBus project [10], address also the problem of public transport accessibility. Significant number of various ETAs have been developed so far trying to solve different mobility difficulties. However, many of the assistive devices and applications address only selected aspects of the mobility problems, and hence have not gained wider acceptance of their target group of users so far. Therefore, there is still a pursuing need to develop complex solutions aiding the visually impaired in mobility as well as aiding other groups of users in travelling in urban environment.

II. System for guidance and public transport assistance

The architecture of the proposed system for guidance and public transport assistance of visually impaired is shown in Fig. 1. The system consists of several subsystems: a mobile user terminal, a network of radio beacons, and application servers. The mobile user terminal can either be a dedicated electronic device or an Android based smartphone. Dedicated terminals, equipped with GSM/UMTS transceivers, GPS receivers, inertial sensors and a camera are used to obtain precise user location information, to provide communication channel to remote assistant of the user, and to present voice messages to the user. The Android smartphone based version of the terminal in general plays the same role, however, its functionality can be easily modified by installing additional applications. In the next section of the article we present a

978-83-60810-53-8/$25.00

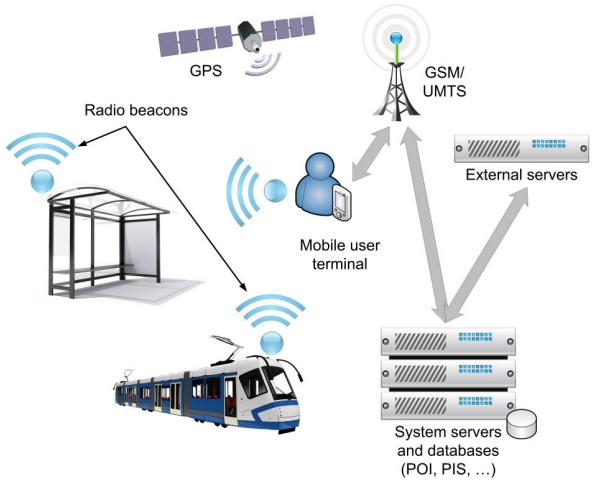

Fig. 1. Architecture of the electronic system for guidance of the visually impaired in urban environment.

set of mobile phone applications aiding in urban navigation and public transport accessibility. The network of low power and low range radio transmitters is used to provide precise information on actual location of the user and to facilitate access to position related data, e.g. a timetable of vehicles arriving at the bus or tram stop [13]. The servers of the system store public transport passenger information data and points of interest databases, as well as expose services enabling communications between all of the system components.

A. Passenger Information System

Currently a lot of cities operate real-time public transport management systems (PTMS). Such systems help transport company to increase the efficiency of running vehicles, reduce travel times and/or improve the punctuality, especially when PTMS is integrated with traffic lights management system. Very often PTMSs include passenger information subsystem (PIS) providing information about estimated arrivals and/or departure times as well as travel times. Usually such data are displayed on dedicated signs located within bus stops. However such approach is very useful for almost all passengers it is completely useless for blind and semi blind people for obvious reasons. Similar system is operated in Lodz, Poland by municipal transportation company MPK. Lodz is mid-size city in central Poland of the area 300 km^2 with more than 700000 inhabitants. MPK operates about 200 trams and 400 buses serving almost 100 routes. Trams and buses fleet is managed by RAPID system delivered by Sigtec, Australia integrated with adaptive traffic system SCATS developed by Road and Maritime Services in Sydney. Currently RAPID controls 14 passenger information signs located on tram stops, in 2013 next 16 signs will be added. Vehicle localization in MPK system is made by on-board GPS receivers. Vehicles send data to the server in 20 seconds intervals. Position messages are also sent when the vehicle enters or exits stops and intersections. This allows the server to estimate travel times and send predicted departure times to stop signs. In case of traffic problems passengers can also see appropriate messages. Unfortunately blind people due to the nature of their disabilities cannot be informed about, vehicles approaching or awaiting at the stops, vehicle delays and temporary changes in route paths introduced in response to serious traffic problems. Visually impaired people may also found problems with stops localization, especially when they do not know city topology or stops were moved to temporary locations due to street construction works. Blind aid system designed in Institute of Electronics is connected with MPK system through VPN tunnel and receives in real time all major information: current timetables, route paths, vehicles allocations, trips cancellations, detours, run-ins and run-outs. The system also incorporates radio tags placed on stops, points of interests as well as vehicles. There are running two services for travel aiding: trip planner and trip assistant. The aim of the trip planner is to find optimal from blind people point of view route from point A to point B. Trip planner optimizes travel time as well as walking distance necessary to reach the destination. Starting and ending trip points may be described as geographic coordinates and/or points of interest including public transport stops. Travel start time interval must also be described. For guided people convenience trip planner allows for maximum one vehicle exchange. Vehicle kind (tram, bus or both) may also be specified. Regardless the form of describing start and end points of the travel trip planner locates up to 10 nearest stops. Even if direct trips were found the system also searches for trips with one exchange. This allows to find several trips serviced with different routes and select the best one for the guided person. In the case where no trips were found system increases default values for the maximum distance between change stops and searches for start and end stops within greater radius. As a result following data for each trip are obtained: trip identifier, route number, direction, vehicle identifier and type (tram or bus), estimated arrive times for first and last stops, distance between starting point and start stop and the distance between ending point and end stop.

Arrive times are calculated by averaging travel times between consecutive stops for given route, type of the day and time of the day. As the type of the day working days, Saturdays and holidays are distinguished. The whole day is divided for 2 hours intervals, so separate calculations are performed for peak and off-peak hours. Trip assistant starts working when the passenger begins journey approaching starting stop. Awaiting passenger may be informed about estimated arrive time of the desired vehicle. Next, when passenger entered the vehicle, he/she may be informed about remaining stops to the destination or the exchange stop as well as about remaining time of the travel.

III. Mobile Applications for the Visually Impaired

To present the information from the public transport Passenger Information System to the users, a set of mobile phone applications was developed. POI Explorer and Public

Transport Explorer applications dedicated for Android based smartphones are used to aid the visually impaired users in urban navigation and travelling. Two other applications use NFC and USSD technologies to access the data. The NFC application can be used with any NFC enabled device. Taking into account low market penetration of NFC capable phones, also USSD messaging was implemented as an option available to almost all the range of mobile phones.

A. Smartphone Based Urban Navigation ij POI Explorer and Public Transport Explorer

Blind users usually use iOS or Android based mobile phones. The reason for that is that both the systems have built-in text to speech modules: Voice Over [14] and TalkBack for iOS and Android respectively. Availability of such system modules allows developers to create their own applications using standard GUI elements which can be easily presented to the visually impaired users. Most of smartphones are equipped with touch screens and have gesture-based screen readers, for example a single tap causes a button's description to be read, requiring a double tap to activate the button's original function. Such an interaction with a smartphone requires the use of both hands and may be especially uncomfortable for blind users who are at the same time using a white cane. That is why we proposed a dedicated electronic device, equipped with Bluetooth module and keyboard which can be used to control selected functions of mobile applications [15]. Moreover, it can be used to read data from a network of radio beacons indicating various point of interest [13], and to pass this information to the phone. Depending on the beacon type, application can present the user information on entering some area, on vehicles approaching a stop, etc. We developed two applications POI Explorer [16] and Public Transport Explorer aiding the visually impaired in travelling with public transport. They are dedicated for the most popular mobile platform: Android. First one uses points of interests to the navigation purposes. They are stored on remote MySQL/PHP server, which allows to keep the database update. Moreover, such a solution allows to provide a universal API for other platforms. To exchange the data between the server and mobile phones XML language was used. Users can also add additional personalized information to the points (text notes, voice records) to enrich the database. POIs are organized into categories and subcategories, which allows to find necessary information easily. After logging in it is possible to add user's private data (paths or points of interests).

Users are navigated along the predefined paths or to the selected point (e.g. selected bus stop) using distance and direction information. Because the electronic device is equipped with an electronic compass, mobile phone can be kept in a pocket and the user can use the device for the orientation purposes. Keyboard allows to select application functions. Text to speech module is used to read messages. Additional feedback is provided by the vibration engine. POI Explorer can be also used without the device, in this case TalkBack screen reader is used for sonification of messages. The POI database can be managed using web application. Such solution is dedicated for sighted persons (for example someone from visually impaired person family) and allows to plan path or to manage private POIs.

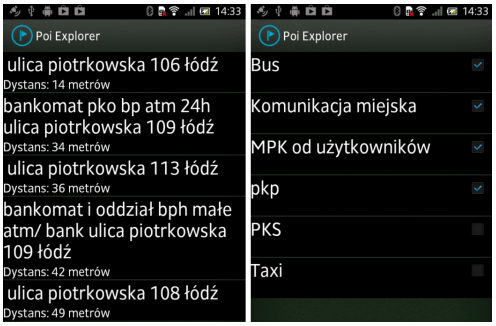

Fig. 2. Screenshots from the POI Explorer application captured by Sony Xperia S Android Phone. The list of the points of interests in the front of the user (direction is calculated based on compass values) are presented in a standard list box. On the right: list of subcategories of the category "Transport".

Public Transport Explorer application uses data served by passenger information system. Users can get timetables, current position of the selected vehicle, they can also plan their travel. As the passenger information system relies on actual GPS based positions of the public transport vehicles, the data presented to the user are up-to-date. It especially important if the user is inside the vehicle, where GPS signal can be very weak. This feature is also of a great value when the stops are moved to new, temporary locations, or when the routes or timetables of public transport vehicles temporarily change. As can be noticed, the graphical user interfaces of POI Explorer and Public Transport Explorer use large, high contrast characters aiding users with moderate visual impairment. System requirements of our applications allow to run them on low cost devices. Both applications have been consulted with the blind users from the Polish Association of the Blind.

B. NFC Enabled Passenger Information System Access

Near Field Communication (NFC) is designed to allow short-distance data exchange. It supports data exchange in two modes: passive mode, where only one device generates electromagnetic field (carrier) while the other device only modulates it. Moreover, modulating device might use power from electromagnetic field generated by another one, thus making one of the devices a transponder. The other mode is an active mode, where both devices generate EM fields alternately. Developed NFC enabled Passenger Information System makes use of the passive NFC tags. The tags are placed close to timetable boards at the bus or tram stops. Every tag stores a code that uniquely identifies a stop and redirects the user to a dynamically generated web page presenting the most up-to-date information on the bus or tram arrival times. The advantage of the electronic timetable is the use of real time data from passenger information system, therefore the web

Fig. 3. Screenshot of an application for NFC enabled passenger information system access.

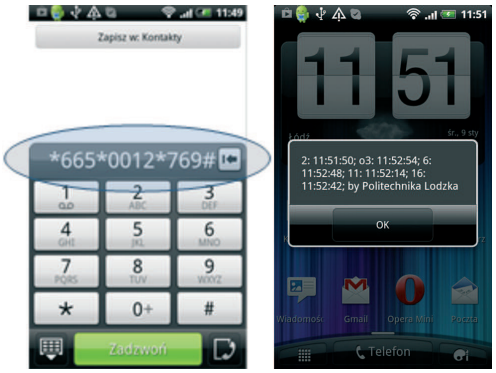

Fig. 4. USSD enabled passenger information system access.

page always displays actual bus or tram departure time as shown in Fig. 3. For this stateless service a dedicated proxy service has been developed. It uses Windows Communication Foundation (WCF) to provide RESTful API for passenger information system.

C. USSD Enabled Passenger Information System Access

Unstructured Supplementary Service Data (USSD) is a protocol used in GSM network for data exchange between mobile phone and Public Land Mobile Network (PLMN) infrastructure. With the use of API exposed in Telco 2.0 model it is possible to use USSD messages for communication between any GSM-enabled device to any Internet service. Proposed access method requires user-initiated USSD session. In the initial message (that is provided in the same manner as number user want call to) user has to provide unique USSD service prefix (assigned by PLMN operator) and a bus or tram stop number. When a user initiates the dialogue, a message is passed through internal PLMN components to Telco 2.0 WebGateway (exposing PLMN features to the Internet) and then to Passenger Information System application server. Information on next bus/tram departure time is then retrieved from the system via aforementioned proxy service and sent back to the user as shown in Fig. 4.

IV. Summary

Although many electronic travel aids have been developed so far, urban spaces and public transport services still remain hardly accessible to the visually impaired. Poor spatial orientation and inability to access textual information makes difficult to locate and identify bus or tram stops and to read public transport timetables or numbers of vehicles arriving at the stops. The system described in the paper is a part of a solution aiming at assisting the visually impaired in travelling with public transport. The passenger information system provides actual data on routes and timetables of the vehicles while proposed mobile applications makes that information accessible to the users equipped only with ordinary mobile phones.

Abstract—The paper is devoted to consideration of an innovative access network dedicated to B2B (Business To Business) applications. We present a network design based on passive optical LAN architecture utilizing proven GPON technology. The major advantage of the solution is an introduction of SDN paradigm to PON networking. Thanks to such approach network configuration can be easily adapted to business customers' demands and needs that can change dynamically. The proposed solution provides a high level of service flexibility and supports sophisticated methods allowing user traffic forwarding in effective way within the considered architecture.

I. Introduction

IN RECENT years Internet traffic is skyrocketing (traffic growth is exponential) as users are consuming more and more Internet services (e.g. video or cloud based solutions). The problem is often highlighted by telecommunications providers but high growth is also observed by organizations like enterprises, universities, governmental entities. Thus many institutions have to adapt and bolster their traditional IT and network infrastructure in order to handle that phenomenon.

In this chapter the overview of legacy campus networks, typically used by institutions, is given. Also LAN (and WAN access) solutions provided to business customers are described.

A. Office networks overview

Nowadays access to Internet is prevalent among companies. Moreover many enterprises have own intranet. In order to provide connectivity to different devices likes PC, laptops or tablets in-building network infrastructure is needed. It can be composed of a single modem/router but also tens of devices and substantial amount of transmission media (optical fibers, twisted pair cables etc.). In case of big organizations all those components form a campus network– computer network interconnecting LANs (Local Area Networks) within a limited geographical area. The infrastructure is usually owned by campus owner / tenant e.g. enterprise, university, hospital.

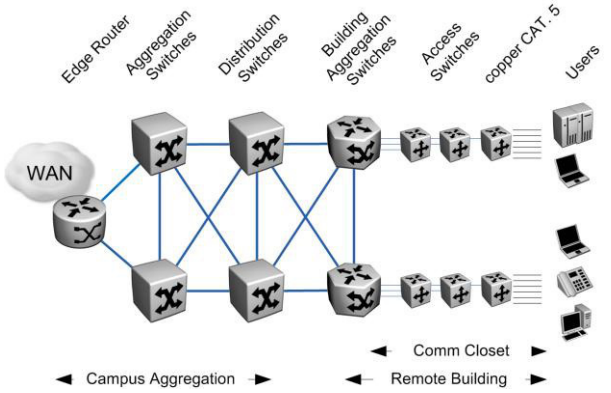

Fig. 1 Campus network hierarchy

Early LANs were large flat networks with peer to peer Layer 2 (L2) communication based on Ethernet [4]. It was a simple approach but with network growth ultimately led to disruptions (e.g. due to broadcast storms). Over the time Layer 3 (L3) has been introduced dividing campus network into smaller segments (allowing avoiding such problems). Additionally numbers of different solutions like VLANs (Virtual LANs [5]), RSTP (Rapid Spanning Tree Protocol [6]) or IP subnets have been developed making campus networks easier to maintain and manage.

Also the topology evolved towards more hierarchical and structured design. 4-tier network architecture (see Fig. 1) has become common ([8], [10]). In that approach access layer provides connectivity to end devices with copper twisted pairs (usually UTP CAT. 5 – Unshielded Twisted Pair Category 5, nowadays CAT. 6 cables are gaining popularity). Fast Ethernet or Gigabit Ethernet (100BASE-TX or 1000BASE-T [4]) are typically used. Access layer contains multiple L2 switches. They are located nearby users, e.g. in communication closets on each floor of the building. At the next level additional switches aggregate traffic for each building (concentrating multiple access layer switches) Interconnection between access layer switches and building aggregation switches can be provided with copper cables, or with fibers. Building aggregation switches are connected to

978-83-60810-53-8/$25.00

campus aggregation and distribution switches which then connect to router (being a gateway to external networks). As a transmission medium for interconnecting building aggregation with campus aggregation segments fiber optic cables are often used due to higher bandwidth requirements (i.e. 10 GbE interfaces) and distance.

Tiered network design gives flexibility in terms of supporting numerous functions and end devices (for example growth of client population can be accommodated by adding access layer switches, but that approach is costly). The logical division for different layers does not need to be done with physical tiers; access and aggregation can be provided on the same equipment. It can be especially useful in case of smaller campus simplifying management of reduced number of devices [9].

Important to note is fact that legacy Ethernet-based campus networks have significant drawbacks. Maximum length of copper Ethernet cables is limited to 100 meters. In fact 4-tier topology with switches on each floor is an answer to that limitation. Ethernet LAN requires a cable connection to every single user port. This means significant number of access layer switches and wires (copper cables) and at the end results in high costs. High-frequency signals (used for Fast and Gigabit Ethernet) require more sophisticated copper cable constructions which are physically larger than for lower frequencies (necessary to avoid signal disturbances). In consequence the space required for racks, communication closets is large. Crucial amount of heat is produced, power consumption is high. Management of high number of active devices is not easy.

For those reasons legacy Ethernet LAN is not always the best answer for campus network requirements. That is why an important issue is to find a more effective approach for office networks infrastructure.

B. Scenarios for B2B services

B2B (Business to Business) telecommunications services' landscape is diverse. It includes services like Internet access, POTS (Plain Old Telephony Service), VoIP (Voice over IP), dedicated links, VPN (Virtual Private Network), etc. One can distinguish large (Enterprise), medium (SME – Small and Medium Enterprises) and small (SOHO – Small Office Home Office) market segments. However service overlapping (the same services) is possible, but often there are special offers for different segments.

Services' requirements largely depend on type of customer. Big entity owning campus network (and considerable number of network equipment) has other needs than company with small branches scattered around the country (and with lack of its own interconnection) and than small company located in single office building.

For entity with campus network usually telecommunications operator provides its services to location where campus edge router is placed, further propagation is the responsibility of the entity itself (compare Fig. 1). In the second case (several branches) it is important to provide interconnection among branches.

For office building, in which many companies are located, there are two most common infrastructure scenarios (see Fig. 2). First one is based on existing copper CAT. 3 cables which reach customers' desk / office and can be reused by telcos. Modem or router is the termination point of the services (Fig. 2 Scenario A).

In the second scenario office building has infrastructure based on active Ethernet LAN with copper cables CAT. 5 (Fig. 2 Scenario B). Telecommunications operators need to provide its interconnecting cables up to building's technology room. Separation of services / between different operators can be provided on logical level e.g. by means of VLANs.

For both scenarios the only responsibility of telco is to somehow access business customers. Herein, one could think of a new role for operators targeting office buildings environment: what added values are possible to be identified

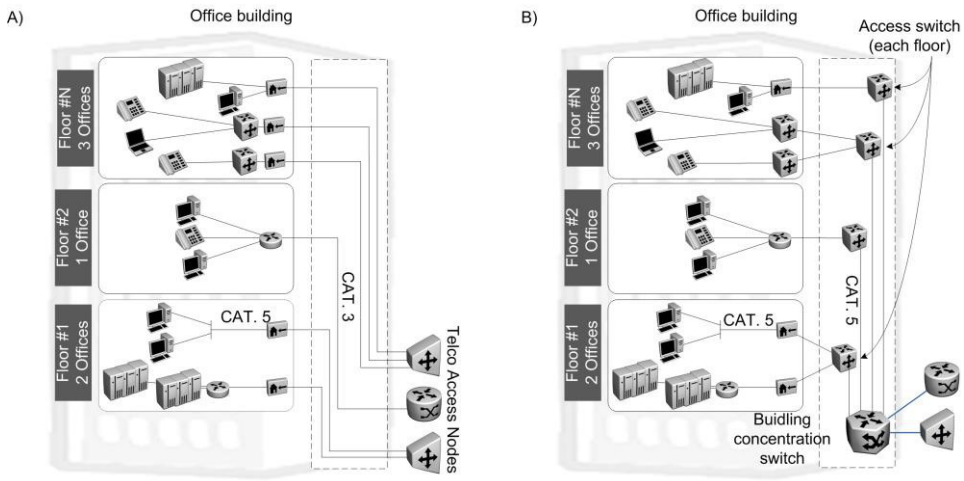

Fig. 2 Legacy infrastructure in office buildings. Scenario A: Telecommunication operators' cables CAT. 3 up to the office. Scenario B: In-building infrastructure based on Active Ethernet LAN (copper cables CAT. 5)

if telcos take the responsibility of building and administrating the entire in-building office network?

II. OPTICAL LAN

Optical LAN is a new approach for office networks infrastructure and an answer to limitations of legacy Ethernet LANs. All-fiber LAN interconnecting existing Ethernet end devices allows reducing costs and making the network more reliable.

Proposed solution is based on GPON (Gigabit Passive Optical Network) [1]. It is standardized, well known and widely adopted telecommunications access technology, used by many operators worldwide. GPON uses point-to-multipoint topology and employ fiber optics as a transmission medium. As a real passive solution – no active equipment is used in-between GPON Access Node: OLT (Optical Line Termination) and line termination at customer side: ONT (Optical Network Termination). In campus network based on Optical LAN number of active equipment is significantly reduced comparing to traditional LAN scenario. From OLT GPON port a single strand of fiber goes out to a passive optical splitter(s) which splits the signal onto fibers terminating at up to 64 (or even 128) ONTs (see Fig. 3). All the fibers, splitters connected to one GPON port on OLT form a GPON tree. ONT device terminates GPON transmission and provides 10/100/1000-BaseT Ethernet connectivity to desktop equipment such as PC computers, laptops, voice over IP phones, and video phones using regular copper patchcords (or by 802.11 WiFi). ONT can be located on customer's desk (ONT per desk) or in office closet (ONT per office). Those two options are called respectively: Fiber-to-the-Desktop (FTTD) or a Fiber-to-the-Communications (FTTC) room. High flexibility of Optical LAN solution allows reusing existing copper infrastructure in buildings (for example GPON access is terminated on ONT located in the floor communication closet, from where existing copper cables are used up to customer's desk, see Fig. 3 – Floor #2).

Thanks to fiber optics-based transmission Optical LAN is a long reach access solution – maximum reach is equal to 20 km in a standard mode. It is a tremendous improvement comparing to traditional copper Ethernet (100 m.). It allows placing OLT in distant locations, giving high flexibility in network design (in case of campus network OLT no longer need to be installed in the same building in which customers reside).

GPON technology assures 2.488 Gbps of downstream bandwidth and 1.244 Gbps of upstream bandwidth. Bandwidth is shared among customers connected to the same GPON tree. Advanced GPON QoS mechanisms assure appropriate bandwidth distribution among many users and different applications.

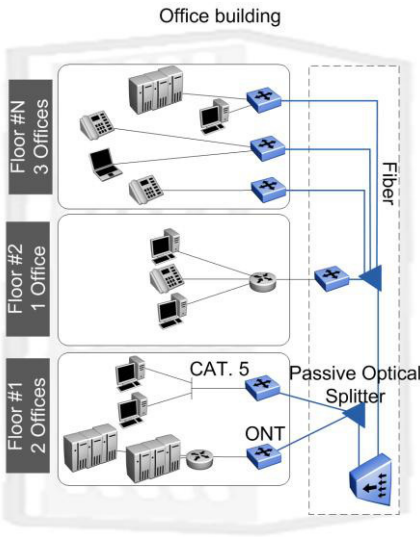

Fig. 3 Office building infrastructure based on Optical LAN

Optical LAN solutions are present in portfolio of several vendors (e.g. Motorola [11], Tellabs [12], Zhone [13]). According to vendors estimations introducing of Optical LAN will reduce power consumption by up to 65%, space requirements by up to 90%, capital costs related to network elements by up to 74% [13]. Optical LAN is seen as a new paradigm in campus networking allowing optimization of investments and at the same time improving overall efficiency of the network.

III. A NOVEL APPROACH TO B2B

In this chapter we formulate three postulates, which are, from our perspective, crucial for deploying future proof access networks for business applications:

1. Applying Optical LAN concept

Currently Optical LAN vendors target big entities with large campus networks. In typical deployment Optical LAN is used by only one organization – the owner and the administrator of the campus network. Office buildings with many tenants, each of them having its own LAN network (at least up to some point) are not yet addressed.

In this paper we propose a solution to that deficiency. It is based on concept known from telecommunications world where many customers are connected to the same Access Node (different users served on the same equipment). In our proposition enterprises no longer need to operate any active network equipment or to build networks itself. LAN becomes a service, provided in similar fashion as e.g. Internet access. LAN service provider is responsible for service creation, administration and adjustment according to needs of customers (enterprises using LAN). That also means that network infrastructure is built for offices by LAN service provider. In fact such network is similar to GPON access networks used by telecommunications operators to provide services to its customers. For B2B scenario different customers are also served by the same GPON OLT unit.

2. A new role for telecommunications operators

Telecommunications operators are well positioned to play the role of Optical LAN service providers. Usually they have necessary experience with GPON technology, operational resources and existing access network. Telcos are able to deploy optical fiber LAN in office buildings and to provide flexibility in management, service creation and administration.

Such approach has many advantages in terms of optimal usage of network resources. Single OLT can be used for several buildings, even if they are located in distant areas (due to long reach offered by GPON technology which capabilities in terms of maximum physical reach are not fully used in current optical LAN implementations). Also interconnection of distant branches becomes easier (in specific cases they can be served by the same OLT). Additionally a new type of services can be introduced called Office LAN services: e.g. on-demand LAN connections between companies located in the same building, access to in-building monitoring system, etc.

This novel approach also creates a new business model for telecommunications companies who become Optical LAN operator (builder and administrator). This opportunity to find new B2B market seems to be a good argument in convincing telco players to work on such solutions.

3. Business-user-oriented access network design

Another assumption for the presented approach is that it is based on user-oriented access network design. Service portfolio dedicated to business customers is typically more complex than the one for residential users. For business applications customized services need to be taken into account. Moreover, customer demands can change dynamically over short periods of time. That is why a challenge for networks deployed in business environments is to provide a high level of service flexibility and to forward user traffic in effective way. To meet those requirements we present in this paper an access network architecture based on SDN (Software-Defined Networking) paradigm which assumes data plane and control plane abstractions separation ([17]). Thanks to such approach network devices become programmable units. In practice it means that network configuration can be easily adapted to the fast-changing needs.

IV. SDN-BASED GPON SOLUTION FOR BUSINESS APPLICATIONS

In order to introduce SDN paradigm to GPONs area one can propose different methods to accomplish that. One of the possible ways would be to develop a brand new protocol allowing GPON devices to become programmable units. Such approach is supposed to be an appropriate one for designing an optimal logical architecture of OLT and ONT in the scope of data processing and forwarding. However, development of generic SDN-based protocol for GPON would require a lot of standardization efforts and probably it would take a few years to obtain a solution being ready for deployment. Moreover, it would be limited to GPON technology and thus it could not be applied for other network types and applications.

In this paper we present another approach. We propose a solution based on OpenFlow ([16]) which is the most widely deployed SDN-based protocol. OpenFlow Switch architecture consists of at least three parts ([15]) – see Fig. 4:

- Flow Table(s) – a structure within switch implementation with an associated actions with each flow entry; the Flow Tables define the ways of how the traffic flows have to be processed by the switch
- Controller – an external unit running a remote control process that manages the switch via the OpenFlow protocol; the Controller can add, remove and update flow entries from the Flow Table(s)
- Secure Channel (also called OpenFlow Channel) – a channel which enables a communication (i.e. sending packets and commands) between the Controller and the switch

For a more detailed description of OpenFlow-specific logical components and functions please refer to [15].

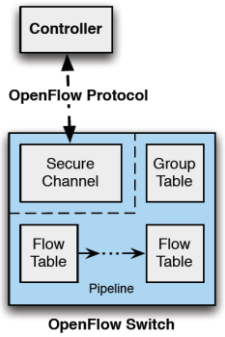

Fig. 4 OpenFlow Switch logical scheme (source: [17])

OpenFlow was originally designed for L2/L3 switches (or routers) equipped with native Ethernet-based physical interfaces. That is why it is important to notice that it is useless to implement pure OpenFlow in GPON OLTs and ONTs. The reason for that is simple: although GPON effectively carries Ethernet frames, in practice it operates at Layer 1 (according the OSI model) with its own dedicated framing and GEM (GPON Encapsulation Method) protocol used for encapsulation higher-layer Protocol Data Units (e.g. Ethernet frames) into GTC (GPON Transmission Convergence) layer. The current specification of Open Flow protocol does not support such kind of non-Ethernet-based physical interfaces. That is why some additional GPON-related functions have to be introduced to OpenFlow.

A. SDN-based protocol for GPON

A single logical connection within the GPON system is called GEM Port and it is identified by GEM Port-ID. A GEM Port can be considered as a channel within GTC layer and is capable to transport one or more traffic flows. In the

upstream direction GPON system also utilizes T-CONTs (Transmission Containers) corresponding to allocated timeslots within TDMA multiplexing existing in GPON. Each T-CONT represents a group of logical connections (GEM Ports) that appear as a single entity for the purpose of upstream bandwidth assignment on the PON (see Fig. 5 – GPON-specific traffic entities identifiers are pointed in brackets).

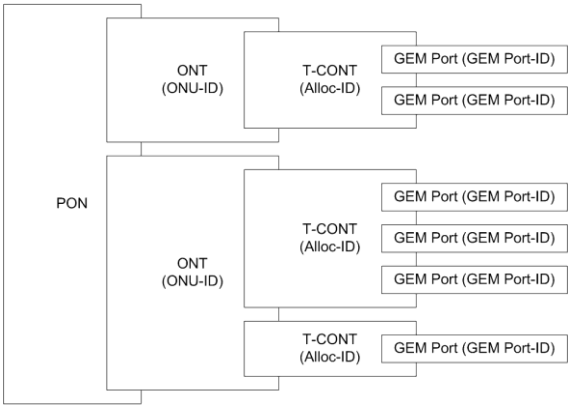

Fig. 5 Upstream multiplexing in GPON system

Each T-CONT can be seen as an instance of upstream queue with a certain bandwidth profile (a set of bandwidth parameters). The bandwidth assignment model applied in GPON system effectively introduces a strict priority hierarchy of the assigned bandwidth components ([2]):

- fixed bandwidth: with highest priority
- assured bandwidth
- non-assured bandwidth
- best-effort bandwidth: with lowest priority

Five T-CONT types are defined by [2]. Depending on the traffic type (latency-sensitive traffic, data transmission, etc.) the most appropriate T-CONT type should be selected to carry considered traffic flows.

Upstream user traffic (Ethernet frames) is encapsulated into GEM Ports and then into T-CONTs. Each GPON ONT uses its own set of T-CONTs and GEM ports, a unique one within a GPON tree which ONT belongs to. A single GEM Port can be encapsulated into only one T-CONT, however a single T-CONT may encapsulate multiple GEM ports. In downstream direction only GEM Ports are used to carry traffic flows since no TDMA multiplexing exists there and thus the notion of T-CONT is not relevant for GPON downstream transmission. For a more detailed explanation please refer to [2].

One of the key aspects of GPON-based network applications is to ensure effective traffic forwarding on the GTC layer. In order to do that it is important to define appropriate rules (consistent and unambiguous ones) allowing to map traffic flows incoming from users to appropriate GEM Ports. In most of commercial implementations mapping rules “built-in” GPON ONTs are mono-criterion- i.e. mapping is based on only one of the following criteria like: VLAN ID (Virtual LAN identifier), p-bit ([5]) or UNI (user port number on ONT). For some cases also double-criterion combinations of aforementioned parameters are available (e.g. VLAN ID + UNI) for the mapping purpose. Since GPON was originally designed for B2C (Business to Customer) market segment for which only Triple-Play (Internet, ToIP and IPTV) services are considered such approach was sufficient. For business applications where not only service portfolio is more complex but also customized services are taken into account, much more sophisticated methods (i.e. mapping rules) are required in order to ensure effective traffic forwarding through the system ([14]). In most scenarios currently deployed GPON ONT with limited set of hardcoded mapping and forwarding functions would not be able to address such needs. In such cases software upgrade is needed but it leads to higher operational costs - especially if business customer demands changes dynamically and it is possible that new set of functions is required. For such a scenario multiple software upgrades have to be taken into account.

The solution for the issue is SDN-based protocol for GPON allowing OLT and ONT to become programmable units. In this paper we propose OpenFlow-based solution. As mentioned before the current specification of OpenFlow protocol does not support GPON natively. That is why our vision is to introduce GPON-related functions to the specification in order to develop a protocol extension which we called OpenFlowPLUS.

The main assumption for the OpenFlowPLUS is that it inherits all the functionality, architecture and capabilities of original OpenFlow. The essential improvement is an introduction of GPON-related functions to the protocol in terms of traffic forwarding in order to make the solution relevant also for GPON technology.

According to OpenFlow Switch architectural assumptions each device (OLT, ONT) within considered GPON tree contains Flow Table(s) and communicates over a Secure Channel with remote Controller via OpenFlowPLUS protocol (see Fig. 6).

For that purpose OLT and ONTs are supposed to have IP address configured. Since Controller and OLT are assumed to be connected to IP/Ethernet network they can establish L3 connection. ONTs are accessible by Controller only via OLT. One could take advantage of that and for the purpose of OpenFlowPLUS messages exchange between ONTs and Controller make use of GPON-specific mechanisms defined by [3]. In such a scenario protocol messages are transported through the PON via a dedicated OMCI (ONT Management and Control Interface) channel towards OLT and then they are sent directly to the Controller using OLT’s Secure Channel. Obviously, employing OMCI by OpenFlowPLUS for some new applications does not mean that the protocol takes the control over the entire GPON system. All functions which are out of the scope of traffic mapping and forwarding

(e.g. ONT discovery and provisioning-related functions, Dynamic Bandwidth Allocation mechanism, optical layer supervision, alarms and performance monitoring etc.) are assumed to be realized in traditional way, i.e. in line with recommendations defined in [2] and [3]. That is why an optimal approach seems to be adding OpenFlowPLUS controller as a functional module to the standard EMS (Element Management System) managing the system.

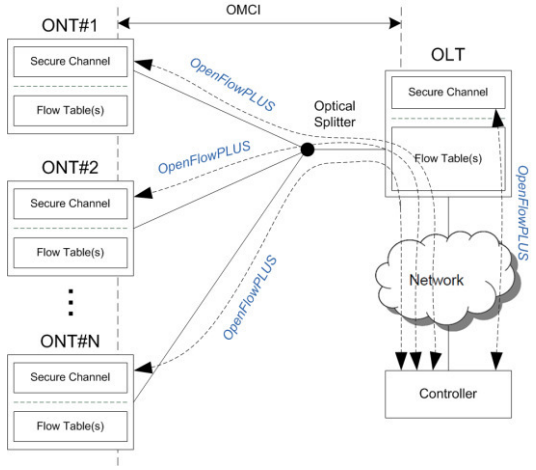

Fig. 6 OpenFlowPLUS–based GPON solution overview

As mentioned before the idea of OpenFlowsPLUS is to provide GPON-related functions to the protocol in terms of traffic mapping and forwarding. Similarly to original OpenFlow, OpenFlowPLUS is assumed to use Flow Table(s) which perform packet lookups, modification and forwarding. Each Flow Table contains multiple flow entries. Each flow entry contains:

- match fields – to match against packets; match fields include packet header fields (e.g. VLAN ID, MPLS label, IP destination address, TCP source port, etc.), an ingress port and metadata that pass information between tables; flow entries match packets in priority order, with the first matching entry in each table being used ([15])
- counters – which can be maintained for each port, table, flow, etc.
- instructions – operations which are executed when a packet matches a flow entry

Instructions define the ways of how single action is processed. Actions represent operations of packet modification or forwarding to the specified port. Actions are grouped by different action types, for instance pop action type (e.g. pop VLAN header action), set action type (e.g. set MPLS traffic class action), etc. Instructions executed during OpenFlowPLUS pipeline processing can either add appropriate actions to the current action set (a set of actions that are accumulated when the packet is processed by the tables and that are executed after exiting the processing pipeline by the packet), or force some actions to be applied immediately. OpenFlowPLUS defines new actions which are relevant to GPON technology. The considered functions are presented in Table I.

TABLE I.
MAIN GPON-RELATED FORWARDING FUNCTIONS PROVIDED BY *OPENFLOWPLUS*

GPON unit	Action type /Action	Remarks
ONT, OLT	gpon: Map to GEM Port	introduction of a new action to the original OpenFlow action set function: mapping Ethernet frames to particular GEM Port instance
ONT	gpon; Map to T-CONT	introduction of a new action to the original OpenFlow action set function: mapping GEM Ports to particular T-CONT instance
ONT, OLT	output	action modification when executed for GPON interfaces new function: GTC framing before forwarding the packet on the GPON port

OpenFlowPLUS introduces a brand new action type called gpon related to GPON-specific mapping methods. The considered action type provides two actions: Map to GEM Port action which represents an operation of mapping Ethernet frames to particular GEM Port instance and Map to T-CONT action which represents an operation of mapping GEM Ports to particular T-CONT instance. Additionally the new functionality for original OpenFlow output action is supposed to be supported: when a packet is destined to be forwarded to the GPON port, GTC framing is performed for the packet before exiting the interface. The aforementioned protocol improvements are the main GPON-related forwarding and mapping functions provided by OpenFlowPLUS.

B. Use case

In this section we present a possible application for SDN-based GPON concept which is proposed in the paper. The following assumptions are made for the considered use case:

- the solution is dedicated to business customers who reside in office buildings
- operator acts not only as a service provider but is responsible also for administration of in-building network
- in-building network is based on Optical LAN solution
- different service types can be offered: Internet access, Metro Ethernet (corporate connections), cloud computing-based services, office LAN services; the considered traffic flows are listed in Table II
- access network architecture is based on OpenFlowPLUS GPON solution (see Fig. 7)

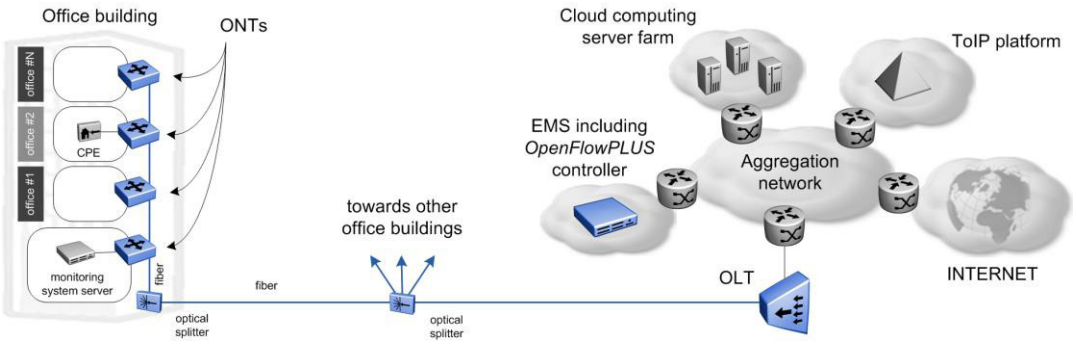

Fig. 7 OpenFlowPLUS-based architecture for business applications overview

TABLE II.
SERVICES AND TRAFFIC FLOWS OVERVIEW

Flow ID	Traffic flow/service	Remarks
F#1	Internet Access: HTTP, FTP, etc.	standard Internet services
F#2	Internet Access: web-based application hosting	connections from Internet are established using HTTPS (SSL + HTTP) protocol (TCP port 443)
F#3	Internet Access: remote access to intelligent installation system controller	connections from Internet to intelligent installation system controller physically located in the office are based on KNXnet/IP protocol (port 3671); IP address of the controller: IP@1.3
F#4	Metro Ethernet: connections to remote company branch	remote company branch is supposed to use IP@2.X address pool;
F#5	ToIP (telephony over IP)	IP phones used in the office are assumed to mark IP ToS field with DSCP "EF" value; IP address of ToIP platform: IP@4.1
F#6	Office LAN: on-demand connections to different companies located in the same building	connections allowed for a designated sub-pools of addresses from IP@1.X and IP@priv (office) and IP@3.X (different company office)
F#7	Office LAN: access to in-building monitoring systems	in-building monitoring system server is assumed to be connected to a dedicated ONT with IP address: IP@5.1
F#8	Cloud computing: remote storage, backups	IP address of cloud computing server: IP@6.1

Each office in the building is connected to the optical network via ONT. Copper cables terminated with RJ-45 sockets are deployed in office rooms. Each user device (PC, IP phone, application server, etc.) is connected to one of multiple Ethernet LAN ports which ONT is equipped with (see Fig. 8). ONT aggregates the entire traffic incoming from user terminals (this traffic contains no VLAN tags) and provides the functionality of L3 gateway. Public IPv4 addresses are assigned to ONT (IP@1.1) and to some selected user devices: web-based application server – IP@1.2 and intelligent installation system controller – IP@1.3. For other devices private addressing is used (IP@priv). ONT is assumed to act as an internal DHCP server for that purpose. Any kind of additional CPE (Customer Premise Equipment) is not required in the considered network.

Thanks to applying OpenFlowPLUS sophisticated mapping rules are supported in order to ensure effective traffic forwarding through the GPON. As an example we show how flow entries match fields with corresponding instructions can be defined within ONT Flow Table for traffic flows transmitted in upstream direction (see Table III).

Based on the user traffic to GPON-specific instances mapping methods (using limited set of parameters like VLAN ID, pbit, UNI) which are currently supported in typical commercial implementations it would be very difficult or even impossible to follow the traffic forwarding model presented in considered use case. For instance, in traditional approach it would be impossible to map traffic flows F#1 and F#3 to different GEM Ports if they originated from the same end-device. The proposed solution is very flexible and convenient from customer perspective. Since OpenFlowPLUS-based GPON is a programmable system its configuration can be easily adapted to support new services and business needs when they appear.

Presented access network model supports also openness for alternative operators what is typically required by country-specific regulations. Each customer served by another operator connects a dedicated CPE to the ONT which is configured as a bridge that passes assigned VLAN(s) through the system up to the first alternative operator's switch or router (see "office #2" in Fig. 7).

V. CONCLUSION

In the paper we presented a novel approach to deploy optical access networks addressed to B2B market segment where we defined a new role for telcos. The major advantage of our solution is its flexibility thanks to introduction of SDN paradigm to GPON-based networking. We believe our work

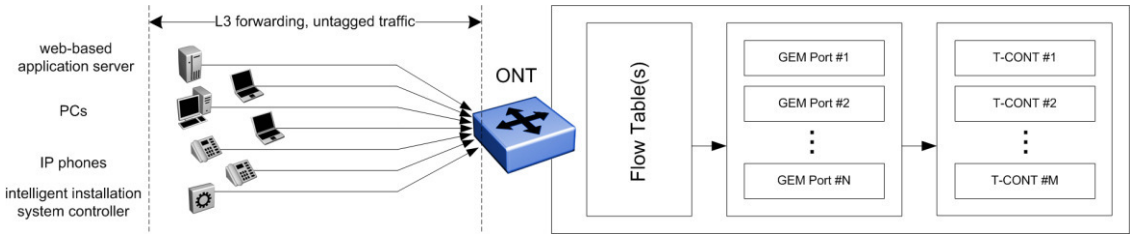

Fig. 8 OpenFlowPLUS-based ONT logical scheme

can be considered as a conceptual framework for further analysis and solution development.

TABLE III.
MATCH FIELDS AND INSTRUCTIONS FOR FLOWS INCOMING TO ONT

match fields of flow entries (in priority order)	Matched flow	Instructions
IPv4 dst = IP@4.1 AND IPv4 ToS bits = EF	F#5	Apply-Actions { Map to GEM Port: 1 Map to T-CONT: 1 (type 1)}

Are Graphical Authentication Mechanisms As Strong As Passwords?

Karen Renaud*, Peter Mayer†, Melanie Volkamer† and Joseph Maguire*

***Abstract*—The fact that users struggle to keep up with all their (textual) passwords is no secret. Thus, one could argue that the textual password needs to be replaced. One alternative is graphical authentication. A wide range of graphical mechanisms have been proposed in the research literature. Yet, the industry has not embraced these alternatives. We use nowadays (textual) passwords several times a day to mediate access to protected resources and to ensure that accountability is facilitated. Consequently, the main aspect of interest to decision-makers is the strength of an authentication mechanism to resist intrusion attempts. Yet, researchers proposing alternative mechanisms have primarily focused on the users' need for superior usability while the strength of the mechanisms often remains unknown to the decision makers. In this paper we describe a range of graphical authentication mechanisms and consider how much strength they exhibit, in comparison to the textual password. As basic criteria for this comparison, we use the standard guessability, observability and recordability metrics proposed by De Angeli *et al.* in 2005. The intention of this paper is to provide a better understanding of the potential for graphical mechanisms to be equal to, or superior to, the password in terms of meeting its most basic requirement namely resisting intrusion attempts.**

I. Introduction

ONE OF the most basic, everyday tasks of computer usage is authentication. Every user will, sooner or later, have to authenticate themselves. Their ability to do this effectively will impact on their ability to do their daily jobs and on their personal lives. The failure of the mechanism to resist intrusions will potentially have an impact on the user personally (e.g., in terms of ID theft or financial losses) or in professional environments on the organisation he or she works for.

Nowadays, the most widely used authentication mechanism is the textual password. However, it is well known, that most users are frustrated by their experiences with these traditional passwords in general [1]. Even if they want to behave securely, they often do not understand what constitutes a "secure" password since guidelines for the creation of secure passwords are seldom adequate [2]. Even with good guidelines in place, human nature will lead users to prefer the path of least resistance e.g. choosing weak passwords, writing them down, storing them in plain text on their mobile phones or reusing them [3], [4]. This is understandable considering the findings of Ives, Walsh and Schneider [5]: users are expected to recall an average of 15 different passwords on a daily basis. Due to human cognitive limitations, four or five is normally the maximum a typical user can handle [3].

Password managers can help users to manage an unlimited number of passwords. However, they constitute a single point of failure and systems cannot be easily accessed from a device that does not have the manager installed. Thus, password managers are no substitution for a secure and usable authentication solution [6]. The same holds for single sign on solutions.

To address the human inability to deal with large amounts of passwords, a new type of authentication system was conceived. The graphical password, first proposed by Blonder [7], required the person to verify their identity by clicking on positions within a picture. This is called a *locimetric* system. Other common types are *searchmetric* (pick a picture from a grid of images) and *drawmetric* (draw your secret) [8]. The most important motivator behind the use of a graphical authentication mechanism is that their memorability is superior to that of textual passwords. In the first place, there is what is called a "picture superiority effect", as described by Paivio [9]. Paivio explained that pictures were encoded using a dual mechanism. So, a password, being textual has only one route whereby the human can reach it. If that route decays, and is forgotten, the password cannot be accessed. If the memory item is visual, there will potentially be multiple routes to access it, and the decay of one access route does not render the item unreachable.

Numerous studies regarding the usability of graphical authentication schemes have been conducted. Yet, many of these sweep security concerns aside or deal with them in a desultory fashion [10]. However, very few graphical mechanisms are used in practice. Notable exceptions are the Windows 8 picture password and the Android lock-screen pattern. A number of reasons could be advanced. In this paper we will consider the elephant in the room: do these mechanisms provide the basic requirement namely resisting intrusion attempts at an equal or higher level than textual passwords do? In order to answer this question, we need to be clear about exactly what variation of the amorphous password we consider, since this impacts the resulting security-level. Hence, we consider textual passwords with a length of at least 8 characters and which are used in a system with a three-times-lockout technique.

We will use the different categories of attacks proposed by De Angeli, Coventry, Johnson and Renaud [11] in 2005 as a starting point. In each case the mechanism will be compared to textual passwords. The remainder of this paper is structured as follows. First, we present the three types of attacks we

978-83-60810-53-8/$25.00

use to evaluate whether the same security level as textual passwords are provided, and show how the most common attacks fit into this framework. Next, we describe the general ideas behind the different classes of graphical authentication mechanisms. Then, we report on efforts that have been made to strengthen these mechanisms. We then compare the security properties of graphical authentication schemes to the security offered by textual passwords. Finally, we summarise, discuss and conclude.

II. Vulnerabilities

To evaluate the security of different authentication mechanisms, the resistance against certain attacks is reviewed. Table I classifies the set of attacks proposed in [12] into the evaluation categories which we use throughout this paper, namely Guessability, Observability, Recordability, and Memorability; which are explained in the following paragraphs.

TABLE I
Common Attack Types

Vulnerability	Attack Type	Tool
Guessability	Brute Force Attack	Offline
	Dictionary Attack	On & Offline
Observability	Shoulder Surfing	Human Observer
	Spyware	Technology
Recordability	Social Engineering	Deception
	Theft	Unsecured Record
Memorability	Forgetting	Coping Techniques

Guessability: Brute force and dictionary attacks are the two types that have to be considered in this category. For dictionary attacks to be possible, passwords have to be predictable so that an attacker can create a dictionary with the most widely used passwords. Obviously having personal knowledge about the user can make it even more predictable. These attacks can in particular be carried out if the database or password file is obtained (without in our setting the account will be blocked after three trials). In this case the attacker can perform an offline attack to test all possible combinations of the password-space and thus has no limitations regarding aspects like a lockout policy etc. One way to resist this kind of attack is to impose password strength requirements when a password is chosen. Another way is for the system to issue strong passwords. This ensures that passwords are unpredictable and that all possible elements of the password space are evenly likely to occur. To be resistant against offline attacks, the password space has to be sufficiently large, where values of 2^{20} to 2^{28} seem to be commonly used on the Internet [13]. To be secure, the password space should be greater than 2^{80}, which is the lowest security strength NIST allows for government applications [14].

Observability: Observing the user while authenticating can be performed either by a human (shoulder surfing), by a human with technical equipment (filming the action of authentication) or using technical means (e.g. spyware). The goal is to collect information that allows an attacker to reproduce the authentication with an as high as possible probability. Shoulder surfing is performed by observing the user while he is authenticating himself with the given implementation. Lately, the ubiquity of mobile phones means that a camera could be used to capture the user's authentication secret without their knowledge. Spyware or malware in general can be installed on the user's system by the attacker. It can monitor input peripherals or obtain screenshots during authentication.

Resisting this kind of attack is challenging. One can resist this to a certain extent by making it necessary for an attacker to capture multiple authentication attempts before they obtain the full authentication secret [15].

Recordability: Attacks exploiting the recordability of an authentication mechanism are always performed through the human factor. The first way a password can leak to an adversary is that the user records their password in some way and it is then stolen (theft). The second way is for the person to be fooled into disclosing their secret to another person (social engineering). Social engineering includes all attacks, which do not target the system as such, but the user.

Both attacks rely on the relative ease with which a user can record his/her authentication secret. An implementation is resistant if it is hard for the secret to be recorded or disclosed. In the era of ubiquitous mobile phones with built-in cameras it is very difficult to resist this kind of vulnerability.

Memorability: While this is not an attack type, it can be a vulnerability if attackers exploit the consequences of a user's coping strategies [3]; e.g. writing down has an impact on observability as someone might not observe the user authenticating but the note with the information about the password. Similar re-usage has an impact on the dictionary attack. Note, with respect to memorability it is important to consider also situations where one might only authenticate once in a while, like once in a semester for students to register or once in a year to file a tax return.

III. Graphical Authentication

In general, graphical authentication works like any other knowledge-based authentication mechanism. The user has to verify knowledge of a secret he or she shares with the system. Contrary to the abstract nature of textual passwords, graphical authentication relies on visual memory. In both cases he or she has to access that secret in stored memory. Memory can be accessed in three ways, as described below, using the password as an example in each case to explain approaches for each way.

Recall: Information is extracted from memory when requested. This is the paradigm adopted by the traditional textual password authentication. Recall is a cognitively difficult task. Therefore, users tend to resort to coping strategies. Graphical passwords that rely on this kind of memory are the drawmetric based schemes like Android screen unlock and the searchmetric grIDsure [16].

Cued-Recall: Information is extracted from memory when cued. One can also ask for a password framed as a response task, similar to Zviran & Haga's associative passwords [17]. In their scheme users provide a number of associations

at enrolment which they are prompted for at authentication. Most of the graphical authentication schemes relying on this memory are locimetric, but exceptions such as the drawmetric BDAS exist [18].

Recognition: Information is presented and the individual is able to identify the correct item. One could conceivably display a number of passwords on the screen and ask a user to identify theirs, but this scheme is so obviously weak that it has not been trialled. Many graphical authentication mechanisms do rely on this mechanism, since it is the least cognitively demanding and particularly suitable for use with images. These are the searchmetric mechanisms. They display a succession of challenge sets, with one "target" image and a number of distractor images. The user identifies the target image in each challenge set by clicking on it.

The following sections provide examples of graphical authentication mechanisms that rely on each of these memory types. The sections are intended to be illustrative and examples of mechanisms have been chosen because they were the first of their kind. The inclusion of a particular mechanism does not suggest that it is in any way superior to others which are not mentioned. There is, unfortunately, no room for an exhaustive review of all mechanisms.

A. Recall

Draw-a-secret or DAS, proposed by [19], is a recall-based graphical authentication mechanism. The approach expects an individual to draw their authentication secret to access an application. These should be more memorable than passwords because they rely on visual, lexical and kinaesthetic memory [8]. DAS does not rely on drawings from a semantic perspective but on the underlying grid sectors.

Thorpe and van Oorschott [20] postulated that *symmetrical graphical secrets* are a real concern, as symmetrical drawings have superior recall. They argue that an attacker could craft a dictionary of symmetrical secrets and use it to compromise DAS which would take only 6 days to crack if the password is symmetrical. Nali and Thorpe conducted an informal user-study with 16 individuals to determine if user-generated DAS secrets exhibited any patterns [21]. Their participants' drawings did exhibit patterns: 45% created symmetrical drawings, 56% of the drawings were centred and 80% of the drawings used fewer than 3 strokes. The authors argue if these results are symptomatic of a larger user-base, then DAS has a much smaller, practical password-space.

The latest drawmetric mechanism is the common Android lock-screen pattern authentication. Such pattern based authentication mechanisms are also vulnerable to attacks based on observations of smudges on the device touchscreen [22].

Another recall-based approach is grIDsure, an authentication scheme that relies on knowledge of a secret pattern [16]. It requires an individual to create a sequenced pattern on a 5x5 grid. The user is presented the same 5x5 grid during authentication, except each one of the 25 cells contains a random value between 0 and 9. The values are randomly generated for each authentication attempt and are not unique to a cell. The secret pattern, generated by the user, is applied to the grid to generate the authentication secret, i.e. a 4-digit PIN. Bond identified some severe security flaws in this scheme [23]. He was able to identify the user's secret using only two forged authentication grids.

B. Cued-Recall

There is some concern that users forget their drawings with recall-based mechanisms such as DAS, or at least the stroke order [24]. To address this, Dunphy and Yan proposed a grid superimposed over a background image Background DAS (BDAS) to act as a cueing mechanism to improve memorability. Unfortunately users still created weak passwords [18].

Building on the ideas of Blonder, Wiedenbeck [25] proposed a mechanism called PassPoints. In PassPoints the user is expected to select five click points on an image. The sequence of click points is the authentication secret. Each position has a small tolerance radius as perfect replication is not expected. The password-space of PassPoints is vast, even with the addition of the tolerance radius, as a single image can contain a large amount of possible click points. The image can be selected from a library or provided by the user, the only requirement being that the image is complex enough to inspire users and protect the secret.

The apparent strength of the PassPoints approach is the large theoretical password-space afforded by the pixel-rich images. Thorpe and Van Oorshot argue the practical password space of PassPoints is reduced because of 'hot-spots', i.e. popular click points, as well as patterns within secret generation [26]. They investigated both human-based attacks and automated attacks. They investigated two highly-detailed images for popular positions. They discovered that 5 points in both images proved popular with individuals, between 24-31% for the first image and 20-24% for the second. Similarly, Dirik, Memon and Birget [27] developed a model that they claim can identify popular regions for points. They cautiously report that they were able to extract 70 - 80% of points. Furthermore, Thorpe and Van Oorshot [26] also suggest that predictable patterns exist in sequence selection.

C. Recognition

Dhamija and Perrig [1] propose Déjà Vu, a recognition-based graphical authentication mechanism. Each image is abstract in nature and the collection is generated using a mathematical formula, the output depends on an initial seed. The beauty of this design is that the actual images do not need to be stored, just the small initial seed. Déjà Vu performed well against competing recall-based approaches such as passwords and PINs. Indeed, Dhamija and Perrig reported that more individuals were unable to recall their username than were unable to recognise the images within their secret sets. Individuals using Déjà Vu felt that it was overall easier to use but at the expense of time and security. However, they reported an interesting insight in regards to the image-type used in Déjà Vu. When using semantic images, i.e. photographic scenes, some individuals selected the same images. One specific image

was selected by 9 out of 20 individuals. Furthermore, these images are far easier to explain and describe, thus, as a consequence an individual's secret set of images is easier to convey to someone else. For example, the aforementioned popular semantic image contained the Golden Gate bridge. Conversely, abstract images rarely overlapped and descriptions of them rarely, if ever, matched. In theory this strengthened the practical password space of the approach as there was no real pattern or popular images. Naturally, further investigation will be required but Dhamija and Perrig highlight the impact the image type can have on the memorability of images.

PassFaces is one of the few commercial graphical authentication mechanisms. The authentication approach assigns an individual a collection of faces as their authentication secret. The user is then presented a series of challenge stages that are each comprised of a nine image grid. In each grid the user has to identify one image from his or her password (*target*) among eight *distractors*. One property which might severely impact guessability (offline attacks) of searchmetric schemes, is that they usually need to store some password information in the clear [28].

IV. Strengthening The Graphical Password

A couple of improvements and also combinations of different approaches have been proposed in order to overcome weaknesses with respect to one or several of the vulnerabilities mentioned in Section II. These are proposed and discussed in this section.

A. Guessability Resistance

Cued-Recall: PassPoints authentication exhibits popular positions or hot-spots which are problematical in terms of guessability. Chiasson, van Oorschot and Biddle [29] propose Cued Click Points or CCP. The approach is a variation on PassPoints, in the sense that an individual selects a position from an image. However, the main difference is that an individual is required to repeat this action over several images. Therefore, the secret is a sequence of click points selected from a series of images with one click point on each image. The images are intended as cues.

There are concerns about the predictability of CCP, primarily those inherited from PassPoints, such as popular click points. Chiasson, Forget, Biddle and van Oorschot tackle this specific problem with Persuasive Cued Click Points or PCCP [30]. This approach uses CCP with the addition of a *persuasive viewport*. During the registration phase a viewport is randomly positioned over the image. The viewport is emphasised by reducing the brightness of the rest of the image. The individual is only allowed to select a click point from within the viewport, which they can shuffle if they do not like the position. Their lab-based experiments showed that the viewport is successful in reducing hot-spots and increases the spread of click points and their web-based trials were equally positive [30]. However, a more longitudinal evaluation is required to confirm whether the findings are replicated in the wild.

Recognition: Graphical authentication relying on recognition requires people to use images. There are three ways of associating people with images: (1) let them supply the images themselves, or (2) allow them to choose from a range of images or (3) assign images randomly to them. Unfortunately, the first two options can cause severe security concerns. If users are allowed to supply their own images they tend to choose predictable images [31]. The same holds, if users select their images from a set of supplied ones. As long as users have a choice they will behave predictably. Davis, Monrose and Reiter [32] discovered that individuals make predictable choices when they are required to select images for use in graphical authentication utilising facial images. Individuals are influenced by attraction, race and familiarity [33]. Even with everyday representational images, humans tend to make predictable choices [34]. To minimise guessability, images should be assigned to users randomly. In this case the theoretical and the practical password-space are the same.

B. Observation-Resistance

The first reaction to graphical authentication is often that it will be too easy for a human observer to gain knowledge of the authentication secret. Thus, a variety of attempts have been made to make it more difficult for observers to do this. Essentially, variants focussing on the observation resistance have been proposed for all three approaches to graphical authentication.

Recall: A DAS secret is easily exposed to onlookers. If an attacker is able to observe entry of a DAS secret, he or she may be able to authenticate using the same drawing (this holds for the cued-recall BDAS as well). Lin, Dunphy, Olivier and Yan proposed Qualitative DAS (QDAS) to tackle the problem of observation [35]. Chakrabarti, Landon and Singhal argued that rotating the canvas which the user draws on could improve the resiliency of DAS to observation [36]. Yet, neither of these has been tested in the wild so only lab-based results about the impact of the scheme on ease of observation have been reported.

Cued-Recall: While originally intended to be used with recognition-based authentication systems, the approach of Dunphy, Heiner and Asokan proposed in [15] can easily be translated to the CCP and the PCCP scheme. They propose to use a portfolio of target images of which only a different random subset is needed for the authentication process each time. Likewise CCP and PCCP could be implemented using a click point portfolio with only a random subset of the images (and the according click point) being needed to authenticate. To the authors' knowledge this has not yet been attempted, but might prove an interesting subject for future research.

Recognition: A range of observation resilient systems have been proposed. Dunphy, Heiner and Asokan [15] tested redundancy with users of a searchmetric system with 8 distractors and one target image. Each user had a portfolio of 6 images, of which only 4 were used at each authentication attempt. Attackers needed 7.5 observations, on average, in order to be able to reconstruct the password.

TABLE II
COMPARISON OF GRAPHICAL PASSWORD SCHEMES TO TEXTUAL PASSWORDS. G=GUESSABILITY, O=OBSERVABILITY, R=RECORDABILITY, M=MEMORABILITY, ?=NO DATA AVAILABLE.

	Scheme	Guessability	Observability	Recordability	Memorability
Recall	QDAS [35]	G ?	O ?	R ?	M ?
	BDAS [18]	$G\downarrow$	O ?	$R=$	M ?
Cued-recall	PassPoints [37]	$G=$ [26], [38]	O ?	$R=$ [39]	$M\uparrow$ [40], [6], [41]
	PCCP [30]	$G\uparrow$ [30]	O ?	$R=$ [39]	$M=$ [30]
Recognition	Passfaces [42]	$G\downarrow$	$O\uparrow$ [43], [15]	$R=$ [39]	$M\uparrow$ [44]
	Passfaces (system issued passwords)	$G\uparrow$	$O\uparrow$ [43], [15]	$R=$ [39]	M ?
	Dynahand [45]	$G\downarrow$ [45]	$O=$ [45]	R ?	$M=$

Wiedenbeck [46] proposes an authentication approach, framed as a game with a cognitive trapdoor, that relies on users generating a convex hull. The cognitive trapdoor is knowledge of 5 icons or pass-icons. The game comprises of a series of challenges, in each challenge the user needs to click within a specific region to 'win'. The specific region is revealed by uncovering a convex hull. During authentication, the user is presented a canvas containing several icons, including *at least* 3 pass-icons. The user is required to envisage the convex hull spanned by the pass-icons and needs to click within the convex hull to complete the challenge. Regardless of whether users click within the correct region or not, they progress to the next challenge when they click on the canvas. Wiedenbeck states that authentication times for the proposed Convex Hull Click approach are lengthy, they are the necessary expense of increased resilience to observation. Moreover, the author argues that energy has been spent to delight and excite the user to maintain interest with the approach.

Searchmetric mechanisms can be morphed into *limited disclosure* searchmetric mechanisms to foil shoulder surfing and key-logging software, since they rely on the use of arrow keys or a mouse to manipulate sets of pictures and the user does not click on their actual image. Most limited disclosure searchmetric mechanisms have some redundancy built in so that the observer is not able to deduce the key from casual observation but has either to observe a number of authentications or carry out an error-prone deduction of the key based on a few observations.

Tetrad [47] was proposed by Renaud and Maguire. Tetrad displays a grid (9x5) of facial images. Users line up their secret images by manipulating rows and columns instead of clicking on the images themselves. This introduces a level of indirection which means that casual observation is less profitable to an attacker.

C. Recordability Resistance

When graphical passwords were originally released, one of the their most touted strengths was the fact that they would be harder to record than passwords. This was naïve, in hindsight. The ubiquity of mobile phones with cameras makes it trivial to record anyone doing anything, including using the mouse to enter the graphical password. Even without the use of additional electronic gadgets incorporating cameras, the computer user can record the graphical password easily using the ever-available screenshot facility. Storing such an image on the hard drive or printing it out is equivalent to an unencrypted textfile or the infamous post-it for the textual password.

V. COMPARISON

Before providing the comparison and discussing it, we discuss some of the requirements of textual passwords relevant for the comparison.

A. Some information about textual passwords

The following information has been considered for the comparison in the next subsection.

Guessability: The susceptibility of textual passwords to guessing attacks has been shown again [2] and again [48]. User-chosen textual passwords are not uniformly distributed in the password space. Malone and Maher showed that Zipf's Law is a relatively good model for password distributions [49]. Consequently, adversaries can easily create a dictionary of the most commonly used passwords. Weir, Aggarwal, Collins and Stern used such dictionaries to conduct an analysis of large sets of revealed textual passwords [2]. They were able to crack at least about one fifth of 8 character passwords in those sets and only slightly less of the passwords with a length of 9 and 10 characters.

Observability: As described above in Section II it is important to differentiate between human and technical observers. Using technical means it is possible to reconstruct textual passwords from video footage or even from the sound of the keyboard input [50]. Human observers have to rely on visual input. Tari, Ozok and Holden [51] discovered that when users type long and obscure passwords, entry is more easily observed by shoulder-surfers than when typing simple and familiar words. Unfortunately, textual authentication secrets generated by users to protect bank accounts and tax records are likely to exhibit exactly these characteristics, so efforts spent by a user to be "secure" might actually backfire. Even so, most users are fairly confident that observers cannot guess their password with any degree of accuracy [52] even though such confidence is probably misplaced.

Recordability: Passwords are trivial to record and users can and will write down their passwords when the burden of recovering a lost password is too high [53]. Security professionals realise that this is an inherent vulnerability of

textual passwords, so they deal with it by instructing people not to take this action. However, their instructions are mostly ignored [3].

B. Overview of the comparison

Table II presents a comparison between the textual password and some graphical authentication schemes. To give a better idea of how secure an authentication scheme is, we introduce the following four levels.

1) A scheme is considered equal to textual passwords in our setting (=), when it offers roughly the same resistance to common attacks as does the password.
2) A scheme is considered worse than textual passwords in our setting (↓), when it offers even less resistance to common attacks than the password.
3) A scheme is considered better than textual passwords in our setting (↑), when it is better than the password in this particular respect.
4) A scheme might not allow a rating (?) if no data regarding the aspect is available or the available data does only allow a very rough estimation instead of a real assessment (e.g. very small sample).

These levels are based on the literature which often reports findings that are extremely difficult to compare, so the comparison should not be considered definitive, but rather based on an understanding of whether the approach is prone to show vulnerabilities. Moreover, it becomes apparent that there are many aspects that do not allow a rating due to missing data or data that only allows a very rough estimation instead of a real assessment.

In terms of *guessability*, graphical mechanisms generally can be as strong as textual passwords in practise are. Most schemes have a variable password space and can therefore easily be adopted to be resistant to pure brute force attacks. This, however, requires special configurations to strengthen them, which have not yet been tested in the wild. Dictionary attacks remain a severe concern for many schemes, but examples such as PCCP show that guiding the user during password choice using persuasive technology can mediate this issue. Recognition-based schemes in which the password is issued by the system can even avoid this problem entirely. *Observability* is a problem across the board and attempts to introduce redundancy or indirection into the process tend to increase authentication times unacceptably (eg. up to 180 seconds [54]). However, it must be acknowledged that comparisons between textual passwords and graphical schemes regarding the vulnerability to shoulder surfing are hard to find, even among those schemes specifically designed to be observation resistant. It could be that they are equally resistant or even better as sometimes appraised by their proponents, but in the absence of hard data we cannot judge. Also, whether the approach of Dunphy, Heiner and Asokan can be successfully applied to a wider range of schemes than initially proposed might be an interesting topic for future research. In terms of *recordability* there does not seem to be much difference between graphical and textual passwords. Recognition-based secrets are mostly more *memorable*, but the other types can display the same memorability as textual passwords.

C. Discussion

The previous section has shown that many of the proposed graphical authentication schemes exhibit advantages and disadvantages in one area or another. Most have advantages regarding their memorability. This is no surprise, as the intention behind graphical passwords was to relieve users of the cognitive burdens of textual passwords.

The predictability of the users' drawings and the complete recreation of the secret during authentication in the drawmetric approaches (both recall and cued-recall based) cause severe concern and it is unclear or open for future research whether they perform good enough with respect to their memorability if the system would set the drawing for the user. However, the iterative processes the locimetric appraoches (i.e. the remaining cued-recall based approaches) and the searchmetric/recognitaion-based approaches have gone through has resulted in a more robust set of mechanisms with respect to guessability. For example, PCCP is very guessability resistant in particular compared to the textual passwords in our setting. The same holds for recognition-based schemes with system issued passwords.

While, the focus of graphical password research was on improving memorability they raised new usability issues: It is clear from the literature that it takes at least as long [6] for users to authenticate using these mechanisms and mostly even longer [30], [55], [1]. Thus, depending on how regularly one needs to authenticate some of the graphical alternatives might not be an alternative although security wise at least as secure as textual passwords. At creation time this makes them inconvenient but also extends the window for observation. Whether the timings achieved by systems more resilient to observation or predictability are acceptable might be up for debate, as the difference decreases the longer the period between two logins with the same password [1].

However, when considering the time it takes to login one should also consider the time and effort it takes to reset passwords. Thus, if it is much less often needed to replace a secret for a particular type of graphical password due to its superior memorability, a longer login time might become acceptable. The resulting benefits in time expenditure and convenience might well be worth the offset. To make a decision here it is very important to have detailed knowledge about the situation and application for which an alternative is considered.

Graphical authentication has its strengths and its weaknesses. Where authentication timings are of the essence other solutions might be a better choice. However, when retention times are high (consider e.g. a task that has to be carried out a few times a year), graphical passwords, with their superior memorability, can mediate.

Another important aspect is that one can never look at authentication in isolation. The context of deployment has to be considered. Different devices impose different constraints

on the authentication process. The two most prominent are desktop computers and mobile devices such as smartphones or tablets. Desktop computers and laptops normally offer high resolution screens and diverse input devices. The variety of techniques that can be applied is thus larger. For recognition-based schemes, however, the available data suggest, that the chosen bitstrength has a severe influence on the efficiency of the systems. Traditionally, mobile devices offer fewer resources such as smaller screens and especially a limited physical keyboard (if at all). Hence, keyboard-based solutions are mostly infeasible in the mobile environment. The most important factor here is eavesdropping through shoulder-surfing, as usage of such devices often occurs in public places [15]. As on mobile devices PIN-equivalent security is the de facto standard, recognition-based authentication schemes using shoulder-surfing resistant variants, as e.g. proposed by Dunphy, Heiner and Asokan, come to mind. They offer an alternative to textual passwords comprising both, high usability and security equal to the PINs they ought to replace.

VI. Conclusion

The base question behind this work was whether graphical authentication can be as strong as textual authentication. Based on our analysis the answer must be: "it can be, if you design it properly." So, what constitutes a proper design? Regarding the three metrics guessability, observability and recordability the following three considerations can serve as a first quick assessment:

(1) Unguided user choice translates to predictable choice. A resistant scheme should specifically encourage or even better force users to choose random passwords or have the system issue passwords.

(2) Obfuscation techniques, such as the asterisks routinely used to obscure textual password entry or portfolio-based approaches are examples of observation resistance.

(3) The scheme should generate secrets that are hard to describe or record.

These three considerations should serve only as a starting point for an evaluation. In some situations not all of the three aspects above might be important. For example, the ubiquitous textual password does not conform to statement (3). Whether a scheme is appropriate for a certain situation depends on the context of use, the risk associated with the asset the authentication mechanism controls access to, the time constraints, the device being used and the frequency of use. If the mechanism is low risk and used infrequently, graphical authentication might well be better than textual authentication.

Graphical schemes have the potential to be as secure as textual systems. Yet, the jungle of diverse graphical authentication schemes easily explains decision-makers' reluctance to adopt graphical authentication. They are rightly sceptical about the strengths of the mechanisms and also still in a one-authenticator-for-everything mindset. If we want this mindset to change, we, as researchers, will have to provide a way for decision makers to start deploying a wider range of mechanisms, in a more nuanced and discriminating fashion than a one-size-fits-all password. What we should be striving for is more diversity of authentication mechanism usage, deploying the wide variety of mechanisms that have been trialled in situations where we can match them to the risk mitigation requirement and deployment context. This way, users would finally benefit from superior memorability of available alternatives and organisations from less secret reuse across systems.

Therefore, we want to encourage the research community to try and fill the gaps in the knowledge about the promising graphical authentication schemes already in existence, rather than proposing even more. Unification of testing methodologies and comparability of approaches should be the goal. This can facilitate decisions to integrate one of the schemes in a particular application or environment and could give insights important not only for the domain of graphical authentication, but for authentication as a whole.

Tests of Smartphone Localization Accuracy Using W3C API and Cell-Id

Grzegorz Sabak
Orange Polska
ul. Św. Barbary 10, 82-300 Warszawa, Poland
e-mail: grzegorz.sabak@orange.com

***Abstract*—Location based services (LBS) are considered very relevant for the users of mobile networks. All local events and facts related to area nearby seem to be more important that others which happen in remote places. Localization data is used in all types of services: weather, traffic, tourist info, etc. One of its most important (and regulated by law) applications is providing persons location in case of emergency.**

This paper presents results of field tests related to assessment of accuracy of two most commonly used localization methods: Cell-Id and W3C Geolocalization. The tests were conducted in the form of test drives along some of the most important roads in Poland. Position of the test vehicle obtained using analyzed methods was logged and compred to localization obtained from the Global Positioning System (GPS).

Data collected during test drives was processed and statistical information about localization accuracy was calculated. Results obtained for different methods were compared and conclusions about localization quality are provided.

The paper also describes test environment and data model which were used during work being reported.

I. Introduction

RECENT surge in number of smartphones used worldwide causes increased interest in development of applications dedicated for advanced mobile phones. There are many types of applications available which can be either bought or downloaded for free. Depending on user's current needs he or she can select from company's application shop (e.g. Google Play, Samsung Apps, iTunes) what suits him best. Typically, after having used application for some time user is expected to assess the application and share his/her opinion for the benefit of its developers and future users.

Smartphones are considered to be personal devices which are almost always carried by their owners and used in all kinds of places and situations. This means that *portability* is one of their key features and all services and content which are based on their localization are more relevant than generally available, non-localization dependent, information.

Valuable and popular services are available not only in the form of applications. To provide a complete offer, application developer very often prepares a version which can be used in a web browser run on a mobile phone. Such services are typically written using HTML5 and Javascript which gives great flexibility in preparing user interface which can be very similar to interface prepared for native application.

This paper focuses on assessment of localization algorithms available to developers of browser based services.

II. Localization Methods

There are different sources of device localization available for the application and service developers. The best accuracy can be obtained using positioning systems based on signals emitted by satellites (e.g. GPS, GLONASS, Galileo) [10], [4]. However, it is not always possible to use this method of localization (due to lack of satellite signal, limitations of device battery capacity or simply lack of required signal receiver in the device). In such cases localization can be obtained from a cellular network or through algorithms provided by operating system vendor.

A. W3C Gelocalization API

This API [9] was proposed by World Wide Web Consortium (W3C) [2] as the uniform way to access mobile device location from the Web browser. It is currently implemented in all popular browsers. The API defines programmatical access to localization data. Taking available information as input data, dedicated algorithms are able to calculate position of the mobile device and asses accuracy of such calculations. The most commonly used data sources include: Wi-Fi connection parameters, device's IP address used for mobile communication, list of sensed GSM/CDMA cells, radio communication signal strength.

Location providers continuously collect data from mobile devices being used worldwide and improve quality of localization accuracy. However, because they do not control configuration of the infrastructure which is used for mobile communication, any major change in it may cause drop in the quality of information obtained through the API.

B. Cell-Id based localization

Localization based on Cell-Id is one of the most commonly methods used by land mobile networks. Its popularity comes from the fact that it relies on the mechanisms already in place which are required for basic voice and data communication.

Implementation of Cell-Id localization requires relatively low investment in network infrastructure. Usually, deployment of a Gateway Mobile Location Center (GMLC) is the key part of projects aiming to launch such capabilities in the mobile network.

In this method, a geographical location (a pair of coordinates) is assigned to every cell in the network. Location error

978-83-60810-53-8/$25.00

depends on the size of a cell and can vary from tens of meters to c.a. 20-30 kilometers.

Localization accuracy is related to the size of the cell which serves the mobile device. Previous work [5], [8], [12], [11] showed that cell sizes depend on the type of the area. Smaller cells are found in city centers which is in accordance with network capacity requirements. In the rural areas, bigger cell sizes are used to ensure network coverage.

Other, more accurate, localization methods are also available: Time of Arrival, Enhanced Observed Time Difference [7], [6]. They rely on information coming from more than one network towers (base stations). Using information about signal strength and/or time parameters of communication between the device and the base station, it is possible to calculate user location with smaller error. This, however, requires additional infrastructure which is not available in many networks.

III. Data Model

Let *a localization* of an object be defined as a pair $p = \langle x, y\rangle \in \Re^2$, where x and y are called *coordinates* of object's location. Distance between two objects will be denoted as $d : \Re^2 \times \Re^2 \mapsto \Re^+ \cup \{0\}$.

Many different coordinate systems are used worldwide. Humanity since centuries needed the ways to represent parts of the Earth surface (modeled as an ellipsoid) as a subsets of a plane (the maps). Nowadays, the projection which is used in GPS (known as WGS84) is a de facto standard in the Internet. In WGS84 *geographic* coordinates i.e. latitude and longitude of a point are provided. Because of that, in order to avoid systematic error in calculations of the objects' distance, coordinates have to be translated to a Cartesian coordinate system. PUWG2000 which is a Polish standard of geodetic coordinates was used during calculations reported in this paper.

Let localization event l be a triple $l = \langle t, p, a\rangle$, where $t \in \Re^+ \cup \{0\}$ is a timestamp of the event, p is object's location at time t and $a \in \Re^+$ is a measure of localization accuracy.

Let $L = \{l_1, l_2, \ldots, l_N\}$ denote *localization event stream* defined as a finite sequence of N localization events ordered according to timestamp values.

L models information about object's location at some points in time. Based on L it is possible to estimate object's location $p'(t, L)$ at any point in time. During calculation of $p'(t, L)$ it is assumed that:

- the object was located at p_1 for all $t < t_1$,
- for $t_k, t_{k+1} \in \langle t_1, t_N\rangle$ the object was moving with constant velocity along line segment $\overline{p_k p_{k+1}}$,
- the object was located at p_N for all $t > t_N$.

During the tests the following localization data was collected:

- L^{GPS}- vehicle track logged by GPS device (Garmin eTrex Vista),
- L^{Orange}- geolocalization using Cell-Id in Orange Polska,
- L^{iPhone}- sequence of localization events of iPhone device,
- L^{Android}- W3C Geolocalization API events obtained for Android device.

The goal of the test was to compare different localization methods. The basic measure of localization quality is a localization error $e \in \Re^+ \cup \{0\}$. It is defined as the distance between point being a result of analyzed localization method and a point $p^{\text{GPS}} = p'(t, L^{\text{GPS}})$ i.e. object's localization according to GPS receiver.

Let $E = \{e_1, e_2, \ldots, e_N\}$ be a localization error stream defined as a finite sequence of localization errors. For each L a localization error stream can be calculated, providing that a reference localization event stream $L^{\text{GPS}}$is available.

In order to compare different localization methods, the basic statistics were calculated for E^{Orange}, E^{iPhone}, E^{Android}which denote localization error streams calculated for L^{Orange}, L^{iPhone}, L^{Android}respectively. The results of these calculations are presented in the following sections of this report.

IV. Test Environment Configuration

The tests were performed in the form of test-drives during which localization of the vehicle was monitored using methods which were to be compared. Additionally a GPS receiver was put onboard of the test vehicle. It was used for logging of the vehicle location with maximum available accuracy and frequency.

During the tests the following devices were used: iPhone 3GS (iOS), ZTE SanFrancisco (Android), and Garmin eTrex Vista GPS receiver. Smartphones were equipped with subscription of Orange Polska mobile network.

The Fig. 1 shows main components of the test environment and main communication channels between them. iPhone and Android smartphones communicate with W3C API servers to receive device localization. When localization is calculated and returned to the device it sends a request to log it in the test application. Devices' localization is concurrently monitored by mobile network through Gateway Mobile Location Centre (GMLC). Position of the vehicle is logged by GPS device.

For the purpose of the test a dedicated web page was designed, developed, and exposed in the Internet. Its role was to trigger calls to W3C Gelocalization API on any device which opened it in the Web browser. Result of the localization API calls was logged in a database which was located on a Web server.

V. Test results

The test drive took place in January 2013. Its route is shown in Fig. 2. The tests covered some of the most popular roads in Poland. Test drive started in Warsaw and then proceeded through Czestochowa, Krakow, Nowy Targ, Kielce, Radom and ended in Warsaw.

A. Maps

After completion of the test-drive, data were processed and visualized using open source Quantum GIS [3] software. Sample maps showing data collected during tests-drives are presented in the Fig. 3, Fig. 4, and Fig. 5.

Places which are results of localization procedures are marked with dots. Dashed line segments connect locations obtained through different methods and actual device's position.

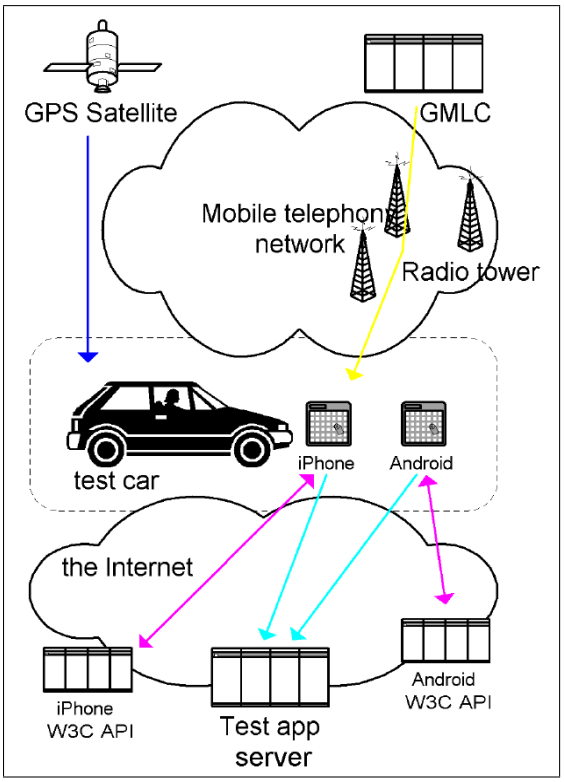

Fig. 1. Test data collection environment

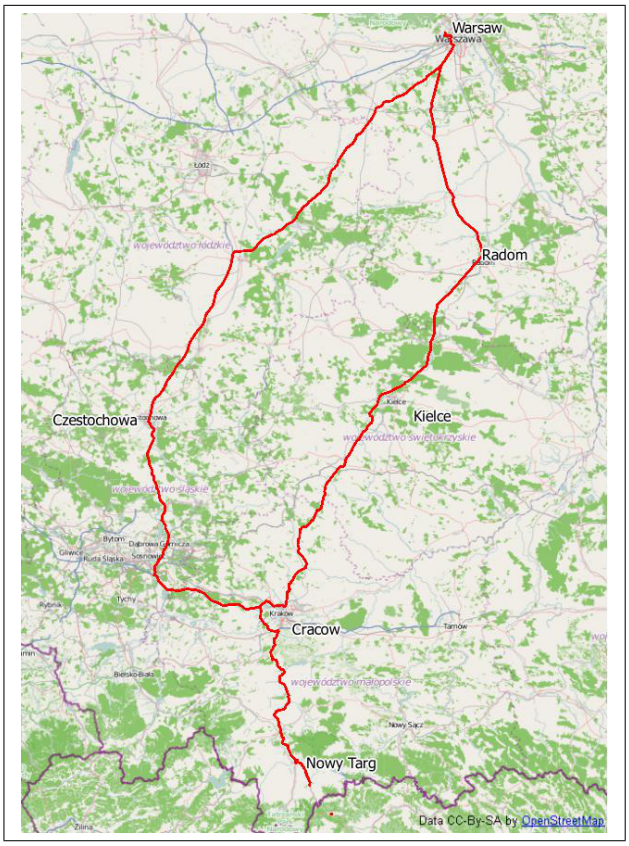

Fig. 2. Test drive routes

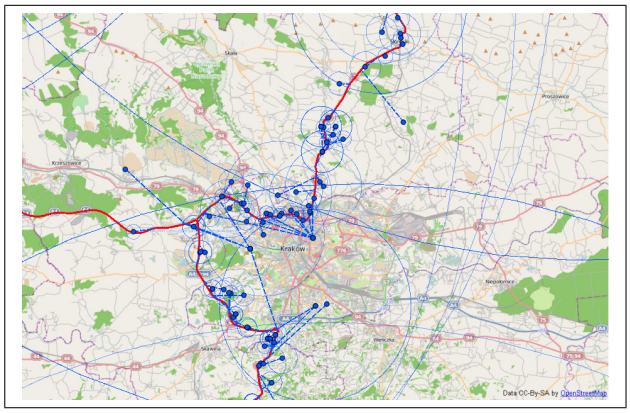

Fig. 3. iPhone location events in Cracow area

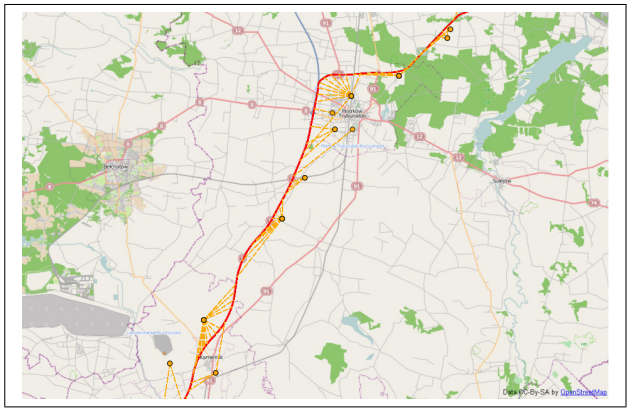

Fig. 4. Cell-Id (Orange Polska) localization events

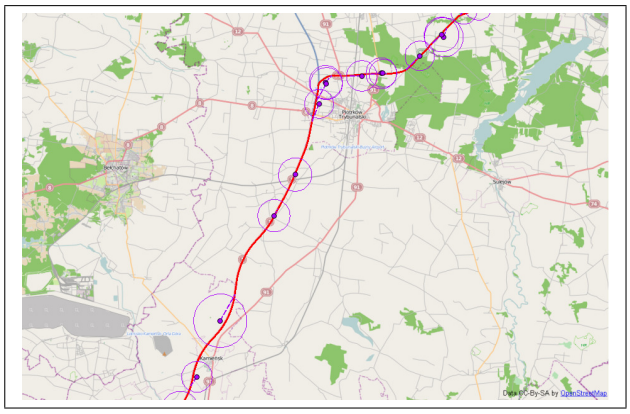

Fig. 5. Android localizations near Piotrkow Trybunalski

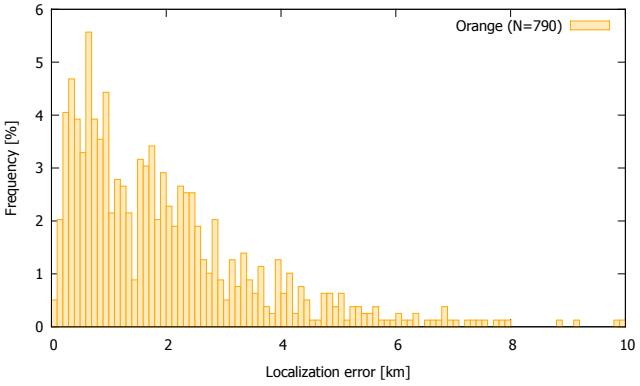

Fig. 6. Cell-Id location error distribution

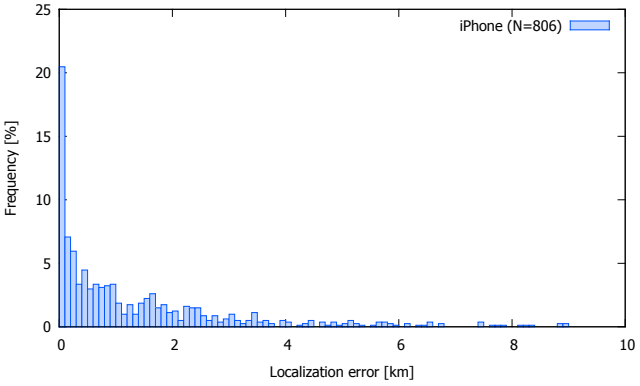

Fig. 8. iPhone location error distribution

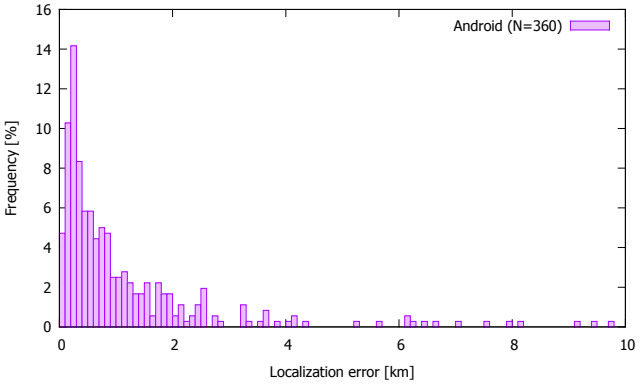

Fig. 7. Android location error distribution

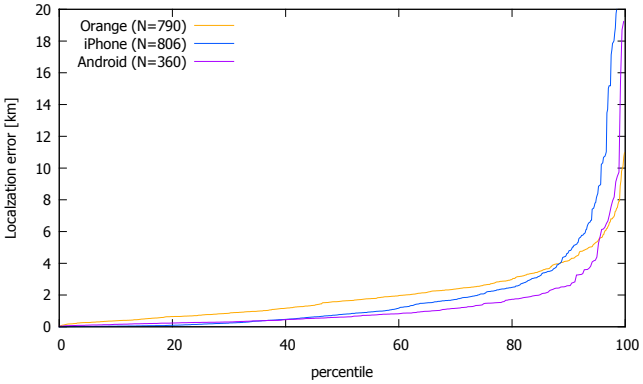

Fig. 9. Error value - cumulative distribution

Circles represent accuracy of localization as returned by W3C Geolocation API.

From the analysis of graphical data it can be concluded that in most of the cases W3C API localization is much more accurate than one based on Cell-Id. However, for some events W3C API localization error (examples can be seen in Fig. 3), is several times higher and is comparable to localization errors found in Cell-Id method.

B. Localization error distribution

In Fig. 6 location error density for Cell-Id is shown in the form of a normalized histogram. The maximum number 5.6% of location events fall in to the bin representing range $\langle 0.6\text{km}, 0.7\text{km}\rangle$ of error value.

Similar histograms visualizing data related to W3C API implemented in iPhone and Android mobile phones are shown in Fig. 7 and Fig. 8.

The bins with maximum percentage of events are: $\langle 0.2\text{km}, 0.3\text{km}\rangle$ for Android phone and $\langle 0.0\text{km}, 0.1\text{km}\rangle$ for iPhone. They account for 14.2% and 20.4% of localization events respectively.

C. Comparison

Localization quality of analyzed methods is compared on chart in Fig. 9 and Fig. 10. It presents cumulative distribution of localization error for all localization methods. It can be noted that for the range from 0m until about the median, iPhone localization is much better than other two. Taking into account about 90% of measurements Cell-Id localization is worse than other two. However, when all results are analyzed, the maximum error values significantly are smaller in case of Cell-Id than in methods based on W3C API.

Summary of basic statistical information is presented in

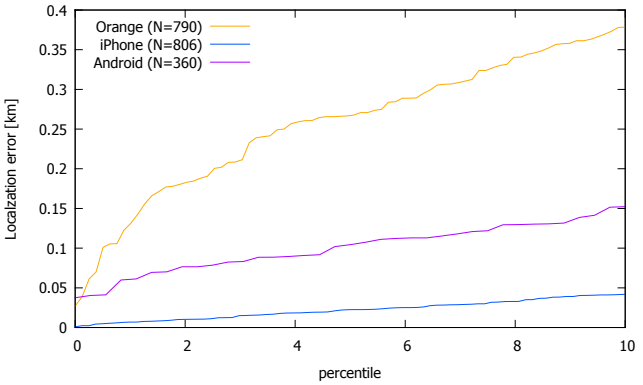

Fig. 10. Error value - cumulative distribution 0-10th percentile

TABLE I
COMPARISON OF LOCALIZATION ERROR STATISTICS. VALUES IN KM

Method	N	e_{avg}	σ	Q_1	Q_2	Q_3	e_{max}
Cell-Id	760	1.99	1.77	0.73	1.62	2.62	10.96
Android	360	1.28	2.16	0.28	0.61	1.40	19.24
iPhone	806	2.18	5.38	0.16	0.78	2.07	80.30

Table I. Taking into account average error value and standard deviation, Cell-Id seems to be the best localization method. However, there is big discrepancy in values of the first, second, and third quartiles in favor of W3C API methods.

VI. CONCLUSIONS

The set of tests showed that both W3C Geolocation API and Cell-Id methods are very good sources of location information for application developers. The quality of the W3C API implementations is very impressive, keeping in mind that API providers do not have any a priori information about spatial configuration of GSM and Wi-Fi networks.

Tests were performed with a kind of black box approach. Probably some results could be explained if geolocation algorithms used by Android and iPhone APIs were known.

***Abstract*—The paper presents an idea of a context-aware application, which collects context data from many different sources, stores them in a dedicated database and makes use of it to support flexible scenarios for end users. Using open APIs it integrates different types of context information provided by: Unified Communication system, APIs exposed by communication service providers and information from Machine to Machine (M2M) framework. Methods for recording and unifying different types of context data are proposed and their performance is compared with results for the most popular database structures. A context-aware contact list application for a mobile phone user is presented as an example illustrating the main ideas of the paper.**

I. Introduction

NOWADAYS, value of information about context of communication is growing and having more impact on next generation of context aware services. Companies such as Google, Twitter or Facebook which are in possession of large databases which contain mostly context information [1] became major players in the ICT market. Information about users and their activities is the base of social networks' owners' business model and has started to be monetized, e.g. mainly in personalized focused advertising.

Availability and usage of precise context information has a very big potential for enterprises and constitutes a catalyst for innovative ICT systems and applications [2]. From a mobile phone user's point of view, participation in social networks implies a change of a lifestyle. People want to "stay in touch" which means that they have to be reachable via phone independently of their location. Most of the businessmen (but not only) can't imagine working without multiple phone numbers: a personal number to contact family, an office phone number to contact coworkers and a business number to communicate with customers.

The idea of easy contact for business users is one of the principles of Unified Communications services – a very popular communication trend in enterprise area. Typically it is implemented with:

- One number service – functionality allows the user to define and manage preferred communication devices via voice and video. Despite of using different terminals, subscriber is identified by one universal telephone number.
- Integrated application – single application supporting in a unified way many different communication channels: voice, video, e-mail, voice mail, Instant Messaging and web collaboration.

Efficient usage of Unified Communication systems and their features requires interaction with the end system user. Usually a user has to pay attention to and consciously set his or her status in UC application (ready, out of office, on holiday etc.), set and activate auto response in corporate e-mail system or set an active phone (office phone, mobile phone, softphone etc.).

From the end user the perspective, these processes preferably should be automated to ease him/her of manual setting of an active phone. All information required for Unified Communication system can be acquired by sensors or software components taking advantage of context information.

The idea of automatic information exchange between devices and sensors is similar to the smart home automation concept, and M2M systems are a very promising source of context information e.g. for potential commercial systems.

The main aim of this paper is propose method to store in one database context information characterized of various data structure from different mentioned above sources (UC, Telco and M2M systems).

978-83-60810-53-8/$25.00

II. BACKGROUND

A. Existing solutions

Many context-aware computing paradigms have been developed in the recent years. For example, Cisco context-aware Healthcare solution, which is a tool for monitoring and simplifying business operations in hospitals [3]. However the most popular context-aware solution is currently the Google Ads Gadget, which displays context based personalized commercials to users browsing a specific website [4].

Cisco solution [3] uses RFID [5] (Radio Frequency Identification) technology for real time tracking of patients, medical personnel and hospital assets, what is crucial for providing the best quality health care services and optimization of workflow and medical staff management. The uniqueness of the approach stems from the fact that Cisco health care solution treats equipment and machines, such as X-ray or wheelchairs, as objects which are considered as the source of the context information. Context aware systems also bring new features into the survey conducting area [6], [7], [8], [9]. In this field, gathering context data and taking advantage of data collected by mobile devices, such as smart phones or tablets, allows developers to invent useful mechanisms which in turn allow to specify the exact target group of a survey. A solution presented in *A survey on context-aware systems* [6] uses a variety of many flexible sources, including widgets, wireless sensors and middleware infrastructure, which is somewhat similar to the mechanism presented in this paper.

B. Unified Communication

Unified Communication [10], [11] systems constitute an important element of private communication networks dedicated to enterprises. Many vendors (e.g.: Avaya, Cisco, IBM, Microsoft, Oracle and Siemens) offer comprehensive UC solutions. An example of such system developed by Siemens Enterprise Communications is OpenScape UC application.

UC system offers many features, e.g. standardization of communications services, support for user mobility, communication medium neutrality and support for any type of equipment (type of terminal). Possibility of virtualization of resources and services and their exposition by using LAN, WAN or Internet networks is of utmost importance for business users. Openscape UC (Fig. 1.) offers VoIP (Voice over IP) services (implemented in the OpenScape Voice subsystem), video communication between employees (OpenScape Video) and integration of e-mail and voice in a single message box (OpenScape Messaging). Integration of external applications and systems with OpenScape system is possible due to availability of Application Programming Interfaces (APIs), implemented in the UC system. Its APIs are exposed as Web Services and are offered using a Service-oriented architecture model (SOA) and SOAP Protocol (Simple Object Application Protocol). By taking advantage of UC open APIs, external developers can create their own specific application and UC system extensions described in [11] and [12].

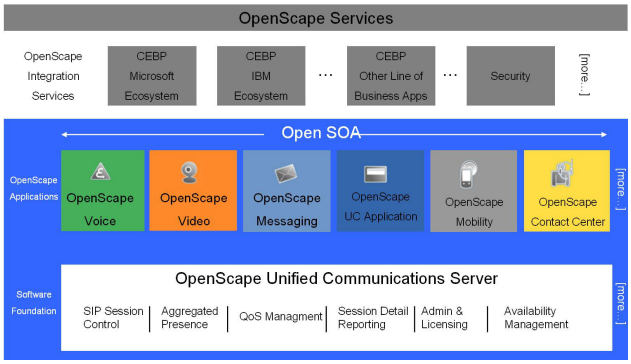

Fig 1.OpenScape UC system architecture [11]

C. Telco 2.0

Telco 2.0 [13] is an idea based on exposition of Communication Service Providers APIs for external developers and third party companies on the Web. From the technical point of view, telecom operator's APIs are exposed using a dedicated entity – a Service Delivery Platform (SDP). An SDP is located between the operating network and the Web. Its southbound interfaces are connected to the operating network and integrate it with enablers offering telecommunications capabilities (e.g.: SMS, MMS, USSD, voice call, etc.). The northbound interface exposes open APIs as Web Services on the Web. The SDP is also connected to an Operations Support Systems responsible for: maintenance, inventory, provisioning and fault management as well as Business Support Systems (responsible for order handling, billing, payments etc.). There are two ways of exposing Telco 2.0 APIs – either via SOAP [15] interfaces or by using REST architectural style [14]. Telecommunications service delivery platforms (SDP) usually allow access to their capabilities in the service-oriented architecture (Parlay X specification [16]) or resource oriented Web Services (RESTful) model compliant with the OneAPI specification [17]. By using open Telco 2.0 APIs, it is possible to develop new applications and services merging IT and the Internet world with telecommunication area [12], [18], [19].

D. M2M approach

The Machine to machine (M2M) concept refers to technologies that allow both the wireless and wireline systems to communicate with other devices with the same capabilities. M2M uses devices, such as e.g. sensors or meters, to capture events or current state indicators (temperature, inventory level, etc.), which are then relayed via a network (wireless, wireline or hybrid) to an application (software

program), that translates them into meaningful information (for example, items need to be restocked) [20]. Such communication was originally implemented using a remote network of machines which relayed information back to a central hub for analysis, which would then be rerouted into a system like a personal computer.

III. System Architecture

Our solution integrates three systems as a context data source (Fig 2). The first data source is the Unified Communication system. Using the SDK (Software Development Kit) provided by Siemens, it is possible to implement a service which captures events reflecting subscriber's activity, e.g. phone status and change of user status. The Openscape UC API enables implementation of the click to call feature as a dedicated button at the website. Web Services exposed by Communication Service Provider in the Telco 2.0 model allow collecting context data from mobile phones (e.g. using terminal status and terminal location APIs). The third source of the context information are events generated by M2M devices. This last area is a comprehensive source, which can send information of all type (presence, alarms, user activities etc.).

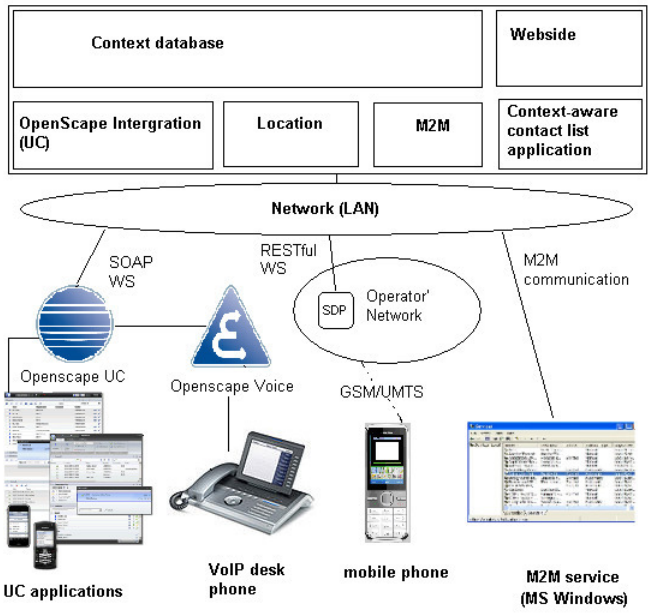

Fig 2. Architecture of system

This chapter presents the main modules comprising the system collecting context information from different sources.

A. Database

The data base is the most important part of our solution. It plays the role of the data repository collecting context records from three mentioned above sources. The data base has to be: scalable, easy to access and fast. Meeting these requirements is easy in case of small databases but must be relaxed in case of large systems handling thousands of records.

The implemented MySQL database uses a relational data model and specifies four main entities (Fig 3.):

- *User* – entity stores information about the user: login information for OpenScape management portal, name, surname, Openscape VoIP terminal and mobile terminal numbers as well as the home address.
- *Locations* – entity stores known addresses of the user for example home address and work address.
- *Context_data* – stores context information: timestamp and context data set which is JSON form of context information (for example latitude and longitude).
- *Context_type* (Fig 4.) – a table which contains information about the context data source.
- *Param_type* – a table which assists in detection of the type of parameters coded in context data set (JSON).

The presented database schema guaranties to be scalable – e.g. there is no need to add new table when the system is integrated with a new context information source in the future. Data sets are easy to access because of the usage of JSON [21] format, which is supported by many programming environments.

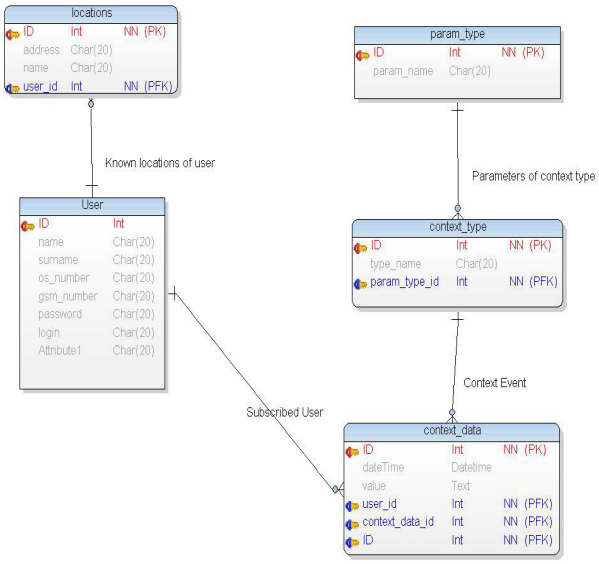

Fig 3. ER diagram of database

id	name	paramtype_id
1	openstageMediaStat	4
2	openstagestat	5
3	gsmlocation	1
6	systemlogin	6

Fig 4. Context type entity

B. Location module

The location module is responsible for collection of information about a mobile phone's geolocation. The location data is collected using terminal location API calls, based on those exposed in the Web by Orange using a dedicated Service Delivery Platform (SDP). The response received from *Terminal Location API* contains approximated latitude and longitude of the mobile terminal. The location information is stored in the database using pooling method. The measurements are repeated every minute. Unfortunately, the pooling method is not very efficient in terms of performance, but currently there aren't any other methods available for small developers and external companies that could be exposed on the Web by Communication Service Provider in the Telco 2.0 model.

C. OpenScape integration module

Siemens provides a high level Software Development Kit for programmers, which allows implementing a method responsible for integration with a UC system. Its main role considered here is implementation of a method, which captures events in relation to the change of media (terminal) status or user status in UC system. There are three possible states of media status: 0. *UNKNOWN* (when the observing user is not authorized to see the recipient status) 1. *AVALIABLE* (when there is no call on the phone line) and 2. *UNAVAILABLE* (when the user is already busy in a call). The events, like e.g. change of the status are captured and stored in the database with a timestamp and an appropriate JSON value.

The second parameter correlated with the user activity by the presence of API is the user status. There are 6 possible states of user status: 1 - *Do not disturb* 2 - *Be right back* 3 - *Unavailable* 4 - *Busy* 5 - *In meeting* 10 – *Available*. This parameter is stored in the database – when an event (triggered by the change of the status) appears. The user status information is stored (in the JSON format) with a timestamp in the database.

Another method implemented in this module is the *click to call* feature. This method requires user login and password information to recognize an active phone from which the call originated.

D. M2M module

This application was implemented in Windows Service form which starts with the user's login and ends with the system user's logout. The module collects information about the user logged on to the workstation. The name of the user is sent to the main system and is stored in the database, using timestamp in JSON format.

E. Module Website

Module Website – the graphical user interface was created using ASP.NET framework. The module contains 4 subpages: *login.aspx*, *contactlist.aspx*, *adduser.aspx* and *about.aspx*. Only a successfully authorized user is able to use the portal. This module implements login and password; the ones required by portal are the login and password from OpenScape UC system. If the logged user is also the administrator, he or she is able to manage the system's administration panel, e.g. add or remove users to the system, (Fig. 4) define work address and home address.

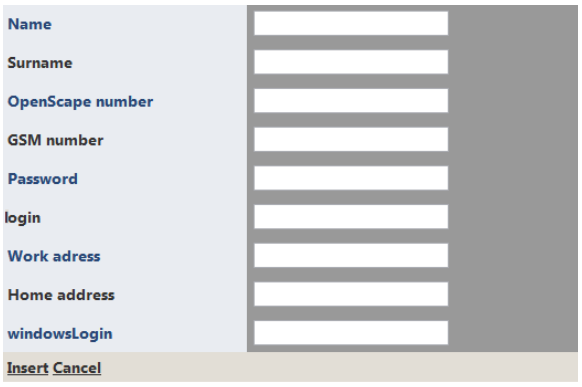

Fig. 4. Module Website - add user form

To add a user, all fields are required, with the condition of setting a correct login and password (same as OpenScape UC). The ending user application of the website is *contactlist.aspx* which contains all contacts, context data and the click to call button (Fig. 5.).

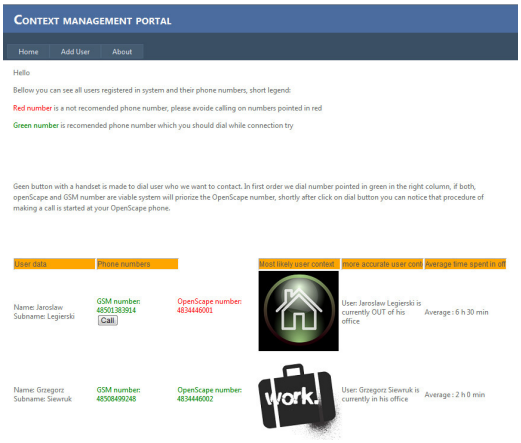

Fig. 5. Context-aware contact list application

F. Context-aware contact list application

The contact list application contains user information, such as: name, surname, mobile terminal number and OpenScape UC number (VoIP office phone). The database also contains location information, such as the user's home address and work address. The application based on the context data can recognize the actual location of the user (using Telco 2.0 and UC data) and can present more specific context data e.g. if the user is at work, it shows the average time spent in the office (M2M based information). The application can even suggest the number of users recommended to contact them. The website also has

a "call" button which allows dialing the recommended phone number using the OpenScape UC system.

IV. Simple Context Based Decision Algorithm

This chapter, based on the contact list application features, presents a simple context-based decision algorithm. The first column of this application (Fig. 5) contains contact data, such as the name and surname from the database. The next column: "Most likely user context" is a field based on information acquired from the Telco 2.0 location API.

The application uses Google Map API to recognize the home address and work address based on geolocation (longitude and latitude), which is recognized by using the distance between the user's current location (the latest database record) – and simultaneously between the current location and home location. If the distances calculated above are less than 1000 m, the algorithm determines that the user is at the defined location (work or home).

The next column - "More accurate user context" - contains information from data collected by the M2M application. If the user is already logged on to the workstation, the algorithm decides that the user is in office and vice versa: if the user is not logged on to the system, the result is interpreted as "out of office".

The column "Average time spent in office" is based on data received from the M2M application. The application measures the time from the timestamp between login and logout, and calculates an average value.

The last column - "Phone numbers" contains all phone numbers defined for a specific user. If the phone number is underlined in red – the number is not recommended to dial, when it is in green– the number is recommended for use.

There are several conditions that must be met for the number to be underlined in red: for the context information from OpenScape UC – *AggregatedMediaStatus* attribute must have value *Unavailable*; *userStatus – In Meeting*, *Unavailable*, *Busy* or *Do not disturb*; however, if *AggregatedMediaStatus* is Available but the user is out of office, the number will also be underlined in red.

Finally, by clicking the "call" button, the user can dial the number which is underlined in green. When all numbers are highlighted in green, the number allocated to Openscape system has higher priority.

V. Information Integrity and Security

A. Context Conflicts

There is a possibility that pieces of the context information which are received from different sources may be inconsistent or conflicting. Situation like this can happen when the subscribed user by mistake leaves his mobile phone at home. In this case M2M module has discovered user as logged in and present in his office however Telco 2.0 module is indicating that the user is at home.

It is extremely important to deal with this kind of situations properly because any inconsistency has impact on reliability of the presented solution. For example in the scenario described above, a source which can authenticate user is selected as the stronger one and other conflicting information will be ignored (however the user will be informed that there is something wrong with his devices). In order to be able to use M2M module, the user has to be logged in to his computer by providing a correct password or plugging a USB token with a certificate.

Submitted solution is efficient enough but can be improved by using semantic algorithms.

B. Information Security

As it is described in the previous chapters presented system deals with sensitive data and implementation of methods preventing data loss is of utmost importance.

There are several mechanisms to perform such tasks both at the application side and at the server side. A list of basic requirements to provide security for this kind of environment is as follows.

Application:

- enforce users to use strong passwords (Uppercase letters, special signs, numbers),
- enforce users to change their passwords every 30 days,
- user roles which give the certain user possibility to perform only allowed operations.

Server:

- up to date antivirus software,
- configured firewall,
- database calls can be made only from the specific IP addresses (website).

In Context-aware contact list application requirements for strong passwords and regular change of password is possible to achieve only if administrator of OpenScape system implement such policy in OpenScape panel (password for application and OpenScape is the same).

Application is immune to the most common SQL-injection and Cross Site Scripting (XSS) attacks.

VI. Measurements

A. Performance tests result

In order to verify the SQL database structure presented in chapter III, some performance tests had been run. The proposed database scheme was compared with a classical database structure based on 5 independent tables (user, *gsmlocationcontext*, *openscapeaggmediacontext*, *openscapestatuscontext*, *m2mcontext*) and filled with context information.

The first test presents time needed to load all the context datasets to the memory. In order to get all the information about a specific user, 4 SELECT statements were executed, whereas getting all the possible information in the presented solution required only one SELECT statement. The results are presented in Table 1.

TABLE 1
. SQL QUERY RESPONSE TIME (4 CONTEXT SOURCES)

Select all context			
Context-aware contactlist database		Standard context database	
Table length [bytes]	SELECT duration [s]	Table length [bytes]	SELECT duration [s]
500	0,00501125	500	0,047842
1000	0,0101115	1000	0,055079
1500	0,01409725	1500	0,206002
2000	0,0230885	2000	0,179314
2500	0,02743775	2500	0,275252

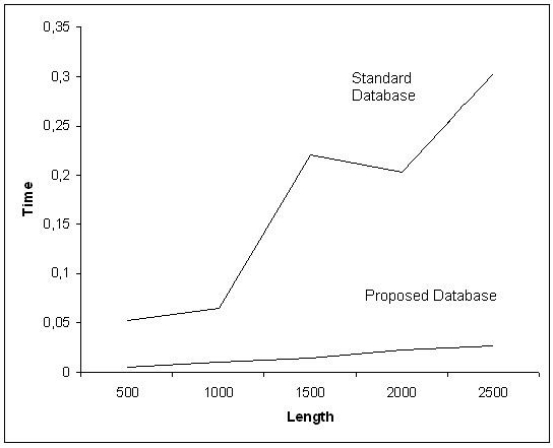

Fig. 6. SQL query response time. (4 context sources)

TABLE 2.
SQL QUERY EXECUTED FOR THE PROPOSED DB SCHEME (4 CONTEXT SOURCES)

```
SELECT * from contextdata where user_id =1
```

TABLE 3
SQL QUERY EXECUTED BASED ON STANDARD SOLUTION. (4 CONTEXT SOURCES)

```
SELECT * from gsmlocation where user_id=1; SELECT * from openscapestatus where user_id=1; SELECT * from openscapeaggmediastatus where user_id=1; SELECT * from m2mcontext where user_id=1
```

The results presented above show dependency of the execution time on the table length. The proposed database structure is more efficient because it decreases the number of SQL Select statements. The execution of one SELECT statement is faster than the execution of four SQL Select statements.

In the next test, the performance of a database based on the information from only one context source was measured. The SQL queries used during the test are presented in Tables 4 and 5 respectively.

TABLE 4.
SQL QUERY EXECUTED FOR THE PROPOSED DB SCHEME (1 CONTEXT SOURCE)

```
SELECT * from contextdata where user_id =1 and cotnexttype=1
```

TABLE 5.
SQL QUERY EXECUTED FOR THE STANDARD SOLUTION (1 CONTEXT SOURCE)

```
SELECT * from gsmlocation where user_id=1
```

The results of the measurement are presented in Table 6.

TABLE 6.
SQL QUERY EXECUTION TIME (1 CONTEXT DATA SOURCE)

Select one context			
Context-aware contact list database		Standard context database	
Table length [bytes]	SELECT duration [s]	Table length [bytes]	SELECT duration [s]
500	0,011354	500	0,019467
1000	0,020775	1000	0,02147375
1500	0,02485975	1500	0,04349075
2000	0,0322245	2000	0,05073
2500	0,04947975	2500	0,05930075

Using the proposed context notation in the JSON format results in the execution time of SQL SELECT function which is shorter than in case of the standard notation. It should be emphasized that in the presented solution, the table has always 4 columns and this value is independent from the number of parameters represented in the context information (context data source).

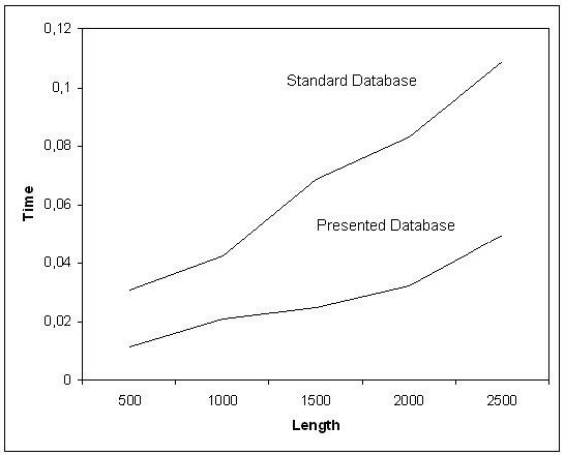

Fig. 7. SQL query response time. (1 context data source)

B. Functionality test results

Figures 8 and 9 present the results of the functional tests. The maps present the location of selected points where the service was invoked, and show the location received by using the Telco 2.0 location API as well as the potential location based on the user's activities in the UC system.

Blue arrow - real location of the user.

Green arrow - location based on the information from UC system.

Red arrow - location based on the mobile network.

For the presentation of the test results, Google maps application was employed. Figure 8 shows the case in which the user forgot to change his or her UC status, and left the office. Based on the mobile terminal location services, the presented context aware system can, in this case, change the status of the user in the UC system automatically. Figure 9 presents the approximate range within which the user is considered to be in his or her office.

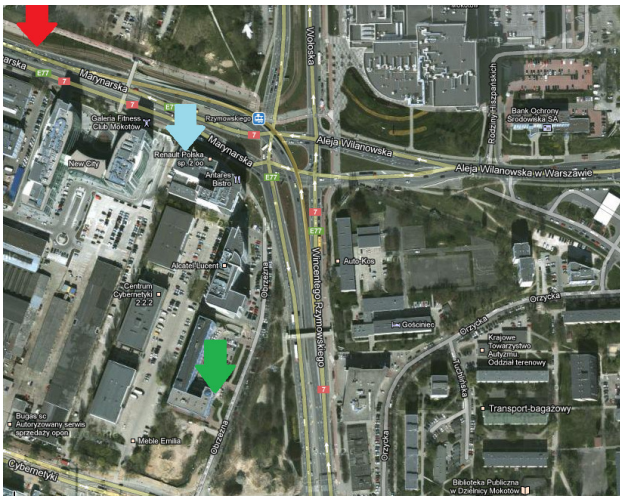

Fig. 8. Sample result – "user out of office"

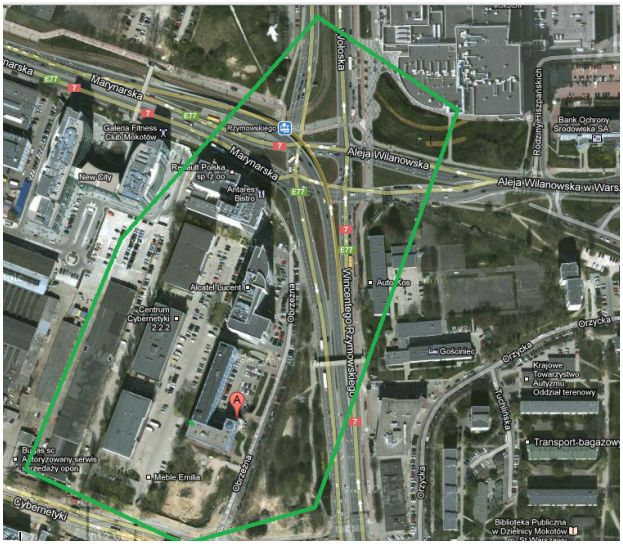

Fig. 9. "user in the office area " - approximate range

When the user passes the border line highlighted in green, he or she can be recognized by the context application as being out of office.

VII. Summary

The architecture of the context aware application presented in the paper features easy access to the context data sets stored in the database. The context information is stored using the JSON format, which is very popular in the IT world.

The main challenge was development of the structure of the database which had to meet many criteria described in the system architecture (chapter II). Further work on the described system should be focused on the usage of NoSQL databases as a data repository.

The presented solution is, first of all, flexible, ready and easy to extend. The most important aspect is the possibility to add another source of context just by inserting a record into the database with a new context data definition.

The functional test results presented in chapter IV show the location error in mobile networks using Terminal Location API and their impact on the context aware application functionality. This error can be minimized using more accurate location algorithms by communication service providers or the implementation of other location methods e.g. based on GPS.

The prototype of the context aware application has been developed under the Orange Labs Open Middleware 2.0 Community program [22] as a part of Grzegorz Siewruk' B.Sc. Thesis.

Abstract — **The following paper presents Mobile Payment System. The system is a prototype of an innovative method of paying for services using the mobile phone. The method is quite straight-forward, basically the user wanting to access some online service supplies his/her cellular phone number to the web form and receives a token via USSD message (Unstructured Supplementary Service Data). Then, introducing the token into the web form gives the user an access to the desired content. At this exact moment the charging is done. The due amount of money is simply added to the monthly bill, in case of postpaid phones, or subtracted from available credits, in case of prepaid mobile phones. The functionality of sending USSD messages from the system to the subscriber mobile phone was achieved by using Telco 2.0 Web Services provided by Orange Labs.**

I. Introduction

As it is observed, nowadays in the global web there are more and more paid services. There are a numerous portals which require registration fees, an access to some scientific articles is restricted until it is paid for. There is of course possibility of buying ticket for a concert or other cultural event and a lot of other services not mentioned here. Some of the services have a great number of users and other not so many. Also as it is commonly known, everybody wants get the access in the shortest time and the easiest way possible. The need therefore arises: quick, easy mobile payment method with no scalability problems.

A. Existing solutions

At the moment there already exist some payment methods like [11]:

- premium-rated SMS
- credit cards
- pay-pal (and alike systems)

Unfortunately each of described above system has some limitations. Premium-rated SMS requires a huge number of users per month to be cost-effective. The problem with credit cards is such that not everybody has one, another is that for some people it may seem risky to send sensitive credit card data over the internet which will discourage them from using this method. Pay-pal and pay-pal-like systems require registration and uses dedicated account which is time consuming and can act like a discouraging factor.

B. Migration from Telco 1.0 to Telco 2.0

Telco 1.0 is about value-added services (VAS) [1] which are all services that are beyond voice calls or fax transmissions. They, as the name indicates, add value to the standard services. Historically, SMS, MMS or data access were considered VAS, however nowadays they are standard services. In that approach only the operator could create new added telecommunication services. The reason for that was the fact that such services used intelligent network platforms (telecommunication platform with centralized management), which were accessible only by the operator. Since a few years migration from Telco 1.0 to Telco 2.0 [2][2] can be observed.

In Telco 2.0, an additional layer in the Intelligent Network Platform architecture has been created. It has been added to make a creation of other VAS possible by parties other than the operator alone. In practice, the operator offers an access to the basic telecommunication functionalities (like sending and receiving USSD, SMS, MMS messages, managing phone calls, locating terminals etc.) in form of easy to use web services. The communication with those services is possible using the SOAP and REST [3][3] protocols. The conceptual difference between Telco 1.0 and Telco 2.0 approaches is

978-83-60810-53-8/$25.00

visualized in the Fig.1. The architecture of the Telco 2.0 solution is presented in Fig. 2.

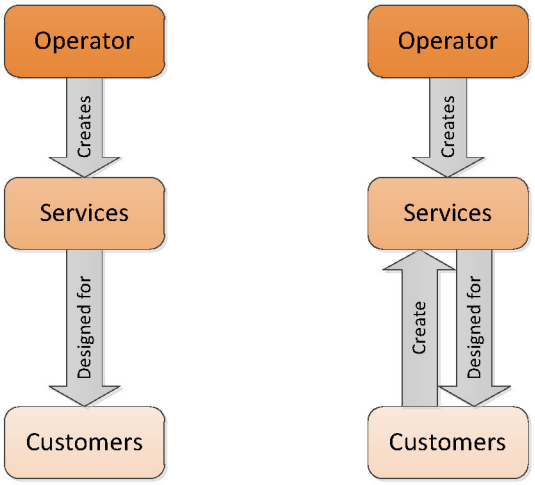

Fig 1. Telco 1.0 vs. Telco 2.0 concepts[7][7]

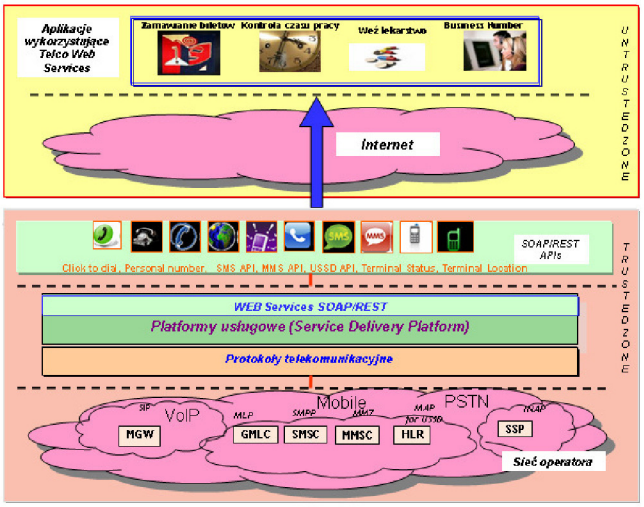

Fig 2. Telco Web Services architecture [10][10]

C. Profits of using Telco 2.0 to solve the presented problem

The great advantage of Telco 2.0 is its the range of usage. It is not restricted to the users of smartphones only but it is accessible by all mobile phone users within coverage area which is over 95% of the inhabitants of Republic of Poland. It implies that the service can be launched from any location covered by the radio access network of the native mobile telecommunication operator. During recent years there were developed a number of applications based on operators networks assets. Some examples are described in literature [6][6], [7][7], [8][8], [9][9], [10][10].

II. THE PAYMENT SYSTEM

Mobile Payment System is a prototype of an innovative method of paying for services using the mobile phone. The system presented in this paper addresses all the arisen needs: it is fast, easy and has no scalability problems.

Implemented solution of the method is just a prototype that should be treated as a proof of concept rather than ready to deploy product. System functionalities are limited to granting access to specific URLs. Apart from that the management panels has been implemented in form of web application.

Fig 3. The schematic of service usage[7]

The method is fairly simple, the user wanting to view restricted content supplies his/her cellular phone number to the web form and receives a token via USSD message. Then, introducing the token into the web form gives the user an access to the desired content. Also at this moment the charging is done. The due amount of money is added to the monthly bill, in case of post paid phones, or subtracted from available credits, in case of pre-paid mobile phones. This is, of course, just the main idea of how the system works. The system itself is more complex. It contains also user account creation, generation and transmitting the account password to the client via SMS, storing the history of subscription, administration panel (managing of 'non-admin' users). Also, the service is protected from unauthorized use thanks to basic authentication mechanism. The functionality of sending SMS and USSD messages from the system to the subscriber mobile phone was achieved by using Telco 2.0 Web Services provided by Orange Labs. These are ready to use services that provide above mentioned functionalities. The whole system was implemented in .NET technology using C# programming language. Entity Framework was used to facilitate all necessary database operations, technology for database is MySQL. The communication with Web Services is

possible with SOAP protocol. The implementation of user interface uses ASP.NET MVC 3 Framework.

III. SYSTEM ARCHITECTURE

A. Functional schematic of the solution

The functionality of the solution is presented in Fig. 4.

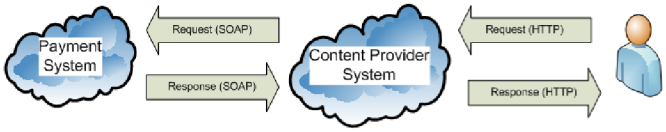

Fig. 4 Functional Schematic of the solution

The end user makes HTTP GET request to Content Provider System if the user is not authorized to view the content SOAP request is made to Payment System where the user is charged. Response is sent to the end user through Content Provider System.

B. Used Telco 2.0 interfaces

The system is based on the functionalities offered by mobile phone networks. SMS API, USSD API and GetOperator API have been used. GetOperator API is used to check if the number provided by the user belongs to Orange operator. SMS API and USSD API provide a possibility to send a message and check the status of the message. SMS API is used in the system to send the generated password to the user. USSD API is used to send generated access token to the user's mobile phone and send notification about charging.

C. Structural architecture of Mobile Payment System

The solution presented in this paper consists of 2 separated systems: Payment System simulating payments and Content System providing resources.

The Payment System (Telco) is responsible for exposing SOAP Web Service providing Payment API functionality. It consists of three parts based on the performed functions shown in Fig 5.

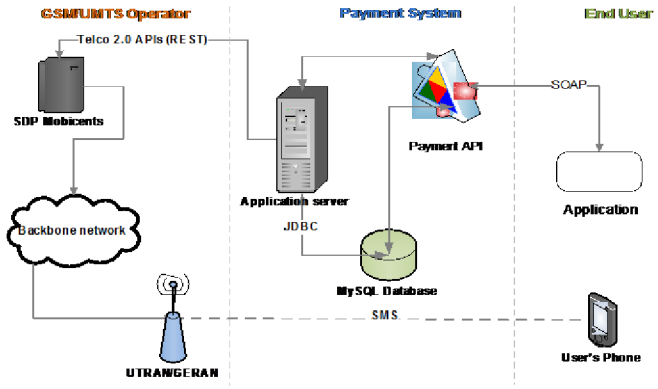

Fig 5. Structure of developed Payment System

• End User – communicates with the system via UTRAN/GERAN access network using mobile phone or SOAP web service.

• Payment System – the logic of the system consists of two applications. First one is the application implementing Web Service and the other is Web application which provides the user interface for database administration. The communication between the system and database is done using Entity Framework. The database stores information about accounts, transactions and web service users. The application uses Telco 2.0 interfaces to send passwords to the user's mobile phones.

• GSM/UMTS Operator – enables the communication with the developed system through exposed Telco 2.0 interfaces.

The second module - content system is responsible for providing paid content to the end user. It consists of three parts based on performed functions shown in Fig. 6.

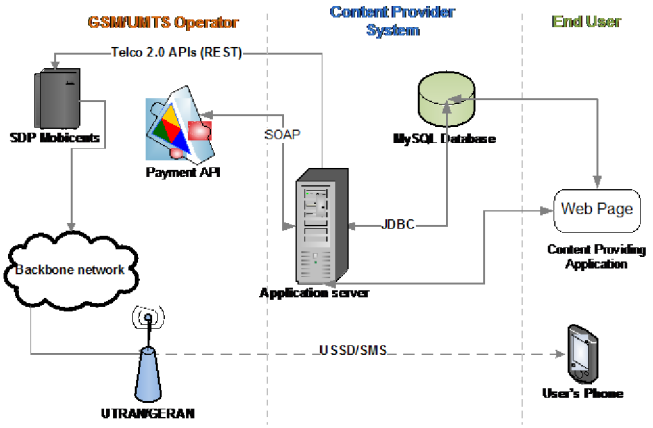

Fig 6. Structure of developed Content System

• End User – communicates with the system via UTRAN/GERAN access network using mobile phone or Web Browser.

• Content Provider System – the logic of the system is implemented as a web application, which provides the user interface for the Content Provider application. The communication between the system and database is done with use of Entity Framework. The database stores information about users, URLs and subscriptions. The application uses Telco 2.0 interfaces to send token to the user wanting to access chosen URL.

• GSM/UMTS Operator – enables communication with the developed system through exposed Telco 2.0 interfaces.

D. Class Diagrams

Presented solution was developed in Model-View Controller (MVC) style. It consists of Controller, Model, ORM and Helper classes. All interesting classes are presented below. Views are simple dynamically generated HTML. Classes in the system:

- Controller classes – responsible for handling HTTP requests. GET and POST requests are mapped to appropriate method called action from the class. Diagram is presented in Fig. 7,8
- Model classes – represents the data objects send within system. Each class consists of properties and the setter/getter methods for each.
- ORM classes – represents the database tables mapped into C# objects. Entities are generated by Entity Framework.
- Helper classes – are responsible for database operations, handling AJAX, sending response to mobile phone end user. Presented in Fig. 9, 10

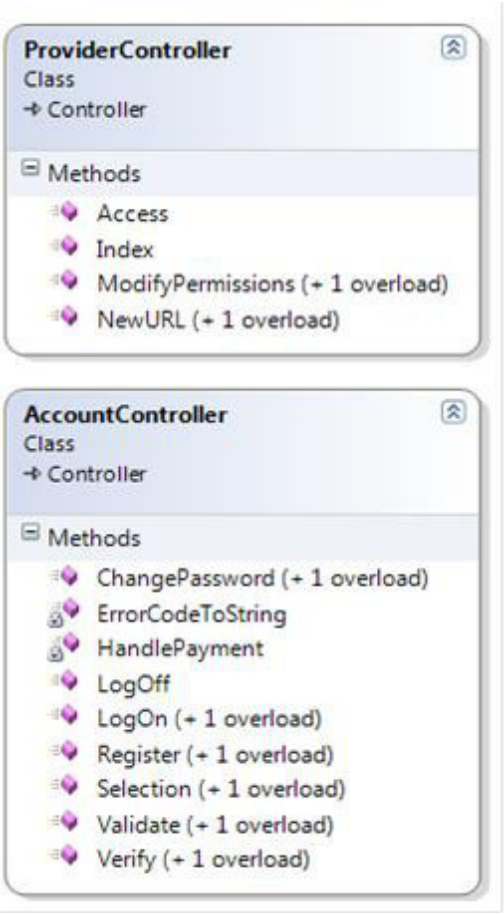

Fig 7. Controller classes

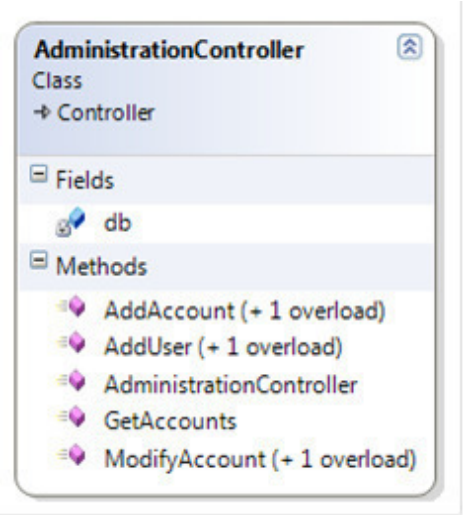

Fig 8. Controller class

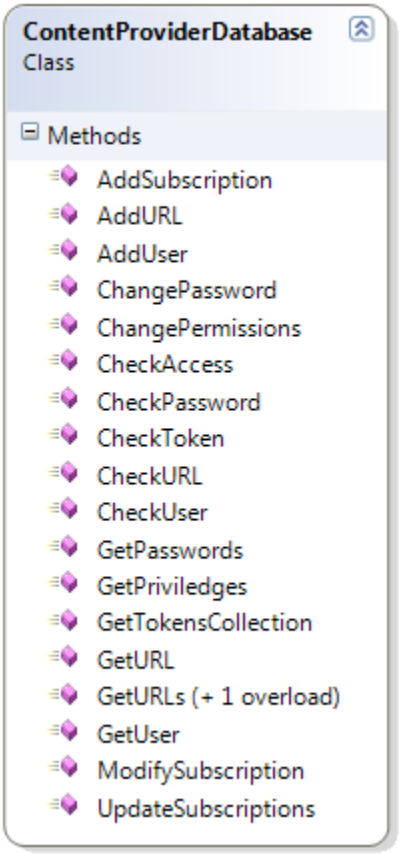

Fig 9. Helper class

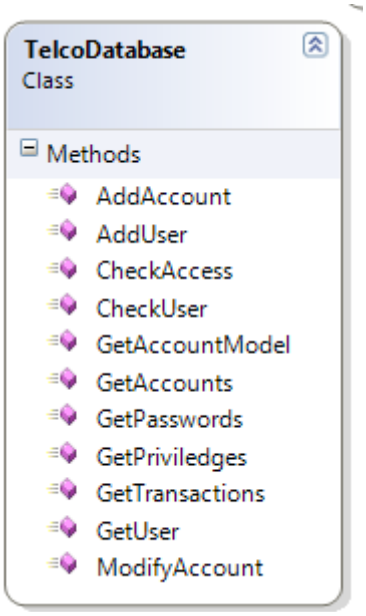

Fig 10. Helper class

IV. USER INTERFACE

The Mobile Payment System was developed using C# programming language and ASP.NET MVC 3 framework. The system has a simple, intuitive web interface. JavaScript was used to create the user interface, Microsoft Internet Information Server was used as an application container. Some interesting views, that user may find in the system, are presented below. Implemented solution supports both types of resources: local and external.

List of URLs

Fig 13. User transactions

V. CHALLENGES

The system that has been developed is just a prototype. The most important part of it is the Payment service. Due to the prototype version, the service provides only the basic functionality and has been secured merely with HTTP Basic Authentication without SSL. Such a solution, in fact, is not secure at all. Hence, in future, the thing of utmost importance will be upgrading the security level of the system. Since the service is responsible for financial operations it must be protected by a top-level security system. The functionalities might also be extended. The current version allows only to: charge account, refund account, check transaction status and get transactions list. The possible directions of development are to extend an existing reservation or release a reservation. Payment service is an XML Web Service supporting exclusively

SOAP protocol. Hence, another enhancement could be handling RESTful architecture style with JSON data serialization support. The advantage of REST protocol is that it is very lightweight and uses normal HTTP methods instead of heavy XML format. Both parts of the system: Telco and Content Provider have very simple user interfaces, designed just to present the system capabilities. This is however, another possibility of enhancement. At last, the mobile version of the system may be created as well.

VI. CONCLUSION

Presented in this paper the prototype of the innovative Mobile Payment System shows the possibility of usage of telecommunication open APIs in very wide mobile payment area. The main goal of presented research was to create the payment service and simulate it using Internet. All requirements were considered when designing system's architecture. The created user interface is simplistic and should be treated rather as a proof-of-concept. Tests showed, that all functional requirements are satisfied. The End User tests and Orange Labs experts comments provoked some changes that made the system more user-friendly.

Prototype of the System service was developed under the program Open Middleware 2.0 Community [5] as a part of Piotr Trusiewicz and Maciej Witan B.Sc, thesis.

***Abstract*—The main objective of this paper is proposition simple, easy to implementation and low cost solution dedicated for parking lots reservation. The presented application uses Unstructured Supplementary Service Data (USSD) as an communication channel between driver and parking system. USSD communication proposed in this paper is more efficient and comfortable for the end user in comparison with SMS used in many existing parking solutions. System is integrated with communication service provider infrastructure using Service Delivery Platform exposed APIs for telecommunication network in Internet. Application can be launched on every phone and does not require Internet access on mobile phone side.**

I. Introduction

THE parking place is costly and sometimes very limited resource in the cities. Every day thousands of car drivers spend a lot of the time to find an empty parking space. The result of this situation is the air pollution in urban areas, increasing traffic congestion and frustration of drivers. In large cities the traffic generated by drivers searching free parking places can achieve about 40 % of total traffic [1]. In order to solve this problem, the implementation of dedicated reservation based parking system in cities for managing parking places is mandatory.

A. Existing solutions

In last years many researchers proposed architecture of advanced parking systems supporting citizen in free parking spaces allocation. In this chapter are described some of them.

The first solution is Smart Parking Reservation System proposed by researches from University Teknologi PETRONAS in Malaysia [2]. Using this system car driver can reserve parking lot using Short Message Services (SMS). SMS messages are read and interpreted by GSM modem installed in micro-RTU (Remote Terminal Unit). Micro-RTU also sends to the car driver information about reserved lot number and password which is dedicated for opening barrier gate.

Another solution Automated Parking Slot Allocation System [3] proposes using RFID technology for allocation free parking slot. In this system the driver is informed about free parking place using SMS communication channel. The driver can use this channel to reserve his parking slot as well.

Another solution SmartParking described in [4] is dedicated for NOTICE. It is a secure and privacy-aware architecture for the notification of traffic incidents. In this system car driver uses dedicated mobile application for PDAs, smartphones, vehicle display and laptops which can read the information from SmartParking based on Internet access (data) to the system.

Smart Parking System developed by University of Nebraska-Lincoln [5] uses Internet (by Wi-Fi or GSM) for communication with end user using Web Application.

Another solution, Wireless Mobile-based Shopping Mall Car Parking System (WMCPS) [6] uses SMS for interaction with the driver. End user of the system can request for reservation car parking spaces using their mobile phone. WMCPS have got implemented GSM modem for integration with mobile network.

B. Description of the problem

Presented above parking systems uses dedicated hardware (modems) for communication with end users. This solution generates additional costs (hardware) and can be not effective in large scale usage (due to performance issues of GSM/UMTS modems). Proposed and implemented SMS communication results need to send an SMS with the specific content and potential mistakes in SMS content results errors in application usage. Another solution for car drivers dedicated or web application for mobile devices uses data connection and generates costs for user. This paper proposes usage of another communication channel available in mobile network - Unstructured Supplementary Service Data and provides an alternative to existing solutions.

C. Telecommunication APIs and Service Delivery Platforms

In last few years we can observe the process of opening communication service provider networks for external developers. For many years the network operators were closed to external companies and programmers and only operator was able to develop innovative telecommunication services.

Telecom operators seeing changes in Internet and competing with Internet companies (Over The Top – OTT players) such as Google, Facebook or Skype, were implementing business models based on API (Application Programming Interfaces) exposure.

Using API telecommunication service providers can expose large sets of functionalities in Internet for external developers. Telecommunication functions such as call management, SMS and MMS communication, USSD, payment or locating terminals can be offered third parties as Web Services. Based of them is possible to create new innovative applications connected Internet assets, telecommunication area and IT functionalities such as [7], [8], [9]. From technical point of view – presented above enablers are exposed in Internet using dedicated system- Service Delivery Platform (SDP). SDP is additional layer between Internet and communication network. South interfaces of SDP are connected with network elements such as SMS Center, MMS Center or GMLC (Gateway Mobile Location Centre) using binary telecommunication protocols based on Signaling No 7 stack (SS7). North interfaces are connected to the Internet and expose APIs using SOA model or RESTful architectural style. The architecture of the API exposition using SDP is presented in Fig. 1.

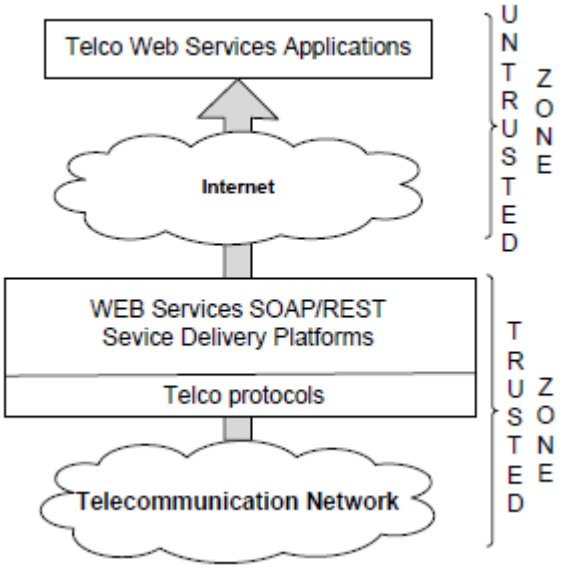

Fig 1. API exposition architecture [7]

Web services were implemented in SDP were standardized using two models: Parlay X specification [10] defined by ETSI and the Parlay Group - based on Service Oriented Architecture [11] and SOAP protocol [12]. Second standard OneAPI [13] was defined by GSMA and the newest version of this specification is based on Representational State Transfer architectural style (RESTful) [14] de facto standard in Web 2.0 and Social Media world.

II. The Parking Reservation System

The Parking Reservation System is an application prototype based on API for operator's network. Presented in this paper system is dedicated for supporting and managing parking places reservation process. The system allows to make reservation or if reservation has been made to cancel it. Application recognizes two types of end users. One is the end mobile user - making the request, the other one is parking security - handling the request using Web based user interface. The mobile users can store in their mobile phone address book two records. The first record is responsible for parking reservation and contains ***665*0015*0#** USSD request**,** the second address book position cancel reservation and is coded as ***665*0015*1#**. To make or cancel reservation the end user must call stored in book number (USSD code) and therefore send specific USSD request.

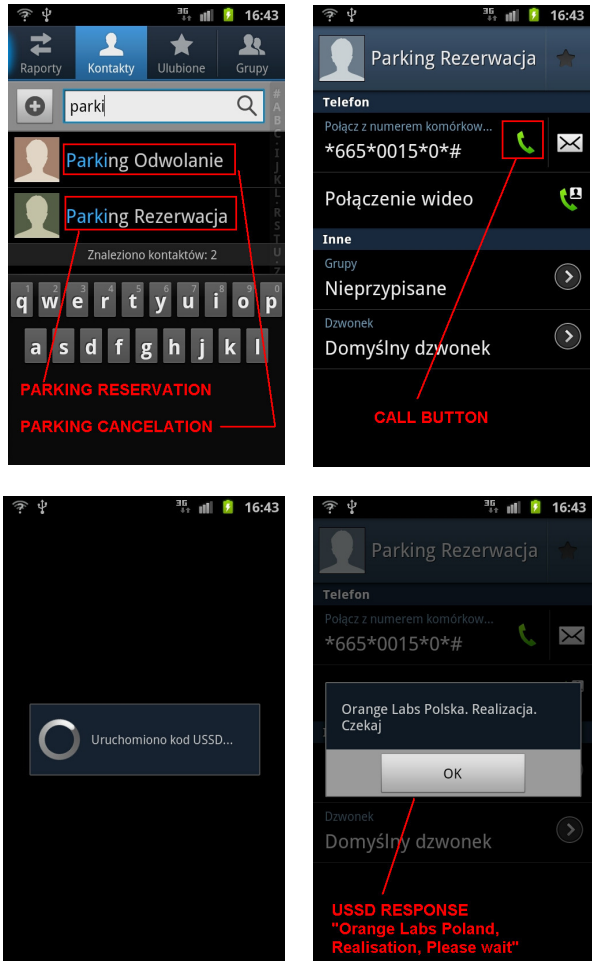

Fig 2. Parking system mobile end user interface

In current version system recognizes only these two described above USSD messages. The request from mobile user in web application is presented to the person responsible for parking place reservation. To handle the request the parking security user selects in web application free parking lot and sends mobile user response using one of the method: USSD or SMS. In a similar way (using another USSD code) is realized parking place reservation cancelation. In case of no free parking places the parking security user can send to the mobile user dedicated message predefined in application (Fig. 3).

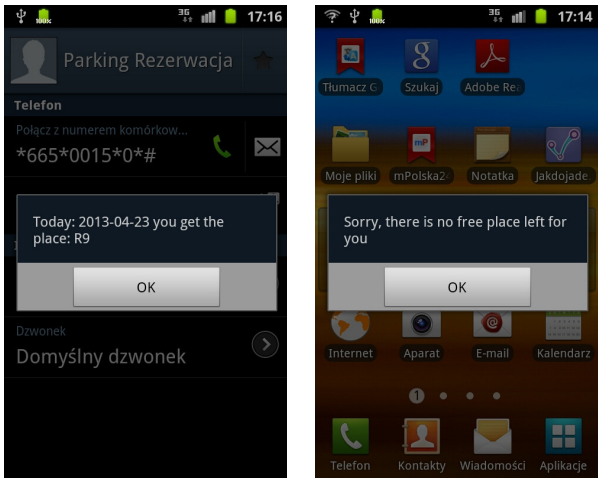

Fig 3. Parking system - example messages

III. System Architecture

A. Functionality of the solution

Using their mobile phone mobile end users sends USSD request to the system. The parking system notifies parking security end user in web application using AJAX request. In the next step the parking security end user using web application (Fig 4.) sends response to the system and application forward it to the mobile phone end user through appropriate SDP's Web Service. The functionality of the system is shown in Fig.4 and Fig 5.

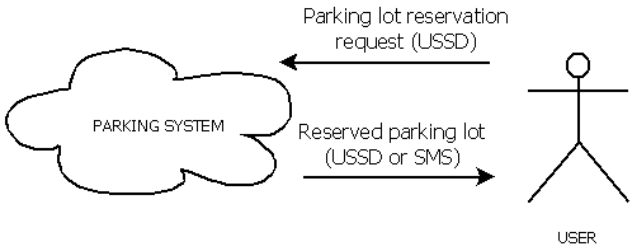

Fig 4. Functionality of the Parking System

B. Used API interfaces

The Parking System functionality is based on API provided by the cellular phone networks. The system is invoked with the USSD request. The response can be send using two methods: USSD or SMS message. Both functionalities are realized by Orange Service Delivery Platform \using Web Services implemented in RESTful architectural style as Receive USSD, Send SMS and Send USSD APIs.

C. Structural architecture of Parking System

The Parking System service consists of three main functional parts based on the performed functions shown in Fig. 5.

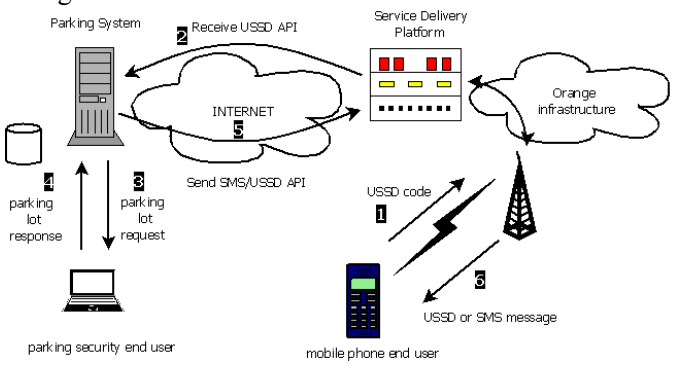

Fig 5. Structure of the developed service

- End Users – there are two types of end users: one communicates with the parking system using mobile phone through UTRAN/GERAN (mobile end user) and the second (parking security end user), which using Web Application maintains parking resources.

- Parking System – the application logic implemented as a Web Application, running on a server. System data is stored in XML files. Data consists of USSD requests, system end users and parking resources data. The system is using telecommunication APIs exposed by Orange for communication between end users.

- GSM/UMTS Operator – enables communication with the Parking System through exposed APIs interfaces.

D. Class Diagrams

Presented solution was developed in Model-View Controller (MVC) style. It consists of Controller, Model and Helper classes. All classes are presented in Fig. 6 and Fig 7. Views are simple dynamically generated HTML. The project consists of following classes:

- Controller classes – responsible for handling HTTP requests. GET and POST requests are mapped to appropriate method called action from the class. Diagram is presented in Fig. 6.
- Model classes – represents the data objects send within system. Each class consists of properties and the setter/getter methods for each.
- Helper classes – are responsible for parsing XML data, handling AJAX, sending response to mobile phone end user and are presented in Fig. 7.

Fig. 6. Controller class diagram

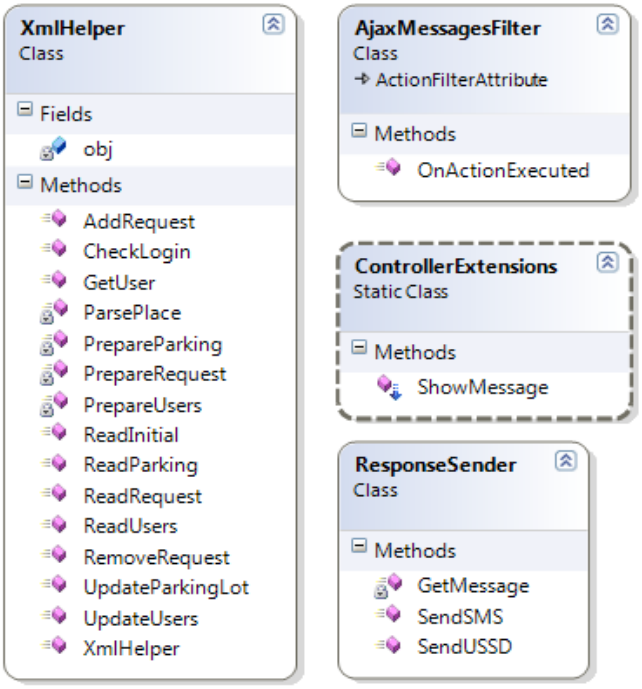

Fig. 7 Helper class diagram

IV. User Interface

The Parking system was developed using C# programming language and ASP.NET MVC 3 framework. The system has a simple, intuitive web interface. The user (parking security end user) logged in to the system, on the main page can see the map of the parking, three tabs on the right (home, make reservation, cancel reservation) and request notification messages on the bottom. On the map reserved parking places are marked with a car pictures. Home page of application is presented in Fig. 8.

Fig. 8. Parking system - home page

Application supports two types of notification messages. One for making reservation and second for canceling. Both types of notification are presented in Fig. 9.

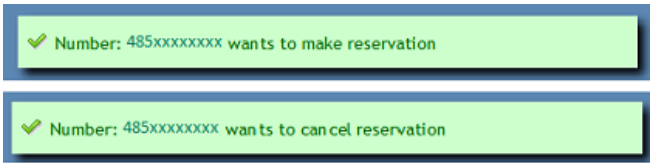

Fig. 9 Notification messages

To make or cancel reservation the parking security end user has to select the appropriate tab and fill up the form and select communication type (USSD or SMS). The forms are shown in Fig. 10 and Fig. 11.

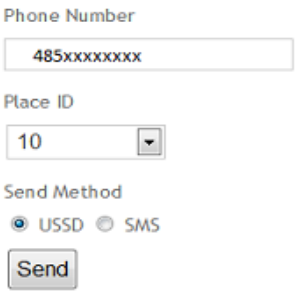

Fig 10. Reservation form

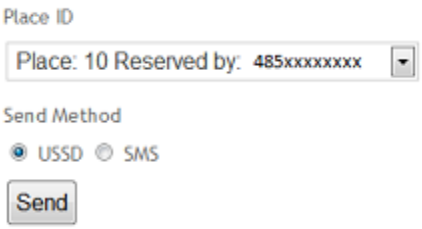

Fig. 11 Cancellation form

After performing the operations the person responsible for parking place management is redirected to the home page with parking map.

AJAX, JSON, JavaScript. technologies were used to create the user interface, Microsoft Internet Information Server was used as an application container.

V. CHALLENGES

The presented in this paper application has some possible future enhancements. It is possible to add new communication channel via SMS for parking place reservation. In the further development of the system it is also possible to create a mobile application dedicated for smartphones. One of the future challenges will be function of navigation to the reserved parking place. This functionality requires a precise localization API (e.g. based on GPS or Wi-Fi) or usage of specific and expansive hardware (e.g. sensors) [3], [4], [5] and implementation of algorithms for parking management strategies [5], [6]. Another enhancement concerns on the functionality of the Parking System. The current system version supports only two mobile end user actions: make reservation and cancel them. There are few more options available such as: check reservation status, change status, extend reservation time, make reservation for some time in future, etc. Potentially interesting idea is automation of system functionality: allowing end user to triggers the application with a USSD or SMS channel without interaction with parking guardian. Based on this the system could automatically reserve the place, recognize the car or end user mobile phone and navigate the user to the reserved place. Parking navigation system would be very helpful, when the mobile end user wants to find the car on the parking.

VI. CONCLUSION

Presented in this paper the prototype of the Parking Reservation System is low cost and effective solution. Because system is based on web application can be hosted in cloud computing environment and offered potential (companies, security agencies) as a service. Because no specific hardware requirements system can be used by everyone and need only mobile phone (smartphone are not necessary) for mobile end user and computer with Internet access for security end user. The implementation telecommunication APIs: Receive USSD, Send SMS and Send USSD in Web Services allowed creating application using standard programming tools in very short time. Using this system car driver can reserve a parking slot on the fly in very easy way by pressing call button on their mobile phone.

Prototype of Parking reservation System was developed under the program Open Middleware 2.0 Community by Orange Labs [15].

Student Information Delivery Platform Using Telecommunications Open Middleware APIs

Piotr Wawrzyniak, Piotr Korbel, and Anna Borowska-Terka
Institute of Electronics
Lodz University of Technology
ul. Wólczańska 211/215, 90-924 Łódź, Poland
piotr.wawrzyniak@dokt.p.lodz.pl, piotr.korbel@p.lodz.pl, anna.borowska-terka@p.lodz.pl

***Abstract*—The paper describes architecture of a prototype networked student information delivery system. Main system functionalities include interactive access to lecture room timetables and group messaging. The system exploits modern mobile technologies to allow flexible usage scenarios. The use of open APIs of telecommunications service delivery platforms in combination with e-mail messaging provides diverse ways of system information delivery. The perceived application scenario of the system is to provide ubiquitous access to up-to-date lecture room timetables and reliable ways of notifying the affected users about changes.**

***Index Terms*—student information systems, web services, mobile applications**

I. Introduction

NOWADAYS, universities worldwide offer a variety of complex campus services addressed to different groups of users: academics, administration staff, and students. Among the information systems facilitating the management of these services we can find systems supporting various fields related to the educations process, like student information database systems [1], [2], [3], [4], systems facilitating students and staff mobility and general cooperation between education institutions [5], [6], [7], learning management systems [8], and many more.

In this paper we propose a system enabling ubiquitous access to up-to-date lecture room timetables and reliable ways of notifying the affected users about unexpected changes. The proposed system exploits modern mobile technologies (mobile phones, tablets) to allow flexible usage scenarios. The use of open APIs of telecommunications service delivery platforms [9] provides reliable and fast way of delivery of system messages to the users.

The remainder of the paper is organized as follows. Section II presents overall architecture of the prototype system and provides details on the system modules. Section III describes user system interactions as well as user interfaces of the system modules. Section IV summarizes the paper.

II. System architecture

Proposed system has a distributed heterogeneous network architecture. In particular the complex solution might be divided in two independent but yet complementary branches. The first one consists of modern interactive lecture room timetable delivery platform that provides the users with the most actual timetables for the auditoriums. The other part of the solution consists of group messaging platform utilizing telecommunications open APIs [9] to deliver messages to the mobile phones.

Both parts were developed separately with the use of different open source and proprietary technologies. The joint use of interactive timetables and group messaging offers possibility to notify system users on the temporary timetable modifications. Moreover, the ability to provide user with additional information makes it possible to offer group messaging in order to improve the communications between students and academic teachers.

The remainder of the section provides detailed description of the aforementioned system modules.

A. Interactive Lecture Room Timetable Delivery Subsystem

As mentioned before in many universities among the world contemporary printed schedule boards are still in use. This way of information delivery has strong advantages among which low usage cost and effectiveness of delivery are the most important. On the other hand, the possibility of live interaction with printed timetables is impossible. Thus, any unusual situations and events require manual updates of the timetables and in urgent cases engagement of additional communication channels to pass the notification of the changes to affected groups of students and academics.

Electronic boards can present information in a similar way to the printed ones but additionally may offer an interaction channel to provide the possibility of on-line data modifications. That was the main idea that led us to design and implement the timetable delivery subsystem.

Proposed system architecture consists of four main elements as presented in Fig. 1. Central application server is responsible for controlling input data, in particular it provides timetable conflicts resolver. It is also responsible for preparing data for each lecture room display. It is also the only element that interacts with incorporated Relational Database Management System (RDBMS). Database server is used to store all the timetable data.

The management of the system is also possible with independent WebGUI service that allows authorized users to enter timetable data for supported lecture rooms. It includes state-of-the-art calendar interface which permits to define events of

978-83-60810-53-8/$25.00

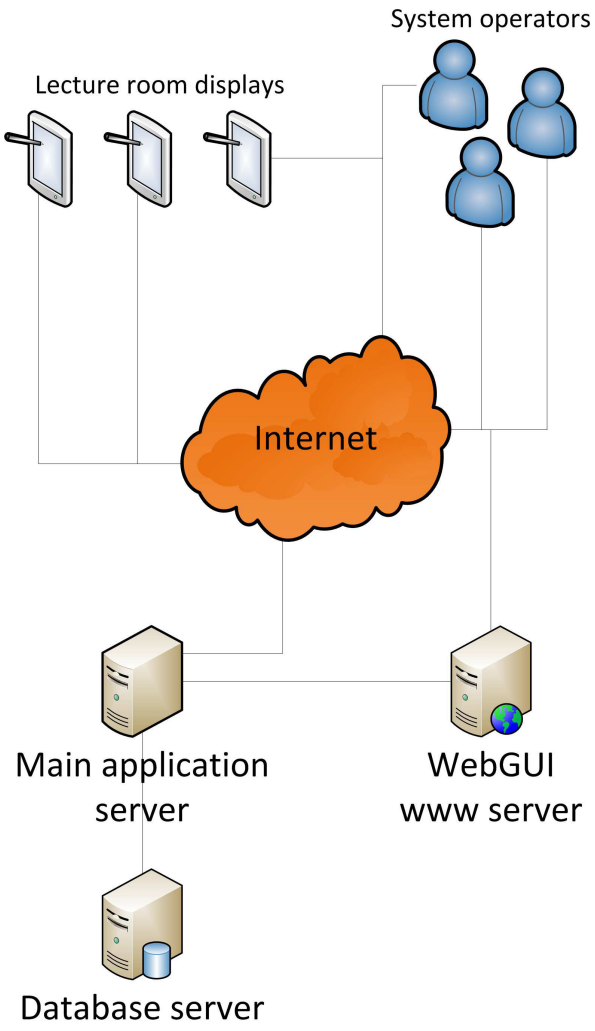

Fig. 1. Timetable delivery system architecture diagram.

different kinds, in particular single-time and periodic events are supported. The last part consists of interactive displays to be mounted at entrances to the lecture rooms.

As the result of conducted market research it was decided to use modern Android OS based tablet devices as the interactive displays. Therefore, dedicated application for Android operating system was developed. The main goal of the application is to display schedule timetable in convenient and accessible way. It is designed to be constantly active and refresh the data for up-to-date timetable delivering. Moreover, after each user interaction application returns to it default state (i.e. displays the timetable for current week).

As extensive user-timetable interaction is expected, it was also decided to develop dedicated pointing device to navigate over schedule application in order to reduce the use of touch screen of the device. The prototype device uses Bluetooth protocol to communicate with tablet device and is equipped with seven buttons. Four of them are used as the four-directional joystick, two are used to change the week view and the last one allows to display additional subject related information in a new window.

B. Student Massive Messaging Subsystem (SMMS)

The ability to send notification to a group of students is the main feature exposed by Student Massive Messaging Subsystem (SMMS). Contemporary messaging services at the university usually use university electronic mail systems as the only way to contact students. However secure and reliable, the effectiveness of information delivery is strongly affected by the necessity of user initiated mailbox checking in order to retrieve new messages. This might be insufficient in the case of unusual changes to timetable caused for example by lecture room equipment failures.

Aforementioned limitations might be omitted by incorporating the use of mobile phones and Public Land Mobile Network (PLMN) messaging services like Short Message Service (SMS) and Unstructured Supplementary Service Data (USSD). In particular these protocols are the most suitable for sending short messages that should be delivered shortly and reliably. Therefore, the proposed service involves SMS and USSD messaging services exposed by Telco 2.0 APIs of Service Delivery Platform WebGateway. The overall SMMS system architecture is presented in Fig. 2.

The main application server exposes a set of SOAP-based stateless web services that allows the following actions:

- It allows to send notifications on exceptional changes in the timetable (i.e. caused by equipment failure or important special event) to previously assigned users (both students and academics),
- It simplifies the communication between academics and groups of students by allowing academic teachers to send short notifications to selected groups of students registered in the system,
- It provides fast and reliable communication channel between university administration and students which improves the quality of administration services.
- It allows end users to sign-in for receiving the messages on selected topic. The user might sign-in in three ways: by sending a USSD code, SMS message or using Web Interface (which communicates with the main server).

This part of system was developed with the use of Windows Communication Foundation (WCF) technology. SOAP protocol was implemented in the northbound interface of the service, although RESTful web services are planned to be developed for final revision of the software.

User interacts with the system using web-based GUI offered by Web Interface server. This web portal was developed in PHP and communicates with SOAP web services from application server. The tool set also allows to manage database of users and news groups. Sensitive data, in particular user personal data and passwords are processed in accordance to widely accepted rules. Fraud detection mechanisms were also considered to prevent unauthorized use of users e-mail addresses and mobile phone numbers. In particular, verification

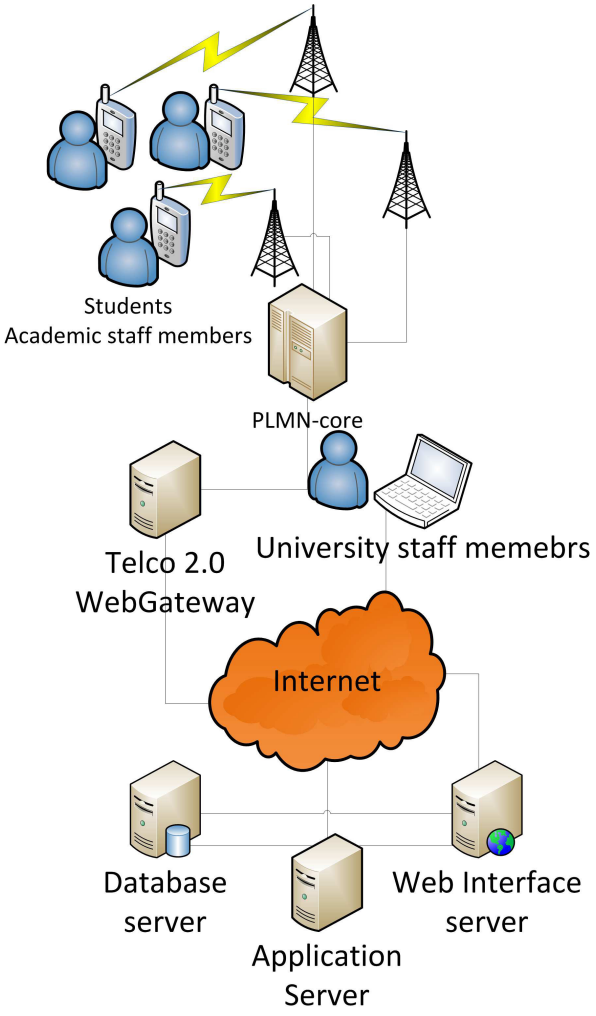

Fig. 2. Architecture diagram of the massive messaging system.

mechanisms are invoked every time the user wants to join the system or messaging group.

All the internal data, as well as user account information are stored in incorporated RDBMS which is accessible for both the application and WebGUI servers.

III. USER SYSTEM INTERACTION

Despite the capabilities of the developed solution user interaction models are the key factors of the deployment success. Thus four complementary user interfaces were proposed:

- Web-based ical User interface for timetable management. This interface allows to easily create and manage timetable for a given lecture room. The access is restricted only to previously defined users. It is also planned to offer students personalized timetables. Sample GUI view is presented in Fig. 3.
- Electronic interactive timetables (EIT) mounted at the entrance to the lecture rooms equipped with wireless 7-buttons pointing device. The primary objective of the EIT is to provide the most up-to-date contemporary timetable

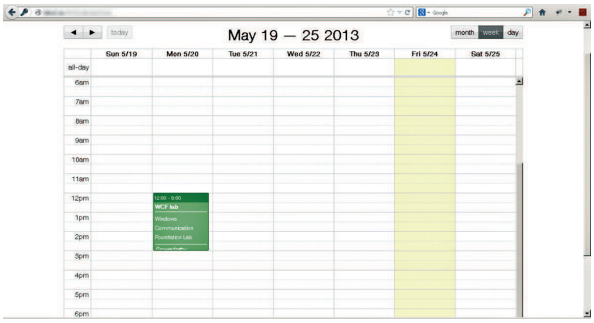

Fig. 3. Example of the timetable manager GUI.

but it is possible to obtain additional information on the selected entry thus EIT strongly extends the timetable capabilities.
- Web based GUI for management of group messaging subsystem. This interface is intended to be used by both academics and students. Staff members might create topic groups (editor role) or join existing ones (notification recipient role). Student may only join the existing groups. As mentioned in section II, to avoid frauds or improper use, e-mail addresses and mobile phone numbers submitted to the system are subjects of verification procedures.
- User might join the messaging group by sending a USSD code. This method is intended for combined use with the capabilities of the EIT in order to minimize the effort needed to join the desired messaging group. It is worth to notice that in this case there no necessity for phone number verification as the action has to be initiated on the target device.

The use of the system includes notifying affected users on changes in the timetables. Nevertheless of the change type, whether it is planned or emergency situation the system allows to improve the communications between building management team and students or teachers. It is especially useful in the case of emergency situations when all the users of the lecture room might be informed on the unexpected changes.
