Modeling the preferences with random distributions may not reflect reality because curators take care of the scenography (therefore the coherence) of each room. So we worked on prefered artists (the visitor can select a set of interesting artists) and we propose to use the artworks description to highlight a kind of intrinsic interest from the point of view of the museum. Indeed, the description displayed to the visitor should show how significant is the artwork for the museum. We valuate each item by analyzing their description (with Automatic Text Summarization) and use it as a base value, considering that even without any preference, some artworks are more interesting than others.

The Musée de l'Orangerie

Due to the time needed to extract and check all the data we worked on this small museum to test our model.

The Musée de l'Orangerie (Museum of Orangerie), in Paris (France), regroups 144 artworks from 14 artists in 10 exhibition rooms. The website[2] of the museum supplies a map (shown in Fig. 1) and indexes information about all the

artworks including the name of the artist, a description of the artwork and its date of creation.

Paper organization

The remaining of this paper is organized as follows. We review the related work in Section II. In Section III, we present a Natural Language Processing (NLP) based approach to compute artwork interest. The Personalized Tour Recommendation Problem is presented in Section IV. To solve this problem, we develop an Integer Linear Programming based method to solve the tour optimization problem in Section V and define a model to represent the visitor preferences in Section VI. The simulations are conducted and numerical results are demonstrated in Section VII. Finally, we conclude the paper in Section VIII.

II. Related work

A first model developed in 2010 [1] proposes to formulate the visitor routing problem as an extension of the open shop scheduling problem (in which each visitor group is a job and each interesting room is a machine). Each visitor group has to pass through all rooms but it is impossible for two groups of visitors to be simultaneously in the same room. This restriction can lead to non optimal or infeasible solutions if there are more visitor groups than rooms in the museum (which is the case if we consider each single visitor as a group).

Relying on the constraint programming model [2], we propose to reduce the number of used variables. In [2], they generate a route by calculating the smallest number K of steps required to cross the museum (to visit all the rooms). This model requires that each artwork is represented as K variables (one per step). Due to the fact that museums often have several thousands of artworks, it leads to a huge number of variables. Moreover they use mathematical distributions to simulate a visitor profile which does not necessary reflect reality (in museums, artworks are often grouped in a room because they are related to each other, a configuration that a random distribution as they used cannot represent).

In 2013, some works [3] used the visiting style of visitors (the way a visitor go from an artwork to another) but their model requires two matrices of size N^2 (where N is the number of artworks). The first one indicates the accessibility to an artwork from another (if they are in the same room or in two rooms directly connected) and the second one contains the distance between two artworks. However as the number of artworks is always greater than the number of rooms, most of the museums are modeled as two sparse matrices with duplicated data (in a room, it is often allowed to freely move between artworks). This makes the use of constraint programming expensive.

III. Artwork description analysis using Textual Energy

Our idea is to use the description of each artwork as an independent measure of their interest. Indeed, two similar artworks (same theme, support, artist) will produce the same result but may be very different. By analyzing the description provided by the museum, we tried to differentiate them.

Automatic Text Summarization (ATS) techniques by extraction [4], [5], [6] allow to rank a set of textual segments (sentences, paragraphs etc.) depending on a measure of similarity. Textual Energy algorithm (Enertex) converts a textual document into a physical object and use Statistical Physics to measure its energy [7]. This energy, to which we should refer as Textual Energy, is then computed and apply to summarization. The physical model of Textual Energy gives rise to a single non iterative algorithm of low complexity. Therefore Textual Energy allows to redefine sentence ranking on simple and efficient matrix operations. The resulting algorithms are

much easier to apply to large texts and give better results without using any post-processing.

A. Starting point: Hopfield Model

Hopfield's approach [8], [9] was based on magnetic Ising model to build a Neural Network (ANN) with pattern learning capabilities. The capacities and limitations of this ANN (an associative memory), were well established in a theoretical framework [8], [9]: the patterns must not be correlated to obtain free error recovery, the system saturates quickly and only a little fraction of the patterns can be stored correctly. Despite these major drawbacks, Hopfield contributed to ANN theory by introducing the concept of energy by analogy with magnetic systems. A magnetic system is a set of N spins like small magnets that can adopt several orientations. The simplest model is the dipole one or Ising model where there are only two opposite possible orientations: up ($\uparrow$ or +1) or down ($\downarrow$ or 0). Ising magnetic model was used in a large variety of systems that can be completely described by a set N of binary variables [10] with 2^N possible configurations (patterns). The spins are equivalent to neurons that can interact following Hebb's rule[3]:

$$J_{i,j} = \sum_{\mu=1}^{P} (s_{\mu,i} \times s_{\mu,j}) \tag{1}$$

$s_{\mu,i}$ and $s_{\mu,j}$ are the states of neurons i and j in the pattern μ. The summation concerns the P patterns to store. This rule of interaction is local, because $J_{i,j}$ depends only on the states of the connected unities. It has the capacity to store and to recover certain number of configurations of the system, because the Hebb rule transforms these configurations into attractors (minimal local) of the energy function [8]:

$$E_\mu = -\frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} (s_i \times J_{i,j} \times s_j) \tag{2}$$

The fundamental concept of magnetic energy is a function of the system configuration, that is, of the state of activation or non-activation of its units. The concept of energy induces a type of interaction. If we present a pattern ν, every spin will undergo a local field: $h^i = \sum_{j=1}^{N} J^{i,j} s^j$ induced by the energy of the others spins. Therefore the total energy of the new system made of the new pattern inserted into the previous system reflects the interaction between the pattern and the initial system.

We shall focus on theoretical objects that are usually considered in Statistical Physics. In magnetic system analysis, these are energy function distributions [11]. Hopfield himself used these functions to show that the recovery is convergent. Our Enertex system is entirely grounded on them.

B. Energy as a document similarity measure

The Vector Space Model (VSM) has also been applied to texts since [12] following a bag of word representation of sentences. In this model vectors represent sentences and a document gives rise to a matrix. We have used VSM to represent documents in our model magnetic system: a sentence (a row vector) is equivalent to a Ising spin chain and a document (a magnetic system) is represented by a matrix of P rows $\times$ N columns. Therefore, sentences can be studied as Ising spin chains. More formally, with a vocabulary of N words (terms) in a document, it is possible to represent a sentence as a chain of N spins, $i = 1, \cdots, N$. A document with P sentences is formed of P chains in the vector space Ξ of dimension N. In this paper, the description of each artwork is assimilated as a long pseudo-sentence. Therefore, a document (the collection of a museum) is constituted of a set of P (pseudo-)sentences.

Documents are preprocessed by removing functional words (by using a stop list), normalized and lemmatized [13], [14]. This preprocessing reduces considerably the document dimensionality. Let be $T = \{t_1, \ldots, t_N\}$ the set of remaining terms after this preprocessing. Once segmented into units, usually sentences, the text is represented by a set $S = \{\vec{s}_1, \ldots, \vec{s}_\mu, \ldots, \vec{s}_P\}$ where each $\vec{s}_\mu$ is the bag of words in segment μ. As usual in text vector model, we consider the matrix $S_{[P \times N]} = (s_{\mu,j})_{1 \leq \mu \leq P, 1 \leq j \leq N}$ of frequency/absence associated to H by:

$$s_{\mu,j} = \begin{cases} tf_{\mu,j} & \text{if } t_j \in \text{ sentence } \mu \\ 0 & \text{otherwise} \end{cases} \tag{3}$$

where $tf_{\mu,j}$ is the term frequency of t_j in the sentence μ.

We therefore consider the presence of term t_j as a spin s_j $\uparrow$ with magnitude $tf_{\mu,j}$ (its absence by a $\downarrow$ respectively), and a description of each artwork (text segment) by a chain of N spins.

It is common to consider that these vectors are correlated according to the shared words. Here the introduction of the magnetic model induces moreover indirect interactions. In this model sentences that do not share any word could however interact because of the magnetic field generated by the other sentences of the document that form the global magnetic system.

We have studied the interactions between the terms and the sentences using Hebb's rule and Ising energy respectively. To obtain the matrix J of interactions between the N terms, we apply Hebb's rule (equation 1) in its matrix form:

$$J = S^T \times S \tag{4}$$

where $J_{i,j}$ is the number of co-occurrences of terms in sentences. The energy function (equation 2) of a (magnetic) system S is:

$$E = S \times J \times S^T = (S \times S^T)^2 \tag{5}$$

Each element $E_{\mu,\nu}$ represents the energy between sentences μ and ν. The values in the first matrix diagonal quantify the interaction energy between words into a sentence meanwhile the other values in the rest of the matrix show the interactions between distinct sentences. The sum of absolute values in one

[3]Hebb [9] suggested that synaptic connections change according to the correlation between neuronal states.

row gives the total energy of interaction of the corresponding sentence μ with the document:

$$E_\mu = \sum_\nu |e_{\mu,\nu}| \quad (6)$$

We use this energy value to rank sentences (description of artwork) by order of decreasing importance. The most energetic will be considered as the most important.

IV. Personalized Tour Recommendation Problem

The Personalized Tour Recommendation Problem (PTRP) can be viewed as an optimization problem and solved by optimization techniques. For this purpose, we first model the museum topology as a graph and then formulate the studied problem as an Integer Linear Programming (ILP) instance. Therefore, the optimal personalized tour can be obtained by solving the ILP model we propose.

A. Museum modeling

A museum is modeled as a 7-tuple $G = \langle V, A, E, X, P, r\rangle$ where:

- V is the set of vertices, each vertex is an exhibition room, an entrance or an exit of the museum.
- A is the set of arcs which connect different rooms. There is an arc $a_{ij} \in A$ between two vertices i and j, if we can go from room i to room j directly without passing through other rooms.
- E is the set of entrances of a museum, which is a subset of V, i.e. $E \subset V$.
- X is the set of exits of a museum, which is also a subset of V, i.e. $X \subset V$.
- P is the set of all artworks in the museum.
- r is a mapping function $P \to V$. For each artwork $p \in P$, $r(p)$ is the room containing p.

Some large museums may have several entrances and exits, that is why E and X are two subsets of V. We also admit that there is always a path from any entrance to an exit. We consider directed arcs and not edges because some museums may impose a flow direction for several reasons (minimizing congestion, pedagogical tour). Note that by definition of A, there is no incoming arc to any entrance and there is no any outgoing arc from any exit neither.

Application to the Musée de l'Orangerie: The Musée de l'Orangerie can be represented as the graph presented in Figure 2. We can see that there is only one entrance and one exit in the museum and they are located at the same place. Therefore, we consider the entrance and the exit as two different vertices in the graph to facilitate the model. The mapping between vertices and rooms is shown in Table I.

B. Personalized tour problem modeling

For the sake of satisfying the visitor maximally, a visit tour should be proposed according to the visitor's preferences and constraints.

A personalized tour problem can be defined as a 6-tuple $\langle G, I, R, u, t, T_{MAX}\rangle$ where:

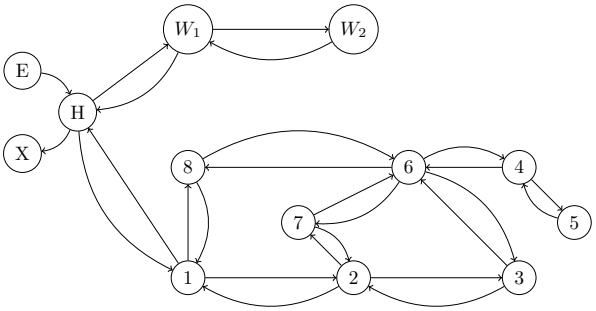

Fig. 2. A possible graph for the Musée de l'Orangerie

TABLE I
The Musée de l'Orangerie: vertices and rooms

Vertex	Room
E	Entrance
X	Exit
H	Hall
W_1	Water Lilies (first part)
W_2	Water Lilies (second part)
1	L'Age d'Or
2	Paul Guillaume Room
3	Impressionism
4	Modern primitives
5	Laurencin room
6	Modern classicism
7	Derain room
8	Soutine / Utrillo room

- G is the museum graph representing the museum topology as defined above.
- I is the set of artworks which have to be included in the tour.
- R is the set of artworks which have to be excluded of the tour.
- u is a mapping $u : P \to \mathbb{R}^+$. For each artwork $p \in P$, $u(p)$ denotes the interest of the visitor for the artwork p.
- t is a mapping $t : A \cup V \cup P \to \mathbb{R}^+$. For each room, arc and artwork, we have a time to spend. It can be the time needed to cross a room or an arc. It can also be the time to see an artwork.
- T_{MAX} is the maximum time that a visitor wants to spend in the museum.

A visit tour may be a simple path without any cycles (an elementary path) or a sophisticate path including cycles (a non-elementary path).

We define a tour as a sequence of pairs $\langle v, P_v\rangle$ where $v \in V$ and $P_v \subseteq r(v)$ (note that P_v may be $\emptyset$ because we can cross a room without seeing any artwork). A tour $T = (\langle v_1, P_{v_i}\rangle, ..., \langle v_n, P_{v_n}\rangle)$ is a solution to the personalized tour recommendation problem when:

1) The vertex v in the first element of T is an element of E (the tour starts by an entrance).
2) The vertex v in the last element of T is an element of X (the tour ends by an exit).
3) All consecutive elements T_1 and T_2 of T share the same vertex or an arc $a_{ij} \in A$ must exist from the vertex i of

T_1 to the vertex j of T_2.

4) The total time required to see all the artworks and pass through all the rooms (and ways) is not bigger than T_{MAX}.

Application to the Musée de l'Orangerie: we may have a visit tour like the following:

$$(\langle E, \emptyset\rangle, \langle H, \emptyset\rangle, \langle W_1, p_1\rangle, \langle W_2, p_5\rangle, \langle W_1, \emptyset\rangle, \langle H, \emptyset\rangle,$$
$$\langle 1, p_{10}\rangle, \langle 8, p_{103}\rangle, \langle 1, \emptyset\rangle, \langle H, \emptyset\rangle, \langle X, \emptyset\rangle)$$

In this tour, the visitor should cross the receiving hall H three times, exhibition room W_1 and 1 twice respectively. Although we may traverse a room several times, the visitor is supposed to visit the room only once. Consider for instance the exhibition room W_1, we may visit the selected artworks when we reach this room for the first time. The second time, we would just cross the room to visit another one.

V. Integer Linear Programming approach to solve the Optimal Personalized Tour Recommendation Problem

Before introducing an ILP model to solve the Personalized Tour Recommendation Problem, we define several decision variables:

- x_p equals 1 if the artwork $p \in P$ is included in the proposed tour, 0 otherwise.
- y_a equals 1 if arc $a \in A$ is crossed in the proposed tour, 0 otherwise.
- f_a denotes the number of rooms crossed when we arrive at arc $a \in A$ in the visit walk.
- z_v equals 1 if room $v \in V$ is traversed in the proposed tour (no matter whether we visit an artwork of this room or not), 0 otherwise.

Given a personalized tour problem (as defined in section IV), the objective function of the Optimal Personalized Tour Recommendation Problem (OPTRP) is to maximize the overall satisfaction of the proposed visit tour for the visitor:

$$\max \sum_{p\in P} x_p \times u(p) \qquad \text{OPTRP} \tag{7}$$

s.t.

$$\sum_{v\in E}\sum_{a\in\delta^+(v)} y_a = 1 \tag{8}$$

$$\sum_{v\in X}\sum_{a\in\delta^-(v)} y_a = 1 \tag{9}$$

$$\sum_{a\in\delta^+(v)} y_a = \sum_{a\in\delta^-(v)} y_a, \qquad \forall v \in V \setminus (E \cup X) \tag{10}$$

$$f_a \geq y_a, \qquad \forall a \in A \tag{11}$$

$$f_a \leq |V| \times y_a, \qquad \forall a \in A \tag{12}$$

$$\sum_{a\in\delta^-(v)} f_a = \sum_{a\in\delta^+(v)} f_a - z_v, \quad \forall v \in V \setminus (E \cup X) \tag{13}$$

$$\sum_{a\in\delta^+(v)} y_a + \sum_{a\in\delta^-(v)} y_a \geq z_v, \quad \forall v \in V \tag{14}$$

$$y_a \leq z_v, \qquad \forall v \in V, \forall a \in \delta^+(v) \cup \delta^-(v) \tag{15}$$

$$x_p \leq z_v, \qquad \forall v \in V, \forall p \in \{p : r(p) = v\} \tag{16}$$

$$x_p = 1, \qquad \forall p \in I \tag{17}$$

$$x_p = 0, \qquad \forall p \in R \tag{18}$$

$$\sum_{v\in V} z_v \times t_v + \sum_{a\in A} y_a \times t_a + \sum_{p\in P} x_p \times t_p \leq T_{MAX} \tag{19}$$

Constraints (8) and (9) ensure that the visitor should enter a museum from a unique entrance and finish the visit by a unique exit respectively (this model considers the case of multiple entrances and exits). Constraint (10) makes sure that a visitor should exit a room v after crossing or visiting it. Constraint (11) expresses that a visitor should have crossed at least a room before arriving at an arc a, while constraint (12) imposes that no flow is moving on the arc a, if it is not crossed in the visit tour. Constraint (13) means that if a room v is crossed in the tour, then the number of rooms crossed before arriving at this room equals the number of rooms crossed after leaving v minus one. Otherwise, they should be equal, since the room will not appear in the tour. Constraint (15) imposes that a room v should be crossed as long as one input arc or one outgoing arc is crossed. Constraint (14) ensures that a room v should not be crossed if none of the input arc or output link is used during the visit. Constraint (16) indicates that if a room v is not crossed, none of its artworks will be proposed for visiting. Constraints (17) and (18) ensure that an artwork should be included or excluded from the proposed tour if the visitor asks for it. The last constraint (19) guarantees that the time spent in front of the artworks and the time required to pass through rooms (and ways) does not exceed the available time for the visitor.

The ILP model we propose provides a visit tour starting from an entrance and terminating at an exit. In [2], authors also proposed an ILP model to plan the personalized visit. They divided the studied proposed into two sub-problems: first determine the number of moves (denoted as K) for a complete walk in the museum graph, and then solve the museum routing problem while maximizing visitor satisfaction. Since both of these sub-problems are NP-Hard, authors of [2] proposed to solve both of them by constraint programming. The complexity of their model depends a lot on K, which is generally large (at least equals to $|V|$). To compare the complexity of our model with the ILP mode in [2], the number of variables and constraints are listed in Table II.

VI. Visitor preferences modeling

The interest function u should reflect the satisfaction of the visitor for each artwork $p \in P$. The nearer to his preferences is an artwork p, the greater is $u(p)$.

Representation of artworks and the visitor preferences

We define C_p as the set of all characteristics of an artwork p and C as the union of all these sets (i.e. $C =$

TABLE II
COMPARISON OF ILP MODELS

Terms	OPTRP ILP	ILP [2]
Variables	x_p, y_a, f_a, z_v	x_p, $x_{p,k}$, $c_{i,j,k}$
Number of variables	$\|P\| + 2\|A\| + \|V\|$	$(\|P\| + \|A\|) \times K + \|P\|$
Constraints	(8)-(19)	(2)-(8) in [2]
Number of constraints	$3 + 4\|A\| + \|P\| + 3\|V\| + \|I\| - 2(\|E\| + \|X\|)$	$\|A\| \times (K-1) + \|P\| \times (2K-1) + K + 3$

$\{c|c \in C_p \forall p \in P\}$). A characteristic may be the theme, the type of support, the date of creation, the name of the artist or anything that identify an artwork.

We can represent any artwork $p \in P$ as a caracteristics vector $v_p = (v_{p_1}, ..., v_{p_n})$ in a vector-space of $|C|$ dimensions. Each element $v_{p_i} \in \mathbb{R}^+$ in the vector is a numerical value measuring the relevance of the artwork p to the associated characteristic. Additionally we define a vector v in the same vector-space as the vector representing the visitor preferences (where each element of v measures the interest of the visitor for the associated characteristic).

Measuring the interest for an artwork

To identify the interest for the visitor to an artwork, we compare v and v_p with the cosine similarity which calculate the angle between two vectors. The formula is the following:

$$similarity(v_p, v) = \frac{\sum_i^n v_{p_i} \times v_i}{\sqrt{\sum_i^n v_{p_i}^2} \times \sqrt{\sum_i^n v_i^2}} \qquad (20)$$

The resulting similarity ranges from 0, meaning that the visitor is not interested at all by the artwork, to 1 meaning that the artwork exactly matches his preferences.

In our model, we used $u(p) = similarity(v_p, v)$ where v_p and v are the vectors of the artwork p and the visitor preferences respectively.

VII. SIMULATIONS AND NUMERICAL RESULTS

We implemented the ILP model described in section V by using the IBM CPLEX 12 library[4].

The program takes several input parameters:

- The graph modeling the museum as defined in section IV
- The interest function f to use. This function produces interest vectors as defined in section VI
- The maximum duration that a visitor can spend in the museum

It outputs the proposed tour (as defined in section IV).

A. Intrinsic interest

As we saw in section III, the Enertex algorithm ranks the sentences of a document. We used Enertex as the following:

1) From the website of the museum, we created an XML file containing the following information for each artwork: the title, the artist name, the year and the description of the artwork.
2) We extracted data from the XML to produce a file where each pseudo sentence is a concatenation of title, artist and description.
3) The latter file is used as an input to Enertex with the query "musée orangerie peinture impressionniste postimpressionniste" to drive the balancing process of the system.

It produces a ranking for artworks depending on the information displayed by the museum (for each artwork, the result is a value ranging from 0 to 1).

Fig. 3 shows the ranking of the artworks in the *Musée de l'Orangerie* provided by Enertex.

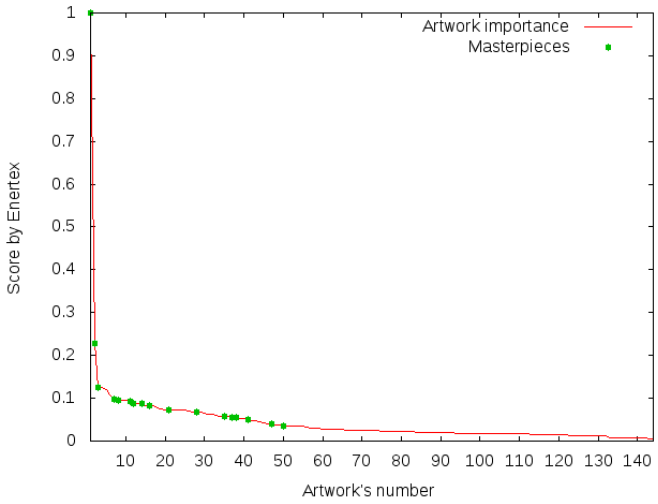

Fig. 3. Ranking by Enertex of the artworks in the Musée de l'Orangerie

As we can see, the resulting ranking is in agreement with the information provided by the museum. Indeed the masterpieces (according to the website of the museum) represent the most important artworks (which have the highest scores).

B. Interest functions

Four different interest function were designed to simulate the visitor preferences.

- f_1: produces the same vector $v = (1)$ for each artwork and visitor preferences
- f_2: produces a vector $v_p = (s_p)$ where s_p is the score given by Enertex for the artwork p and produces a vector $v = (1)$ as the visitor preferences.
- f_3: produces vectors $v = (v_1, ..., v_n)$ of size n equals to the number of artists. Each artwork is represented as a

[4]http://www-01.ibm.com/software/commerce/optimization/cplex-optimizer/

vector where $v_i = 1$ if the artwork is created by the artist i, 0 otherwise. The visitor preferences are represented as a vector where $v_i = 1$ if the visitor is interested by the artist i, 0 otherwise.

- f_4: produces vectors $v = v_{f_2} \| 10 \times v_{f_3}$ where v_{f_2} and v_{f_3} are the vectors produces by f_2 and f_3 respectively.

The first function defines the baseline: the visitor has no interest at all. The second uses the ranking provided by Enertex: the visitor wants to discover the most important artworks of the museum. The third uses the visitor preferences (a set of interesting artists). The last combines both visitor preferences and museum point of view (we multiply by 10 because we want to give more importance to the visitor preferences than to the museum point of view).

C. Evaluation

To evaluate the output tour, we measure the relevance percentage defined as :

$$rp = \frac{100 * \sum_{p \in T} f(p)}{\sum_{p \in P} f(p)} \tag{21}$$

where T is the set of artworks proposed in the tour (i.e. $T \subseteq P$) and f the interest function used (as saw above). The relevance percentage rp denotes a satisfaction rate of the visitor.

D. Results

For each function f, we ran the program with different time limits from 30 to 330 minutes (the time required to visit the entire collection) by steps of 15 minutes. For f_2 and f_3, we randomly pre-generated 5,000 combinations of 2, 3, 4 and 5 artists (i.e. the same combinations are used with f_2 and f_3) and calculated the arithmetic mean relevance percentage for each duration.

Figure 4 shows the evolution of rp for each function f. As expected, the first interest function f_1 produces a linear evolution of the relevance percentage (given that all artworks have the same interest, the tour includes the greatest number of artworks). With Enertex we are able to propose efficent tours to visitors who want to discover the museum (without particular preferences). The combination of both visitor preferences and intrinsic preferences produces the best results up to 49% of relevance improvement. It also appears that after 150 minutes, the improvement is less significant, we could assume that, from the visitor point of view, the optimal tour duration is about 2 hours and a half.

VIII. Conclusion and future works

This research tackles the problem of optimizing museum visits according to visitors preference and artwork importance. As a first milestone for next works taking into account the individual behavior in museum visits, it sets an original model combining computational optimisation and automatic learning via artificial intelligence. We first drew the optimization framework based on graph theory to depict the spatial organization of the museum (including rooms and paths), that requires an Integer Linear Programming to maximize the visitor overall satisfaction and to generate an optimal path, that is to say a series of rooms and artworks to be seen by the visitor. In complement, we compute an artwork description analysis by a natural language processing based on textual energy (using an algorithm called Enertex). This leads to ranking the different artworks according to the descriptions given by the museum, related to their artistic importance. Associating those two complementary approaches, we are then able to design optimal paths for visitors according to different interest functions based on artwork objective values assigned by museums.

Future works concern more subjective behavior of visitors depending on their profiles and leisure practices. Indeed, the project aims at finding relevant recommendations for optimal visit tours that rise a better fitness between the visitor wishes and the museum artistic supply. We can think about using natural language processing to generate the set of characteristics for all the artworks in a museum and calculate better interest vectors but also produce a summary of the proposed tour.

This information may advantageously be used by existing and potential visitors to refine the way they get involved in their cultural pratices. Indeed, it is admitted that the museum connoiseurs use to develop a critical mind about new services in a numerical society. Thence, aware visitors become able to appreciate the personalized routing recommendation system provided by their prefered museums.

***Abstract*—Motivated by improving the efficiency of pattern matching on graphs, we define a new kind of equivalence on graph vertices. Since it can be used in various graph algorithms that explore graphs, we call it exploratory equivalence. The equivalence is based on graph automorphisms. Because many similar equivalences exist (some also based on automorphisms), we argue that this one is novel. For each graph, there are many possible exploratory equivalences, but for improving the efficiency of the exploration, some are better than others. To this end, we define a goal function that models the reduction of the search space in such algorithms. We describe two greedy algorithms for the underlying optimization problem. One is based directly on the definition using a straightforward greedy criterion, whereas the second one uses several practical speedups and a different greedy criterion. Finally, we demonstrate the huge impact of exploratory equivalence on a real application, i.e., graph grammar parsing.**

I. Introduction

GRAPHS are an ubiquitous format for structural-data representation and are gaining popularity in various scientific disciplines. They are used to represent diverse types of entities and relations between them in various areas, ranging from chemistry [1], [2], economy [3], politics [4], to popular culture [5]. Such representation enables a more general and global view on the data. Additionally, researchers may benefit from powerful theoretical tools developed in graph theory to extract new insights.

One of the most general problems on various graphs is search for patterns, i.e., finding occurrences of small graphs in larger graphs. In theory, this is known as the subgraph isomorphism problem and has been thoroughly studied, as this is one of the fundamental problems in theoretical computer science. The decision version of this problem is *NP*-complete, and the counting version of the problem is $\#P$-complete. Furthermore, no exponential-time algorithm with a lower bound better than the naive enumeration of pattern is known [6]. This makes the problem intrinsically hard. Despite these pessimistic results, various algorithms exist for finding patterns, a vast majority of them based on the branch-and-bound method (e.g., [7], [8]). In many practical instances, however, these algorithms perform much better than the expected worst-case scenario and are able to solve relatively large instances (e.g., patterns of 1000 vertices in graphs of 10,000 vertices, and even larger).

Despite the practical usability of the current algorithms, there is a large set of problem instances that are often very hard for all the search algorithms. These are graphs with a lot of symmetries, i.e., graphs with many automorphisms. Detecting these symmetries before the start of the search can speed up the algorithm by very large constants, since the search does not have to be repeated for the symmetrical vertices. The goal of this paper is to formally define an equivalence on graph vertices, called *exploratory equivalence*, that captures such symmetries in graphs and can be easily utilized in algorithms for finding patterns (e.g., subgraph isomorphism) in graphs. Since there can be many exploratory equivalences in a graph (and some capture more symmetries than others), we also define the corresponding optimization problem. Our work is based on the ideas already developed by Fürst *et al.* [9] for the purpose of improving the Rekers-Schürr parser [10] for context-sensitive graph grammars. However, while Fürst *et al.* recognized the concept of exploratory equivalence (under the name 'interchangeability'), they did not treat it in a general graph-theoretic and group-theoretic manner. Besides that, they did not consider the possibility of having multiple exploratory equivalences for a single graph, nor did they define the notion of optimal exploratory equivalence. In this paper, we address all of these issues.

Informally, if a group of k vertices in an unlabeled graph belong to the same exploratory equivalence class, then they are interchangeable in the following sense: if each of them were labeled with a unique label, their labels could be arbitrarily interchanged with each other without affecting the graph. The graph would remain isomorphic after any of the $k!$ possible interchanges. It is important to note that a single graph may have multiple exploratory equivalences, i.e., multiple ways of partitioning the graph vertex set into a set of exploratory equivalent classes. Among all possible exploratory equivalences for a given graph, the algorithms proposed in this paper seek the one that captures the largest number of symmetries. As we show later, this is the equivalence with the largest product of the factorials of the cardinalities of its equivalence classes.

Graph grammars [11] are production-based graph rewrite systems and are regarded as a generalization of well-known string-based formal grammars. The Rekers-Schürr parser is an algorithm that, for a given graph and a context-sensitive graph grammar, determines whether the graph belongs to the language generated by the grammar and returns a derivation of the graph in the grammar if this is the case. However, the algorithm may exhibit a heavily exponential behavior when presented with a grammar containing many symmetries. In particular, given a simple grammar for chemical formulas of linear alkanes, the algorithm failed to parse the structural formula of propane within several hours. By exploiting the symmetries in the grammar, the parser's performance is brought down to polynomial for several meaningful classes

978-83-60810-58-3/$25.00

of grammars [9]. For instance, the parsing of propane now takes less than a second. In general, however, the worst-case performance remains exponential, since the graph grammar parsing problem is *NP*-hard even for highly restricted graph grammar formalisms [12].

Symmetry reduction techniques are not unique to graph-related decision and optimization problems. Liberti [13], for instance, proposed a novel approach to symmetry reduction in branch-and-bound-based MIP (mixed integer programming) solvers. His approach was applied to the discretizable molecular distance problem in the field of organic chemistry [14].

The paper is structured as follows. In the next section, we briefly present definitions and notions used in the rest of the paper. The third section includes the definition of exploratory equivalence, the optimization problem of finding the best exploratory equivalence in a given graph, and an example demonstrating the introduced concepts. We also present the argument that exploratory equivalence does not belong to the class of well-known regular equivalences. The fourth section presents two heuristic algorithms for solving the optimization problem. In Section V, we briefly describe the relevant portion of the Rekers-Schürr parser, its improvement with regard to exploratory equivalence, and some experimental results. Finally, Section VI concludes the paper and gives some ideas for the future work.

II. Preliminaries

Given a (finite) set S, a family $\{P_1, P_2, \ldots, P_s\}$ of nonempty subsets of S is a *partition* of S if every element in S is exactly in one of the subsets, i.e., $P_i \subseteq S$ and $P_i \neq \emptyset$, where $1 \leq i \leq s$, $\bigcup_{1 \leq i \leq s} P_i = S$, and $P_i \cap P_j = \emptyset$ for all $1 \leq i, j \leq s$ where $i \neq j$. When the partition $\{P_1, P_2, \ldots, P_s\}$ is given explicitly, we usually use $\{i \in P_1 \mid i \in P_2 \mid \ldots \mid i \in P_s\}$ as a short form, e.g., $\{\{1,2\},\{3\},\{4\}\}$ is shortened to $\{1,2 \mid 3 \mid 4\}$. In what follows, the order of the sets in a partition is often important. In such cases, we use the form $\langle i \in P_1 \mid i \in P_2 \mid \ldots \mid i \in P_s \rangle$, e.g., $\langle 1,2 \mid 3 \mid 4 \rangle$.

A *group* $\Gamma = (A, \circ)$ with the underlying set A and the binary operation $\circ$ on the elements of A is an algebraic structure satisfying the following conditions: *closure*, i.e., $x \circ y \in A$, *associativity*, i.e., $(x \circ y) \circ z = x \circ (y \circ z)$, *identity element* e, i.e., $\exists e \in A \forall x \in A : e \circ x = x \circ e = x$, and *inverse element*, i.e., $\forall x \in A \exists x^{-1} \in A : x \circ x^{-1} = x^{-1} \circ x = e$.

A *permutation* σ is a bijective function of a finite set S onto itself, i.e., $\sigma \colon S \to S$. Let $\Pi[S]$ denote the set of all permutations of the elements in the set S. Notice that the set $\Pi[S]$ together with the operation of function composition forms a group, which is called the *symmetric group*. Since all the groups discussed in this paper are subgroups of a symmetric group, we write as a group its underlying set only. Additionally, we also define $\Pi[n] = \Pi[\{1, 2, \ldots, n\}]$.

Let Γ be a subgroup of $\Pi[S]$. An element $i \in S$ is called a *fixed point* of the permutation $\sigma \in \Gamma$ if $\sigma(i) = i$. The set of all permutations for which i is a fixed point is a subgroup and is called the *stabilizer subgroup*, i.e.,

$$\mathrm{Stab}_\Gamma(i) = \{\sigma \in \Gamma \mid \sigma(i) = i\}.$$

Notice that all stabilizer subgroups include the identity permutation.

Now let us generalize the definition of a stabilizer from an element to a set. Given $P \subseteq S$, a stabilizer on P is a set of permutations which have a fixed point for all the positions in P:

$$\mathrm{Stab}_\Gamma(P) = \{\sigma \in \Gamma \mid \forall i \in P : \sigma(i) = i\}.$$

Equivalently, $\mathrm{Stab}_\Gamma(P)$ can also be defined in terms of intersections of $\mathrm{Stab}_\Gamma(i)$, where $i \in P$, i.e.,

$$\mathrm{Stab}_\Gamma(P) = \bigcap_{i \in P} \mathrm{Stab}_\Gamma(i).$$

From the latter definition it is clear that $\mathrm{Stab}_\Gamma(P)$ also satisfies all four group conditions. We thus have the following theorem.

Theorem 1: Given a set S, a set $P \subseteq S$, and a subgroup Γ of the group $\Pi[S]$, $\mathrm{Stab}_\Gamma(P)$ is a subgroup of Γ.

We also write $\mathrm{Stab}_\Gamma(P)$ as $\mathrm{Stab}(\Gamma, P)$.

The set of all images of $i \in S$ under permutations of the group Γ is called the *group orbit* of i, i.e.,

$$\mathrm{Orbit}_\Gamma(i) = \{\sigma(i) \mid \sigma \in \Gamma\}.$$

Let $G = (V, E)$ denote a simple undirected graph, where $V = \{1, 2, \ldots, n\}$ is a set of vertices and $E \subseteq V \times V$ is a set of edges. When two graphs are considered, the second is usually denoted with $H = (U, F)$. To denote an edge $(i, j) \in E$, we usually use a shorter version $ij \in E$. A *neighborhood* of a vertex $i \in V$, i.e., a set of vertices adjacent to i, is denoted with $\mathcal{N}(i)$. More formally,

$$\mathcal{N}(i) = \{j \in V \mid ij \in E\}.$$

A *coloration* C of a graph G is an assignment of colors to the vertices V of G, i.e., a surjective function C from V onto $\{1, 2, \ldots, c\}$ for some c, where colors are denoted with integers from 1 to c. Any coloration defines a partition of the vertices V, and vice versa. If $S \subseteq V$, then the *spectrum* of S, denoted $C(S)$, is a set of all colors assigned to the vertices of S. If $S = \{i\}$ is a singleton, then $C(i) = C(S)$ denotes the color assigned to the vertex $i \in V$. A coloration C induces a graph partition $\{C^{-1}(1), C^{-1}(2), \ldots, C^{-1}(c)\}$, and vice versa. A coloration C_1 is *finer or equal* than a coloration C_2 (denoted $C_1 \preceq C_2$) if

$$\forall i, j \in V \colon C_2(i) < C_2(j) \implies C_1(i) < C_1(j).$$

This implies that each set of the C_1-induced partition is a subset of (or equal to) some set of the C_2-induced partition.

A graph *homomorphism* from a graph $G = (V, E)$ to a graph $H = (U, F)$ is a mapping $f \colon V \to U$ such that for each $ij \in E$ it also holds that $f(i)f(j) \in F$. Homomorphism $f \colon V \to U$ is usually denoted with $f \colon G \to H$. We also write $G \to H$ if there exists a homomorphism from G to H. A graph *isomorphism* is a bijective homomorphism, i.e., a mapping $f \colon G \to H$ such that $ij \in E$ if and only if $f(i)f(j) \in F$. We write $G \simeq H$ if there exists an isomorphism from G to H; such graphs G and H are called isomorphic. Since isomorphisms are bijective, every isomorphism also has an inverse. A graph *endomorphism* is a homomorphism whose domain is equal to its codomain, i.e., $f \colon G \to G$.

A graph *automorphism* is both an endomorphism and an isomorphism, i.e., a mapping $f \colon G \to G$ such that $ij \in E$ if

and only if $f(i)f(j) \in E$. Notice that every automorphism is a permutation. If identity is the only automorphism of a graph, we say that the graph is *rigid*. The set of all automorphisms of a graph G is denoted with

$$\mathrm{Aut}(G) = \{a \in \Pi[n] \mid G \simeq a(G)\}$$

and is called the *automorphism group* of a graph G. Constructing $\mathrm{Aut}(G)$ is at least as difficult as solving the graph isomorphism problem, since graphs G and H are isomorphic if and only if the disconnected graph formed by the disjoint union of G and H has an automorphism that swaps the two components. Several practical algorithms are known for finding $\mathrm{Aut}(G)$; the most well-known is probably NAUTY [15].

III. PROBLEM DESCRIPTION

As already mentioned in the introduction, our goal is to find equivalent (also called indistinguishable) vertices of a graph. There are many types of equivalences already discussed in the literature. We give several examples later in this section. Our definition of equivalence is associated with the algorithmic exploration of a graph; for example, when the task is to find a pattern graph that is a subgraph in another target graph. In particular, branch-and-bound search algorithms could exploit such equivalences by reducing the number of (partial) matches established between a set of equivalent vertices in the pattern graph and a corresponding set of vertices in the target graph. In the remainder of this section, we formally describe our type of equivalence and the problem of finding the corresponding equivalence classes. Additionally, we also discuss several other similar equivalences and argue that our type is novel.

First, let us define a few additional notions. Let S be a set, and let $P \subseteq S$ be a set of positions. We say that a permutation $\sigma_1 \in \Pi[P]$ is *covered* by a permutation $\sigma_2 \in \Pi[S]$ if the two permutations have the same image on the positions P, i.e.,

$$\sigma_1 \preceq \sigma_2 \equiv \forall i \in P\colon \sigma_1(i) = \sigma_2(i).$$

Observe that P is equal to the domain of σ_1.

Now let $A \subseteq \Pi[S]$. We say that a set A of permutations *covers* a set P of positions if every permutation of P is covered by a permutation in A. More formally,

$$\mathrm{cover}(A, P) \equiv \forall \sigma \in \Pi[P]\ \exists a \in A : \sigma \preceq a.$$

Given a graph $G = (V, E)$, we say that a partition $\{P_1, P_2, \ldots, P_s\}$ of V is *exploratory equivalent* if for all $1 \leq i \leq s$ the following two conditions hold:

$$\mathrm{cover}(A_{i-1}, P_i) \text{ and } A_i = \mathrm{Stab}(A_{i-1}, P_i), \tag{1}$$

where $A_0 = \mathrm{Aut}(G)$. The sets $P_1, P_2, \ldots, P_s$ are the equivalence classes. Notice that the order of classes regarding the partition $\{P_1, P_2, \ldots, P_s\}$ is irrelevant, but it is important when checking the conditions (1), since not all orders of $P_1, P_2, \ldots, P_s$ satisfy them. In this sense the exploratory equivalence is an algorithmic concept. In particular, an algorithm processing a vertex $u \in P_i$ may ignore all other vertices in P_i, since the automorphisms A_{i-1} cover all permutations of P_i. However, it is important to observe that equivalence classes are not independent. For example, when a vertex $u \in P_i$ is processed, this may influence the rest of the algorithm. Therefore, when determining the next class P_{i+1}, one must exclude the automorphisms corresponding to the already processed classes $P_1, P_2, \ldots, P_i$, which is the same as restricting to the automorphisms where the positions $P_1 \cup P_2 \cup \cdots \cup P_i$ are fixed points. That is the reason why in each step the automorphism group is restricted from A_{i-1} to $A_i = \mathrm{Stab}(A_{i-1}, P_i)$.

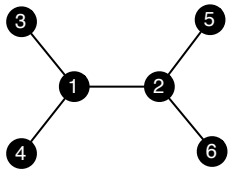

Fig. 1. An example graph with several exploratory equivalences.

Let us demonstrate the introduced concepts with an example. Consider the 6-vertex graph of Fig. 1. Its automorphism group consists of the following eight permutations (written in the one-line notation):

$$123456, 123465, 124356, 124365, \\ 215634, 215643, 216534, 216543. \tag{2}$$

There are twelve exploratory equivalent partitions of the graph. They are given in the form of a Hasse diagram (using the refinement relation $\preceq$ between two partitions) in Fig. 2. The

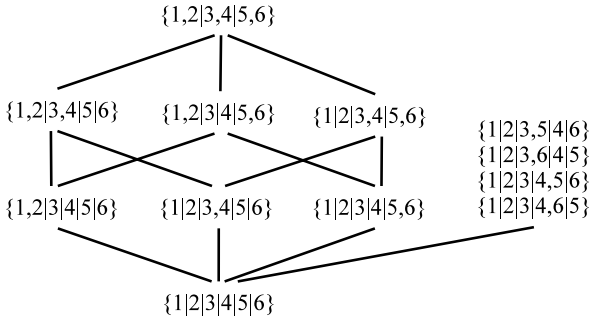

Fig. 2. Hasse diagram of all the exploratory equivalent partitions of the graph from Fig. 1. (The four partitions on the right-hand side are actually four separate vertices in the diagram.)

trivial partition ($\{1 \mid 2 \mid 3 \mid 4 \mid 5 \mid 6\}$ in the case of the graph of Fig. 1) is always exploratory equivalent. For the trivial partition, any ordering of its constituent sets satisfies the conditions (1). By contrast, for the exploratory equivalent partition $\{1, 2 \mid 3, 4 \mid 5, 6\}$, only the orderings $\langle 3, 4 \mid 5, 6 \mid 1, 2\rangle$ and $\langle 5, 6 \mid 3, 4 \mid 1, 2\rangle$ satisfy those conditions.

Corollary 1: Given a graph and its partition $\{P_1, P_2, \ldots, P_s\}$, let $A_0 = \mathrm{Aut}(G)$ and $A_i = \mathrm{Stab}(A_{i-1}, P_i)$ for $1 \leq i \leq s$. Then each A_i, where $1 \leq i \leq s$, is a subgroup.

Proof: $\mathrm{Aut}(G)$ is a group. By repeatedly applying Theorem 1, we know that A_i is a subgroup of A_{i-1}, for all $1 \leq i \leq s$. ∎

Now we are ready to define the problem. The input of the problem is a graph $G = (V, E)$ and its automorphism group $\mathrm{Aut}(G)$, and the goal of the problem is to find an exploratory equivalent partition $\{P_1, P_2, \ldots, P_s\}$ of V that maximizes the

product

$$\prod_{i=1}^{s} |P_i|!.$$

The reason for using the product of factorials in the objective function is that each class P_i covers $|P_i|!$ automorphic graphs, and the total number of automorphic graphs covered is thus the product above. In the following sections, we denote the problem with MAXEXPLOREQ.

In the paper [16], a large class of the so-called regular equivalences (called colorations therein) is surveyed. A coloration of a graph is *regular* when the equality of the spectra of two vertices implies the equality of the spectra of the corresponding neighborhoods. More formally, a coloration C of graph G is *regular* if and only if for all $i, j \in V$

$$C(i) = C(j) \implies C(\mathcal{N}(i)) = C(\mathcal{N}(j)).$$

Many different types of colorations are regular, e.g., strong and weak structural coloration, orbit coloration, perfect coloration, and exact coloration. See [16] for details. For example, coloring each orbit of $\mathrm{Aut}(G)$ gives orbit coloration. However, as it turns out, exploratory equivalence is not regular. To demonstrate this, consider again the graph from Fig. 1 and its exploratory equivalent partition $\{1, 2 \mid 3, 4 \mid 5, 6\}$, where the color of each class is different. It is easy to see that it is not regular, since $C(1) = C(2)$ but $C(\{3, 4\})$ is not equal to $C(\{6, 7\})$.

IV. ALGORITHM DESCRIPTION

In this section, we will describe two greedy algorithms for the MAXEXPLOREQ problem. The first algorithm is based on restricting the set of automorphisms to the stabilizer of the equivalent vertices found in one iteration. The second algorithm is more time-efficient owing to a faster detection of equivalent sets.

A. Greedy algorithm based on stabilizer restrictions

The first algorithm for the optimization problem MAXEXPLOREQ is based on the definition and will represent a reference algorithm that can be further improved. The idea of the algorithm is to start with the initial automorphism group, find one equivalence class of the partition, reduce the set of automorphisms only to the stabilizer of A, and recursively find new equivalence classes until the entire set of vertices is contained in the equivalence.

The input to this problem is the set of automorphisms (permutations) A and a set $V' \subseteq V$ of vertices not yet included in any equivalence class; initially V' is the entire set V.

If the set of automorphisms contains only the identity, then each vertex in V' represents a different equivalence class (i.e., no new indistinguishable vertices exist in the graph). If there is more than one automorphism in A, then at least two vertices are indistinguishable. At this point, the goal of the algorithm is to find a subset $S \subseteq V'$ that is covered by A. Usually, however, there are many possibilities for S, and different choices can lead to very different final solutions. The greedy criterion for this choice is the size of S, i.e., among many possibilities, the largest set S is chosen. When there are more sets with the same size, the algorithm chooses the one that has the largest stabilizer in A. The described algorithm is shown in more detail as Algorithm 1.

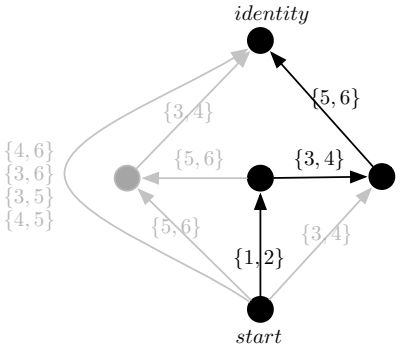

Fig. 3. The search space of Algorithm 1 for the graph in Fig. 1

Algorithm 1 Greedy algorithm for MAXEXPLOREQ based on stabilizer restrictions.

```
1:  function GREEDY1(A, V')
2:      if |A| = 1 then return singletons(V')
3:      bestP = ∅
4:      bestA = ∅
5:      for all P: P ⊆ V' ∧ cover(A, P) do
6:          A' ← Stab(A, P)
7:          if |P| > |bestP| ∨
8:             |P| = |bestP| ∧ |A'| > |bestA| then
9:              bestP ← P
10:             bestA ← A'
11:     return {bestP} ∪ GREEDY1(bestA, V' \ bestP)
```

To make this algorithm a little more clear, we will show its trace on the simple example graph of Fig. 1. The initial set of all automorphisms A is already shown in equation (2). From this set, the algorithm finds the equivalence class $\{1, 2\}$ and reduces A to the set $\mathrm{Stab}(A, \{1, 2\})$, which is:

$$A' = \{123456, 123465, 124356, 124365\}$$

In this automorphism group, it finds the equivalence class $\{3, 4\}$ and reduces the automorphisms to the stabilizer:

$$A' = \{123456, 123465\}$$

The final equivalence class from this group is $\{5, 6\}$, and the corresponding stabilizer contains only the identity. This yields the final result, namely the partition $\{1, 2 \mid 3, 4 \mid 5, 6\}$. If, at the moment when A' contained only the identity, the current partition did not include all six vertices of the graph, each of the missing vertices would be added as a singleton set to the equivalence. The entire search space for this example is shown in Fig. 3. Each vertex in this graph represents an automorphism group. The bottom vertex is the set of all automorphisms, and the top vertex is the set containing only the identity. Each edge represents a stabilization with the set that is written as the label of the edge. The bold vertices and edges are the ones that our algorithm follows.

Now we will discuss the correctness of the described algorithm.

Fig. 4. Two graphs on which Algorithm 1 returns a suboptimal solution. The left graph is the smallest counterexample in terms of the number of vertices, and the right one is the smallest counterexample in terms of the number of edges.

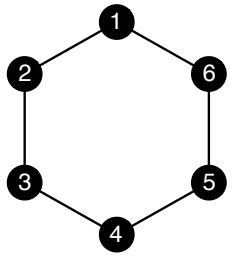

Fig. 5. A sample graph

Theorem 2: Algorithm 1 returns a partition of exploratory equivalent vertices.

Proof: Since the algorithm closely follows the definition, the proof is trivial. Each partition is covered by the automorphism group; the loop only iterates over the subsets that are covered. The second criterion from the definition is guaranteed by the recursion, since the set of automorphisms used in the recursion is only the stabilizer of the equivalence class found in the previous step. ■

Another question we need to address is the optimality of this algorithm. Unfortunately, the greedy criterion does not guarantee the optimality of the solution. We will demonstrate this by two examples shown in Fig. 4. These two examples were found by the exhaustive enumeration of all non-isomorphic connected graphs (starting with the smallest graph), and the graphs of Fig. 4 are the smallest examples where Algorithm 1 does not find an optimal solution. The optimal solution for the left graph in Fig. 4 is one with value 8 (partition $\{1,4 \mid 2,5 \mid 3,6\}$), whereas the algorithm returns a solution with value 6 (partition $\{1,3,5 \mid 2 \mid 4 \mid 6\}$). A similar situation occurs with the right graph, where the optimal solution is 8 (partition $\{1 \mid 2,3 \mid 4,5 \mid 6,7\}$), but the algorithm returns a suboptimal solution with value 6 (partition $\{2,4,6 \mid 1 \mid 3 \mid 5 \mid 7\}$).

Because of the exhaustive search over all subsets of V', the described algorithm is not very practical for larger graphs. In the next subsection, we will describe a more efficient algorithm that utilizes an incremental procedure to find the possible equivalence classes.

B. Greedy algorithm based on positional restriction of automorphisms

For a more convenient presentation of our second greedy algorithm, let us define a few auxiliary terms. The *positional restriction* of an automorphism (permutation) $a \in \Pi[S]$ to a set $R \subseteq S$ (denoted $\rho(a,R)$) is a partial function $a' \colon S \to S$ with $a'(i) = a(i)$ for all $i \in R$ and $a'(i)$ being undefined for all $i \in S \setminus R$. For example, $\rho((3,2,1,4),\{2,4\}) = (\uparrow,2,\uparrow,4)$. We use the one-line notation for representing automorphisms ($(1,2,3,4) \equiv 1234$) and the symbol $\uparrow$ for indicating the undefined values. Therefore, $a = (\uparrow,2,\uparrow,4)$ represents the fact that both $a(1)$ and $a(3)$ are undefined, whereas $a(2) = 2$ and $a(4) = 4$.

The positional restriction of a set of automorphisms $A \subseteq \Pi[S]$ to a set $R \subseteq S$ (denoted $\rho(A,R)$) is a set $\{\rho(a,R) \mid a \in A\}$. For example, $\rho(\{(1,2,3,4),(3,2,1,4)\}, \{2,4\}) = \{(\uparrow,2,\uparrow,4)\}$. As illustrated by this example, several automorphisms may collapse into one as a side-effect of a positional restriction.

For a given set S and a given set of (positionally unrestricted or restricted) set of automorphisms $A \subseteq \Pi[S]$, a *permofix* is a pair (P,F) such that the following conditions hold: (1) $P \subseteq S$, (2) $F \subseteq S$, (3) $P \cap F = \emptyset$, and (4) for each permutation $\sigma \in \Pi[P]$ there exists an automorphism $a \in A$ such that $a(i) = \sigma(i)$ for all $i \in P$ and $a(i) = i$ for all $i \in F$. In other words, a pair (P,F) is a permofix if there exists a set of automorphisms $A' \subseteq A$ that covers the set P (i.e., all permutations of P) and simultaneously fixes all elements of F. Given a permofix (P,F), the sets P and F will be called the *perm-set* and the *fix-set*, respectively. A k-permofix is a permofix (P,F) with $|P| = k$. The *potential* of a permofix (P,F) is the product $|P|!\,|F|!$. A permofix (P',F') is *contained* in a permofix (P,F) (denoted $(P',F') \sqsubseteq (P,F)$) if $P' \subset P$ (a *strict* subset) or $P' = P$ and $F' \subseteq F$.

As an example, consider the graph of Fig. 5. The 12 automorphisms of this graph are as follows:

$$\begin{aligned} a_1 &= (1,2,3,4,5,6) \\ a_2 &= (2,3,4,5,6,1) \\ a_3 &= (3,4,5,6,1,2) \\ a_4 &= (4,5,6,1,2,3) \\ a_5 &= (5,6,1,2,3,4) \\ a_6 &= (6,1,2,3,4,5) \\ a_7 &= (1,6,5,4,3,2) \\ a_8 &= (2,1,6,5,4,3) \\ a_9 &= (3,2,1,6,5,4) \\ a_{10} &= (4,3,2,1,6,5) \\ a_{11} &= (5,4,3,2,1,6) \\ a_{12} &= (6,5,4,3,2,1) \end{aligned} \tag{3}$$

For this graph, the pair $(\{1,3\},\{2,5\})$ is a permofix, since the automorphisms a_1 and a_9 cover both permutations of the set $\{1,3\}$ while fixing the elements 2 and 5. The pair $(\{1,3,5\},\emptyset)$ is a permofix as well, since the automorphisms a_1, a_3, a_5, a_7, a_9, and a_{11} collectively cover all permutations of the set $\{1,3,5\}$. We also have $(\{1,3\},\{2,5\}) \sqsubseteq (\{1,3,5\},\emptyset)$.

Given the set of automorphisms $A \subseteq \Pi[n]$ of a n-vertex graph, the algorithm works as a greedy iterative process. In each iteration, it produces the set of all permofixes in the current set of automorphisms (in the first iteration, this is the unrestricted set A) and greedily selects a permofix with the

largest potential. After making its selection, the algorithm positionally restricts all automorphisms to the fix-set of the selected permofix. The positionally restricted set of automorphisms serves as the input to the next iteration. The process stops once all automorphisms have become completely undefined functions. The output of the algorithm is a set composed of all perm-sets of the permofixes selected in individual iterations and of the singletons containing the individual vertices that are not present in any of the selected perm-sets. Later, we shall show that the algorithm's output is an exploratory equivalent partition of the vertex set.

The rationale for selecting a permofix with the highest potential is based on the following heuristics: Recall that the algorithm's goal is to find a partition $\{P_1, \ldots, P_s\}$ of $\{1, \ldots, n\}$ with a maximum value of $|P_1|! \ldots |P_s|!$. A permofix (P, F) is guaranteed to contribute at least a factor of $|P|!$ to the target product $|P_1|! \ldots |P_s|!$ (since the perm-set of the selected permofix is part of the algorithm's output), but it can potentially contribute up to $|P|!\,|F|!$. The optimal scenario takes place when the entire fix-set F serves as a perm-set of some permofix selected later in the process. Therefore, a permofix (P, F) having the largest value of $|P|!\,|F|!$ may potentially contribute the largest factor to the target product.

The pseudocode of the greedy algorithm based on positional restrictions of the automorphism set is shown as Algorithm 2.

To show that the output produced by the algorithm conforms to our problem definition, we shall first prove the following lemma:

Lemma 1: Each element of the set returned by the procedure GREEDY2 is a perm-set of the input set A of automorphisms.

Proof: The singletons are perm-sets by definition, so let us focus on the elements of the set $\mathcal{P}$ inside the procedure GREEDY2. In each iteration, the algorithm first applies the procedure FIND2PERMOFIXES to the current set of automorphisms A. This procedure returns a set of all pairs $(\{p, q\}, \{r_1, \ldots, r_t\})$ such that there exists an automorphism a with $a(p) = q$, $a(q) = p$, and $a(r_1) = r_1$, …, $a(r_t) = r_t$. By the definition of automorphism group, the set A always contains the identity automorphism a_{id} with the property $a_{\mathrm{id}}(p) = p$, $a_{\mathrm{id}}(q) = q$, and $a_{\mathrm{id}}(r_1) = r_1$, …, $a(r_t) = r_t$. The automorphisms a and a_{id} jointly form a proof that the pair $(\{p, q\}, \{r_1, \ldots, r_t\})$ is indeed a permofix.

The procedure EXTEND iteratively produces k-permofixes based on sets of $(k-1)$-permofixes in the set of automorphisms A. For $k = 3$, the procedure creates a pair $PF = (\{p, q, r\}, F_1 \cap F_2 \cap F_3)$ from the permofixes $PF_1 = (\{p, q\}, \{r\} \cup F_1)$, $PF_2 = (\{p, r\}, \{q\} \cup F_2)$, and $PF_3 = (\{q, r\}, \{p\} \cup F_3)$. Neglecting the sets F_1, F_2, and F_3 for the time being, the permofix PF_1 represents the permutation $(p\ q)(r)$ in the cycle notation. Likewise, PF_2 and PF_3 represent the permutations $(p\,r)(q)$ and $(q\,r)(p)$, respectively. Since $(A, \circ)$ is a group, the permutation $(p\,q)(r) \circ (p\,r)(q) \circ (q\,r)(p) = (p\,q\,r)$ has to be completely present in A; in other words, A has to contain an automorphism for each of the 3! permutations of the set $\{p, q, r\}$. Therefore, $\{p, q, r\}$ is a perm-set in A. The fix-set corresponding to this perm-set is (a superset of) the intersection of the fix-sets of PF_1, PF_2, and

Algorithm 2 Greedy algorithm based on positional restrictions

```

42: function CLEANUP(R)
43:     for all (P, F) ∈ R do
44:         for all (P', F') ∈ R \ {(P, F)} do
45:             if (P', F') ⊑ (P, F) then
46:                 R := R \ {(P', F')}
47:     return R
```

PF_3. Consequently, PF is a permofix in A. This reasoning can be straightforwardly extended to the general case of $k > 3$. Therefore, every pair created by the procedure EXTENDS is a permofix in the current set of automorphisms.

The procedure CLEANUP does not produce anything new; it merely reduces the number of permofixes. For a permofix (P, F), all permofixes (P', F') with $(P', F') \sqsubseteq (P, F)$ are heuristically pronounced redundant. If $P' = P$ and $F' \subseteq F$, the permofix (P', F') is clearly superfluous. If $P' \subset P$, then the permofix (P, F) has been created from (P', F') within the EXTEND procedure.

The positional restriction can only reduce the set of permofixes. It is easy to see that if a pair (P, F) is a permofix in a positionally restricted set of automorphisms, then it is a permofix in the original set, too.

In summary, the set $\mathcal{R}$ consists of permofixes of the initial set of automorphisms A, and every element of the set returned from the procedure GREEDY2 is a perm-set of A. ■

In the following theorem, we show that the algorithm produces a solution to our problem, i.e., an exploratory equivalent partition of the vertex set.

Theorem 3: The procedure GREEDY2 returns an exploratory equivalent partition of the vertex set V.

Proof: Let $\{P_1, \ldots, P_s, \{i_1\}, \ldots, \{i_r\}\}$ be the result of the algorithm GREEDY2, where P_1, …, P_s are the perm-sets produced in individual iterations, and $\{i_1\}, \ldots, \{i_r\}$ are the singletons created from the vertices that do not belong to the set $P_1 \cup \ldots \cup P_s$. By construction, the elements of the output set are mutually disjoint sets that collectively cover the entire vertex set. The output set is thus a partition of the vertex set.

By definition, each of the produced perm-sets P_1, …, P_s is covered by the initial set of automorphisms $A_0 \equiv A$, i.e., we have cover(A_0, P_i) for all $i \in \{1, \ldots, s\}$. Let us now show that cover(Stab(A_0, P_s), P_{s-1}) also holds. The perm-set P_s has to be a subset of the fix-set F_{s-1}; otherwise, the algorithm would, at some earlier stage, have set $a_1(j) := \uparrow$, …, $a_{|A|}(j) := \uparrow$ for at least one $j \in P_s$ and hence could not produce P_s. By the definition of permofix, there exists a set of automorphisms that fixes F_{s-1} and simultaneously covers P_{s-1}. Since $P_s \subseteq F_{s-1}$, the same set of automorphisms also fixes P_s. Consequently, the set of automorphisms where P_s is fixed (i.e., Stab(A_0, P_s)) covers P_{s-1}. In the same manner, we can prove cover(Stab(Stab$(A_0, P_s), P_{s-1}), P_{s-2}$), etc. Therefore, the perm-sets P_s, P_{s-1}, P_{s-2}, …, P_1, together with the singleton sets formed by the missing elements, constitute an exploratory equivalent partition of the vertex set V. ■

In practice, the algorithm GREEDY2 is more efficient than GREEDY1. For each combination P of the current set of vertices, the first greedy algorithm checks whether P is covered by the current set of automorphisms (in other words, whether P is a perm-set in the current set of automorphisms). By contrast, the algorithm GREEDY2 generates candidate perm-sets (and the associated fix-sets) in an incremental fashion: a perm-set with k elements is generated by merging k perm-sets with $k - 1$ elements. If no k-element perm-sets are generated, the algorithm will not attempt to generate any $(k + 1)$-element perm-sets.

Let us illustrate the algorithm GREEDY2 with two examples. Consider the graph of Fig. 5. Given the set of its automorphisms as input (enumerated in Eq. 3), the algorithm produces the following 2-permofixes (after executing the procedure CLEANUP):

$$
\begin{array}{lll}
(\{1,2\},\emptyset) & (\{2,3\},\emptyset) & (\{3,6\},\emptyset) \\
(\{1,4\},\emptyset) & (\{2,5\},\emptyset) & (\{4,5\},\emptyset) \\
(\{1,6\},\emptyset) & (\{3,4\},\emptyset) & (\{5,6\},\emptyset) \\
(\{1,3\},\{2,5\}) & (\{1,5\},\{3,6\}) & (\{2,4\},\{3,6\}) \\
(\{2,6\},\{1,4\}) & (\{3,5\},\{1,4\}) & (\{4,6\},\{2,5\})
\end{array}
$$

The procedure EXTEND produces two 3-permofixes: $(\{1,3,5\},\emptyset)$ and $(\{2,4,6\},\emptyset)$. The procedure CLEANUP subsequently removes all permofixes (P, F) with $|P| = |F| = 2$. In the next step, the algorithm selects a permofix with the highest value of $|P|!\,|F|!$. This is either $(\{1,3,5\},\emptyset)$ or $(\{2,4,6\},\emptyset)$. In either case, the fix-set is empty, so the procedure RESTRICT sets all elements of all automorphisms to $\uparrow$. As a result, the algorithm immediately stops with the result $\{1,3,5 \mid 2 \mid 4 \mid 6\}$ (or $\{2,4,6 \mid 1 \mid 3 \mid 5\}$, depending on its selection). Among all exploratory equivalent partitions, these two both have the highest product of the factorials of the cardinalities of their constituent sets and hence represent two optimal solutions to the MAXEXPLOREQ problem.

The graph of Fig. 1 has 8 automorphisms:

$$
\begin{aligned}
a_1 &= (1,2,3,4,5,6) \\
a_2 &= (1,2,3,4,6,5) \\
a_3 &= (1,2,4,3,5,6) \\
a_4 &= (1,2,4,3,6,5) \\
a_5 &= (2,1,5,6,3,4) \\
a_6 &= (2,1,5,6,4,3) \\
a_7 &= (2,1,6,5,3,4) \\
a_8 &= (2,1,6,5,4,3)
\end{aligned}
$$

In the first iteration, the algorithm produces the following permofixes:

$$
\begin{array}{ll}
(\{3,5\},\emptyset) & (\{1,2\},\emptyset) \\
(\{3,6\},\emptyset) & (\{3,4\},\{1,2,5,6\}) \\
(\{4,5\},\emptyset) & (\{5,6\},\{1,2,3,4\}) \\
(\{4,6\},\emptyset) &
\end{array}
$$

The set of automorphisms contains no permofixes (P, F) with $|P| > 2$. Using the highest-potential criterion, the algorithm selects either the permofix $(\{3,4\},\{1,2,5,6\})$ or the permofix $(\{5,6\},\{1,2,3,4\})$. Let us assume that the former is selected; the latter permofix leads to the same output. After the selection, the set of automorphisms is positionally restricted with respect to the fix-set $\{1,2,5,6\}$):

$$
\begin{aligned}
a'_1 &= (1,2,\uparrow,\uparrow,5,6) \\
a'_2 &= (1,2,\uparrow,\uparrow,6,5) \\
a'_5 &= (2,1,\uparrow,\uparrow,3,4) \\
a'_6 &= (2,1,\uparrow,\uparrow,4,3)
\end{aligned}
$$

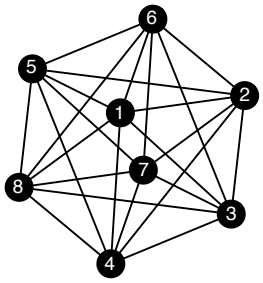

Fig. 6. The smallest graph on which Algorithm 2 returns a suboptimal solution.

The automorphisms a'_3 and a'_4 are equal to a'_1 and a_2', respectively, and an analogous situation occurs with the automorhpisms a'_7 and a'_8. In the second iteration, only two permofixes are produced: $(\{1,2\},\emptyset)$ and $(\{5,6\},\{1,2\})$. The latter has a greater potential than the former and is hence selected, restricting the set of automorphisms to $\{(1,2,\uparrow,\uparrow,\uparrow,\uparrow), (2,1,\uparrow,\uparrow,\uparrow,\uparrow)\}$. The restricted automorphisms give rise to the sole permofix $(\{1,2\},\emptyset)$, which is selected in the third iteration of the algorithm. The algorithm thus outputs the partition $\{3,4 \mid 5,6 \mid 1,2\}$, which is again an optimal solution to the MAXEXPLOREQ problem.

For a vast majority of input graphs, the algorithm GREEDY2 produces optimal exploratory equivalent partitions. The smallest graph (in terms of vertex count) with a suboptimal result is shown in Fig. 6. For this graph, the algorithm produces the partition $\{1,7 \mid 2,8 \mid 3,5 \mid 4,6\}$ with the target cardinality factorial product being $2!\,2!\,2!\,2! = 16$. The optimal solution, however, is the partition $\{1,2,3,4 \mid 5 \mid 6 \mid 7 \mid 8\}$ with the target product of $4! = 24$. In the first iteration, the algorithm produces 20 permofixes, two of which are $(\{1,2,3,4\},\ \emptyset)$ and $(\{1,7\},\{2,3,4,5,6,8\})$. The former permofix would lead to an optimal solution, but the algorithm chooses the latter, since $2!\,6! > 4!$. However, the fix-set of the selected permofix eventually contributes only $2!\,2!\,2!$ instead of the potential $6!$ to the target product, making the algorithm's first-iteration choice suboptimal.

Interestingly, the graphs of Fig. 4 are not counterexamples for the second greedy algorithm, and the graph of Fig. 6 is not a counterexample for the first algorithm. In contrast to the algorithm GREEDY1, the algorithm GREEDY2 considers the combined sizes of individual perm-sets and fix-sets when making greedy selections. In the right graph of Fig. 4, for example, the algorithm GREEDY2 has to choose between the permofix $(\{2,3\},\{1,4,5,6,7\})$ (or an equivalent permofix with potential $2!\,5!$) and the permofix $(\{2,4,6\},\emptyset)$ (or an equivalent permofix with potential $3!$). The first permofix is obviously preferable, leading to an optimal partition. Conversely, since the algorithm GREEDY1 considers perm-sets without the associated fix-sets, it prefers the perm-set $\{1,2,3,4\}$ over all 2-element perm-sets (regardless of the sizes of their associated fix-sets) when dealing with the graph of Fig. 6.

V. EXPLORATORY EQUIVALENCE AND THE IMPROVED REKERS-SCHÜRR PARSER

As we mentioned in the introduction, the concept of exploratory equivalence was developed by Fürst *et al.* [9] for the purpose of improving the Rekers-Schürr graph grammar parser [10], although the authors did not provide a rigorous graph-theoretic and group-theoretic definition of exploratory equivalence and did not consider the possibility of multiple exploratory equivalent partitions for a single graph. In this section, we show how a proper consideration of exploratory equivalence may lead to immense performance gains when parsing graphs against graph grammars.

The Rekers-Schürr graph grammar parser (both the original and the improved version) accepts a graph and a context-sensitive graph grammar on its input. A context-sensitive graph grammar (called just 'grammar' in the sequel) is a quadruple $(\mathcal{N}, \mathcal{T}, \mathcal{P}, \mathcal{A})$, where $\mathcal{N}$ is a set of *nonterminal* labels, $\mathcal{T}$ is a set of *terminal* labels, $\mathcal{P}$ is a set of *productions*, and $\mathcal{A}$ is a set of *axioms*. Each production p is a rule of the form $Lhs[p] ::= Rhs[p]$, where $Lhs[p]$ (the left-hand side – LHS) and $Rhs[p]$ (the right-hand side – RHS) are subgraphs of a graph $Union[p]$ whose elements (vertices and edges) have labels from $\mathcal{N} \cup \mathcal{T}$. The graph $Common[p] = Lhs[p] \cap Rhs[p]$ is called the *context* of the production. Let $Xlhs[p] = Lhs[p] \setminus Common[p]$ and $Xrhs[p] = Rhs[p] \setminus Common[p]$; note that $Xlhs[p]$ and $Xrhs[p]$ might not be proper graphs, since they may contain dangling edges. A sample production, as well as the graphs and the graph element sets associated with it, is shown in Fig. 7. In contrast to the graph depictions shown so far, the inscriptions inside the vertices represent vertex labels rather than vertex indices. The indices are displayed next to individual vertices. The yellow-colored vertices belong to the graph $Common[p]$ and hence to both the LHS and RHS simultaneously; this is also reflected in the fact that such vertices have the same index on both sides of the production.

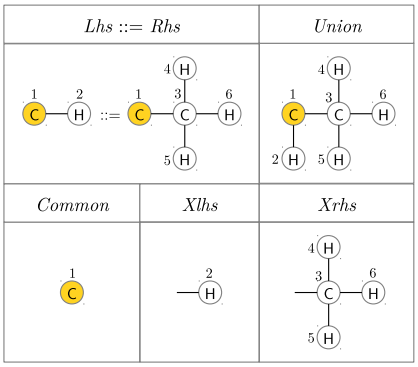

Fig. 7. A sample production and the associated graphs and graph element sets.

An *l-homomorphism* $h\colon Lhs[p] \to G$ for a production p is a graph homomorphism whose restriction to $Xlhs[p]$ is injective. An *l-occurrence* of a production p in a graph G is a graph $L' \sqsubseteq G$ such that $L' = h(Lhs[p])$ for some l-homomorphism h. The terms *r-homomorphism* and *r-occurrence* are defined symmetrically (with $Rhs[p]$ and $Xrhs[p]$ instead of $Lhs[p]$ and $Xlhs[p]$, respectively).

To *apply* a production p to a graph G, the following three steps are performed: (1) find an l-occurrence of p in G (let $h\colon Lhs[p] \to G$ be the associated l-homomorphism); (2) remove the elements $h(Xlhs[p])$ from the graph G; (3) attach fresh copies of the elements $Xrhs[p]$ to the elements

$h(Common[p])$ in the same way as the elements $Xrhs[p]$ are attached to the elements of $Common[p]$ within the graph $Rhs[p]$. A *derivation* of a graph G in a graph grammar is a sequence of production applications beginning with an axiom graph and ending with the graph G. The *language* of a graph grammar GG is the set of all terminally labeled graphs that have a derivation in GG. (A graph is *terminally labeled* if all of its elements are labeled by labels from the set $\mathcal{T}$.) A *parser* is an algorithm that, for a given graph G and a given graph grammar GG, determines whether G belongs to the language of GG and produces a derivation of G in GG if this is the case. Figure 8 shows a grammar for generating the structural formulas of linear alkanes. All graph labels belong to the set $\mathcal{T}$, including the 'non-label' — a fictitious label for unlabeled edges. Figure 9 displays the derivation of the propane graph in that grammar. The derivation starts with the axiom (the methane graph) and passes through the ethane graph.

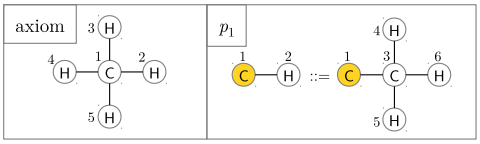

Fig. 8. A grammar for generating the structural formulas of linear alkanes.

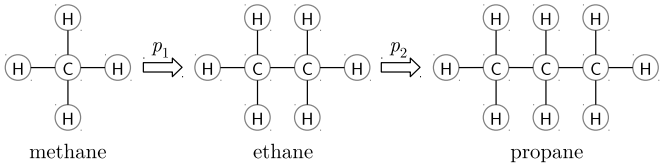

Fig. 9. Derivation of the propane graph in the grammar of Fig. 8.

The Rekers-Schürr parser works as a two-stage process. In the first stage, the input graph G is analyzed in order to obtain a partially ordered redundant set $\mathcal{S}$ of candidate production applications that might take part in a potential derivation of G. In the second stage, the parser tries to find, using backtracking if necessary, a sequence of production applications within the set $\mathcal{S}$ that constitutes a correct derivation of the graph G. The improvement by Fürst *et al.* pertains only to the first stage of the parsing process.

At the beginning of the first stage, the parser creates a graph $\overline{G}$ as a copy of the input graph G. After that, it iteratively searches the graph $\overline{G}$ for all r-occurrences of individual productions. For each discovered r-occurrence of a production p, the graph $\overline{G}$ is augmented by attaching fresh copies of the elements $Xlhs[p]$ to the r-occurrence, giving rise to a *production instance* — a homomorphic image of the entire production p that defines a candidate application of p in a potential derivation of G. The augmentation of the graph $\overline{G}$ might result in new r-occurrences among the added elements. The discover-and-augment cycle finishes once all r-occurrences of all productions have been discovered.

To guarantee the discovery of all r-occurrences, each RHS has to be matched against the graph $\overline{G}$ in all possible ways. In other words, all RHS-to-$\overline{G}$ r-homomorphisms have to be established, including different r-homomorphisms between a production and *each* of its r-occurrences. However, exploratory equivalence can make some (or all) of the r-homomorphisms between a production and its r-occurrence redundant. Let us assume that a production p contains k distinct vertices $v_1, \ldots, v_k$ with the following properties:

- either $v_1, \ldots, v_k \in Xrhs[p]$ or $v_1, \ldots, v_k \in Common[p]$;
- $v_1, \ldots, v_k$ constitute an equivalence class in at least one exploratory equivalent partition of the graph $Rhs[p]$;
- $v_1, \ldots, v_k$ constitute an equivalence class in at least one explorationally equivalent partition of the graph $Union[p]$.

Then it can be shown [9] that the set of r-homomorphisms $h\colon Rhs[p] \to \overline{G}$ established between the production p and the graph $\overline{G}$ can be safely restricted to those r-homomorphisms h for which $index(h(v_1)) < \ldots < index(h(v_k))$, where $index(v)$ is a unique index assigned to a vertex $x \in \overline{G}$. This rule reduces the number of established p-homomorphisms between the production p and each of its occurrences by a factor of $k!$. Since each discovered r-homomorphism is followed by an augmentation of the graph $\overline{G}$, immense performance gains can thus be attained. This rule can be straightforwardly extended to multiple non-singleton classes of an exploratory equivalent partition.

Consider the grammar of Fig. 8. The optimal exploratory equivalent partition for the axiom graph is $\{1 \mid 2,3,4,5\}$. This implies that we can employ the rule $h(2) < h(3) < h(4) < h(5)$ whenever searching for occurrences of the axiom graph in the graph $\overline{G}$. For the RHS of the production p_1, the optimal partition is $\{1 \mid 3 \mid 4,5,6\}$. Since the graph $Union[p_1]$ also has an exploratory equivalent partition in which the vertices 4, 5, and 6 are part of the same equivalence class, we can enforce the rule $h(4) < h(5) < h(6)$ for every r-homomorphism established between the RHS of the production p_1 and the graph $\overline{G}$. Because of the interleaved discover-and-augment cycle, the enforcement of these rules may significantly reduce the parsing time.

For the task of parsing the graphs of methane, ethane, and propane against the grammar of Fig. 8, Table I compares the duration of parsing without considering exploratory equivalence (EE) and the duration of parsing when exporatory equivalence is taken into account in the form of imposing constraints on r-homomorphisms between the RHSs and the graph $\overline{G}$. The experiments were conducted on a 3.40-GHz Intel Core i7 machine.

The difference between the two versions of the parser is striking. Without using the rules based on exploratory equivalence, the parser quickly succumbs to a combinatorial explosion as the size of the input graph increases; it took more than 11 hours to parse the graph of propane with 3 vertices C and 8 vertices H. By contrast, when exploratory equivalence is taken into account, the parser takes less than one second (0.989 seconds) even when parsing the graph $C_{30}H_{62}$ (30 vertices C, 62 vertices H). Asymptotically, for a graph with n vertices C, the original parser creates $\Omega(6^n)$ production instances (possibly much more than that), while the version that makes use of exploratory equivalence generates exactly

$12n - 7$ production instances. For many grammars containing symmetries in the sense of exploratory equivalence, the use of exploratory equivalence can reduce the asymptotical parsing time from exponential to polynomial (see [9] for additional examples).

TABLE I. THE TIME REQUIRED TO PARSE THE INDIVIDUAL GRAPHS OF FIG. 9 AGAINST THE GRAMMAR OF FIG. 8.

Graph	Without EE	With EE
methane (CH_4)	0.16	0.14
ethane (C_2H_6)	1.03	0.15
propane (C_3H_8)	41000.	0.16

VI. CONCLUSION

We introduced a novel type of graph equivalence, called exploratory equivalence because of its applicability to various graph search algorithms. Exploratory equivalence was defined as an automorphism-based equivalence relation on graph vertices. In contrast to our usual perceptions about equivalence, exploratory equivalence may induce several distinct vertex set partitions for a given graph.

In addition to defining exploratory equivalence itself, we have also introduced the concept of an optimal exploratory equivalent partition for a given graph. We presented two greedy algorithms for finding such a partition. Both algorithms produce optimal results for a vast majority of input graphs. For instance, considering all non-isomorphic graphs on 8 vertices, the second greedy algorithm produces an optimal partition for 11116 graphs out of 11117, the sole exception being the graph of Fig. 6. Among all non-isomorphic 9-vertex graphs, the algorithm produces suboptimal results for only 2 graphs out of 261080.

In subgraph search algorithms, exploratory equivalence can be employed to prevent or at least reduce multiple discoveries of individual occurrences of graph patterns in a given host graph. In the Rekers-Schürr graph grammar parser, this strategy may bring about immense performance gains, since each discovery of a graph in a host graph results in an augmentation of the same host graph.

A possible direction for the future work is a generalization of exploratory equivalence. As defined in this paper, exploratory equivalence can be regarded as a global relation between vertices. Informally, a pair of vertices may potentially belong to the same exploratory equivalence class only if the entire graph 'looks the same' from the viewpoint of both vertices. For this reason, exploratory equivalence is a fairly infrequent phenomenon for large random graphs, except for sets of leaf vertices attached to the same internal vertex. A natural generalization of 'global' exploratory equivalence is therefore a 'local' version of this concept, where only a limited neighborhood is inspected when determining the equivalence of a set of vertices. However, practical implications of such a definitions have yet to be discovered.

As shown in Section V, exploratory equivalence can be used to impose constraints on graph homomorphisms when searching for occurrences of a given pattern graph inside a given host graph. The purpose of such constraints is to eliminate multiple discoveries of the same occurrence. However, in some cases, the constraints induced by exploratory equivalence do not suffice to cover all automorphisms of the pattern graph. Consider, for example, the graph of Fig. 5. This graph has 12 automorphisms, but the optimal exploratory equivalent partition ($\{\{1, 3, 5 \mid 2 \mid 4 \mid 6\}\}$) only covers half of them. Consequently, the rule $h(1) < h(3) < h(5)$ still allows for two different isomorphisms between a pair of 6-cycles. Besides the constraints induced by the optimal exploratory equivalence, we would need another constraint to cover the rotational symmetry of the graph. The relationship between exploratory equivalence (and other types of equivalence) and graph search constraints is thus another promising direction for the future work.

***Abstract*—The Molecular Distance Geometry Problem (MDGP) is the one of finding molecular conformations that satisfy a set of distance constraints obtained through experimental techniques such as Nuclear Magnetic Resonance (NMR). We consider a subclass of MDGP instances that can be discretized, where the search domain has the structure of a tree, which can be explored by using an *interval* Branch & Prune (*i*BP) algorithm. When all available distances are exact, all candidate positions for a given molecular conformation can be enumerated. This is however not possible in presence of interval distances, because a continuous subset of positions can actually be computed for some atoms. The focus of this work is on a new scheme for an adaptive generation of a discrete subset of candidate positions from this continuous subset. Our generated candidate positions do not only satisfy the distances employed in the discretization process, but also additional distances that might be available (the so-called pruning distances). Therefore, this new scheme is able to guide more efficiently the search in the feasible regions of the search domain. In this work, we motivate the development and formally introduce this new adaptive scheme. Presented computational experiments show that *i*BP, integrated with our new scheme, outperforms the standard *i*BP on a set of NMR-like instances.**

I. Introduction

LET $G = (V, E, d)$ be a simple weighted undirected graph where the vertices V represent the points of a Euclidean space and where $d : E \to \mathbb{R}_+$ assigns positive weights d_{uv} to edges (u, v) when the distance between u and v is available. The Distance Geometry Problem (DGP) [9] asks to find an embedding $x : V \to \mathbb{R}^3$ satisfying constraints based on the available edge weights, i.e. to find a conformation x in the Euclidean space such that:

$$\underline{d}_{uv} \leq \|x(u) - x(v)\| \leq \overline{d}_{uv}, \quad \forall (u, v) \in E, \tag{1}$$

where $\underline{d}_{uv}$ and $\overline{d}_{uv}$ denote, respectively, the lower and upper bounds for the distance d_{uv} ($\underline{d}_{uv} = \overline{d}_{uv}$ if d_{uv} is an exact distance).

One of the most interesting applications of the DGP arises in biology, where vertices of G represent atoms of a given molecule, and weighted edges provide the relative distances between some atom pairs. When molecules are concerned, the DGP is generally referred to as the Molecular DGP (MDGP) [3], [5]. The interested reader can make reference to a recent survey [9] and to an edited book [13] for additional information about the MDGP and methods for its solution.

The MDGP is generally formulated as a continuous optimization problem where the objective function is a penalty function capable of measuring the violation of the constraints. Under certain assumptions, the domain of this optimization problem can be discretized, so that it becomes combinatorial [7], [12]. The discrete search domain has the structure of a tree, where the candidate positions for a given atom of the molecule belong to the same layer of the tree. We employ an *interval* Branch & Prune (*i*BP) algorithm [8] for exploring such a tree with the aim of finding solutions to discretizable MDGPs. The reader is referred to Section II for more details about the discretization.

The basic idea behind the *i*BP algorithm is to construct the search domain of the optimization problem branch by branch (*branching phase*), and to verify, every time a new branch is added, whether it is feasible or not (*pruning phase*). Atomic positions are generated by intersecting 3 Euclidean objects (spheres and spherical shells), which we can define on each layer of the tree because of the discretization assumptions. When discovered, infeasible positions are pruned away, so that the search can be focused on the parts of the tree where there are feasible solutions. Only a subset of available distances is employed in the discretization process (the *discretization distances*), while others can be exploited for pruning purposes (the *pruning distances*).

In the discretization process, if all considered distances are exact, there can be at most two feasible positions for the current atom [7]. If some distances are represented by intervals, the feasible positions belong to a continuous Euclidean object, that can be discretized by sampling D candidate positions [8]. In this phase, the number D of chosen sample positions plays a very important role.

Experiments reported in previous publications (see for example [2], [8]) show in fact that the obtained results can be strongly influenced by the choice of D. If D is too small, only

978-83-60810-58-3/$25.00

infeasible branches may be generated, so that the whole tree is pruned and no solutions are found. On the other hand, if D is too large, the consequent combinatorial explosion might make the experiments too expensive. Finding a trade-off D value is not an easy task in general.

This paper presents a new scheme for an adaptive branching during the execution of the *i*BP algorithm, which is based on the idea of including, during the intersection of the Euclidean objects related to the known discretization distances, other objects, related to pruning distances, that might be available at the current layer. This way, it is possible to generate branches that are feasible, with respect to the pruning distances, up to the current layer.

The rest of the paper is organized as follows. In Section II, we will briefly discuss the discretization assumptions, present the *i*BP algorithm, and give some details about the generation of the coordinates of candidate positions at each iteration of *i*BP. In Section III, we will propose a new scheme, based on the intersection of several Euclidean objects, for the computation of candidate positions that are *all feasible* at the current layer. Section IV will show some experiments on artificially generated instances, while conclusions will be drawn in Section V.

II. The *i*BP algorithm

Let $G = (V,E,d)$ be an MDGP instance. The subclass of MDGP instances that we consider in this paper is defined as follows. Let $E' \subset E$ be the subset of edges for which their weights d are exact distances.

The interval *Discretizable DGP in dimension 3 (iDDGP$_3$).* Given a simple weighted undirected graph $G = (V,E,d)$, we say that G represents an instance of the *i*DDGP$_3$ if and only if there exists an order on the vertices of V verifying the following conditions:

(a) $G_C = (V_C, E_C) \equiv G[\{1,2,3\}]$ is a clique and $E_C \subset E'$;
(b) $\forall i \in \{4,\ldots,|V|\}$, there exists $\{i',i'',i'''\}$ such that
  1) $i''' < i$, $i'' < i$, $i' < i$;
  2) $\{(i'',i),(i',i)\} \subset E'$ and $(i''',i) \in E$;
  3) $d_{i',i'''} < d_{i',i''} + d_{i'',i'''}$.

Orders satisfying (a) and (b) are named "Discretization Orders". We refer to $\{i''',i'',i'\}$ as *reference atoms*, and to $d_{i''',i}$, $d_{i'',i}$ and $d_{i',i}$ as *reference distances*.

Notice that assumption (a) allows us to place the first 3 atoms uniquely, avoiding to consider congruent solutions that can be obtained by rotations and translations [7]. Assumption (b1) ensures the existence of three reference atoms for every $i > 3$, and assumption (b2) ensures that at most one of the three reference distances may be represented by an interval [12]. Finally, assumption (b3) avoids the reference atoms to be collinear. We remark that assumption (b3) cannot always be verified before the solution of an instance, because some of the necessary distances may not be available (the corresponding edges may not be in E). However, this assumption can fail to be satisfied with probability 0, and therefore we do not really need to verify it in advance [6]. Under these assumptions, the MDGP can be discretized, i.e. the instance at hand belongs to the *i*DDGP$_3$ class. In this case, the search domain becomes a tree, where nodes contain candidate atomic positions, organized layer by layer.

Algorithm 1 The *i*BP algorithm.

```

2:  if (i > n) then
3:    // one solution is found
4:    print current conformation;
5:  else
6:    // coordinate computation
7:    if (d_{i''',i} is an interval) then
8:      compute the two candidate arcs;
9:      add them to the list L;
10:   else
11:     compute the two candidate positions;
12:     add them to the list L;
13:   end if
14:   for h = 1,...,|L| do
15:     if (L(h) is an arc) then
16:       take D samples from the arc; set N = D;
17:     else
18:       set N = 1;
19:     end if
20:     // verifying the feasibility of the computed positions
21:     for k = 1,...,N do
22:       if (x_i^{h,k} is feasible) then
23:         iBP(i+1,n,d,D);
24:       end if
25:     end for
26:   end for
27: end if
```

We employ an *interval* Branch & Prune (*i*BP) algorithm [8] for the solution of discretizable instances. Alg. 1 is a sketch of this algorithm. The *i*BP algorithm performs a recursive search on the tree which represents the search domain. At each recursive call, candidate positions for the current atom are computed by exploiting the coordinates of previously placed atoms and the distance information ensured by the discretization assumptions. When all reference distances are exact, then two candidate positions are computed. When one of the references is an interval, two *feasible arcs* are rather identified (see Fig. 1).

In the algorithm call, i is the current atom for which candidate positions are currently searched, n is the total number of atoms forming the considered molecule, d is the list of available distances (exact and interval distances), and D is the discretization factor, i.e. the number of sample points that are taken from the arcs when the distance $d_{i''',i}$ is represented by an interval (see assumption (b2)). In the algorithm (see lines 9 and 12), we make use of a list L of positions and arcs, from which candidate positions are extracted.

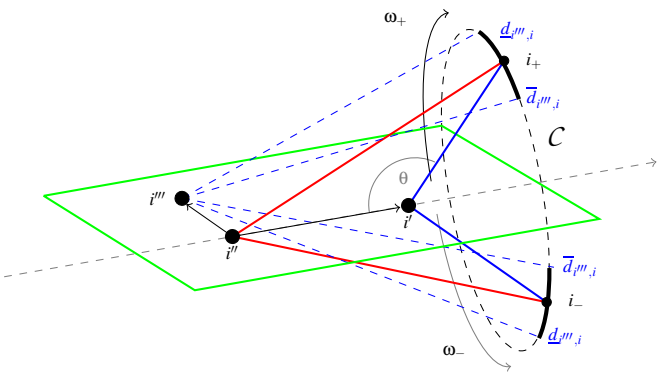

Fig. 1. The two feasible arcs (in bold, black) obtained by intersecting two spheres and one spherical shell.

When working on the atom i, feasible positions for its three reference atoms $\{i''', i'', i'\}$, on the current tree branch, are already available. These reference atoms define a local coordinate system centered at i' [4], [14]. The possible positions for the atom i verifying $d_{i',i}$ and $d_{i'',i}$ can be described by two angles θ_i and ω_i. Using $d_{i'',i'}$ and the cosine law, we can obtain a value for $\theta_i \in [0,\pi]$. Thus, the circle $\mathcal{C}$ of possible positions for atom i (see Fig. 1) can be described in terms of ω_i:

$$x_i(\omega_i) = x_{i'} + U_{i'} w_i, \tag{2}$$

where

$$w_i = \begin{bmatrix} -d_{i',i}\cos\theta_i \\ d_{i',i}\sin\theta_i\cos\omega_i \\ d_{i',i}\sin\theta_i\sin\omega_i \end{bmatrix},$$

$\omega_i \in [0, 2\pi]$, and $U_{i'}$ is the rotation (change of basis) matrix from the local system at i' to the canonical system of coordinates [4].

If $d_{i''',i}$ is exact, at most two values for ω_i, say $\{\omega_i^+, \omega_i^-\}$, can be computed. Two possible positions x_i^+ and x_i^- can be therefore identified for the atom i. These positions are symmetric with respect to the plane defined by the reference atoms. If $d_{i''',i}$ is instead an interval, then two disjoint and symmetric candidate arcs are obtained, as shown in Fig. 1. They correspond to two intervals, $[\underline{\omega}_i^+, \overline{\omega}_i^+]$ and $[\underline{\omega}_i^-, \overline{\omega}_i^-]$, for the angle ω_i. By selecting D equidistant angles in $[\underline{\omega}_i^+, \overline{\omega}_i^+]$ and other D equidistant angles in $[\underline{\omega}_i^-, \overline{\omega}_i^-]$, $2 \times D$ atomic positions for the current atom i can be computed.

In the standard *i*BP, the feasibility of these candidate atomic positions is verified by exploiting the so-called pruning distances. The Direct Distance Feasibility (DDF) is the pruning device that, for each candidate position related to the current atom i, verifies whether the inequality

$$\underline{d}_{ij} - \varepsilon \leq ||\mathrm{x}_i - \mathrm{x}_j|| \leq \overline{d}_{ij} + \varepsilon, \tag{3}$$

is satisfied for each atom $j < i$ that is not involved in the discretization, where $\varepsilon > 0$ is a given tolerance. This way, however, a large number of generated positions may be pruned and only a few of them may be actually feasible. The scheme we propose in this paper aims at overcoming this issue.

Finally, we remark that an essential pre-processing step, before applying the *i*BP, is to find a discretization order for the vertices of the graph G that allow to satisfy the assumptions in the *i*DDGP$_3$ definition. This preprocessing step can be performed efficiently, in polynomial time [11], so that the necessary assumptions can be fulfilled by graphs related to proteins.

III. Adaptive branching in *i*BP

The discretization of the two candidate arcs, used in the standard *i*BP algorithm when interval data are available, represents the simplest way to deal with imprecise information about the distances [8]. The candidate arcs are discretized by considering a finite number of samples in the two intervals $[\underline{\omega}_i^+, \overline{\omega}_i^+]$ and $[\underline{\omega}_i^-, \overline{\omega}_i^-]$, and then a new branch is created for each of them. If D is the discretization factor (see Alg. 1), $2 \times D$ positions are generated, and $2 \times D$ new branches are added to the tree at the current layer. When considering this approach, it is expected that at least one of such samples is able to fulfill the pruning distance constraints at the current layer.

The value given to D plays a critical role. On the one hand, too small values can generate trees where no solutions can be found (all branches are pruned, because no positions are compatible to the pruning distances). On the other hand, too large D values can drastically increase the width of the tree. Unfortunately, no upper bound on D can theoretically be defined: in the case only one specific singleton in the given arcs is actually feasible, only an infinite number of samples could guarantee that this singleton can be discovered. However, this is the worst case scenario: nondegenerate subarcs generally result to be feasible w.r.t. the available pruning distances.

In the standard *i*BP, after the generation of candidate atomic positions, their feasibility is verified by employing pruning devices, such as DDF (see Section II). There are two extreme situations:

1) all positions are feasible: this suggests that we could consider a smaller D value without harming the computations;
2) all positions are infeasible: since a finite number of samples on the two arcs are taken, this information does not allow us to discriminate between "the two arcs are infeasible" and "the chosen samples are infeasible".

The adaptive scheme that we propose was conceived for tailoring the branching phase of the *i*BP algorithm so that all computed candidate positions are feasible at the current layer. The basic idea is to identify, before the branching phase of the algorithm, the subset of positions (if it exists) on the two candidate arcs that is feasible with respect to all pruning distances to be verified at the current layer.

Let us consider expression (2), which is able to give the Cartesian coordinates of the atom i as a function of the torsion angle ω_i. For simplifying the notations, we will omit, in the following, the subscripts of the angles θ_i and ω_i.

In case the distance $d_{i''',i}$ is represented by an interval, i.e. $d_{i''',i} \in [\underline{d}_{i''',i}, \overline{d}_{i''',i}]$, two candidate arcs can be computed (see

Section II). These two arcs correspond to the two interval torsion angles $[\underline{\omega}^+,\overline{\omega}^+] \subset [0,\pi)$ and $[\underline{\omega}^-,\overline{\omega}^-] \subset [\pi,2\pi)$. All points in those two arcs satisfy therefore the interval distance $[\underline{d}_{i''',i},\overline{d}_{i''',i}]$, as well as the two exact distances $d_{i'',i}$ and $d_{i',i}$. However, there can be pruning distances (between already placed atoms and i) that we could exploit for tightening these two arcs. Therefore, instead of using these distances for pruning pre-computed positions, our idea is to exploit pruning distances for tightening the two arcs before sampling, so that all generated positions can be feasible (at least at the current layer).

Tightening the feasible arcs

Let us suppose there is an $h \in \{j < i \mid j \notin \{i''',i'',i'\}\}$, such that the pruning distance $d_{h,i}$ is known. Solutions to the equation

$$d_{h,i} = \|x_h - x_i(\omega)\| \tag{4}$$

give the values for the angle ω that are compatible with the distance $d_{h,i}$. By squaring equation (4), and by using (2), we obtain

$$\begin{aligned} d_{h,i}^2 &= \|x_h - x_i(\omega)\|^2 \\ &= \|x_h - (x_{i'} + U_{i'} w_i)\|^2 \\ &= \|x_h - x_{i'}\|^2 - 2\langle x_h - x_{i'},\ U_{i'} w_i\rangle + \|U_{i'} w_i\|^2, \end{aligned}$$

where $\langle\cdot,\cdot\rangle$ denotes the inner product between two vectors. Since $U_{i'}$ is an orthogonal matrix, we have

$$d_{h,i}^2 = \|x_h - x_{i'}\|^2 - 2\langle x_h - x_{i'},\ U_{i'} w_i\rangle + d_{i',i}^2.$$

Let $v = x_h - x_{i'}$ and let $\hat{x},\hat{y},\hat{z}$ be the columns of $U_{i'}$. Then:

$$\begin{aligned} d_{h,i}^2 &= \|v\|^2 - 2\langle v,\ U_{i'} w_i\rangle + d_{i',i}^2 \\ &= \|v\|^2 + d_{i',i}^2 - 2\langle v, (-d_{i',i}\cos\theta)\hat{x} + \\ &\quad (d_{i',i}\sin\theta\cos\omega)\hat{y} + (d_{i',i}\sin\theta\sin\omega)\hat{z}\rangle \\ &= \|v\|^2 + d_{i',i}^2 - 2\big(\langle v,\hat{x}\rangle(-d_{i',i}\cos\theta) + \\ &\quad \langle v,\hat{y}\rangle(d_{i',i}\sin\theta)\cos\omega + \langle v,\hat{z}\rangle(d_{i',i}\sin\theta)\sin\omega\big). \end{aligned}$$

If we set

$$A = 2\langle v,\hat{y}\rangle(d_{i',i}\sin\theta), \tag{5}$$

$$B = 2\langle v,\hat{z}\rangle(d_{i',i}\sin\theta),$$

$$\Delta = \|v\|^2 + d_{i',i}^2 + 2\langle v,\hat{x}\rangle(d_{i',i}\cos\theta),$$

and

$$C = \Delta - d_{h,i}^2,$$

we obtain the following equation:

$$A\cos\omega + B\sin\omega = C. \tag{6}$$

Solving $A\cos\omega + B\sin\omega = C$

In order to solve equation (6), we consider the following approach. We set

$$A = R\cos\alpha, \tag{7}$$

$$B = R\sin\alpha, \tag{8}$$

and, in order to obtain R, we square and sum the two equations (7) and (8):

$$A^2 + B^2 = R^2\cos^2\alpha + R^2\sin^2\alpha = R^2(\cos^2\alpha + \sin^2\alpha) = R^2.$$

If we consider the positive square root (R can be seen as the length of a triangle side), we have

$$R = \sqrt{A^2 + B^2}.$$

If $A \neq 0$, we can divide (8) by (7), and obtain

$$\frac{B}{A} = \frac{\sin\alpha}{\cos\alpha} = \tan\alpha,$$

or, equivalently

$$\alpha = \tan^{-1}\left(\frac{B}{A}\right).$$

The correct quadrant for α can be identified by checking the signs of $\cos\alpha$ and $\sin\alpha$.

Notice that, when both A and B are zero, we can have either no solutions or an infinite number of solutions. When $A = B = 0$, then $v = x_h - x_{i'}$ is on the $\hat{x}$ axis, because $\sin\theta \neq 0$ (assumption (b3)) and $d_{i',i} > 0$ (see equation (5)). Atoms h,i'',i' are therefore aligned and the sphere centered in x_h does match with the whole dashed circle $\mathcal{C}$ (when there are infinite solutions) or does not (when there are no solutions). If $A = 0$ and $B \neq 0$, then $\cos\alpha = 0$ and α is either $\pi/2$ or $-\pi/2$, depending on the sign of B.

When $A \neq 0$, from equations (6), (7) and (8), we can obtain

$$\begin{aligned} A\cos\omega + B\cos\omega &= R\cos\alpha\cos\omega + R\sin\alpha\sin\omega \\ &= R\cos(\omega - \alpha), \end{aligned}$$

and hence

$$R\cos(\omega - \alpha) = C,$$

which is

$$\omega = \alpha \pm \cos^{-1}\left(\frac{C}{R}\right). \tag{9}$$

Therefore, we usually have two solutions for equation (6) in $[0,2\pi)$. There are two exceptions. When $C = R$, we have only one solution; when $C/R \notin [-1,1]$, there are no intersection points.

Solutions to equation (6) (and therefore to equation (4)) provide the points where the sphere, centered at x_h and with radius $d_{h,i}$, intersects the circle $\mathcal{C}$ in Fig. 1. Those points are the extreme points of the feasible arcs: they define feasible intervals for the angle ω. Fig. 2 shows some possible intersections between the spherical shell centered in x_h (having minimum radius $\underline{d}_{h,i}$ and maximum radius $\overline{d}_{h,i}$) with the dashed circle $\mathcal{C}$.

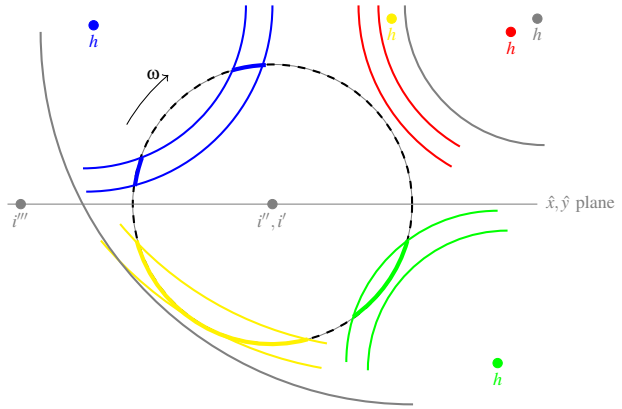

Fig. 2. Possible intersections between the spherical shell related to the distance $d_{h,i}$ and the circle of candidate positions related to $d_{i',i}$ and $d_{i'',i}$.

Managing different scenarios

The feasible positions for the current atom i can be obtained by intersecting the two arcs (computed by using the discretization distances, in bold in Fig. 1) and several spherical shells, each of them defined by considering a pruning distance between $h < i$ and i. In order to perform this intersection, the following two equations need to be solved

$$A\cos\omega + B\sin\omega = \Delta - \underline{d}^2_{h,i}, \tag{10}$$

$$A\cos\omega + B\sin\omega = \Delta - \overline{d}^2_{h,i}, \tag{11}$$

for every pruning distance $d_{h,i}$. There are three situations that can occur while performing the intersections (i.e. while solving equations (10) and (11)).

Both equations have no solutions: If both equations (10) and (11) have no solutions, then the entire candidate circle is either completely valid, or completely invalid. If we can find at least one value for ω such that

$$\underline{d}^2_{h,i} < \|x_h - x_i(\omega)\|^2 < \overline{d}^2_{h,i},$$

then the entire circle $\mathcal{C}$ is feasible w.r.t. the distance $d_{h,i}$. If not, it is sufficient to verify whether one of these 2 equations is satisfied

$$\max_{\omega\in[0,2\pi]} \|x_h - x_i(\omega)\|^2 < \underline{d}^2_{h,i},$$

$$\min_{\omega\in[0,2\pi]} \|x_h - x_i(\omega)\|^2 > \overline{d}^2_{h,i},$$

for stating that the entire circle is infeasible.

Only one equation has solutions: Let us suppose that only equation (10) has solutions. In this case, the resulting intersection is an interval $[\underline{\omega}, \overline{\omega}]$ whose extreme points are the solutions of equation (10). In order to find the right orientation of the arc on the circle $\mathcal{C}$, we define the function

$$F(\omega) = \|x_h - x_i(\omega)\|^2 = \Delta - A\cos\omega - B\sin\omega,$$

and we consider its derivative

$$F'(\omega) = A\sin\omega - B\cos\omega. \tag{12}$$

The orientation at an extreme point (solution of (10)) is the one for which $F(\omega)$ increases, and this information is given by (12) evaluated in such an extreme point. Notice that we might need to add 2π to one of the extreme points in order to have $\overline{\omega} > \underline{\omega}$. The analysis in the case in which only equation (11) has solutions is analogous.

Let $[\underline{\omega^*}, \overline{\omega^*}]$ be the obtained interval for ω. If this interval has an empty intersection with the two initial arcs in $\mathcal{C}$, then there are no feasible positions, and the current branch of the search domain can be pruned. If this intersection is instead non-empty, then the result provides the interval for ω that is feasible w.r.t the discretization distances, as well as the pruning distance $d_{h,i}$. Notice that, when more than one pruning distance is available, the same procedure can be repeated as many times as the number of available pruning distances.

Both equations have solutions: When both equations (10) and (11) have solutions, we obtain four values for ω: two from equation (10) and other two from equation (11). Two intervals can be therefore defined for ω, related to two arcs in $\mathcal{C}$. Both arcs need to be intersected with the initial arcs. The procedure to apply is analogous to the one presented for the previous case.

iBP and the new adaptive scheme

After considering all pruning distances, after performing all intersections, the final result provides a list of arcs on $\mathcal{C}$ that are feasible with all the distances that can be verified at the current layer of the *i*BP tree. All positions that can be taken from these arcs are feasible at the current layer: all of them generate a new branch and may serve as a reference for computing new candidate positions on deeper layers of the tree. In order to integrate the *i*BP algorithm with this adaptive scheme, there are two main changes to be performed on Alg. 1. On line 8 and 11, the adaptive scheme needs to be invoked for taking into consideration the information about the pruning distances. Moreover, line 22 needs to be removed, because this verification is not necessary anymore (unless other pruning devices rather than DDF are employed).

IV. Computational Experiments

Experiments of Nuclear Magnetic Resonance (NMR) [10] are able to provide estimates of some relative distances between pairs of atoms of a molecule. We present in this section some computational experiments on artificially generated NMR instances, where we compare the standard *i*BP algorithm to the new *i*BP integrated with our adaptive scheme for the generation of feasible atomic positions (accordingly to all available distances at the current tree layer). In this work, we do not consider real NMR data because the experiments here presented have the only aim of showing the advantages in using this new adaptive scheme. Later on, this scheme will be integrated in a more general framework capable of dealing with real NMR data. All codes were written in C programming language and all the experiments were carried out on an Intel Core 2 Duo @ 2.4 GHz with 2GB RAM, running Mac OS

TABLE I
EXPERIMENTS ON OUR ARTIFICIALLY GENERATED NMR INSTANCES.

X. The codes have been compiled by the GNU C compiler v.4.0.1 with the `-O3` flag.

The instances that we consider in the experiments have been generated as follows. We consider a subset of proteins from the Protein Data Bank (PDB) [1] that are related to human immunodeficiency. Together with the coordinates of the atoms available on the PDB, we suppose having the chemical structure of the protein, i.e. information about bond lengths and angles. Once the coordinates are loaded from the PDB files, we compute all distances between atom pairs belonging to the protein backbone, and we add a distance in our instances if the computed distance is between:

1) two bonded atoms (considered as exact);
2) two atoms that are bonded to a common atom (considered as exact);
3) two atoms belonging to a quadruplet of bonded atoms forming a torsion angle (considered as an interval);
4) two hydrogen atoms (considered as an interval, if the distance belongs the interval [2.5,5] Å).

We remark that the first 3 items are related to the chemical structure of the molecule; only the last item concerns distances that simulate NMR data. The distances that are derived from the information mentioned in item 3 are generally intervals; however, when one of the possible torsion angles is related to the peptide bond (that connects pairs of consecutive amino acids), the distance is considered as exact, because the peptide bond forces all atoms to lie on the same plane. Interval distances coming from torsion angles are computed so that all possible values for the torsion angle are allowed. The interval distances related to item 4 have instead length equal to 2Å, and their bounds were generated so that the *true* distance is randomly placed inside the interval. After the computation of the distance information, the atoms in every instance have been reordered by considering the discretization order published in [11], which is valid for every protein backbone.

In Table I we compare the performance of the previous version of *i*BP [8] with our new one, where the adaptive branching scheme presented in Section III is implemented. For each instance, we report the label of the corresponding file on the PDB, the total number $|V|$ of atoms and the number $|E|$ of available distances. Moreover, for each *i*BP version, we report the number D of samples to be taken from each candidate arc, the number of *i*BP calls and the CPU time in seconds, that are necessary to find one solution. In the DDF pruning device (equation (3)), the used tolerance ε is 10^{-3}.

The D values in Table I are actually the smallest ones for which *i*BP could find at least one solution in a given time limit (10 seconds in these experiments). When using our adaptive branching scheme, the D value never increased and it was reduced in some cases. This was expected because our adaptive scheme is able to guide the sample points in the feasible regions of the candidate arcs. Even if the computation of the intersections may increase the computational cost for single *i*BP recursive calls, the overall CPU time for each experiment is lower when the adaptive scheme is employed. This is due to the fact that, when the branching phase in *i*BP is adaptive, only feasible coordinates are generated: there are no useless computations (i.e. computed positions that are immediately discarded).

V. CONCLUSIONS

We proposed a new adaptive branching scheme that was integrated in the *i*BP algorithm to solve discretizable MDGPs with interval data. When interval data are used in the discretization process, candidate positions for the current atom are generally represented by two candidate arcs. By exploiting the interval pruning distances that can be verified at the current layer, we can guide the branching phase of the *i*BP algorithm to take samples only on the feasible regions of the candidate arcs.

As it was assessed by our computational experiments, this approach improves the overall performances of the *i*BP algorithm, thereby improving its robustness. Using the intersections of the spherical shells defined by the pruning distances with the candidate arcs provided by the discretization, we avoid the generation of useless samples in infeasible portions of the candidate arcs.

However, it is important to mention that, as in the previous *i*BP version, the presented scheme does not guarantee that the chosen sample positions can lead to feasible positions at further layers: our scheme ensures the feasibility only up to the current layer. Predicting the compatibility of sample positions with the atoms that *follow* the current one is a topic of future research.

***Abstract*—This paper presents a theory and an empirical evaluation of Higher-Order Quantum-Inspired Genetic Algorithms. Fundamental notions of the theory have been introduced, and a novel Order-2 Quantum-Inspired Genetic Algorithm (QIGA2) has been developed. Contrary to all QIGA algorithms which represent quantum genes as independent qubits, in higher-order QIGAs quantum registers are used to represent genes strings, which allows modelling of genes relations using quantum phenomena. Performance comparison has been conducted on a benchmark of 20 deceptive combinatorial optimization problems. It has been presented that using higher quantum orders is beneficial for genetic algorithm efficiency, and the new QIGA2 algorithm outperforms the old QIGA algorithm tuned in highly compute-intensive metaoptimization process.**

I. Introdution

RESEARCH on quantum-inspired computational intelligence techniques was started by Narayann[1] in 1996, and the first proposal of Quantum-Inspired Genetic Algorithm (QIGA1) has been presented by Han and Kim in [2]. Quantum-Inspired Genetic Algorithms belong to a new class of artificial intelligence techniques, drawing inspiration from both evolutionary[3] and quantum[4] computing. Current literature on the subject consists of about a few hundreds scientific papers. Only a few papers attempt to theoretically analyse the properties of that class of algorithms. Among those there are i.a. [22,28], which has been emphasized in conclusions of recent comprehensive surveys [18,29].

In QIGA algorithms, representation and genetic operators are based on computationally useful aspects of both biological evolution and unitary evolution of quantum systems. QIGA algorithms use quantum mechanics concepts including qubits and superposition of states. QIGA algorithms have been successfully applied to a broad range of search and optimization problems[5,6,7]. The algorithms have demonstrated their particular efficacy for solving complex optimization problems. Recent years have witnessed successful applications of Quantum-Inspired Genetic Algorithms in a variety of fields, including image processing[8,9,10], flow shop scheduling[11,12], thermal unit commitment[13,14], power system optimization[15,16], localization of mobile robots[17] and many others.

For a current and comprehensive survey of Quantum-Inspired Genetic Algorithms and the necessary background of Quantum Computing and Quantum-Inspired Computational Intelligence techniques, the reader is referred to [1,2,18,29].

This work was supported in part by PL-Grid Infrastructure

This paper is structured as follows. In Section 1, an introductory background and the most important references for the subject field have been given. In Section 2, the theory of Higher-Order Quantum-Inspired Genetic Algorithms has been presented. In Section 3, details of the original Order-2 Quantum-Inspired Genetic Algorithm have been provided. In Section 4, experimental results have been provided and evaluated. In Section 5, the article has been briefly summarized, final conclusions have been drawn, and also possible directions for future research have been suggested.

II. Theory of Higher-Order Quantum-Inspired Genetic Algorithms

Let $N \in \mathbb{N}^+$ denote the length of chromosomes in the algorithm (i.e. problem size), X – search space of the optimization problem, Q – quantum population (a set of quantum individuals in QIGA algorithm), and P – classical population (a set of elements in X space). Let us assume that each individual in the algorithm consists of a single quantum chromosome.

We introduce the following new notions.

Definition 1 (quantum order $r \in \mathbb{N}^+$): the size of the biggest quantum register used in the algorithm.

$$1 \leq r \leq N \tag{1}$$

We say an algorithm is Order-r, if r is the size of the biggest quantum register used in that algorithm. All Quantum-Inspired Genetic Algorithms that use independent qubits to represent binary genes are Order-1. All existing algorithms, presented in the literature so far are Order-1 in terms of this theory. To simplify the further discussion, let us assume that all quantum registers used in the algorithm have the same size.

Definition 2 (relative quantum order w): – the ratio of quantum order r to quantum chromosomes length N (problem size) in the algorithm.

$$w = \frac{r}{N} \in (0, 1] \tag{2}$$

If a certain QIGA algorithm uses a representation of solutions based on 100 independent qubits (binary quantum genes), the relative quantum order for that algorithm is $w = \frac{1}{100}$. If the size of a problem (the number of binary variables) is $N = 60$, and the representation is based on 3-qubit registers, then the relative quantum range is $w = \frac{3}{60} = 0.05$ etc.

The algorithms characterised by $w = 1$ are "true" quantum algorithms, where a single quantum register contains all the

978-83-60810-58-3/$25.00

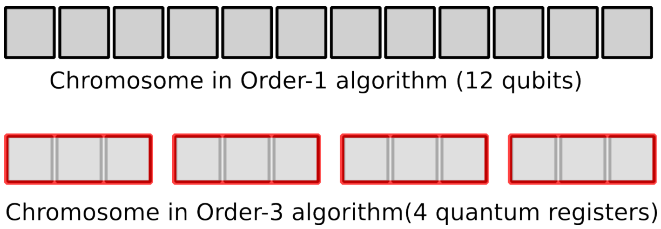

Fig. 1. Examples of chromosomes of length $N = 12$ for Order-1 and Order-3 algorithms. Consecutive genes are joined to r-qubit quantum registers. In Order-1 algorithm, the chromosome consists of 12 independent qubits, each one is a unit vector in 2-dimensional space. In Order-3 algorithm, the chromosome consists of 4 quantum registers, each one is a unit vector in $2^3 = 8$-dimensional space.

binary variables. For $w = 1$, when the number of binary variables (the size of the problem N) grows linearly, the cost of simulation grows exponentially (which corresponds to a simulation of a real quantum computer).

Definition 3 (quantum factor $\lambda \in [0, 1]$): For a given algorithm, the quantum factor is defined as a ratio of the dimension of space in a given class of algorithms to the dimension of space of the full quantum register of N qubits. Additionally, if there are no quantum elements in the algorithm (e.g. a simple genetic algorithm SGA[30], operating in a discrete space of binary strings), then $\lambda = 0$.
Thus, the numerical value of the factor is expressed as:

$$\lambda = \frac{2^r \frac{N}{r}}{2^N} = \frac{2^r}{w2^N} \tag{3}$$

where r is the quantum order of an algorithm and N is the problem size. The 2^r in the numerator of the above formula corresponds to the dimension of the state space in the r-qubit quantum register (the biggest quantum register used in an algorithm of that class). Such quantum register codes a 2^r-point probability distribution (it shows the probability of choosing one from 2^r elements of a solution space X). 2^N corresponds to the dimension of the state space of a quantum register containing all N qubits.

In Order-1 algorithms, chromosomes consist of N independent qubits. According to the Quantum Computing theory the state of each qubit is described by a unit vector in a 2-dimensional space ($|q\rangle = [\alpha \ \ \beta]^T$), so the space dimension for the chromosomes in such algorithms is $2^r \frac{N}{r} = 2N$.

In Order-2 algorithms, chromosomes consist of $\frac{N}{2}$ size-2 quantum registers. The state for each register is described by a unit vector in a 4-dimensional space ($|q\rangle = [\alpha_0 \ \alpha_1 \ \alpha_2 \ \alpha_3]^T$). Therefore, the dimension of space for the chromosomes in such algorithms is also $2^2 \frac{N}{2} = 2N$. However, in Order-1 algorithms only one qubit coordinate might be independently modified (one degree of freedom), while in Order-2 algorithms the same can be done with 3 out of 4 coordinates of the 2-qubit quantum register state. Consequently, it allows for modelling of relations between two neighbouring genes joined in a common register.

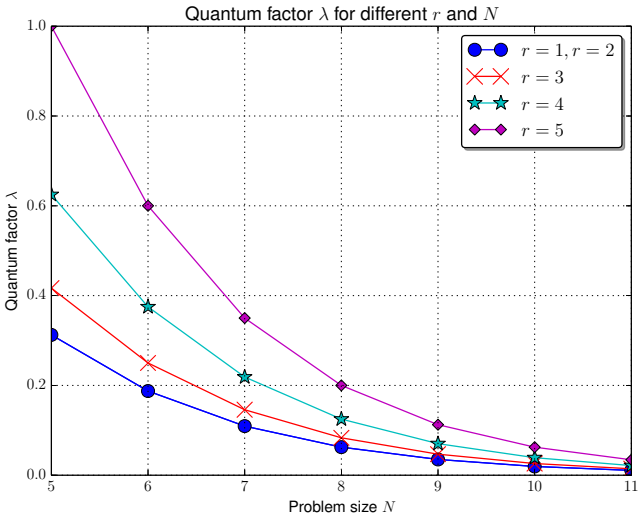

Fig. 2. Quantum factor λ for different problem size N and different quantum orders $r \in \{1, 2, 3, 4, 5\}$

For even Higher-Order algorithms ($r \geq 3$), simulating quantum element makes the algorithm exponential computational complexity. Relationship between quantum factor λ, quantum order r for growing problem size N has been presented in Figure 2.

It should be noted that for $r = 1$ (all regular Order-1 QIGA algorithms):

$$\lambda = \frac{2^1 \frac{N}{1}}{2^N} = \frac{2 \cdot N}{2^N}$$

Thus, for example, in an algorithm coding solutions in the form of 10-element strings of independent qubits, $\lambda = \frac{20}{2^{10}} \approx 0.02$. It means that the size of space in such algorithm comprises 2% of the full quantum register state space, which would include 10 binary variables. Together with the increase of size of a problem N and for a constant quantum order $r = 1$, the quantum factor decreases exponentially and becomes $\lambda < 10^{-10}$ for $N = 50$.

For that reason, for a constant quantum order $r = 1$ (QIGA Order-I quantum-inspired algorithms) and for an increasing size of a problem N, the quantum factor λ has a limit that equals zero:

$$\lim_{\substack{r=1 \\ N \to \infty}} \lambda = \lim_{\substack{r=1 \\ N \to \infty}} \frac{2 \cdot N}{2^N} = 0$$

However, for $r = N$ (typical quantum algorithms)

$$\lambda = \frac{2^N \frac{N}{N}}{2^N} = \frac{2^N}{2^N} = 1 \tag{4}$$

For $\lambda = 1$, when the number of variables (the size of a problem N) grows linearly, the cost of simulation grows exponentially (which corresponds to a full simulation of a real quantum computer).
Thus, algorithms can be classified according to quantum factor λ value as follows:

Algorithm 1 Order-2 Quantum-Inspired Genetic Algorithm

1: $t \leftarrow 0$
2: Initialize quantum population $Q(0)$
3: **while** $t \leq t_{max}$ **do**
4: $t \leftarrow t + 1$
5: Generate $P(t)$ by observing quantum pop. $Q(t-1)$
6: Evaluate classical population $P(t)$
7: Update $Q(t)$
8: Save best classical individual to b
9: **end while**

1) $\lambda = 0$ – a classical algorithm without any quantum elements, operating in a discrete finite space (e.x. SGA[30] operating in finite discrete binary strings space).
2) $\lambda \in (0, 1)$ – a quantum-inspired algorithm, like QIGA1 (order $r = 1$), or higher-order algorithm.
3) $\lambda = 1$ – a "true" quantum algorithm which requires either a real quantum level hardware, or an exponential complexity simulation on classical computer.

Order-r Quantum-Inspired Genetic Algorithms are capable of modelling relations between separate genes which are joined into the same quantum register of size r. This allows the algorithm to work better for deceptive combinatorial optimization problems and to better solve strong epistasis in deceptive problems. This is presented empirically the next sections of the paper.

III. Order-2 Quantum-Inspired Genetic Algorithm

In this section, a novel Order-2 Quantum-Inspired Genetic Algorithm (QIGA2) has been presented. The algorithm has been developed based on the theory of higher-order quantum-inspired algorithms presented in the previous section.

Pseudocode of the algorithm has been presented in Algorithm 1, and in general it is very similar to a typical evolutionary algorithm scheme. The general principle of operation of the algorithm is very similar to the initial QIGA 1 algorithm, but instead of independent qubits modelling successive binary genes, the QIGA 2 algorithm uses 2-qubit quantum registers representing successive pairs of genes.

In each generation of the algorithm a classic population P (a set of elements from the solution space X) is sampled through observation of quantum states of the quantum population Q i.e. $|P|$-times repeated sampling of the space X according to probability distributions stored in Q. The classical population P is then evaluated exactly as in a typical evolutionary algorithm. The quantum population Q, however, is updated in consecutive generations in such a way that it increases the probability of sampling the best solution b neighbourhood, which has been recorded in previous generations of P.

The key new elements distinguishing QIGA2 from the previous Order-1 algorithms are the modified method of representing solutions and the new genetic operators working in a space of a higher dimension and described by 4×4 unitary matrices in the quantum-mechanic sense. Both original elements have been described in the next subsections respectively.

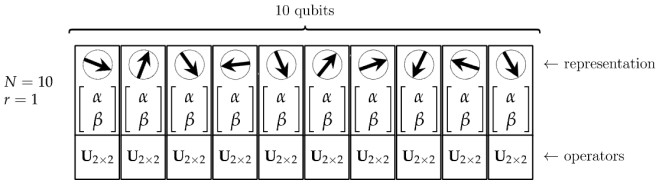

Fig. 3. In QIGA1, representation is based on isolated qubits / binary quantum genes

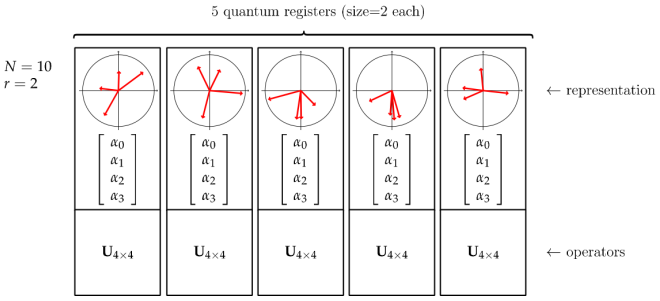

Fig. 4. In QIGA2, quantum registers are used to represent pairs of genes

A. Representation of solutions in QIGA2

The fundamental difference between the already existing QIGA1 and QIGA2 algorithms lies in the way they represent solutions. In QIGA1 algorithms, quantum genes are modelled with qubits i.e. two-level quantum systems $|q\rangle = \alpha|0\rangle + \beta|1\rangle = [\alpha \quad \beta]^T$ which are able to code two-point probability distributions. It corresponds to a possibility of each gene to have a value 0 or 1 with a probability of $|\alpha|^2$ and $|\beta|^2$ accordingly. It has been depicted in Figure 3.

In the authors' QIGA2 algorithm, the representation of solutions is based on using the adjacent 2-qubit quantum registers. For that purpose the adjacent genes are consecutively paired. The corresponding 2-qubit registers $|q\rangle = [\alpha_0 \quad \alpha_1 \quad \alpha_2 \quad \alpha_3]^T$ code 4-point probability distributions. So, in a single quantum register 4 values of probability $|\alpha_0|^2$, $|\alpha_1|^2$, $|\alpha_2|^2$, $|\alpha_3|^2$ are recorded. These are probabilities of having a value of 00, 01, 10 and 11 for each given pair of genes accordingly. It is presented in Figure 4. Similarly to QIGA1 algorithms, the proposed QIGA2 uses only the real parts of probability amplitudes. It ignores the imaginary part of amplitudes $\alpha_0, \ldots, \alpha_3$.

At the stage of the $Q(0)$ base population initialization, all genes can be given the value of $q_{ij} = [\frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2}]^T$, which corresponds to a situation when the algorithm samples the entire solution space X with the same probability.

B. Order-2 quantum genetic operators

The second original element of the QIGA2 algorithm is the use of genetic operators. In the QIGA1 algorithm genetic operators are created by unitary 2×2 quantum gates (thanks to the limiting of the amplitudes to a set $\mathbb{R}$, they become just matrices of a normalised state vector rotation on a plane). By contrast, in the QIGA2 algorithm the genetic operators can be described by 4×4 quantum gates in the quantum-mechanical sense.

Algorithm 2 Observation of genes pair in QIGA2

Require: $q_{ij} = [\alpha_0 \quad \alpha_1 \quad \alpha_2 \quad \alpha_3]^T$ – quantum register of 2 qubits

```
r ← uniformly random number from [0,1]
if r < |α0|^2 then
    p ← 00
else if r < |α0|^2 + |α1|^2 then
    p ← 01
else if r < |α0|^2 + |α1|^2 + |α2|^2 then
    p ← 10
else
    p ← 11
end if
```

Algorithm 3 Update of quantum genes states in QIGA2

```
for i in 0, ..., |Q| − 1 do
    for j in 0, ..., N/2 do
        q' = [0 0 0 0]^T
        bestamp ← j-th pair of binary genes in b as decimal
        sum ← 0
        for amp in {0, 1, 2, 3} do
            if amp ≠ bestamp then
                q'[amp] ← μ · q_ij
                sum ← sum + (q'[amp])^2
            end if
        end for
        q'[bestamp] ← sqrt(1 − sum)
        q_ij ← q'
    end for
end for
```

The pseudocode for the operation of measuring the states of a 2-qubit quantum register $q_{ij} = \alpha_0|00\rangle + \alpha_1|01\rangle + \alpha_2|10\rangle + \alpha_3|11\rangle = [\alpha_0 \quad \alpha_1 \quad \alpha_2 \quad \alpha_3]^T$ coding a pair of classic binary genes is presented in the Algorithm 2. The observation function returns strings of binary genes 00, 01, 10 and 11 with a probability of $|\alpha_0|^2$, $|\alpha_1|^2$, $|\alpha_2|^2$ oraz $|\alpha_3|^2$ respectively.

Algorithm 3 presents the pseudocode of the proposed new genetic operator (observing the state of a 2-qubit quantum gene) in QIGA2. Index i of the main operator's loop iterates through all the individuals in the quantum population $q_0, \ldots, q_{|Q|-1}$. Index j iterates through all the consecutive *pairs* of genes $j \in \{0, 1, \ldots N/2\}$ of a given quantum individual q_i. Within these loops, a new state q' of the quantum gene pair number j of the character q_i is calculated.

The update is performed in the following manner: If the amplitude $\alpha_{amp}(amp \in \{0, 1, 2, 3\})$ does not correspond to a j-th pair of bits of the currently best found individual b, the amplitude is decreased (amplitude contraction) according to the rule: $q_{ij}[amp]' = \mu \cdot q_{ij}[amp]$, where $\mu \in (0, 1)$ is the algorithm's parameter. The amplitude of a pair of bits on position j in the best individual b is modified to preserve the normalization condition of the state vector (i.e. unit sum of probabilities $\sum_{amp=0}^{3} |\alpha_{amp}|^2 = 1$).

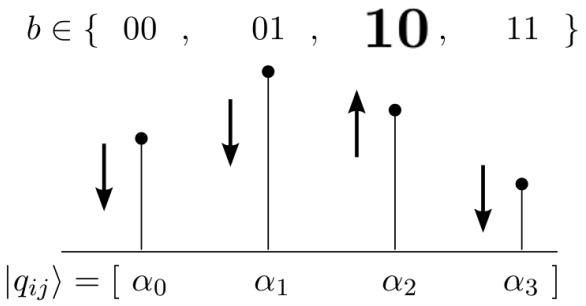

Fig. 5. The new quantum genetic operator idea in QIGA2

Based on empirical experiments it has been established that the the best efficacy of an algorithm is achieved for the parameter value $\mu \approx 0.99$. In order to further increase the efficacy, the value of the parameter μ in the QIGA2 algorithm might be subject to metaoptimalisation (similarly to [19,20,21,31]).

The way the new operator works is illustrated in Figure 5. The vertical bars represent probability amplitudes $|\alpha_0|^2, |\alpha_1|^2, |\alpha_2|^2, |\alpha_3|^2$. If on the position $j \in \{0, 1, \ldots, \frac{N}{2}\}$ of the individual b there is a pair of bits 10, all the amplitudes get contracted by the factor of μ, except for α_2 which will increase. If on the position j of the individual b there is a pair of bits 00, all the amplitudes get contracted by the factor of μ, except for α_0, which will increase etc. Therefore, the only amplitude that increases is the one that corresponds to the j-th pair of bits in the best individual b. This makes the algorithm converge to the best individual b gradually, but also doing global exploration of the search space X.

Simplicity is an unquestionable advantage of the QIGA2 algorithm. It is not only simpler than QIGA1, but also less complicated than its later modified variants, whose authors also tried improve on the efficacy of the original algorithm. It should be noted that in QIGA2 the use of the Lookup Table (used in the original Han's QIGA1 algorithm[2]) has been eliminated completely.

IV. Numerical experiments

For empirical comparison of the algorithms performance, there was used a benchmark consisting of a broad set of 20 recognized combinatorial optimization problems of different sizes $N \in \{48, 90, \ldots, 1000\}$, encoded in the form of the NP-complete SAT. Objective of the combinatorial optimization process was to find a binary string that have maximum fitness value. The benchmark has been taken from [32], and all details about the test functions are available there.

The compared algorithms were SGA[30], the original QIGA1[2], the QIGA1 tuned in meta-optimization process[31] and the authors' QIGA2. Numerous publications to date present that QIGA1 is more effective than other modern stochastic search methods and hence its comparison to other algorithms has been omitted in this paper as it has been assumed to be superior to other newest algorithms.

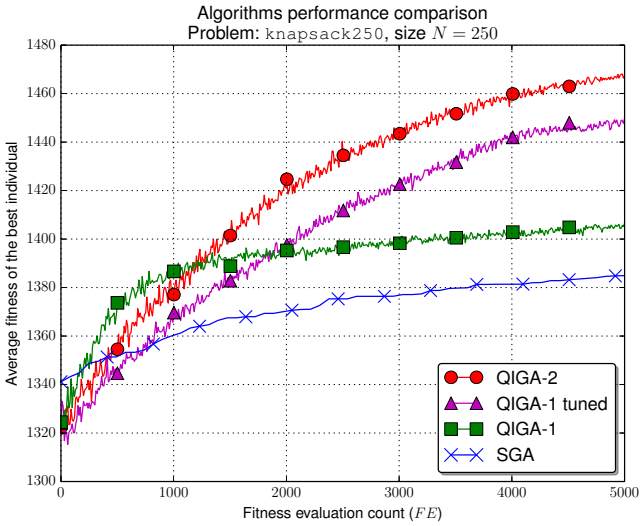

Fig. 6. Detailed comparison of the algorithms for a selected problem knapsack, size $N = 250$

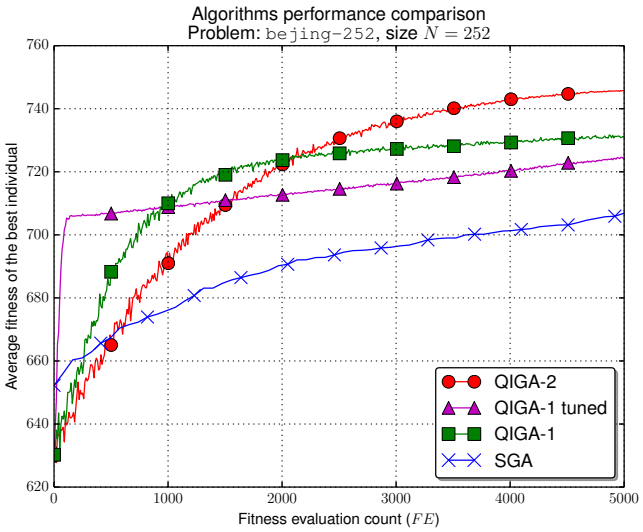

Fig. 7. Detailed comparison of the algorithms for a selected problem bejing, size $N = 252$

The classic SGA algorithm was run with its typical parameters values taken from [30]: the population size was set to 100 individuals (binary solutions), evolving for 50 generations. Thus, the total number of fitness evaluations was equal in all algorithms, and the stopping criterion was maximum number of fitness evaluations $MaxFE = 5000$. In SGA, single point crossover operator with probability $P_c = 0.65$ and mutation operator with probability $P_m = 0.05$ were used. The selection was based on the roulette wheel method. Implementation of SGE algorithm was taken from the external PyEvolve library [26] The parameters for the original QIGA1 algorithm were taken from [2] as were the parameters for the tuned QIGA1, where the only changed parameters were those that had been meta-optimized. The QIGA2 algorithm was run with the value of the parameter $\mu = 0.9918$. For each of the test problem, each algorithm was run 50 times.

As a means for evaluating the algorithms efficacy the authors used the fitness value of the best individual after the number of generations which reached the 5000th call of the fitness evaluation function. Because of stochastic nature of evolutionary algorithms, that value was later averaged for 50 runs of a given algorithm.

In Table 1, the results for each algorithm are presented. **In 17 out of 20 test problems (85%), the authors' QIGA2 algorithm presented on average a better solution than both the original and the tuned QIGA1 algorithm.** Table 2 presents a ranking of the compared algorithms ordered according to the number of test problems for which a given algorithm achieved the best result comparing to algorithms. Figures 6-8 present a detailed comparison of the algorithms performance for three selected test problems of size $N = 250$, $N = 1000$ and $N = 252$. The graph shows the mean value of the best solution found by each of the algorithms versus number of calls of the individual fitness evaluation function.

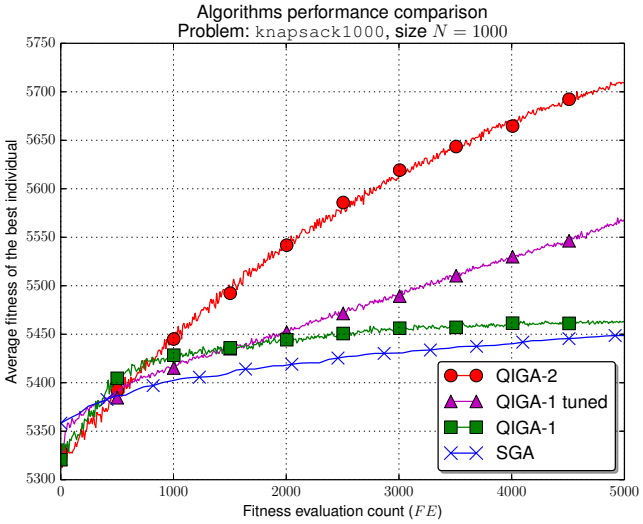

Fig. 8. Detailed comparison of the algorithms for a selected problem knapsack, size $N = 1000$

The presented data is averaged for 50 runs of each algorithm.

Thanks to the simplification of the algorithm and, specifically, owing to the elimination of the LookupTable, also **the implementation of QIGA2 algorithm is 15-30% faster than that of the QIGA1** (the algorithms were implemented in the same programming languages, with the same compiler versions and on the same hardware platforms).

V. Conclusions

In this paper, fundamentals of Higher-Order Quantum-Inspired Genetic Algorithms have been presented. The authors' original QIGA2 algorithm has been created on the basis of this theory. The paper introduces a new way of representing solutions using adjacent quantum registers and

a new genetic operator working in the space of a higher dimension in quantum-mechanical sense. Based on empirical data gathered from 20 varied deceptive test problems of diverse sizes $N \in \{48, \ldots, 1000\}$, it has been shown that the authors' QIGA2 algorithm achieves a better performance than both the original and the tuned QIGA1 algorithms. Consequently, it shows that using quantum order $r = 2$ is a method for improving the performance of Quantum-Inspired Genetic Algorithms. Further investigations may include the application of the presented theory of Higher-Order Quantum-Inspired Genetic Algorithms to a very important field of problems of numerical optimization.

***Abstract*—A deoxyribonucleic acid (DNA) sequence can be represented as a sequence with 4 characters. If a particular property of the DNA is studied, for example, GC content, then it is possible to consider a binary sequence. In many cases, if the probabilistic properties of a segment differ from the neighbouring ones, this means that the segment can play a structural role. Therefore, DNA segmentation is given a special attention, and it is one of the most significant applications of change-point detection. Problems of this type also arise in a wide variety of areas, for example, seismology, industry (e.g., fault detection), biomedical signal processing, financial mathematics, speech and image processing. In this study, we have developed a Cross-Entropy algorithm for identifying change-points in binary sequences with first-order Markov dependence. We propose a statistical model for this problem and show effectiveness of our algorithm for synthetic and real datasets.**

I. Introduction

THE eukaryotic genomes are packaged into nucleosomes, composed of approximately 147 base pairs. There are 4 different bases: adenine (A), cytosine (C), guanine(G) and thymine (T). We can consider different approaches to base partition that depend on chemical and physical structure. One type of separation is pyrimidines (T and C) and purine (A and G). The second type of separation is keto (T and G) and amino (A and C) groups. In this paper, we consider groups of complemental bases: GC and AT pairs.

In this study, we are interested in finding regions that differ from neighbouring ones in GC level. It is well-known that genomic sequences are nonhomogeneous with respect to GC level, differences in GC proportion may be over scale of 100 kb to megabases. These long segments are called GC-content domains or isochores [1], [2]. Many studies propose that the differences of GC proportion appear as an outcome from a selection process [3]. It is well-known that an average GC proportion in chromatin organization and, hence, gene regulation is significant [4]. So GC proportion has been revealed to correlate with genomic properties such as DNA bendability and regulated replication.

In the last years, this topic has been investigated by many researchers [5], [6], [7]. This stimulates the elaboration of computational techniques that are applied to large-scale biological experimental data. Positive relationships have been discovered between GC level and recombination in humans, birds, and plants [8], [9], [10], [11]. Spencer *et al.* [5] have discovered that recombination proportions are too fast-evolving to have permanent meanings on base composition.

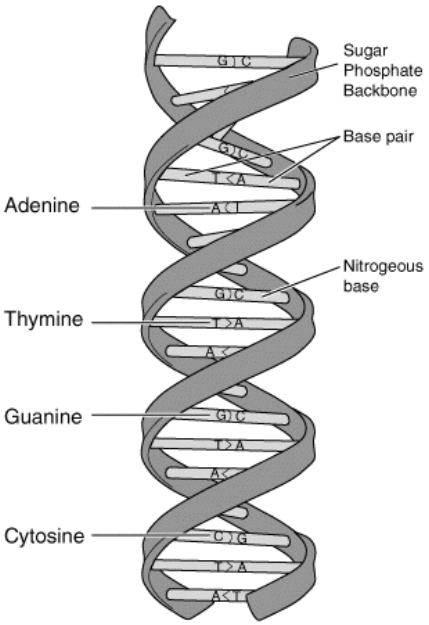

Fig. 1. The DNA structure. http://www.niherst.gov.tt/scipop/sci-bits/genetics-and-epigentics.htm

Positions in a DNA sequence at which nucleotides C or G are situated can be represented by a 1, and locations with T or A are situated can be represented by a 0. More formally, a sequence $a = \{a_1, \ldots, a_L\}$ of length L is given, where $a_m \in \{A, C, G, T\}$. The sequence may be transformed to a binary sequence $b = \{b_1, \ldots, b_L\}$ in which

$$b_m = \begin{cases} 1 & \text{if } a_m \in \{C, G\}, \\ 0 & \text{if } a_m \in \{A, T\}. \end{cases}$$

This work was carried out when the first author was at the Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, NO 7491, Trondheim, Norway.

978-83-60810-58-3/$25.00

From mathematical point of view we can designate a bound of segments with different GC ratio as a break-point or a change-point. Biological applications of the change-point problem, in particular, to DNA sequences, have been extensively considered in literature (see, for example, [12], [13], [14], [15], [16]). Note that the multiple change-point problem is a flexible model, which can be applied in many areas such as economics, finance, environmental control [17], [18], [19], signal detection, quality control [20], health and surveillance [21], [22]. Various techniques to the change-point problem with independent observations have been developed [16], [23], [24], [25], including stochastic optimization methods [13], [26], [27], [28], [29], [30], [31] and Markov chain Monte Carlo (MCMC) algorithms [14], [32], [33], [34], [35]. The Cross-Entropy (CE) method for independent case was developed in [13].

We can formulate a more general change-point problem for a sequence of dependent observations. The case of the Markov dependence in biological sequences was investigated in different articles. Polansky [36] considered cases with known and unknown number of change-points. The author applied the likelihood ratio, the bootstrap for estimation p-values for these cases, the Bayesian information criterion (BIC) and the Akaike information criterion (AIC) with unknown number of change-points. Zhang and Siegmund [37] proposed a new penalty component in the modified BIC. Avery and Herderson [12] investigated a problem of prediction of the occurrence of the definite sequence in DNA. For this purpose they considered the first-order, the second-order and the higher-order Markov chain models. Then the authors [38] developed a nonparametric method based on the approach of Pettitt [39]. Krauth [15], [40] used the exact Fisher test and the finite conditional tests for the multiple change-point problem in binary first-order Markov sequences. In this paper, we develop the CE method for identifying change-points in the first-order Markov dependence in binary sequences for artificial and real data.

We use the genome of the Bacteriophage *lambda*, a virus of the intestinal bacterium *Escherichia coli*, and a part of the Human Major Histocompatibility Region. Consideration of individual chromosomes is one of the most common approaches in the literature [41], [42]. Particularly it is very important for the analysis of the cancer genome [43].

The paper is structured as follows. Section 2 provides a statement of the multiple change-point problem in mathematical terms. In Section, 3 we describe a general framework of Cross-Entropy method. Section 4 contains developing the Cross-Entropy algorithm for the multiple change-point problem in dependent case. In Section 5, we discuss the results of numerical experiments.

II. The Multiple Change-Point Problem in Binary Markov Sequences

In mathematical terms we can describe the general multiple change-point problem as follows. A binary sequence $b = (b_1, \dots, b_L)$ of length L is given. A segmentation of the sequence is specified by giving the positions of the change-points $c = (c_1, \dots, c_N)$ and the number of change-points N, where $1 = c_0 < c_1 < \cdots < c_N < c_{N+1} = L$. This means that a change-point is a boundary between two neighbouring regions, and the value c_n is the sequence position of the rightmost character of the segment to the left of the n-th change-point.

In this model we assume that characters within each region are generated by Bernoulli trials with first-order Markov dependence. The probability distribution, which depends on the segment, can be represented by a transition matrix

$$\begin{pmatrix} \theta_0 & 1-\theta_0 \\ \theta_1 & 1-\theta_1 \end{pmatrix},$$

where $\theta_0 = P(X_{m+1} = 0 \mid X_m = 0)$, $1-\theta_0 = P(X_{m+1} = 1 \mid X_m = 0)$, $\theta_1 = P(X_{m+1} = 0 \mid X_m = 1)$, $1-\theta_1 = P(X_{m+1} = 1 \mid X_m = 1)$.

Thus, the likelihood function of N, $c = (c_1, \dots, c_N)$, and

$$\theta = (\theta_{00}, \theta_{10}, \dots, \theta_{0n}, \theta_{1n}, \dots, \theta_{0N}, \theta_{1N}),$$

is given by

$$\begin{aligned} f(N, c, \theta) &= P(X_1 = b_1) \\ &\times \prod_{n=0}^{N} \theta_{0n}^{\mathbf{I}_{00}(c_n, c_{n+1})} (1-\theta_{0n})^{\mathbf{I}_{01}(c_n, c_{n+1})} \\ &\times \theta_{1n}^{\mathbf{I}_{10}(c_n, c_{n+1})} (1-\theta_{1n})^{\mathbf{I}_{11}(c_n, c_{n+1})}, \end{aligned}$$

where $\mathbf{I}_{ij}(c_n, c_{n+1})$ is the number of times i ($i = 0, 1$), is followed by j ($j = 0, 1$) in the segment bounded by sequence positions $c_n + 1$ and c_{n+1}.

In order to simplify optimization, we consider the log-likelihood function at point $x = (N, c, \theta)$, having observed $b_1, \dots, b_L$,

$$\begin{aligned} \pi(x) &= \ln P(X_1 = b_1) \\ &+ \sum_{n=0}^{N} \Big(\mathbf{I}_{00}(c_n, c_{n+1}) \ln \theta_{0n} \\ &+ \mathbf{I}_{01}(c_n, c_{n+1}) \ln(1-\theta_{0n}) \\ &+ \mathbf{I}_{10}(c_n, c_{n+1}) \ln \theta_{1n} + \mathbf{I}_{11}(c_n, c_{n+1}) \ln(1-\theta_{1n}) \Big). \end{aligned} \tag{1}$$

III. The Cross-Entropy Method

From mathematical point of view the multiple change-point detection problem can be interpreted as a maximization problem of the log-likelihood function defined in (1).

Let F be a real valued performance function on $\mathcal{X}$, where $\mathcal{X}$ is a finite set of states. We want to find the optimum of F over $\mathcal{X}$, and the state corresponding to this value (which is a vector of positions of change-points). We can apply stochastic optimization methods for this optimization problem, in particular, the CE method.

The CE method is a technique for the estimation of rare event probabilities [44], [45], [46]. This estimation problem can be reformulated as an optimization problem. Thus we

define a set of indicator functions $\{I_{\{S(x)\geq\gamma\}}\}$ on $\mathcal{X}$ for different levels $\gamma \in R$. Let $\{f(\cdot,u)\}$ be a family of probability density functions (pdfs) on $\mathcal{X}$ with a real-valued parameter u. Following [45], we associate the optimization problem with the problem of estimating

$$l(\gamma) = \mathbf{P}_u(S(X) \geq \gamma) = \sum_x I_{\{S(x)\geq\gamma\}} f(x,u) = \mathbf{E}_u I_{\{S(X)\geq\gamma\}},$$

where γ is a known or unknown parameter and $\mathbf{P}_u$ is the probability measure under which the random state X has the pdf $f(\cdot,u)$.

The problem of estimating l is not trivial. Adaptive changes to the pdf are based on the Kullback-Leibler (or the CE) distance. Thus it allows to create a sequence $f(\cdot,u_0), f(\cdot,u_1), \ldots, f(\cdot,u^*)$. The final pdf $f(\cdot,u^*)$ corresponds to the density at an optimal point. This means that the CE method creates a sequence of pairs $\{(\gamma_t,u_t)\}$, which converges quickly to a close neighbourhood of the optimal tuple (γ^*,u^*). More specifically, we should set up u_0 and simulation parameters, and then we carry out the following procedure [45]:

1) **Adaptive updating of** γ_t. For a fixed u_{t-1}, let γ_t be a $(1-\rho)$-quantile of $\widehat{S}(X)$ under u_{t-1}. A simple estimator $\widehat{\gamma}_t$ of γ_t is
$$\widehat{\gamma}_t = \widehat{S}_{(\lceil(1-\rho)N_2\rceil)},$$
where, for a random sample $X_1,\ldots,X_{N_2}$ from $f(\cdot,u_{t-1})$, $\widehat{S}_{(i)}$ is the i-th order statistic of the performances $\widehat{S}(X_1),\ldots,\widehat{S}(X_{N_2})$.
2) **Adaptive updating of** u_t. For fixed γ_t and u_{t-1}, derive u_t from the solution of the CE program
$$\max_u D(u) = \max_u \mathbf{E}_{u_{t-1}} I_{\{\widehat{S}(X)\geq\gamma_t\}} \ln f(X,u).$$

IV. The Cross-Entropy Method for the Multiple Change-Point Problem

Let N be the number of change-points and c be a set of the change-points, which is a nondecreasing N-dimensional vector.

We apply the CE algorithm that uses normal distributions to simulate the change-point positions. The CE method updates the parameters in each step and updating is continued until a convergence state is achieved. A variance-based stopping criterion is used to estimate the fit of the combinations of change-points in each step.

Our study differs from previous [13] in the following aspects. Firstly, we consider a change-point problem for a sequence of dependent observations. Secondly, we apply the BIC (Bayesian information criterion) [47], [48] in order to estimate the number of change-points, which is usually unknown. The combination that minimizes F (our performance function) under the corresponding N is considered as the optimal solution. Therefore, we replace the problem of maximization of log-likelihood function with minimization problem of the BIC.

TABLE I
Parameters θ in Example 1

positions	θ_1	θ_2
1–2000	0.9	0.5
2001–4000	0.4	0.15
4001–6000	0.1	0.6
6001–8000	0.6	0.9
8001–10000	0.2	0.4
10001–12000	0.4	0.2
12001–14000	0.2	0.7
14001–16000	0.6	0.5
16001–18000	0.4	0.9
18001–20000	0.2	0.2
20001–22000	0.7	0.5

For each change-point vector c in the sample, we obtain the maximum likelihood estimate of parameters with respect to the each of the segments and evaluate the performance function F. The performance function, the BIC, which we minimize is

$$F = -2\pi(x) + k\ln(L), \tag{2}$$

where $\pi(x)$ is the log-likelihood as in (1) of the sequence. We use the standard penalty

$$k\ln(L) = (3N+2)\ln(L).$$

In each iteration an *elite* sample is defined as the best performing combinations of change-points with respect to the performance function score. The process is carried out until a specific stopping criterion is achieved.

In each step, the simulation parameters are updated accordingly. The main steps of our algorithm are described in Algorithm 1.

We should specify N_1, ρ, ε , the parameters of the algorithm as well as the initial values for the simulation parameters μ and σ^2. Note that we choose the parameters under the conditions which guarantee convergence of the algorithm [49].

V. Numerical Results

In this section, we include results of numerical experiments that illustrate the performance of the CE method. In the first example, we consider a synthetic sequence with a known distribution, which allows us to provide direct comparison of estimated and true profiles in terms of the Root Mean Squared Error (RMSE). The second and the third examples use real DNA sequences and we do not have any information about the structure of dependence. We apply a test of independence for these examples.

A. Example 1: Artificial data

Let $(b_1, b_2, ..., b_{22000})$ be a sequence of random variables generated with the parameters from Table I.

At first, we assume that we do not know the number of change-point and apply our algorithm for different N. We run our algorithm with the following simulation parameters: the elite proportion value $\rho = 0.1$ and the sample size $N_1 = 1500$.

Algorithm 1 Algorithm for change-point detection

1: Choose initial sets for

$$\mu^{(0)} = \left(\mu_1^{(0)}, \mu_2^{(0)}, \ldots, \mu_N^{(0)}\right)$$

and

$$(\sigma^2)^{(0)} = \left((\sigma_1^2)^{(0)}, (\sigma_2^2)^{(0)}, \ldots, (\sigma_N^2)^{(0)}\right).$$

The length of both vectors is N. Set $t = 1$.

2: Generate a random sample $c^{(1)}, c^{(2)}, \ldots, c^{(N_1)}$ from the normal distributions with parameters $\left(\mu^{(t-1)}, (\sigma^2)^{(t-1)}\right)$, where $c^{(i)} = \left(c_1^{(i)}, c_2^{(i)}, \ldots, c_N^{(i)}\right)$, $i = 1, 2, \ldots, N_1$, is a change-point vector.

3: For $i = 1, 2, \ldots, N_1$ order $\left(c_1^{(i)}, c_2^{(i)}, \ldots, c_N^{(i)}\right)$ from smallest to biggest.

4: Evaluate the performance of each $c^{(1)}, c^{(2)}, \ldots, c^{(N_1)}$ based on (2).

5: Define the elite sample, which is the best performing combinations of the change-points.

6: Let $N_{elite} = \rho N_1$ be the size of the elite sample.

7: For all $j = 1, 2, \ldots, N$, estimate the parameters $\mu_j^{(t)}$ and $(\sigma_j^2)^{(t)}$ using the elite sample and update the current parameter sets as follows:

$$\mu_j^{(t)} = \frac{\sum\limits_{i \in I} c_j^{(i)}}{N_{elite}}, \qquad \left(\sigma_j^2\right)^{(t)} = \frac{\sum\limits_{i \in I} \left(c_j^{(i)} - \mu_j^{(t)}\right)^2}{N_{elite}},$$

where I is the set of indices of the best performing samples.

8: Stopping criterion is $\max_j (\sigma_j^2)^{(t)} < \varepsilon$.

9: **if** Stopping criterion is met **then**

10: stop the process and identify the combination of the positions of change points $c^{(i)}$ that minimizes the BIC

11: **else**

12: $t = t + 1$;

13: and iterate from step 2.

14: **end if**

Then we obtain the best solution for different models in each of the N situations which minimize the BIC. We can see from Figure 2 that the minimum value of the BIC at $N = 10$, which corresponds to the number of change-points in Table I.

The true profiles of this sequence as well as the estimated profile can be seen in Figures 3, 4. We can see that the estimated and the true plots are very similar to each other. This indicates that the CE method works very well and it properly captures the segments in the binary sequence.

To test the efficiency of the CE method, we have applied this algorithm with various values for the parameter ρ, which is used to obtain the elite sample. We calculate the RMSE for the different algorithms when applied to the synthetic sequence

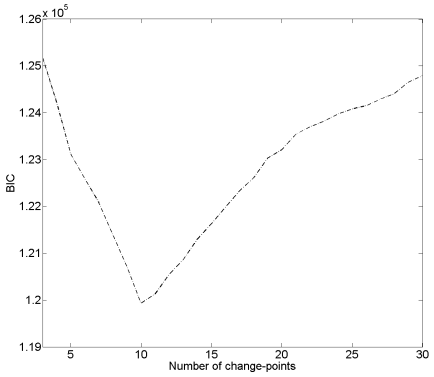

Fig. 2. The scores of the BIC for different N

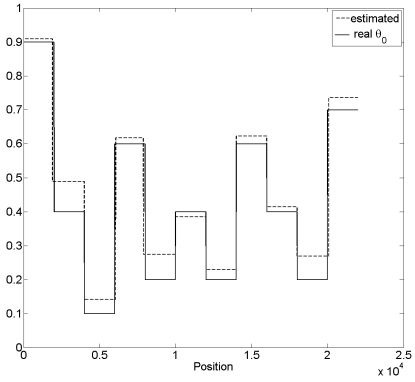

Fig. 3. The profile of θ_0 obtained by the CE algorithm

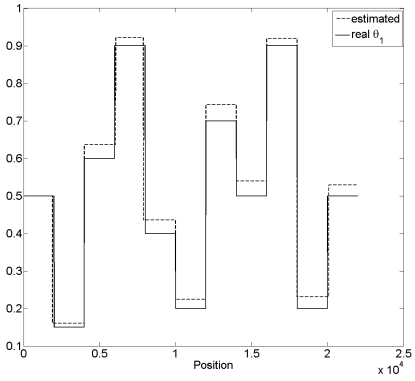

Fig. 4. The profile of θ_1 obtained by the CE algorithm

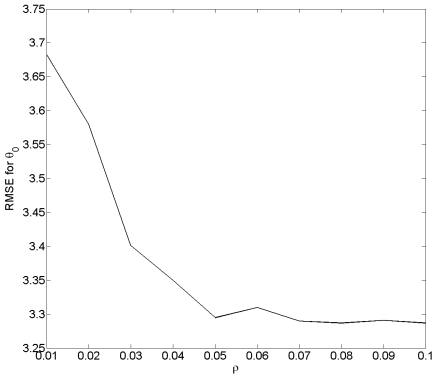

Fig. 5. The values of the RMSE for θ_0 depending on ρ

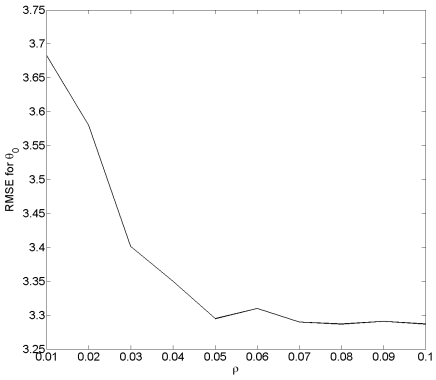

Fig. 6. The values of the RMSE for θ_1 depending on ρ

of 22000 characters

$$\text{RMSE} = \sqrt{\sum_{i=1}^{22000} (t(i) - e(i))^2},$$

where $e(i)$ is estimated value at position i and $t(i)$ is the true parameter value.

The RMSE and CPU time are obtained for ρ values from 0.01 to 0.1 with step of 0.01 for the model when number of change-points is 10. We have obtained the average results based on 50 simulations under each of the ρ values. We can see from Figures 5, 6 that the plots are slowly decreasing, at the same time the plot on Figure 7 is increasing. In this study, we focus on the RMSE, though it would be possible to choose ρ in such a way that will balance the trade-off between the RMSE and the CPU time.

B. Example 2: Real data (Bacteriophage lambda)

We apply the CE with the same parameter specification as above to the genome of the Bacteriophage *lambda*, a virus of the intestinal bacterium *Escherichia coli*. The length of the sequence is 48,502 bases. Boys and Henderson [50] studied this sequence with 4 multinomial outcomes (each base is one of either A, C, G, T) for the comparison of different algorithms

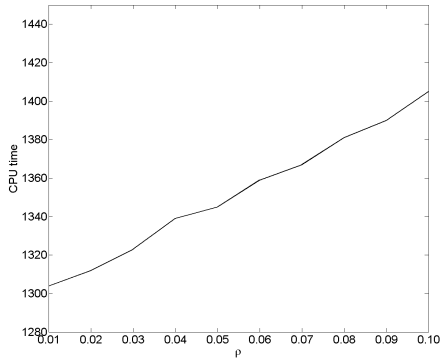

Fig. 7. CPU time for different ρ

TABLE III
OBSERVED FREQUENCIES OF THE 4 POSSIBLE PAIRS OF BASES FOR EXAMPLE 2. EXPECTED FREQUENCIES ASSUMING INDEPENDENCE OF SUCCESSIVE BASES ARE GIVEN IN PARENTHESES

First base	**Second base**	**Second base**	**Total**
	0	1	
0	12544	11776	24320
	(12194.85)	(12125.15)	
1	11776	12405	24181
	(12125.15)	(12055.85)	
Total	24320	24181	48501

under the independence assumption. Table II presents a brief summary of the results obtained in [51].

Table III shows the observed frequencies and the expected frequencies for the Pearson χ^2-test of independence. It can be calculated from the table that the value of the test statistic is 40.22. On comparing with a χ^2-distribution with 1 degree of freedom, we conclude that the hypothesis about independence should be rejected ($p < 10^{-6}$). Therefore, we consider a case with the first-order Markov dependence.

We can calculate the BIC for different number of change-points. From Table II we can see that the authors found 8 change-points based on the use of 4-symbol alphabet. According to our approach we found that 6236 was the minimum value of the BIC at $N = 9$. Next, we check each change-point using the Fisher exact test. We calculate p-values and conclude that there are evidences for change-points at 5806 ($p_1 = 7.82 \cdot 10^{-4}$), 19503 ($p_4 = 0.018$), 22109 ($p_5 = 1.25 \cdot 10^{-11}$), 27660 ($p_6 = 6.18 \cdot 10^{-6}$), 38018 ($p_8 = 0.0045$), and 46259 ($p_9 = 5.19 \cdot 10^{-4}$).

Note that our main objective is to identify change-points in GC ratio, not in the model parameters θ_0, θ_1. Therefore, we present our conclusions without profiles of θ_0 and θ_1 and locations of false change-points. The GC profile can be seen on Figure 8. The discordance can be explained by the fact that the results in Table II were obtained using a different model with 4-character alphabet, whereas we used a binary representation. From this comparison we can see that both methods identify

TABLE II
ESTIMATED SEGMENTS AND ESTIMATED PROPORTIONS OF A, C, G, AND T FOR EACH SEGMENT

the most significant change-points and the proposed method provides a smoother profile of GC ratio.

C. Example 3: Real data (MHC Region)

This example uses a part of the Human Major Histocompatibility Region (MHC) (for further detail, see [52]). Due to this being real DNA, we do not know the true profile (as well as in Example 2). Instead we look for agreement between the CE and two well-known methods: IsoFinder [16], [23], [24] and the BAIS [34], [35]. At first, we repeat the Pearson test of independence. The value of the test statistic from Table IV is 51.35. This means that the hypothesis about independence should also be rejected ($p < 10^{-6}$).

We use the same algorithm parameters as before. We found a change-point vector and checked each position using the exact Fisher test. There are 6 significant change-points in this part of MHC sequence: 953 ($p_1 = 3.67 \cdot 10^{-4}$), 7257 ($p_4 = 0.0078$), 9132 ($p_5 = 7.80 \cdot 10^{-6}$), 13041 ($p_6 = 6.28 \cdot 10^{-12}$), 16114 ($p_7 = 3.19 \cdot 10^{-11}$), and 18954 ($p_8 = 1.05 \cdot 10^{-30}$).

Figure 9 shows the GC profiles for the CE algorithm, the BAIS and the IsoFinder. We use the following simulation parameters: the BAIS algorithm for 1000 iterations and $K = 50$ parallel chains, and IsoFinder with a 0.95 significance level and tract size of 1,000. It is clear that all algorithms can detect the major regions within the MHC sequence. IsoFinder identifies seven major regions while the other methods all identify several smaller regions within these major regions. The agreement between these methods allows for a great deal of confidence in the exactness of the CE method as both the BAIS method and IsoFinder are well established.

VI. CONCLUSION

In this paper, we have developed the Cross-Entropy method for identifying change-points in binary Markov sequences. In order to identify the correct number of change-points we propose to use the BIC. This approach is easy to implement and can also be extended to more general multiple change-point models. We have demonstrated the effectiveness of this technique in examples using both real and synthetic sequences. The method has been shown to be highly effective on synthetic data and real DNA sequences and compete well with existing approaches.

The proposed approach gives results similar to previous outcomes but it is not sufficient for understanding of dependence mechanism in DNA sequences. Our future research will include consideration of Markov dependence of a higher order (the second or more). The proposed method can be implemented using parallel computing, which will significantly decrease the CPU time. For the independent case, this feature was realized in R-package *breakpoint* [53].

***Abstract*—Let $H = (V(H), E(H))$ be a simple connected graph of order n with the vertex set $V(H)$ and the edge set $E(H)$. We consider a blow-up graph $G[H]$.**

We are interested in the following problem. We have to decide whether there exists a blow-up graph $G[H]$, with edge densities satisfying special conditions (homogeneous or inhomogeneous), such that the graph H does not appear in a blow-up graph as a transversal.

We study this problem for unicyclic graphs H with the cycle C_3. We show an efficient algorithm to decide whether a given set of edge densities ensures the existence of H in the blow-up graph $G[H]$.

***Index Terms*—blow-up graph; density; Turán density problem; unicyclic graph.**

I. Introduction

TURÁN [10] stated the first results in extremal graph theory. Then many authors extended this subject and formulated similar and new Turán density problems. [1], [3], [4], [6], [8], [9] and [11] obtained interesting results for some families of graphs.

In this paper we present an algorithm for testing whether a unicyclic graph with a given set of edge densities is a factor (transversal) of a blow-up graph. Our algorithm has the time complexity at most $\mathcal{O}(n^2)$, where n is the number of vertices of the unicyclic graph.

Csikvári and Nagy [5] discovered some interesting algorithm for testing whether a tree with a given set of edge densities is a factor of a blow-up graph. We extend their algorithm to the family of unicyclic graphs with the cycle C_3.

Now we define some notions and notations. Other definitions one can find in [2] and [7].

Let $H = (V(H), E(H))$ be a simple connected graph of order n with the vertex set $V(H)$ and the edge set $E(H)$. By P_k we denote the path with k vertices. By C_k we denote the cycle with k vertices. The set $S \subset V(H)$ is called *an independent vertex set* if the subgraph of H induced by S has empty set of edges.

Let

$$N_H(v) = \{x \in V(H) \mid \{v, x\} \in E(H)\}$$

be *the neighbourhood* of the vertex $v \in V(H)$ in the graph H. $|N_H(v)|$ is called *the degree* of v in $V(H)$. Each vertex of degree 1 in a graph H is called *a leaf* of the graph H.

We say that the graph H is *r-regular* if each vertex of H has degree r. The set $M \subset E(H)$ is called *the matching* (or *independent edge set*) in the graph H if the subgraph of H induced by M is 1-regular.

For a connected graph H we define *a blow-up graph* $G[H]$ of the graph H as follows. First we replace each vertex $i \in V(H)$ by an independent set of vertices A_i. Throughout this paper A_i is called *a cluster*. Next we connect vertices between the clusters A_i and A_j if i and j are adjacent in H, $i, j \in V(H)$. The graph induced by $A_i \cup A_j$ in $G[H]$ is a subgraph of a complete bipartite graph. See Fig. 2 and Fig. 3 which present examples of a blow-up graphs $G[H]$ of the graph H presented in Fig. 1.

For any two clusters we define *the density* between them by the following formula

$$d(A_i, A_j) = \frac{e(A_i, A_j)}{|A_i||A_j|},$$

where $e(A_i, A_j)$ denotes the number of edges between the clusters A_i and A_j.

The graph H is *a transversal* of $G[H]$ if H is a subgraph of $G[H]$ such that we have a homomorphism

$$\phi : V(H) \to V(G[H])$$

for which $\phi(i) \in A_i$ for all $i \in V(H)$. Other terminology: H is *a factor* of $G[H]$. An edge $e = \{i, j\}$ of the graph H we denote by $e = ij$.

The density Turán problem can be defined as follows. Let us determine the critical edge density, denoted by d_{crit}, which ensures the existence of the subgraph H of $G[H]$ as a transversal. Precisely, assume that all edges $e = \{i, j\}$ in the graph H satisfy the condition

$$d(A_i, Aj) > d_{crit},$$

where $i, j \in V(H)$. Then, no matter how we construct the blow-up graph $G[H]$, it contains the graph H as a transversal.

978-83-60810-58-3/$25.00

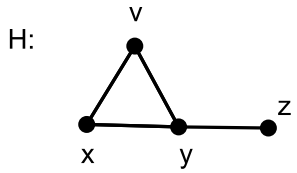

Fig. 1. The graph $H \in \mathcal{U}_{n,3}$ with the vertex set $V(H) = \{x, y, z, v\}$.

On the other words, for any value $d < d_{crit}$ there exists a blow-up graph $G[H]$ such that

$$d(A_i, A_j) > d$$

for all edges $ij \in E(H)$ and it does not contain H as a transversal. This problem was studied in [9].

By [5] we know that it is useful to consider more general problem. Let us assume that for every edge $e \in E(H)$ a density γ_e is given. Now our task is to decide if the set of densities $\{\gamma_e\}_{e \in E(H)}$ ensure the existence of the graph H as a transversal or we can construct a blow-up graph $G[H]$ such that

$$d(A_i, A_j) \geq \gamma_{ij},$$

but it does not induce the graph H as a transversal. This more general setting allows to use inductive proofs (see the proof of Theorem 7). We call this general case as *the inhomogeneous condition* on the edge densities, while the above condition of having a common lower bound $d_{crit}(H)$ for densities is called *the homogeneous case*.

Let $\mathcal{U}_{n,p}$ be a family of unicyclic graphs of order n with the cycle C_p. The path P_2 and the cycle C_3 are trivial unicyclic graphs for further considerations. In this paper we study the inhomogeneous density Turán problem for unicyclic graphs in the family $\mathcal{U}_{n,3}$, i.e. with the unique cycle C_3 (see Fig. 1).

Fig. 2 and Fig. 3 present two blow-up graphs $G_1[H]$ and $G_2[H]$ of the graph H presented in Fig. 1. In both cases we have the following values of the densities between clusters

$$d(A_x, A_y) = d(A_y, A_z) = \frac{3}{20},$$

$$d(A_x, A_v) = \frac{3}{16},$$

$$d(A_y, A_v) = \frac{1}{10}.$$

Let us recall the definition of *the multivariate matching polynomial* of the graph. The polynomial is the useful tool for the proof of our results.

Definition 1. *Let H be a graph and let $\underline{x_e}$ be the vector of variables x_e, $e \in E(H)$. We define the multivariate matching polynomial F_H of the graph H as follows*

$$F_H(\underline{x_e}, t) = \sum_{M \in \mathcal{M}} \left(\prod_{e \in M} x_e \right) (-t)^{|M|},$$

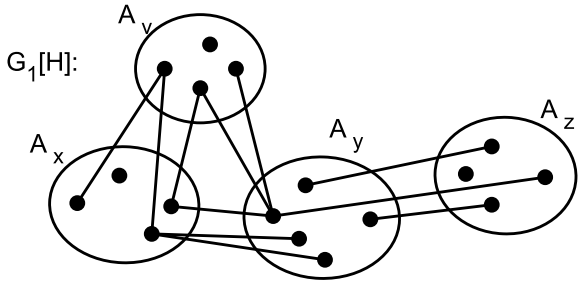

Fig. 2. An example of the blow-up graph $G[H]$ of the graph H presented in Fig. 1 with a transversal H.

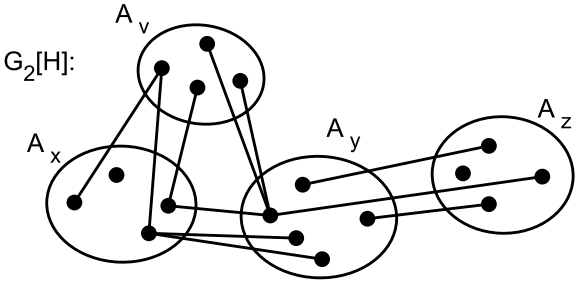

Fig. 3. An example of the blow-up graph $G[H]$ of the graph H presented in Fig. 1 without a transversal H.

where the summation goes over all matchings of the graph H, including the empty matching.

Fig. 4 and Fig. 5 present the paths P_2, P_4 and the unicycle graph $H \in \mathcal{U}_{6,3}$ with variables x_e assigned to each edge.

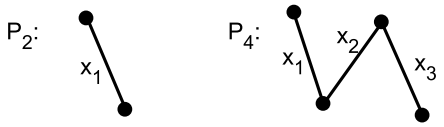

Fig. 4. Paths P_2 and P_4 with variables x_e assigned to each edge.

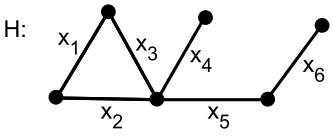

Fig. 5. Graph $H \in \mathcal{U}_{6,3}$ with variables x_e assigned to each edge.

By definition of the multivariate matching polynomial we have

$$F_{P_2}(\underline{x_e}, s) = 1 - sx_1,$$

$$F_{P_4}(\underline{x_e}, s) = 1 - s(x_1 + x_2 + x_3) + s^2 x_1 x_3,$$

$$F_H(\underline{x_e}, s) = 1 - s(x_1 + x_2 + x_3 + x_4 + x_5 + x_6) +$$

$$s^2(x_1x_4 + x_1x_5 + x_1x_6 + x_2x_6 + x_3x_6 + x_4x_6) - s^3 x_1 x_4 x_6.$$

II. Some results for the homogeneous case

For the completness of this paper we present some results for the homogeneous Turán density problem in this section. For this case Nagy [9] presented the following lower and upper bounds for the critical density d_{crit}.

Theorem 1 (Nagy [9]). *For a graph H we have*

$$\left(1-\frac{1}{\Delta(H)}\right) \leq d_{crit}(H) \leq \left(1-\frac{1}{\Delta^2(H)}\right),$$

where $\Delta(H)$ is the maximal degree of H.

Then Csikvári and Nagy [5] improved the upper bound.

Theorem 2 (Csikvári and Nagy [5]). *Let $\Delta(H)$ be the largest degree of the graph H. Then we have*

$$d_{crit}(H) \leq 1-\frac{1}{e(2\Delta(H)-1)},$$

where e is the base of the natural logarithm.

Now let us recall the definition of *the matching polynomial* of the graph.

Definition 2. *Let H be a weighted graph with constant weight function $w(e)=1$ for all edges $e \in E(H)$. Then the matching polynomial is defined as*

$$M(H,t)=\sum_{k=0}^{n/2}(-1)^k m_k(H) t^{n-2k},$$

where $m_k(H)$ denotes the number of k independent edges in the graph H.

Using this polynomial Csikvári and Nagy [5] stated the upper bound for the critical density as in Theorem 3.

Theorem 3 (Csikvári and Nagy [5]). *Let $\Delta(H)$ be the largest vertex degree in the graph H and let $t(H)$ be the largest root of the matching polynomial. Then we have*

$$d_{crit}(H) \leq 1-\frac{1}{(t(H))^2}.$$

In particular,

$$d_{crit}(H) < 1-\frac{1}{4(\Delta(H)-1)}.$$

What is more Nagy [9] showed the exact value of the critical density for trees.

Theorem 4 (Nagy [9]). *Let T be a tree. Then we have*

$$d_{crit}(T)=1-\frac{1}{\lambda^2_{max}(T)},$$

where $\lambda_{max}(T)$ is the maximum eigenvalue of the adjacency matrix of the tree.

Furthermore, Nagy [9] showed that for the cycle of order n and for the path of order $n+1$ the critical densities are equal.

Theorem 5 (Nagy [9]). *Let C_n be a cycle on n vertices and P_{n+1} be a path on $n+1$ vertices. Then we have*

$$d_{crit}(C_n)=d_{crit}(P_{n+1})=1-\frac{1}{4\cos^2\frac{\pi}{n+2}}.$$

We formulate the followig open problem.

Open problem: count the critical density $d_{crit}(H)$ for $H \in \mathcal{U}_{n,p}$, $p \geq 3$.

III. Inhomogeneous case: unicyclic graphs with the cycle C_3

In this section we study the inhomogeneous case when graph $H \in \mathcal{U}_{n,3}$, e.i. H is unicyclic with the cycle C_3 and for each edge $e \in E(H)$ the edge density γ_e is given. We extend some results presented in [5], where authors studied the inhomogeneous case for trees and proved the following theorem.

Theorem 6. *(Csikvári, Nagy [5]) Let T be a tree of order n and let v be a leaf of T. Assume that for each edge of T a density $\gamma_e = 1-r_e$ is given. Let $T^{'}$ be a tree obtained from T by deleting the leaf v and the edge uv, where u is the unique neighbour of v. Let the edge densities $\gamma_e^{'}$ in $T^{'}$ be defined as follows*

$$\gamma_e^{'}=\begin{cases}\gamma_e=1-r_e, & \text{if } e \text{ is not incident to } u,\\ 1-\frac{r_e}{1-r_{uv}}, & \text{if } e \text{ is incident to } u.\end{cases}$$

Then the set of densities $\{\gamma_e\}_{e\in E(T)}$ ensures the existence of the factor T if and only if all $\gamma_e^{'} \in (0,1]$ and the set of densities $\{\gamma_e^{'}\}_{e\in E(T')}$ ensures the existence of the factor $T^{'}$.

Theorem 6 provides authors of [5] with an efficient algorithm to decide whether a given set of edge densities in tree ensures the existence of a transversal or does not ensure. Their algorithm is presented below as **Algorithm** T for the completeness of our paper.

We extend the algorithm (**Algorithm** T) to the family of unicyclic graphs with the cycle C_3. The new algorithm (**Algorithm** $\mathcal{U}_{n,3}$) is based on the following Theorem 7 proved below by an extension of the method discovered in [5].

Theorem 7. *Let $H \in \mathcal{U}_{n,3}$ be a unicyclic graph of order n with the cycle C_3 and assume that for each edge $e \in E(H)$ a density $\gamma_e = 1-r_e$ is given. If the order of H is greater then 3, let v be a leaf of H and u be the unique neighbour of v, then let $H^{'}$ be a graph obtained from H by deleting the leaf v and an edge uv. Let the densities $\gamma_e^{'}$ in $H^{'}$ be defined as follows*

$$\gamma_e^{'}=\begin{cases}\gamma_e=1-r_e, & \text{if } e \text{ is not incident to } u,\\ 1-\frac{r_e}{1-r_{uv}}, & \text{if } e \text{ is incident to } u.\end{cases}$$

If the order of H is equal to 3 (i.e., H is isomorphic to C_3 with $V(H)=\{a,b,c\}$), then let $H^{'}$ be a graph obtained from H by deleting the vertex a and edges ab and ac. $H^{'}$ is a path P_{bc}. Let the density $\gamma_{bc}^{'}$ in $H^{'}$ be defined as follows

$$\gamma_{bc}^{'}=1-\frac{r_{bc}}{(1-r_{ab})(1-r_{ac})}.$$

Algorithm T

Step 0.
Let there be given a tree T^0 and edge densities γ_e^0. Set $T := T^0$ and $r_e = 1 - \gamma_e^0$.

Step 1.
Consider (T, r_e).

- **if** $|V(T)| = 2$ *and* $0 \leq r_e < 1$ **then**

  STOP: the densities γ_e^0 ensure the existence of a factor T^0.

- **if** $|V(T)| \geq 2$ *and there exists an edge for which* $r_e \geq 1$ **then**

  STOP: the densities γ_e^0 do not ensure the existence of a factor T^0.

Step 2.
if $|V(T)| \geq 3$ *and* $0 \leq r_e < 1$ *for all edges* $e \in E(T)$ **then**

DO pick a vertex v of degree 1 and let u be its unique neighbour. Let $T^{'} := T - v$ and

$$r_e^{'} = \begin{cases} r_e, & \text{if } e \text{ is not incident to } u, \\ \frac{r_e}{1-r_{uv}}, & \text{if } e \text{ is incident to } u. \end{cases}$$

Jump to *Step 1* with $(T, r_e) := (T^{'}, r_e^{'})$.

Then the set of densities $\{\gamma_e\}_{e \in E(H)}$ *ensures the existence of the factor* H *if and only if all* $\gamma_e^{'} \in (0, 1]$ *and the set of densities* $\{\gamma_e^{'}\}_{e \in E(H')}$ *ensures the existence of the factor* $H^{'}$.

Proof. Let $H \in \mathcal{U}_{n,3}$ and let the set of densities $\gamma_e = 1 - r_e$ be given for each $e \in E(H)$. First we prove the following statement: if all $\gamma_e^{'}$ are indeed densities and they ensure the existence of a factor $H^{'}$, then the original densities γ_e ensure the existence of a factor H.

Let $G[H]$ be a blow-up of the graph H such that the density between A_i and A_j is at least γ_{ij}, where A_i is a cluster of the vertex $i \in V(H)$. We show that it contains a factor H.

Let us consider a graph $H \in \mathcal{U}_{n,3}$ with $n > 3$ vertices.

Let $v, u \in V(H)$, where v is a leaf of H and $u \in N_H(v)$.

Define $R_{v,u}$ as the subset of A_u in the following way (see Fig. 6).

$$R_{v,u} = \{x \in A_u \mid x \text{ is incident to some edge between } A_u \text{ and } A_v\}.$$

Note that

$$|R_{v,u}||A_v| \geq e(R_{v,u}, A_v) = \gamma_{uv}|A_u||A_v|.$$

Hence

$$|R_{v,u}| \geq \gamma_{uv}|A_u|.$$

Now we show the lower bound for the number of edges incident to $R_{v,u}$. Let $k \in N_H(u)$. By the inclusion - exclusion formula we count the lower bound for the number of edges between $R_{v,u}$ and A_k as follows.

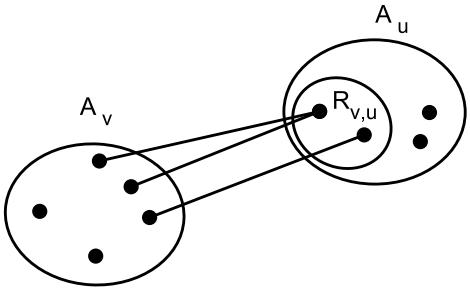

Fig. 6. Clusters A_v and A_u with the set $R_{v,u}$.

$$e(R_{v,u}, A_k) \geq e(A_u, A_k) - (|A_u| - |R_{v,u}|)|A_k| =$$
$$|R_{v,u}||A_k| + (\gamma_{ku} - 1)|A_k||A_u| \geq$$
$$|R_{v,u}||A_k| + (\gamma_{ku} - 1)\frac{1}{\gamma_{uv}}|R_{v,u}||A_k| =$$
$$\left(1 - \frac{r_{ku}}{1 - r_{uv}}\right)|R_{v,u}||A_k| = \gamma'_{ku}|R_{v,u}||A_k|.$$

Now, by deleting the vertex set A_v and $A_u \backslash R_{v,u}$ from $G[H]$, we obtain a graph which is a blow-up of $H^{'}$ with edge densities ensuring the existence of the factor $H^{'}$.

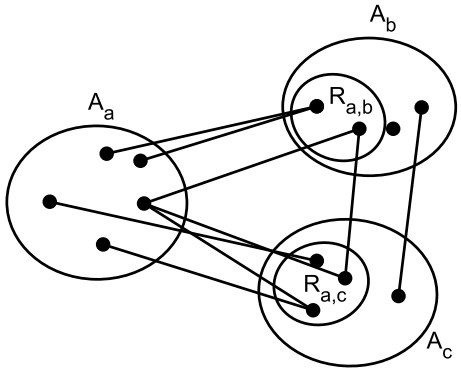

Fig. 7. Clusters A_a, A_b and A_c with the sets $R_{a,b}$ and $R_{a,c}$.

Moreover, by the definition of $R_{v,u}$ the factor $H^{'}$ can be extended to a factor H.

Now consider the situation when $n = 3$ and graph H is a cycle C_3 with the vertex set $\{a, b, c\}$. Let A_a be a cluster of vertex a. Define sets $R_{a,b}$ and $R_{a,c}$ in the following way (see Fig. 7).

$$R_{a,b} = \{x \in A_b \mid x \text{ is incident to some edge between } A_b \text{ and } A_a\},$$

$$R_{a,c} = \{x \in A_c \mid x \text{ is incident to some edge between } A_c \text{ and } A_a\}.$$

Note that

$$|R_b||A_a| \geq e(R_b, A_a) = \gamma_{ab}|A_a||A_b|,$$
$$|R_c||A_a| \geq e(R_c, A_a) = \gamma_{ac}|A_a||A_c|.$$

Hence we have the following lower bounds for the cardinalities of $R_{a,b}$ and $R_{a,c}$

$$|R_{a,b}| \geq \gamma_{ab}|A_b|$$

and

$$|R_{a,c}| \geq \gamma_{ac}|A_c|.$$

Next we show how many edges are incident to $R_{a,b}$ and $R_{a,c}$. Using the inclusion - exclusion formula we count the lower bound for the number of edges between $R_{a,b}$ and $R_{a,c}$

$$e(R_{a,b}, R_{a,c}) \geq e(A_b, A_a) - (|A_b| - |R_{a,b}|)|A_c| -$$
$$(|A_c| - |R_{a,c}|)|A_b| + (|A_b| - |R_{a,b}|)(|A_c| - |R_{a,c}|) =$$
$$|R_{a,b}||R_{a,c}| + (\gamma_{bc} - 1)|A_b||A_a| \geq$$
$$|R_{a,b}||R_{a,c}| + (\gamma_{bc} - 1)\frac{1}{\gamma_{ab}}\frac{1}{\gamma_{ac}}|R_{a,b}||R_{a,c}| =$$
$$\left(1 - \frac{r_{bc}}{(1 - r_{ab})(1 - r_{ac})}\right)|R_{a,b}||R_{a,c}| = \gamma^{'}_{bc}|R_{a,b}||R_{a,c}|.$$

Now, by deleting the vertex sets A_a, $A_b \backslash R_{a,b}$ and $A_c \backslash R_{a,c}$ from $G[C_3]$, we obtain a graph which is a blow-up of $C^{'}_3 = P_2$, $V(P_2) = \{b, c\}$, with edge densities ensuring the existence of the factor P_2. Moreover, by the definition of $R_{a,b}$ and $R_{a,c}$ the factor P_2 can be extended to a factor C_3.

Note that if

$$\gamma^{'}_{ku} < 0,$$

then

$$\gamma_{ku} + \gamma_{uv} < 1.$$

So there exists a construction which does not induce the path P_3 with the consecutive vertices k, u, v, where $i \in A_i$ ($i \in \{k, u, v\}$) in this case. Therefore, if some $\gamma^{'}_{ku} < 0$ then there exists a construction for a blow-up graph of H without a factor of H.

Next assume that all the $\gamma^{'}_e$ are proper densities, but there is a construction of a blow-up graph, say $G^{'}[H^{'}]$, with edge densities at least $\gamma^{'}_e$, but which does not induce a factor $H^{'}$. Thus we construct a blow-up $G[H]$ of the graph H not inducing H. We consider two possible cases. First let the picked vertex v be a leaf in H and $H^{'} = H - v$. Then set $A_u = \{u^*\} \cup A^{'}_u$ and $A_v = \{v\}$. We connect v to all elements of $A^{'}_u$ but do not connect to u^* without changing densities in $G^{'}[H^{'}]$ and with density γ_{vu} (see Fig. 8).

Now let $H^{'} = H - c$, where c is a vertex of C_3, $V(C_3) = \{a, b, c\}$. Then set $A_a = \{a^*\} \cup A^{'}_a$, $A_b = \{b^*\} \cup A^{'}_b$ and $A_c = \{c\}$. We connect c to all elements of $A^{'}_a$ and $A^{'}_b$ but do not connect to a^* and b^* without changing densities in $G^{'}[H^{'}]$ and with densities γ_{ca} and γ_{cb} (see Fig. 9). □

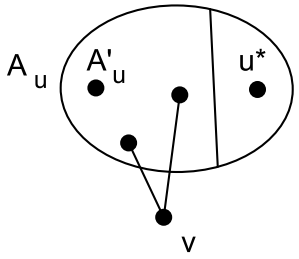

Fig. 8. We assume that $G^{'}[H^{'}]$ is without transversal $H^{'}$. The construction of the blow-up graph $G[H]$ without transversal H for the case where v is a leaf in H and $H^{'} = H - v$. The cluster $A^{'}_u$ is in $G^{'}[H^{'}]$. Let $A_u = A^{'}_u \cup u^*$ and $A_v = \{v\}$ be clusters in $G[H]$.

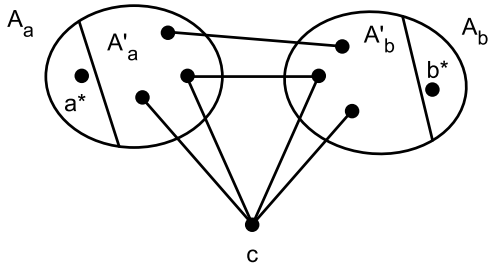

Fig. 9. We assume that $G^{'}[H^{'}]$ is without transversal $H^{'}$. The construction of the blow-up graph $G[H]$ without transversal H for the case where c is a vertex of C_3, $V(C_3) = \{a, b, c\}$ in H and $H^{'} = H - c$. The clusters $A^{'}_a$ and $A^{'}_b$ are in $G^{'}[H^{'}]$. Let $A_a = \{a^*\} \cup A^{'}_a$, $A_b = \{b^*\} \cup A^{'}_b$ and $A_c = \{c\}$ be clusters in $G[H]$.

Theorem 7 provides us with the algorithm (**Algorithm** $\mathcal{U}_{n,3}$) to decide whether a given set of edge densities ensures the existence of a transversal H in a blow-up graph $G[H]$ or does not ensure, where $H \in \mathcal{U}_{n,3}$.

For further considerations recall some results presented in papers [3] and [5]. First lemma gives condition on edge densities in the triangle C_3 which allows us to check if these densities ensure existing of C_3 in a blow-up graph $G[C_3]$. The second results gives condition on existing graph H as a factor in a blow-up graph $G[H]$ in terms of the multivariate matching polynomial F_H.

Lemma 1. *(Bondy, et al. [3]) Let α, β, γ be the edge densities between the clusters of a blow-up graph of the triangle - a cycle C_3. If*

$$\alpha\beta + \gamma > 1, \beta\gamma + \alpha > 1, \gamma\alpha + \beta > 1,$$

then the blow-up graph contains a triangle as a transversal.

Theorem 8. *(Csikvári, Nagy [5]) Assume that for the graph H we have*

$$F_H(\underline{r_e}, t) > 0$$

for all $t \in [0,1]$ and some vector $\underline{r_e}$ of weights, where $r_e \in [0,1]$ for each edge $e \in E(H)$. Then the densities $\gamma_e = 1 - r_e$ ensure the existence H as a transversal.

Let $H := C_3$ with vertices a, b, c and edge densities $\gamma_e = 1 - r_e$, where $e \in \{ab, bc, ac\}$. Assume that all $r_e \in [0,1)$ and run the **Algorithm** $\mathcal{U}_{n,3}$ by deleting vertex a from the graph C_3 with edges incident to it (means ab and ac). As a result we get a graph $H^{'}$ as a path $P_2 = bc$ with edge density

$$\gamma'_{bc} = 1 - r'_{bc} = 1 - \frac{r_{bc}}{(1 - r_{ab})(1 - r_{ac})}.$$

For $H^{'}$ we have

$$F_{H'}(\underline{r_e}, t) = 1 - tr'_{bc}.$$

By Theorem 8 we need

$$F_{H'}(\underline{r_e}, t) > 0$$

for $t \in [0,1]$.

Hence

$$\frac{1}{r'_{bc}} > 1,$$

$$(1 - r_{ab})(1 - r_{ac}) - r_{bc} > 0$$

and

$$\gamma_{ab}\gamma_{ac} + \gamma_{bc} > 1.$$

Similar inequalities are received when, instead of a vertex a, we delete in **Algorithm** $\mathcal{U}_{n,3}$ vertex b or c. As we can see we have a result presented in Proposition 1 consensual with Lemma 1.

Proposition 1. *Let a, b, c be vertices in a triangle C_3. Assume that $\gamma_e = 1 - r_e$ be an edge density assigned to each edge $e \in E(C_3)$, where $E(C_3) = \{ab, ac, bc\}$. If*

$$\frac{r_{ab}}{(1 - r_{ac})(1 - r_{bc})} < 1, \ \frac{r_{ac}}{(1 - r_{ab})(1 - r_{bc})} < 1$$

and $\dfrac{r_{bc}}{(1 - r_{ab})(1 - r_{ac})} < 1,$

then the set of densities $\{\gamma_e\}_{e \in E(C_3)}$ ensures existence of a transversal C_3 in a blow-up graph $G[C_3]$.

By running **Algorithm** $\mathcal{U}_{n,3}$ on some unicyclic graph $H \in \mathcal{U}_{n,3}$ with $\gamma_e = 1 - tr_e$ and using the multivariate matching polynomial $F_H(\underline{r_e}, s)$ we can prove the following lemma.

Lemma 2. *Let H be a weighted unicyclic graph of order $n > 2$ with the cycle C_3. Let $\gamma_e = 1 - tr_e$ be densities assigned to each edge $e \in E(H)$, where $r_e \in [0,1)$. Assume that after running Algorithm $\mathcal{U}_{n,3}$ we get a cycle C_3 with*

$$F_{C_3}(\underline{r_e}, t) = 0,$$

then t is a root of the multivariate matching polynomial $F_H(\underline{r_e}, s)$ of the graph H.

Proposition 2. *Let H be a weighted unicyclic graph of order $n > 2$ with the cycle C_3. Let $\gamma_e = 1 - tr_e$ be the densities assigned to each edge $e \in E(H)$. Assume that after running Algorithm $\mathcal{U}_{n,3}$ we get a cycle C_3 with the vertex set $V(C_3) = \{a, b, c\}$ and with $F_{C_3}(\underline{r_e}, t) = 0$ and, after restart Algorithm $\mathcal{U}_{n,3}$, we get a path P_2 (by deleting the vertex a and edges ab, ac), then*

$$F_{P_2}(\underline{r_e^{'}}, s) = \frac{t^2 r_{ab} r_{ac} + t r_{bc}}{(1 - tr_{ab})(1 - tr_{ac})} - s\frac{tr_{bc}}{(1 - tr_{ab})(1 - tr_{ac})}.$$

Proof. Assume that after running **Algorithm** $\mathcal{U}_{n,3}$ we get a cycle C_3 with edge densities $\gamma_e = 1 - tr_e$. Let $V(C_3) = \{a, b, c\}$ and $r_{ab}, r_{ac}, r_{bc} \in [0,1)$. The multivariate matching polynomial

$$F_{C_3}(\underline{r_e}, s) = 1 - s(r_{ab} + r_{ac} + r_{bc})$$

has exactly one root

$$t = \frac{1}{(r_{ab} + r_{ac} + r_{bc})}.$$

By deleting vertex a from the cycle C_3 with the edges $e_{ab} = ab$ and $e_{ac} = ac$ we obtain a path $P_2 = bc$. By Theorem 7 we get that

$$F_{P_2}(\underline{r_e^{'}}, s) = 1 - sr_{bc}^{'} = 1 - s\frac{tr_{bc}}{(1 - tr_{ab})(1 - tr_{ac})}.$$

By multiplying both sides by

$$(1 - tr_{ab})(1 - tr_{ac})$$

we have

$$(1 - tr_{ab})(1 - tr_{ac})F_{P_2}(\underline{r_e^{'}}, s) =$$

$$(1 - tr_{ab})(1 - tr_{ac}) - str_{bc} =$$

$$1 - t(r_{ab} + r_{ac} + r_{bc}) + tr_b c + t^2 r_{ab} r_{ac} - str_{bc}.$$

So

$$(1 - tr_{ab})(1 - tr_{ac})F_{P_2}(\underline{r_e^{'}}, s) - t^2 r_{ab} r_{ac} - tr_{bc} + str_{bc} =$$

$$F_{C_3}(\underline{r_e}, t) = 0.$$

Algorithm $U_{n,3}$

Input: a unicyclic graph $H \in \mathcal{U}_{n,3}$ with the set of edge densities $\{\gamma_e\}_{e\in E(H)}$.

Output: a boolean value

$$D = \begin{cases} TRUE, & \text{the densities } \gamma_e \text{ ensure the existence of a factor } H, \\ FALSE, & \text{the densities } \gamma_e \text{ does not ensure the existence of a factor } H. \end{cases}$$

Consider a weighted graph (H, r_e), where $r_e = 1 - \gamma_e$.

Step 1.

- **if** $|V(H)| = 2$ *(means H is a path P_2) and* $0 \le r_e < 1$ **then**

  STOP: D :=TRUE.

- **if** $|V(H)| \ge 2$ *and there exists an edge for which* $r_e \ge 1$ **then**

  STOP: D :=FALSE.

Step 2.

- **if** $|V(H)| = 3$ *(means H is a cycle C_3) and* $0 \le r_e < 1$ *for all edges* $e \in E(H)$ **then**

  pick a vertex c of the graph H and let a, b be its neighbours. Let $H' := H - c$ and

$$r'_{ab} = \frac{r_{ab}}{(1 - r_{ac})(1 - r_{bc})}.$$

- **if** $|V(H)| > 3$ *and* $0 \le r_e < 1$ *for all edges* $e \in E(H)$ **then**

  pick a vertex v of degree 1 and let u be its unique neighbour. Let $H' := H - v$ and

$$r'_e = \begin{cases} r_e, & \text{if } e \text{ is not incident to } u, \\ \frac{r_e}{1 - r_{uv}}, & \text{if } e \text{ is incident to } u. \end{cases}$$

Go to *Step 1* with $(H, r_e) := (H', r'_e)$.

Hence

$$F_{P_2}(\underline{r'_e}, s) = \frac{t^2 r_{ab} r_{ac} + t r_{bc}}{(1 - t r_{ab})(1 - t r_{ac})} - s \frac{t r_{bc}}{(1 - t r_{ab})(1 - t r_{ac})}.$$

By the definition of $F_{P_2}(\underline{r'_e}, s)$ we have

$$\frac{t^2 r_{ab} r_{ac} + t r_{bc}}{(1 - t r_{ab})(1 - t r_{ac})} = 1$$

and

$$t(r_{ac} + r_{ab} + r_{bc}) = 1.$$

Note that if

$$\gamma'_{bc} = 1 - \frac{t r_{bc}}{(1 - t r_{ab})(1 - t r_{ac})} = 0,$$

then

$$t r_{bc} = (1 - t r_{ab})(1 - t r_{ac})$$

and

$$\frac{t^2 r_{ab} r_{ac}}{(1 - t r_{ab})(1 - t r_{ac})} = 0,$$

$$t r_{ab} t r_{ac} = 0.$$

Therefore,

$$t(r_{ac} + r_{ab} + r_{bc}) = 1 + t r_{ab} t r_{ac} = 1.$$

So t is the root of $F_{C_3}(\underline{r_e}, t)$. □

From above consideration we deduce that **Algorithm** $\mathcal{U}_{n,3}$ works correctly with time complexity at most $\mathcal{O}(n^2)$. **Algorithm** $\mathcal{U}_{n,3}$ can be implemented in such a way that a vertex of the subgraph C_3 be considered (picked) in the last step of the algorithm.

IV. Conclusion

We have presented **Algorithm** $\mathcal{U}_{n,3}$ for testing whether the unicyclic graph $H \in \mathcal{U}_{n,3}$ with the set of edge densities $\{\gamma_e\}_{e\in E(H)}$ is a factor of a blow-up graph $G[H]$. Precisely, we have the answer whether the edge densities ensure the existence of the factor or do not ensure. In future work we will study the density Turán problem for an arbitrary graph of the family $\mathcal{U}_{n,p}$, $p \geq 4$, and for other families of graphs. Moreover, we wish to construct efficient algorithms for testing the existence of blow-up graphs with factors of the families.

Open problem: Look for the density Turán problem algorithm for families of connected graphs with blocks (i.e., 2-connected components) isomorphic to cycles and/or P_2 .

***Abstract*—We address here a large scale routing and scheduling transportation problem, through introduction of a flow model designed on a dynamic network. We deal with this model while using a master/slave decomposition scheme, and testing the behavior on this scheme of both a GRASP algorithm and a Genetic algorithm.**

I. Introduction

WE ALREADY introduced (see [9]), in the context of a partnership with an industrial player, a flow/multi-commodity flow model **FMS** which aimed at optimizing the management of a urban shuttle fleet. This model involved a dynamic network (see [2, 10]), that is a network with time indexed vertices, which made easy expressing temporal constraints. At this time we designed a GRASP algorithmic scheme, which allowed us handling a kind of large scale pre-emptive *Pick Up and Delivery* problem (see [10]), while using an ad hoc aggregation mechanism and performing random negative circuit cancelling.

We consider here the same model **FMS**, close to **CFA** (*Capacitated Flow Assignment*) models (see [1]) used in telecommunications, but we deal with it in a simpler way, while using an auxiliary cost vector as the master variable of a master/slave decomposition scheme. This scheme induces the design of resolution heuristics which mainly rely on simple shortest path procedures instead of complex negative circuit cancelling procedure, and whose generic features makes implementation easier. While next section II is devoted to a rough description of the **FMS** model, our main contribution is about the description in Section III of this master/slave decomposition scheme, from which we derive (sections IV and V) both a GRASP (*Greedy Random Adaptive Search Procedure*, see [5, 6]) algorithm, and a *genetic* algorithm (see [6, 7, 8]). We detail the way those algorithms are implemented, and test (Section VI) their respective behaviors.

II. The FMS Model

A. Main Notations and Definitions

A network G, with vertex set X and arc set E, is denoted by $G = (X, E)$. A *flow* vector is an arc indexed vector f with rational or integral values such that, for every vertex x, we have $\Sigma_{e \text{ enter into } x} f_e = \Sigma_{e \text{ comes out } x} f_e$ (*Kirchhoff Law*). The *arc support* of f is the arc subset $Arc\text{-}Supp(f) \subseteq E$, which contains all arcs $e \in E$ such that $f_e \neq 0$. A *multi-commodity flow* vector f is a flow vector collection $f = \{f(k), k \in K\}$. $Sum(f)$ is the *Aggregated Flow* $Sum(f) = \Sigma_{k \in K} f(k)$.

B. The Shuttle Problem (see [16])

We consider a *Urban Area* network $H = (Z, U)$: nodes of H mean either production sites $y_1,\ldots,y_m$ ($m = 7$ in the original application), or *residential* areas, and arcs mean elementary connections. A demand D_k, $k \in K$, is a 4-uple (o_k, d_k: *origin/destination nodes*, L_k: *Load*, t_k: *deadline*): L_k users have to be transported from o_k and to d_k (at least one of both nodes being an industrial node) while starting (arriving) after (before) time st_k (at_k). *Quality of Service* (QoS) requires this trip not to last more than T_k time units. Users alternatively walk and use a *shuttle* system; so, every arc e of H is endowed with a *walking* length $l_p(e)$ and with a *vehicle* length $l_v(e)$. Vehicles start from and end into a *Depot* node. Our goal is to route the shuttles while meeting the demands and minimizing both the number of vehicles (*Fixed Investment Cost*) and their running times (*Running Cost*). ***Route preemption* is allowed**: several vehicles may be involved in meeting a given demand.

C. The Dynamic Network H-Dyn.

We derive it from H by associating (see 2, 8, 10), with any node x of Z, (NP+1) copies of x, indexed from 0 to NP, which represent the states of x at the instants 0, δ,…, NP.δ;

δ is an elementary time unit, chosen between 3 mn and 6 mn in our application; *NP* is a parameter which fixes the planning period (between 2 and 3 h). We add 2 fictitious vertices *DP, DP** and set $X = \{x_r, x \in Z, r \in 0,\ldots, NP\} \cup \{DP, DP^*\}$. As for the arc set *E*, we round modulo δ the *vehicle* and *walking* lengths of any arc *u* in *U* by setting: $l^*_p(u) = \lceil l_p(u)/\delta \rceil$, $l^*_v(u) = \lceil l_v(u)/\delta \rceil$; then we define the labeled arc family *E* as containing:

- *wait* arcs (x_r, x_{r+1}), $x \in Z$, $r \in 0,\ldots, NP$-1 : such an arc is considered twice, with *walk* and *vehicle* labels;
- arcs $(DP, Depot_r)$, $(Depot_r, DP^*)$, $r \in 0,\ldots, NP$, with *vehicle* labels.
- arcs $(x_r, z_{r+l^*v(u)})$, $u = (x, z) \in U$, r such that $0 \le r \le NP - l^*_v(u)$, with *vehicle* label;
- *walk* arcs $(x_r, z_{r+l^*p(u)})$, $u = (x, z) \in U$, r such that $0 \le r \le NP - l^*_p(u)$, with *walk* label;
- a *backward* arc (DP^*, DP).

We denote by *A* the subset of *E* defined by the *vehicle* arcs. We provide, in a natural way, any arc *e* with an *Economical Cost* c_e and a *QoS Cost* p_e.

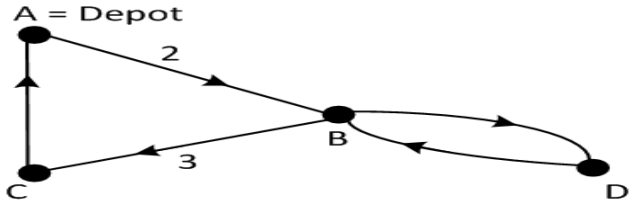

Fig. 1: Urban Transit Network *H* = (*Z*, *U*)

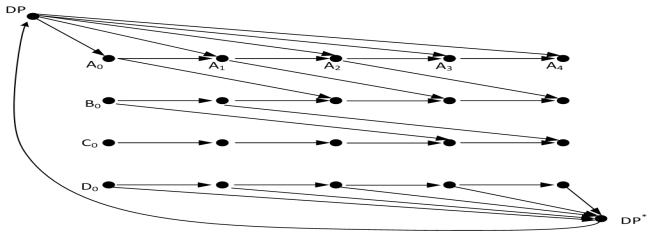

Fig. 2: Dynamic Network *H-Dyn* = (*X, E*).

Remark 1: *Size of H-Dyn*. We consider that (x, y) is an arc of *H* if a vehicle may move from *x* to *y* during time unit δ. If *H* contains 200 nodes, *H-Dyn* may contain up to 10^5 arcs.

D. The Flow/Multi-commodity Shuttle Model (FMS)

We want to route both vehicles and users. Aggregating vehicle routes yields, on the dynamic network *H-Dyn* = (*X, E*), some **integral flow vector *F***, and that user's routes may be represented as a **rational multi-commodity flow** $f = \{f(k), k \in K\} \ge 0$. Measuring *f* in such a way the capacity of any vehicle becomes equal to 1 yields the following **FMS**: *Flow/Multi-Commodity Flow Shuttle* model:

FMS: *Flow/Multi-Commodity Flow Shuttle* Model.
Input: The *Urban Area* network *H* = (*Z*, *U*), and the discrete time space $\{0,.., N\delta\}$;
Output: Compute, on the dynamic network *H-Dyn* an integral flow vector *F*, and a **rational multi-commodity flow** $f = \{f(k), k \in K\} \ge 0$, such that:

- *F* is null on the *walk* arcs ;
- For any $k \in K$, $f(k)$ routes L_k users from o_k to d_k between time st_k and time at_k;
- $g = Sum(f)_e = \Sigma_{k,e} f(k)_e \le F_e$, for any arc of *H-Dyn* with *vehicle* label;
- $Cost(F) + QoS(f) = c.F + p.Sum(f) = \Sigma_{e \text{ in } A} c_e.F_e + \Sigma_{e \text{ in } E} p_e.Sum(f)_e$ is minimal

Conversely, if *F* and *f* satisfy **FMS** constraints and if *Route Preemption* is allowed, then they yield a feasible solution of the *Shuttle* Problem. Our model casts *temporal constraints* into the construction of the network *H-Dyn*. We denote by $\mathbf{FMS}_g$ the time-polynomial min cost integral flow problem which derives from **FMS** by fixing $g = Sum(f)$.

Remark 2: ***FMS Model Size***. If the number of demands is 250, then the size of *f* may be up to $25\ 10^6$: the resulting **FMS** model is a large scale NP-Hard MIP problem.

III. FUNDAMENTAL TOOLS

Before describing algorithm, we need to specify which objects and procedures they will involve.

A.A Master/Slave Encoding of a FMS Solution

The quality of a **FMS** solution relies on its ability to make users share vehicles. While the size *H-Dyn* may eventually be very large, the number of arcs which are going to support non null *F* and $g = Sum(f)$ is comparatively small. So, a key object in our model should be the *arc support set* $A = Arc\text{-}Supp(F) = \{e \in E$ such that $F_e \ne 0\}$ of *F*. The following theoretical result, whose proof can be obtained through standard mathematical programming techniques, will help us in dealing with this *arc support set*:

***Dualization* Theorem**: *Let (F, f) an optimal solution of the **FMS** model. Then there exists a price vector $\mu \ge 0$, with indexation on the arc set of H-Dyn, such that:*

- *$\mu_e = 0$ for any arc e which is a walk arc or a wait arc and which is not in A;*
- *$\mu_e \ge c_e$ for any arc e in A; $\mu_e = +\infty$ for any vehicle arc e which is not in A;*
- *Every flow f(k) is an optimal solution of the min cost flow problem defined by: (E1)*
  - *for every $k \in K$, f(k) routes load L_k f(k) from o_k to d_k between time st_k and time at_k;*
  - *$\Sigma_e (\mu_e + p_e).f(k)_e$ is the smallest possible.*

So, the knowledge of both *arc support set* A and cost vector μ allow us to derive, through shortest path procedures, the aggregated flow $g = Sum(f)$. Flow vector F is computed as a solution of $\mathbf{FMS}_g$. We impose every vector $f(k)$, $k \in K$, to be routed along a single path. So, a well-fitted representation of a **FMS** solution is given by:

- the *set Arc-Supp*$(F) = \{e \in E$ such that $F_e \neq 0\}$;
- the related cost vector $\mu = \mu_e$, $e \in A$.

Those objects define the *Master* part of such a solution, whose *Slave* part is defined by F and the collection $\Gamma(k)$ of the paths followed by the flow vectors $f(k)$, k in K.

B. Dealing with the FMS_g Problem

We deal with $\mathbf{FMS}_g$ through *column generation*, while using an arc/path formulation of $\mathbf{FMS}_g$:

> $\mathbf{FMS}_g$:{Λ denotes the set of paths from *DP* to *DP**;
> Compute a vector $G = (G_\gamma, \gamma \in \Lambda) \geq 0$, with rational values, such that:
> - for any arc e of *H-Dyn* with *vehicle* label, $\Sigma_{\gamma \text{ such that } e \in \gamma} G_\gamma \geq \lceil g_e \rceil$;
> - $\Sigma_\gamma Cost(\gamma).G_\gamma$ is minimal}

If Λ_0 is some *active* subset of Λ, and if $\lambda = (\lambda_e, e$ in the arc subset of *H-Dyn* with *vehicle* label$) \geq 0$ is a dual solution of the restriction of $\mathbf{FMS}_g$ to Λ_0, then the related *Pricing* (search for the new entering column) sub-problem is as a largest path problem, handled by Bellman algorithm. So, when dealing with the $\mathbf{FMS}_g$ problem, we do in such a way that we are always provided with some current *active* path subset Λ_0 of Λ, which evolves in an incremental way.

C. Deriving the paths $\Gamma(k)$ from A and μ.

Dualization Theorem tells us that support set A and cost vector μ should identify the arcs along which users are going to share a same vehicle. If A and μ were conveniently chosen, paths $\Gamma(k)$, $k \in K$, should be shortest paths for cost vector $(p + \mu)$. So, all throughout the execution of our processes, we derive paths $\Gamma(k)$, $k \in K$, as shortest paths for the following cost vector $C^{A,\mu}$:

- If e is a *walk* other *wait* arc which is not in A, then $C^A_e = p_e$;
- If e is in A, then $C^A_e = \mu_e + p_e$;
- Else $C^A_e = p_e + c\mu^*$, where $\mu^* = \text{Max}_{e \in A} \mu_e/c_e$. (E2)

As a matter of fact, for a given *vehicle* arc $e \notin A$, we apply (E2), which means that we want to keep paths $\Gamma(k)$, $k \in K$ from using vehicle arcs which are not in A, only when no path $\Gamma(k)$, $k \in K$ involves e. Else, we use μ^* defined by:

$\mu^* = \text{Mean Value}_{e \in A} \mu_e$.

D. A Randomized Initialization

This initialization procedure **FMS-INIT** works through successive insertions of demands D_k, $k \in K$, into a current aggregated flow vector g:

> **FMS-INIT Procedure**:
> - g: current aggregated flow vector; K_0: set of inserted demands;
> - F and λ: primal and dual solutions of $\mathbf{FMS}_g$;
> - Λ_0 = set of *active vehicle* paths;
>
> While $K - K_0$ is not empty do
>
> Randomly Pick up $k \in K - K_0$ and *Insert* it into K_0: route demand k according to some path $\Gamma(k)$ in *H-Dyn*, in such a way that: (I1)
> - $\Gamma(k)$ connects o_k to d_k, while satisfying related temporal constraints;
> - the induced increase in the cost $\lambda.\lceil g \rceil + p.g$ is the smallest possible ;
>
> Update F, λ and Λ_0.
>
> Set $A = Arc\ Support$ of F; For every arc e in A, set:
> $\mu_e = \lambda_e.\lceil g_e \rceil$. (I2)

The above *Insert* instruction (I1) is handled by a *shortest path* Bellman-like Algorithm.

E. Local Transformation and Mutation Operators

The **FMS-INIT** previous process gives rise in a generic way to a local transformation operator *TRANS*, which acts on a current solution A, μ, F, $\Gamma = \{\Gamma(k), k \in K\}$ as follows:

> **Local Operator *TRANS***(K_0: K_0 subset of K)
> - Randomly select $K_0 \subseteq K$ and withdraws paths-flows $\{f(k), k \in K_0\}$ from g; Update flow vector F;
> - Reinsert demands D_k, $k \in K_0$, according to the III.D, while starting from current partial solution (F, g);
> - Consequently update A and μ.

Operator **TRANS** will be used here in both GRASP scheme, according to a *Descent* strategy and in a genetic meta-heuristic scheme, as a *mutation* operator.

F. Crossover Operator

Given two feasible **FMS** solutions A_1, μ_1, F_1, $\Gamma_1 = \{\Gamma_1(k), k \in K\}$ and A_2, μ_2, F_2, $\Gamma_2 = \{\Gamma_2(k), k \in K\}$. *SON-CREATE* derives children (A, μ) and (A', μ') as follows:

Crossover Operator SON-CREATE:

For every arc e in $(A_1 \cap A_2)$, insert e into both A and A' and randomly assign related value μ_e or μ'_e with one of both values $(\mu_{1,e} + \mu_{2,e})/2$ and $(3.\mu_{1,e} - \mu_{2,e})/2$;
For every arc e in $(A_1 - A_2) \cup (A_2 - A_1)$, randomly insert e into either A or A' and randomly assign related value μ_e or μ'_e with one of both values $(\mu_{1,e} + \mu_{2,e})/2$ or $(3.\mu_{1,e} - \mu_{2,e})/2$;
Compute path collections $\Gamma = \{\Gamma(k), k \in K\}$ and $\Gamma' = \{\Gamma'(k), k \in K\}$ as in III.C; Compute F and F' flow vectors as in III.B, together with dual vectors λ and λ';
Update cost vectors μ and μ' according to (I2).

IV. A GRASP ALGORITHM FMS-GRASP FOR FMS

A GRASP: *Greedy Random Adaptive Search Procedure* (see [5, 6]) algorithmic scheme works by performing first a greedy randomized initialization process, and next a descent loop. It may be run according to several replications, either in a sequential or in a parallel mode. Here, we get:

FMS-GRASP(*R*: *Replication Number*, *Q*: *Subset Size*, *Loop*: *Loop Length Bound*);
For i = 1..*R* do
  Initialize A, μ, F, $\Gamma = \{\Gamma(k), k \in K\}$ through **FMS-INIT**; *Possible*;
  While *Possible* do (I3: *Descent* loop)
    Modify A, μ, F, $\Gamma = \{\Gamma(k), k \in K\}$ in such a way cost $c.F + p.g$ is improved;
    If *Failure*(*Modify*) then Not *Possible*;
The result of **FMS-GRASP** is the best A, μ, F, $\Gamma = \{\Gamma(k), k \in K\}$ ever obtained.

(I3) involves the *TRANS* operator as follows:

Possible;
While *Possible* do
  Trial-Number <- 1; *Success* <- *False*;
  Do Until *Success* or *Trial-Number* > *Loop*
    Generate $K_0 \subseteq K$ with cardinality Q; Save current A, μ, F, $\Gamma = \{\Gamma(k), k \in K\}$; (I4)
    Apply $TRANS(K_0)$ to A, μ, F, Γ; If $c.F + p.g$ is improved then *Success* Else
      Restore A, μ, F, Γ;
      Trial-Number <- *Trial-Number* + 1;
  Possible <- *Success*;

Choosing K_0 in the (I4) Instruction: it is defined by the paths $\{\Gamma(k), k \in K\}$ which contain the arcs e with the highest $(\mu_e + p_e)$ values.

A *Random Walk* Variant of FMS-GRASP: Because of the computing costs induced by Instruction (I4), we also implement a *Random Walk* strategy:

FMS-GRASP-1(*R*: *Replication Number*; *RW*: *Loop Length Bound; Q: Subset Size*);
For i = 1..*R* do
  Initialize A, μ, F, $\Gamma = \{\Gamma(k), k \in K\}$ through **FMS-INIT**;
  For *Counter* = 1..*RW* do (I4.1: *Random Walk* loop)
    Generate $K_0 \subseteq K$ with cardinality Q;
    Apply $TRANS(K_0)$ to A, μ, F, Γ;
The result is the best (A, μ, F, Γ) ever obtained.

V. A GENETIC ALGORITHM FMS-GEN FOR FMS

The main components of a *Genetic* algorithm are (see [6, 7, 8]): its *Encoding* scheme (*Chromosome* Representation); the *Initialization* Procedure which yields the initial *population* Σ; its *Mutation* operator; its *Crossover* operator.

Clearly, the *Encoding* scheme is the encoding scheme of Section III.A whose *master* objects are:
- the *arc support set Arc-Supp*$(F) = \{e \in E$ such that $F_e \neq 0\}$ of F;
- the related cost vector $\mu = \mu_e$, $e \in A$;

and the *slave* objects are the flow vector F and the path collection $\Gamma = \{\Gamma(k), k \in K\}$.
Initialization is performed through Card(Σ) successive applications of **FMS-INIT**.
Mutation results from application of the operator *TRANS*, with parameter K_0 generated with a given cardinality Q, Q becoming a parameter of the global process:

FMS-Mutation(A, μ, F, $\Gamma = \{\Gamma(k), k \in K\}$, Q);
  Generate some subset K_0 of K with cardinality Q;
  Apply $TRANS(K_0)$ to A, μ, F, Γ;

The *FMS-Crossover crossover* operator is the **SON-CREATE** operator of Section III.F.

What remains to be discussed here is the *Fitness* Criterion, and the way *FMS-Crossover* is applied:
- Given $(A_1, \mu_1, F_1, \Gamma_1 = \{\Gamma_1(k), k \in K\})$ and $(A_2, \mu_2, F_2, \Gamma_2 = \{\Gamma_2(k), k \in K\})$ in current population Σ, *Fitness* is related here to the cardinality of the difference set $(A_1 - A_2) \cup (A_2 - A_1)$: the smallest is it, the largest is the *Fitness* measurement;
- Best-fitted pairs are selected, in order to avoid *cloning*, with the constraint that no solution σ belongs to more than 2 pairs. It is done in a heuristic way.

The main parameters of the deriving Genetic Algorithm **FMS-GEN** are the *population* size P, the number LG of iterations of *mutation/crossover* process and the *size* Q.

VI. NUMERICAL EXPERIMENTS

Experiments are performed on a LINUX server CentOS 5.4, Processor Intel Xeon 3.6 GHZ, with help of the CPLEX 12 library.

A. Instance Generation

An instance is defined by: the *Urban Area* network $H = (Z, U)$, with n vertices and m arcs; *demands* D_k, $k \in K$; *walking* lengths $l_p(e)$, and *vehicle* lengths $l_v(e)$, $e \in U$; *Vehicle* cost vector c and *User* cost vector p; the size NP of the time-space; the arc number NA of *H-Dyn*. We generate our own small and large instances: nodes of H are points of the 2D Euclidean space, with adjacency related to distance thresholds; *demands* D_k, $k \in K$ are randomly generated through uniform distribution.

B. Evaluation of FMS-INIT.

We first consider small instances, for which we get an exact optimal value through the CPLEX.12 Library, and next consider larger size instances, with focus on the large scale issue. In both cases:

- n, m are respectively the node and arc numbers of H, NP is the period number, NOD is the number of demands; L is the mean value of loads L_k, $k \in K$, and α is the mean ration p_e/c_e, $e \in E$.
- R is the replication number of **FMS-INIT**.

Small instances: We focus on precision of **FMS-INIT**, and test packages of 10 instances. *GAP-MEAN* is the mean error $GAP = (VAL - OPT)/OPT$: VAL = cost value computed by **FMS-INIT**, OPT = optimal value computed by CPLEX.12. *GAP-VAR* is the variance of *GAP*. We get:

R	*GAP-MEAN*	*GAP-VAR*
1	22.5	25.8
5	17.3	20.7
10	13.4	17.9
20	11.9	15.4
50	10.5	13.6

Table 1: **FMS-INIT** Evaluation, Small Instances, 10 instances/packages; **Group-Instance***: n = 10, m = 30, NP = 10; NOD = 10; α = 0.5; L = 0.2;* Impact of R.

Analysis: Parameter R plays a key role. *GAP-VAR* is usually large: a single **FMS-INIT** run may yield poor solutions.

Large instances: We focus here on CPU times and on the sensitivity to parameter R: $V(R)$ is the mean value $(Max(R) - Min(R))/Min(R)$, where $Max(R)$ and $Min(R)$ are respectively the worse and best values obtained through **FMS-INIT**(R), while *Var-V*(R) is the related variance. *Mean-CPU* is the mean running time, while *Var-CPU* is the related variance.

R	*V*(*R*)	*Var-V*(*R*)	*Mean-CPU (in s)*	*Var-CPU*
1	0.0	0.0	24.8	12.5
5	0.08	0.05	98.5	67.2
10	0.14	0.04	177	101.0
20	0.18	0.04	329	151.4
50	0.22	0.03	745	256.1

Table 2: **FMS-INIT** Evaluation, Large Instances, 10 instances/packages; **Group-Instance***: NA = 66256; NOD = 100; α = 0.5; L = 0.2;* Impact of R.

Analysis: The replication mechanism is crucial.

C. Evaluation of FMS-GRASP.

We focus on the respective ability of the standard Descent loop with parameter *TH* and of the random walk with parameter *RW* to improve the initial solution.

Small instances, 10 instances/packages with n = 10, m = 30, NP = 10, NOD = 10, L = 0.2; α = 0.5: *GAP-MEAN* is the mean error $GAP = (VAL - OPT)/OPT$, where VAL is computed by **FMS-GRASP**, and *GAP-VAR* is the variance of *GAP*. We use R = 10, Q = 3.

TH	*GAP-MEAN*	*GAP-VAR*
1	13.1	17.8
4	11.3	11.0
8	9.4	9.5
15	7.2	8.3

Table 3: **FMS-GRASP/Descent**: Impact of *TH*

RW	*GAP-MEAN*	*GAP-VAR*
1	13.3	17.8
4	11.5	13.1
10	9.3	11.8
40	6.8	8.8
80	3.8	5.1

Table 4: **FMS-GRASP/Random Walk**: Impact of *RW*

Analysis: *Random Walk* is more efficient than *Descent*.

Large instances, 10 instances/packages, with NA = 66256; NOD = 100; α = 0.5; L = 0.2. $IMPROVE = (Min(R) - Val(R, RW))/Val(R,W)$, where $Min(R)$ is computed by **FMS-INIT**(R) and $Val(R, W)$ is computed by **FMS-GRASP**(R, RW). $IMPROVE(R, RW)$ is the mean *IMPROVE* Value.

R	*RW*	*IMPROVE*(*R*, *RW*)	*Mean-CPU*
1	5	2.3	39
1	100	9.8	249
5	5	1.7	151
5	100	9.1	1012
10	5	1.4	257
10	100	6.7	1618

Table 5: **FMS-GRASP** Evaluation, Large Instances: Impact of R and RW.

Analysis: Computing times remain under control. Improvement margin induced by the *Random Walk* loop are close to the values obtained for small instances.

D. Evaluation of FMS-GEN.

We use the same tests as in Section VI.C. *P* is the size of the population, *LG* is the length of the main loop of the process. The population Σ is initialized by **FMS-INIT**(*P*).

Small instances: 10 instance packages with $n = 10$, $m = 30$, $NP = 10$; $NOD = 10$; $L = 0.2$; $\alpha = 0.5$; *GAP-MEAN* is the mean error GAP = (*VAL* – *OPT*)/*OPT*, where *VAL* is the cost value of the solution which is computed by **FMS-GEN**, and *OPT* is the optimal result computed by CPLEX.12 *GAP-VAR* is the variance of *GAP*. We focus on difficult instances, and deal with rather small populations (no more than 30) and small *LG* values. We use $P = 10$, $Q = 3$; $\Pi = 1$;

P	*GAP-MEAN*	*GAP-VAR*
4	10.3	14.7
10	6.2	8.0
20	4.2	5.4
30	3.8	4.5

Table 6: **FMS-GEN** Evaluation, Impact of *P*.

LG	*GAP-MEAN*	*GAP-VAR*
10	9.3	11.7
20	9.1	11.4
50	6.2	7.0
100	2.9	4.1

Table 7: **FMS-GEN** Evaluation, Impact of *LG*.

Large instances: For any instance, we evaluate the improvement ratio *IMPROVE* = (*Min*(*P*) - *Val*(*P, LG*))/*Val*(*P,LG*), where *Min*(*P*) is the value obtained while running **FMS-INIT**(*P*) and *Val*(*P, LG*) is the value obtained while running **FMS-GEN**(*P*, *LG*). *IMPROVE*(*P*, *LG*) is the mean *IMPROVE* value on 5 instance package defined by parameter values: *NA* = 66256; *NOD* = 100; $\alpha = 0.5$; $L = 0.2$. We use $Q = 15$ and $\Pi = 1$.

P	*LG*	*IMPROVE*(*P*, *LG*)	*Mean-CPU*
4	10	4.6	451
4	20	7.2	828
4	50	9.6	1830
10	10	3.3	1296
10	20	5.8	2265
10	50	7.3	4520

Table 8: **FMS-GEN** Evaluation, Large Instances, Impact of *P* and *LG*.

General comment: The GRASP scheme is less accurate the the GA scheme, but it is more flexible and tackles more easily large scale instances. When it comes to practical applications, accuracy is not such an issue. So it comes that we may consider here that, from this point of view, GRASP performs better.

VII. CONCLUSION

Reformulating the **FMS** model through through implicit representations allows us to design efficient GRASP and genetic algorithms. Still, we notice that since those algorithms rely on sophisticated LP techniques, we should now study the way to efficiently involve recently emerging generic framework, like ILP software SCIP/CPLEX, in such a way development and maintenance costs be minimized.

***Abstract*—We present here new results and algorithms for the *Linear Arrangement* Problem (LAP). We first propose a new lower bound, which links LAP with the *Max Cut* Problem, and derive a LIP model as well as a branch/bound algorithm for the general case. Then we focus on the case of interval graphs: we first show that our lower bound is tight for unit interval graphs, and derive an efficient polynomial time approximation algorithm for general interval graphs.**

I. Introduction

LET G = (X, E) be a non oriented graph where X and E respectively denote the vertices and edges of G. The *Linear Arrangement* Problem (LAP) consists of finding a one-to-one mapping ϕ from X to $\{1, \ldots, |X|\}$ that minimizes:

$$f(G,\varphi)=\sum_{(x,y)\in E}|\varphi(y)-\varphi(x)|$$

The LAP problem has applications (see [3, 11]) in Information Retrieval and Industrial Storage, and may also appear as a sub-problem of some Network Design models (see [4]). It is, even in practice, a very difficult combinatorial optimization problem. The corresponding decision LAP was first shown to be *NP*-complete for arbitrary graphs (see for example [8, 9]) and next, for interval graphs [5] and bipartite graphs [9]. However, polynomial time algorithms were designed for trees [4], unit interval graphs [6], paths, cycles, complete bipartite graphs, grid graphs [11] and restricted series-parallel graphs [1]. A survey is available in [3].

Since LAP is *NP*-hard, even for graphs which usually turn most difficult problems into time-polynomial ones, the heuristic approach is therefore justified to deal with it. So the goal of this theory oriented study is to provide tools for the design of exact and approximation LAP algorithms with some focus on interval graphs. The paper is organized as follows. Section 2 introduces an linear ordering based reformulation of LAP. In Section 3, we propose a general lower bound, which links LAP with the well-known *Max Cut* Problem, and next derive, in Section 4 and 5, an ILP model together with a branch/bound algorithm. Finally, in section 6 we restrict our study to the case of interval graphs and propose an approximation algorithm, whose efficiency is briefly tested in Section 7.

II. Notations, definitions, LAP reformulation

A simple (non oriented) graph with no loop is denoted by G = (X, E): X (E) is the node (edge) set of G. We denote by (x, y) = (y, x) an edge with end-nodes x and y in X. If $A \subseteq X$, then G_A is the sub-graph induced by A from G. If $x \in X$, then $\Gamma_G(x) = \{y \in X$ such that $(x, y) \in E\}$ is the *neighbour* set of x. The complementary graph $G^c = (X, E^c)$ of G is defined by: $E^c = \{(x, y)$ such that (x, y) ¿ E and $x \neq y\}$. A *triangle* of G is a clique with 3 nodes. An *anti-edge* is a pair $e = (x, y) = (y, x)$, $x \neq y$, such that $(x, y) \notin E$. A *fork* with *root* x is any (non oriented) triple $f = \{x, y, z\} = \{x, z, y\}$ such that $(x, y), (x, z) \in E$, and $(y, z) \notin E$. An *anti-fork* with *root* z is any triple $f = \{x, y, z\} = \{y, x, z\}$ such that $(x, y) \in E$ and $(x, z), (y, z) \notin E$.

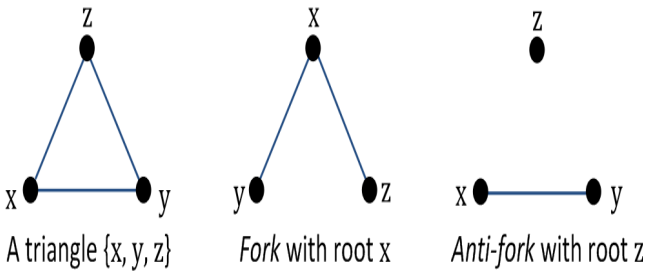

Figure 1: Triangles, Forks and Anti-Forks

LAP Reformulation: A *linear ordering* of a set X is a binary order relation σ such that, for any pair x, y in X, $x \neq y$, we have either $x \sigma y$ or $y \sigma x$. Given a graph G = (X, E) and a linear ordering σ of X. For any edge e = (x, y), we set BE(e, z, σ) = (*elementary break* of e by z according to σ) = 1 if $x \sigma z \sigma y$ or $y \sigma z \sigma x$, and 0 otherwise. We set BG(G, σ) = (*Global Break* of G according to σ) = $\Sigma_{e,z}$ BE(e, z, σ). If $\phi(\sigma)$ is the one-to-one mapping from X into $\{1, \ldots, |X|\}$ which derives from σ, then: $f(G, \phi(\sigma)) = \Sigma_{(x,y) \in E} |\phi(y) - \phi(x)| = BG(G, \sigma) + |E| = \Sigma_{e,z}$ BE(e, z, σ) + |E|.

So, solving LAP means seeking σ that minimizes the *Global Break* $BG(G, \sigma)$: we denote by LAP(G) the related optimal value $Inf_{\sigma} BE(G, \sigma)$.

III. Linking Max Cut and LAP: A General Lower Bound

Computing a good linear ordering σ of the vertices of a graph $G = (X, E)$ means efficiently deciding, for any $x \in X$, which vertices of the *neighbour* set $\Gamma_G(x)$ are located before x according to σ. This local decision process may be linked to the well-known *Max Cut* Problem [2,7,10]:

> ***Max Cut* Problem**: Let $H = (Z, F)$ be a simple graph. We denote by $Z = A \cup^{Ex} B$ any partition of Z into 2 disjoint subsets, and *Cut*(A, B) the number of edges of H with one extremity into A and the other into B. Solving the *Max Cut* Problem means seeking a *partition* $Z = A \cup^{Ex} B$ that maximizes *Cut*(A, B). We denote by *Max-Cut*(H) the related optimal value.

Let us consider now some graph $G = (X, E)$. We denote by *Tr*(G) the number of triangles of G. For any vertex x in X, we set:

- $H(x)$ = the complementary graph of the sub-graph of G which is induced by $\Gamma_G(x)$. Note that x is not a node of the graph H(x), since G has no loop;
- $m(x)$ = the number of edges of H(x); $V(x) = m(x) - Max\text{-}Cut(H(x))$.

Theorem 1: *For any graph G = (X, E), we have:* $LAP(G) \geq Tr(G) + \Sigma_x V(x)$.

Proof: Let us consider a linear ordering σ of G, and set:

- $Fk(G, \sigma)$ = number of *forks* f = {x, y, z}, f with root x, of G, such that $((x \sigma y) \wedge (x \sigma z)) \vee ((y \sigma x \wedge z \sigma x))$.
- $AFk(G, \sigma)$ = number of *anti-forks* f = {x, y, z} of G, f with root z, such that $(x \sigma z \sigma y) \vee (y \sigma z \sigma x)$.

Let us first check that: $BG(G, \sigma) = Tr(G) + Fk(G, \sigma) + AFk(G, \sigma)$. (E1)

In order to do so, we consider an edge e = (x, y), and a node z, different from x and y. While counting $BE(e, z, \sigma)$, we consider three cases:

Case 1: x, y and z define a triangle. Then $BE(e, z, \sigma) = 1$ if either $x \sigma z \sigma y$ or $y \sigma z \sigma x$. In such a case no quantity $BE((x, z), y, \sigma)$, $BE((z, y), x, \sigma)$ is equal to 1. So, if x, y, z define a triangle, there exists exactly one node t in{x, y, z} such that $BE(e(t), t, \sigma) = 1$, where e(t) is the edge which is defined by {x, y, z} – t. We get $\Sigma_{e = (x, y), z \text{ such that } (x, y, z) \text{ is a triangle}} BE(e, z, \sigma) = Tr(G)$.

Case 2: f = {x, y, z} is a *fork* with root x. Then $BE((x, y), z, \sigma) = 1$ if either $x \sigma z \sigma y$ or $y \sigma z \sigma x$, and then $BE((x, z), y, \sigma) = 0$. Conversely, $BE((x, z), y, \sigma) = 1$ if either $x \sigma y \sigma z$ or $z \sigma y \sigma x$, and then $BE((x, y), z, \sigma) = 0$. So, (x, y, z) yields an elementary break iff y and z are located on the same side of x according to σ. Then:

$$\Sigma_{e = (x, y), z \text{ adjacent to exactly 1 extremity of } e} BE(e, z, \sigma) = \Sigma_x \Sigma_{y,z \in \Gamma G(x), (y, x) \notin E, y, z \text{ located the same way with respect to x}, \sigma} 1 = Fk(G, \sigma).$$

Case 3: f = {x, y, z} is an *Anti-Fork* with root z. Therefore, we have:

$\Sigma_{e = (x, y), z \text{ such that } (x, z) \notin E \text{ and } (y, z) \notin E} BE(e, z, \sigma) = AFk(G, \sigma)$.

We get (E1) from the relation: $\Sigma_{e, z} BE(e, z, \sigma) = \Sigma_{e = (x, y), z \text{ such that } (x, y, z) \text{ is a triangle}} + \Sigma_{e = (x, y), z \text{ adjacent to 1 extremity of } e} BE(e, z, \sigma) + \Sigma_{e = (x, y), z \text{ adjacent to no extremity of } e} BE(e, z, \sigma)$.

For any $x \in X$, a feasible solution $A(x,\sigma) \cup^{Ex} B(x, \sigma)$ of *Max Cut* is defined on H(x), by setting: $A(x,\sigma) = \{y \in \Gamma_G(x), \text{ such that } y \sigma x\}$; $B(x, \sigma) = \{y \in \Gamma_G(x), \text{ such that } x \sigma y\}$. Its value, in *Max Cut* sense, is: $m(x) - \Sigma_{y,z \in \Gamma G(x), (y, x) \notin E, y, z \text{ located the same way with respect to x}, \sigma} \mathbf{1} \leq Max\text{-}Cut(H(x))$. It follows that, for any $x \in X$, $\Sigma_{y,z \in \Gamma G(x), (y, x) \notin E, y \text{ and } z, \text{ located the same way with respect to x}, \sigma} \mathbf{1} \geq V(x)$. Then we get: $Fk(G, \sigma) = \Sigma_x \Sigma_{y,z \in \Gamma G(x), (y, x) \notin E, y, z \text{ located the same way with respect to x}, \sigma} \mathbf{1} \geq \Sigma_x V(x)$. We conclude. □

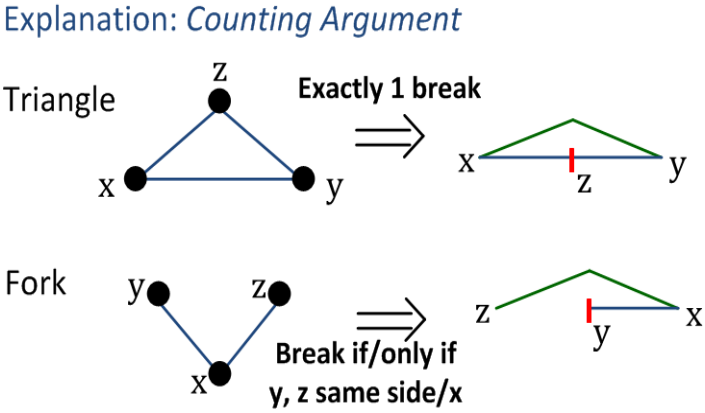

Figure 2: Theorem 1 Counting Argument

Remarks: Small experiments make appear that this bound is often tight, specifically in the case of *chordal* graphs. Still, the *Max Cut* Problem, which has been extensively studied, is *NP*-Hard [9]. So, one may ask about the practical use of the above lower bound. The answer is two-sided:

1. Even though *Max Cut* is NP-Hard, it may be considered as easier to handle than LAP: it admits a natural quadratic {0,1} formulation ([4, 11]) and instances related to the H(x), $x \in X$, are smaller than for original LAP.
2. We shall see in Section 6 that, in the case of interval graphs, our bounding scheme gives rise to an efficient polynomial time approximation scheme.

IV. Quadratic and linear models for LAP

The counting argument of Theorem 1 may also be used in order to derive a quadratic model for LAP. For every pair of nodes (x, y), we need to decide whether y is located right or left in relation to x according to the linear ordering σ. We express this information through a {0, 1} valued $W = (W_{x,y}, x \neq y)$ whose semantics is that: $W_{x,y} = 1$ (0) $\Leftrightarrow$ y located on the right (left) side of x according to linear ordering σ. Counting argument of Theorem 1 tells us that the number of elementary breaks induced by some linear ordering σ is a sum of:

- the number of triangles, which does not depend on linear ordering σ;
- the number of fork {x, y, z}, which are such that y and z are located on the same side with respect to root x according to σ ; (Q1)
- the number of anti-fork {x, y, z}, which are such that x and y are located on different side with respect to root z according to σ. (Q2)

In order to deal with quantity Q1, we introduce a {0, 1} valued vector $U = (U_{x,y}, (x, y) \text{ edge} \in E)$, whose semantics are: $U_{x,y} = 1$ (0) $\Leftrightarrow$ y located on the right (left) side of x. In order to deal with quantity Q2, we introduce a {0, 1} valued vector $V = (V_{x,y}, (x, y) \text{ anti-edge} \notin E)$, whose semantics are: $V_{x,y} = 1$ (0) $\Leftrightarrow$ y located on the right (left) side of x. While it is easy to state the constraints which must be satisfied by U, V, W in order to make them define a consistent linear ordering σ, we see that Q1 becomes equal to:

(Number of *forks* with root x) –

$$\Sigma_x \Sigma_{z,\ y \text{ such that } (y,z) \in E^c} U_{x,y}.\ (1 - U_{x,z}).$$

Also Q2 becomes equal to:

$$\Sigma_z \Sigma_{x,\ y \text{ such that } (x,y) \in E} V_{z,x}.(1 - V_{z,y}).$$

We deduce the following quadratic LAP model:

A Quadratic Linear Formulation of LAP.

- **Variables**
  - $U_{x,y}$, x, y such that (x, y) edge $\in$ E: $U_{x,y} = 1$ (0) $\Leftrightarrow$ y located to the right (left) of x
  - $V_{x,y}$, x, y such that (x, y) anti-edge $\in E^c$: $V_{x,y} = 1$ (0) $\Leftrightarrow$ y located to the right (left) of x
  - $W_{x,y}$, $x \neq y$: $W_{x,y} = 1$ (0) $\Leftrightarrow$ y located to the right (left) of x

- **Constraints** *(Consistency)*
  - For any x, y, $W_{x,y} + W_{y,x} = 1$
  - For any edge (x, y) $\in$ E, $U_{x,y} = W_{x,y}$
  - For any anti-edge (x, y) $\in E^c$, $V_{x,y} = W_{x,y}$
  - For any x, y, z, all distincts, $W_{x,y} + W_{y,z} \geq W_{x,z}$
  - For any x, y, z, all distincts, $(1 - W_{x,y}) + (1 - W_{y,z}) \geq (1 - W_{x,z})$

- **Minimize**

$$\Sigma_z \Sigma_{(x,y) \in E} V_{z,y}.(1 - V_{z,x}) - \Sigma_x \Sigma_{(y,z) \in E^c} U_{x,z}.\ (1 - U_{x,y})$$

If we denote by *Fork*(G) the number of forks of the graph G, we easily get:

Theorem 2 : *The optimal value of this quadratic {0,1} program is equal to LAP(G) – Tr(G) – Fork(G).*

This quadratic {0, 1} model may be easily turned into a linear one by introducing additional vectors S and T as follows:

- $S = (S_f, f = (x, y, z)$, fork with root x) subject to: $S_f \leq (1 - U_{x,z})$ and $S_f \leq U_{x,y}$; we consider here that forks are oriented, that means that (x, y, z) and (x, z, y) define 2 distinct forks with root x;

- $T = (T_f, g = (x, y, z)$, anti-fork with root z) T_g subject to: $T_g \geq (1 - V_{z,x})$ and $T_g \geq V_{z,y}$; we consider here that anti-forks are oriented, that means that (x, y, z) and (y, x, z) define 2 distinct anti-forks with root z.

Then minimizing the quadratic quantity $\Sigma_z \Sigma_{(x,y) \in E} V_{z,x}.(1 - V_{z,x}) - \Sigma_x \Sigma_{(y,z) \in E^c} U_{x,y}.\ (1 - U_{x,z})$ means minimizing the linear quantity $\Sigma_g T_g - \Sigma_f S_f$.

V. A BRANCH/BOUND ALGORITHM FOR LAP

We may derive from previous section an exact Branch/Bound method for LAP:

- *Branching* is performed by picking up some pair (x, y) of nodes and considering the two alternatives x σ y and y σ x according to linear ordering σ; Any sequence of such decisions may be extended through transitivity into a partial ordering of the node set X;

- *Bounding* is performed through integer linear programming, while extending Theorem 1 in a natural way: if σ is a partial ordering of the node set X obtained as above, we may set, for any node x:

  - $Max\text{-}Cut_\sigma(H(x))$ = Optimal value of the *Max-Cut* instance which is defined on the graph H(x), augmented with the following constraints:
    - If y such that (x, y) $\in$ E is also such that y σ x , then y must be on the subset A of the partition $\Gamma_G(x) = A \cup^{Ex} B$;
    - If z such that (x, z) $\in$ E is also such that x σ z , then z must be on the subset B of the partition $\Gamma_G(x) = A \cup^{Ex} B$;

  - $V_\sigma(x) = m(x) - Max\text{-}Cut_\sigma(H(x))$;

  - $W_\sigma(x) = \text{Inf}_{\text{partitions } A \cup Ex\ B \text{ of } X - \{x\} - \Gamma G(x)}$ Card({(x, y) $\in$ E, with x, y such that x $\in$ A, y $\in$ B})

  Then we see that the quantity $Tr(G) + \Sigma_x V_\sigma(x) + \Sigma_x W_\sigma(x)$ provides us with a lower bound for the best (in LAP sense) linear extension of σ.

- Branching strategy comes in a natural way: we give priority to pairs (x, y) which define edges of the graph G, and choose them in such a way the difference between the best alternative and the worst one is the largest possible.

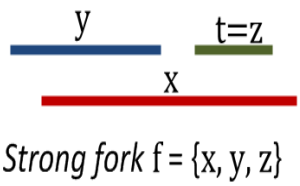
VI. THE CASE OF INTERVAL GRAPHS: A RESTRICTED VERSION OF LAP

We first introduce additional definitions related to interval graphs:

- A simple graph with no loop G = (X, E) is an *interval graph* if it is the intersection graph of a set [o(x), d(x)], x $\in$ X, of closed intervals of the real line. Those intervals may be chosen such that points o(x), d(x), x $\in$ X, are distinct. We assume this hypothesis to be always satisfied. We set:
  - x $\subset$ y if o(x) < o(y) and d(y) < d(x);
  - x << y if d(x) < o(y);
  - x *Ov* y if o(x) < o(y) < d(x) < d(x).

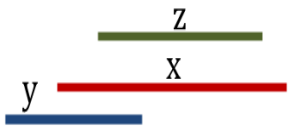
- In case X is an interval family with distinct endpoints, we say that a linear ordering σ of X is (*Ov*, <<)-*consistent* if it is consistent with both orderings *Ov* and <<. We denote by σ-*can* the *canonical linear ordering,* which is defined as follows: x σ-*can* y if, and only if, o(x) < o(y).

- Then, we say that a *fork* f = {x, y, z} with root x of such an interval graph G = (X, E) is a *strong fork* if there exists t $\in$ {y, z} such that t $\subset$ x, and that a triangle (x, y, z) is a *strong triangle* if at least some node is contained into another one (for instance z $\subset$ x).



Strong fork f = {x, y, z}

Figure 3: *Strong fork* f = {x, y, z}



Strong triangle = {x, y, z}

Figure 4: *Strong triangle* = {x, y, z}

- We say that G is a *Unit Interval graph* if intervals [o(x), d(x)], x $\in$ X may be chosen in such way that no pair x, y exists such that x $\subset$ y.

- We finally say that a subset Y of X is a *Left-(Ov, <<)-Section* (*Right-(Ov, <<)-Section*) if, for any x, y $\in$ X such that x $\in$ Y and (y Ov x) $\vee$ (y << x), then we also have y $\in$ Y (x $\in$ Y).

A. A Direct Application of Theorem 1 to Unit Interval Graphs

In the case of unit interval graphs, Theorem 1 allows us to state:

Theorem 2: *If G = (X, E) is a unit interval graph, then σ-can is an optimal solution of LAP.*

Proof: Let us suppose that an *elementary break* (e = (x,y), z, σ-*can*) exists, and that x *Ov* y, which implies that x σ-*can* y. If x << z then y σ-*can* z and z does not break e. Similarly, if z << x then z << x and z does not break e. It comes that x $\cap$ z is not empty. By the same way, y $\cap$ z is not empty and{x, y, z} is a *triangle*. So, there is a one-to-one correspondence between *triangles* and *elementary breaks*. So, BG(G, σ-*can*) = *Tr*(G), and we conclude. □

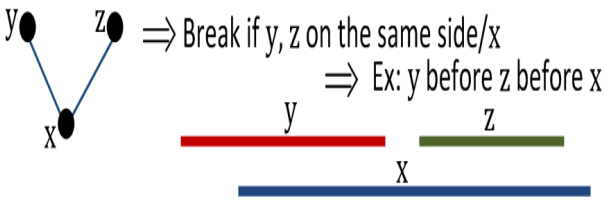


Figure 5: Theorem 2 Argument

B. An Approximation Result.

In the case of general interval graphs, σ-*can* may not be optimal. As a matter of fact, optimal solution may even not be (*Ov*, <<)-*consistent*:

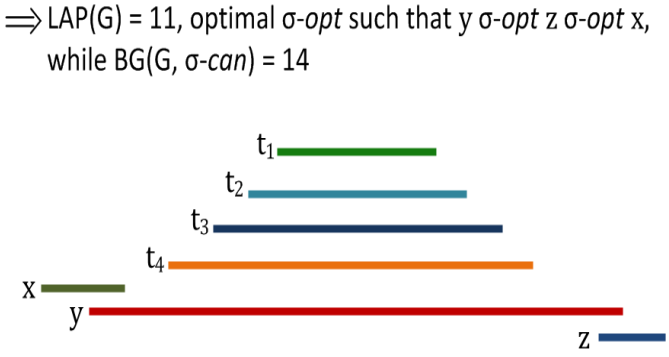

Figure 6: non consistency of (*Ov*, <<)

Still, what can be easily checked is that σ-*can* produces a 2-approximation if we refer to the standard definition of LAP:

Theorem 3: *Given an interval graph G = (X, E) with m edges. Then the following inequality holds:*

$BG(G, \sigma\text{-}can) \leq 2LAP(G)+m.$

Proof: A *Global Break* oriented proof comes by induction on the cardinality of X. Let x_0 be the first (smallest) element of X according to σ-*can*, and σ-*opt* some optimal solution of LAP. Induction tells us that: (E2)

$$\Sigma_{e,\, z \neq x0}\, BE(e, z, \sigma\text{-}can) \leq$$
$$m - |\Gamma_G(x_0)| + 2.\, \Sigma_{e,\, z \neq x0}\, BE(e, z, \sigma\text{-}opt).$$

Since all vertices of $\Gamma_G(x_0) \cup \{x_0\}$ are consecutive according to σ-*can*, we get that:

$$\Sigma_{x \in \Gamma G(x0),\, z \in X}\, BE((x_0, x), z, \sigma\text{-}can) =$$
$$\Sigma_{x,\, z \in \Gamma G(x0)}\, BE((x_0, x), z, \sigma\text{-}can)$$
$$= |\Gamma_G(x_0)| \times (|\Gamma_G(x_0)| - 1)/2.$$

On the other hand, if we refer to σ-*opt*, we get: (E3)

$$\Sigma_{x \in \Gamma G(x0),\, z \in X}\, BE((x_0,x), z, \sigma\text{-}opt) \geq$$
$$\Sigma_{x,\, z \in \Gamma G(x0)}\, BE((x_0,x), z, \sigma\text{-}opt) \geq$$
$$\lfloor |\Gamma_G(x_0)|/2 \rfloor (\lfloor \Gamma_G(x_0) \rfloor - 1)/2 + \lceil |\Gamma_G(x_0)|/2 \rceil (\lceil |\Gamma_G(x_0)|/2 \rceil - 1)/2.$$

We derive the result by combining (E2) and (E3). □

C. A Restricted Version CLAP of LAP.

However, experiments will show that best linear orderings are most often (*Ov*, <<)-*consistent.* So we are going to study the following restriction CLAP of LAP:

(*Ov*, <<)-*Consistent Linear Arrangement* Problem (*CLAP*): {Compute a (*Ov*, <<)-consistent linear ordering σ which minimizes BG(G, σ)}.

The following lemma bridges CLAP with Theorem 1.

Lemma 1: *In the case the linear ordering σ is (Ov, <<)-consistent, we have that: BG(G, σ) = Tr(G) + SFk(G, σ), where SFk(G, σ) is the number of strong forks f = (x, y, z), x = Root(f) such that ((x σ y) ∧ (x σ z)) ∨ (y σ x) ∧ (z σ x)).*

Proof: left to the reader (same proof as for Theorem 1). □

Extending Theorem 1 to CLAP leads us to introduce a specific version of *Max-Cut*:

(Ov, <<)-Consistent Unit Cost Max-Cut Problem (C-Max-Cut): Given a graph H = (Z, F), which is the complementary graph of an interval graph H^c = (Z, F^c), and two disjoint subsets A_0 and B_0 of Z, such that:

- A_0 (B_0) is a *Left-(Ov, <<)-Section* (*Right-(Ov, <<)-Section*) of H^c;
- Both A_0 and B_0 define complete sub-graphs of H^c = (Z, F^c).

Compute a partition $Z = A \cup^{Ex} B$, such that:

1. A contains A_0 and is a *Left-(Ov, <<)-Section* of H^c;
2. B contains B_0 and is a *Right-(Ov, <<)-Section* of H^c;
3. the number of edges of H which connect A and B = $|\{(x, y) \in E, x \in A, y \in B\}|$ is the largest possible;
4. A is maximal for the set inclusion order, provided 1, 2, 3 are satisfied.

We denote by *C-Max-Cut*(H, A_0, B_0) the related optimal value. Then we set, for the interval graph G = (X, E) and for any vertex x in X:

- $\Gamma^{Ov,\subset}{}_G(x)$ = (*0v*, ⊂)-*neighbour* set of x = {y ∈ $\Gamma_G(x)$, y ≠ x, such that (y ⊂ x) or (y *Ov* x) or (x Ov y)};
- H(x) = complementary graph of the sub-graph induced by $\Gamma^{Ov,\subset}{}_G(x)$;
- $A_0(x)$ = {y ∈ Z such that y *Ov* x}; $B_0(x)$ = {y ∈ Z such that x *Ov* y};

- m(x) = number of edges of H(x); CV(x) = m(x) - *C-Max-Cut*(H(x), $A_0(x)$, $B_0(x)$).

Then we get:

Lemma 2: *CLAP(G)* $\geq$ *Tr(G)* + Σ_x *CV(x).*

Proof: For every x $\in$ X, we set E*(x) = {non oriented pairs (y, z) such that:

- y $\in \Gamma^{Ov,\subset}{}_G(x)$, z $\in \Gamma^{Ov,\subset}{}_G(x)$; (y, z) $\notin$ E ;
- at least one of both relations y $\subset$ x or z $\subset$ x holds;
- relation ((x σ y) $\wedge$ (x σ z)) $\vee$ ((y σ x) $\wedge$ (z σ x)) holds}

SFk(G, σ) may be written as $\Sigma_{x \in X}$ |E*(x)|. Since σ is (*Ov*, <<)-consistent, we may relax the "*at least … y* $\subset$ *x or z* $\subset$ *x holds*" constraint which characterizes E*(x).

So, for any x $\in$ X:

|E*(x)| $\geq$

$\Sigma_{y,z \in \Gamma G(x),\ (y,x) \notin E,\ y,z \text{ are located the same way with respect to x, } \sigma}$ **1**.

For any x $\in$ X, we get a feasible solution A(x,σ) $\cup^{Ex}$ B(x, σ) of the *C-Max-Cut* instance defined by H(x), $A_0(x)$, $B_0(x)$, by setting: A(x,σ) = {y $\in \Gamma^{Ov,\subset}{}_G(x)$, such that y σ x}; B(x, σ) = {y $\in \Gamma^{Ov,\subset}{}_G(x)$, such that x σ y}. Its value is:

m(x) –

$\Sigma_{x,y \in \Gamma Ov,\subset G(x),\ (y,x) \notin E,\ y,z \text{ located the same way with respect to x, } \sigma}$ **1**

$\leq$ *C-Max-Cut*(H(x), $A_0(x)$, $B_0(x)$).

It follows that, for any x $\in$ X:

|E*(x)| $\geq$

$\Sigma_{x,y \in \Gamma Ov,\subset G(x),\ (y,x) \notin E,\ y,z \text{ located the same way with respect to x, } \sigma}$ **1**

$\geq$ CV(x).

Then, we get that SFk(G, σ) = Σ_x |E*(x)| $\geq$ Σ_x CV(x). We conclude. □

D.Solving C-Max-Cut and Evaluating CV(x)

The complexity of the *Max Cut* problem in the case of the complementary graph of an interval graph is still an open issue. However, things are easier with *C-Max-Cut*:

Theorem 4: *Given = (Z, F), A_0 and B_0 as in the definition of C-Max-Cut. Let us set, for every vertex z* $\in$ *Z* – (A_0 $\cup$ B_0)*:*

- $d_H^-(A_0, z)$ = |{*t* $\in$ *Z* – A_0 *such that t* << *z* }| + |{*t* $\in$ A_0 *such that t* << *z*}|;
- $d_H^+(B_0, z)$ = |{*t* $\in$ *Z* – B_0 *such that z* << *t* }| + |{*t* $\in$ B_0 *such that z* << *t* }|.

Then we solve C-Max-Cut by setting:

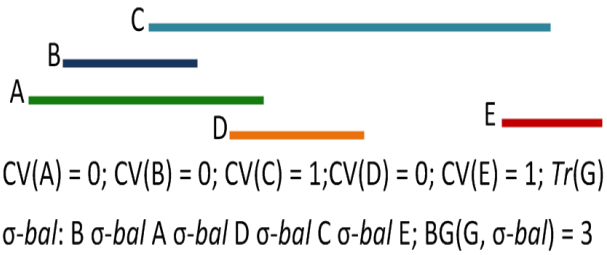
- *A* = {*z* $\in$ *Z* – (A_0 $\cup$ B_0) *such that* $d_H^-(A_0, z) \geq d_H^+(B_0, z)$} $\cup A_0$;
- *B* = {*z* $\in$ *Z* – (A_0 $\cup$ B_0) *such that* $d_H^-(A_0, z) < d_H^+(B_0, z)$} $\cup B_0$.

Proof: Left to the reader. □

E. An Exact Solution σ*-bal for CLAP.*

We construct this solution σ-*bal*, by setting, for any pair x, y in X, x σ-*bal* y if, and only if, one among the following options holds:

- (x << y) or (x *Ov* y);
- (x $\subset$ y) and $d_{H(y)}^-(A_0(y), x) \leq d_{H(y)}^+(B_0(y), x)$; (E5)
- (y $\subset$ x) and $d_{H(x)}^-(B_0(x), y) < d_{H(x)}^+(A_0(x), y)$. (E6)



CV(A) = 0; CV(B) = 0; CV(C) = 1;CV(D) = 0; CV(E) = 1; *Tr*(G) = 2;

σ-*bal*: B σ-*bal* A σ-*bal* D σ-*bal* C σ-*bal* E; BG(G, σ-*bal*) = 3

Figure 7: A σ-*bal* construction

Lemma 3: *The* σ*-bal relation is transitive.*

Proof: left to the reader. □

We are now ready to state the optimality of σ-*bal*.

Theorem 5: *The relation* σ*-bal is an optimal solution of CLAP, which satisfies:*

1. *BG(G,* σ*-bal)* $\leq$ *BG(G,* σ*-can).*
2. *Tr(G)* $\leq$ *BG(G,* σ*-bal) = Tr(G) +* Σ_x *CV(x)* $\leq$ *Tr(G) + Strong-Fork/2, where Strong-Fork is the number of strong forks of the interval graph G.*

Sketch of the Proof: From Lemma 3, we have that σ-*bal* is a (<<, *Ov*)-consistent linear ordering. Then the optimality of σ-*bal* (and so, the fact that BG(G, σ-*bal*) $\leq$ BG(G, σ-*can*)) derives, through a simple computation, from the fact that since it locally achieves, for any node x, the lower bound CV(x), then it also globally achieves the lower bound of Lemma 2. □

We easily deduce that this result has an algorithmic interpretation:

Corollary 3 (left to the reader): *Computing σ-bal may be done in O(Arc-⊂) time, where Arc-⊂ is the number of arcs of the digraph induced on X by the ⊂ ordering.*

VII. NUMERICAL EXPERIMENTS

We implemented both the Branch/Bound algorithm of Section 5 and the Approximation algorithm σ-*bal*. We did it on a LINUX server CentOS 5.4, Processor Intel Xeon 3.6 GHZ, while using the CPLEX 12 library when dealing with integer linear programs. For interval graphs, our Branch/Bound scheme could solve, in no more than few minutes, instances with up to 40 nodes. This allowed us to perform a comparative analysis of the precision of the Lower Bound LB(G) = $Tr(G) + \Sigma_x V(x)$ provided by Theorem 1, and of both approximation algorithms σ-*can* and σ-*bal*.

We use 10 instance groups related to Card(X) = 10, 20, 30 and 40, and for every instance group, compute:

- the mean gap LB-GAP = (LAP(G) –LB(G))/LB(G) between the optimal LAP value and the lower bound LB;
- the mean gap CLAP-GAP = (BG(G, σ-*bal*) -LAP(G))/LAP(G) between the optimal value of CLAP, computed by σ-*bal*, and the optimal value;
- the mean gap CAN-GAP = (BG(G, σ-*can*) -LAP(G))/LAP(G) between the value defined by the canonical ordering σ-*can*, and the optimal value.

We get results which are described in the following Table 1.

N	**10**	**20**	**30**	**40**
LB-GAP	9.8%	12.5%	10.7%	14.5%
CLAP-GAP	3.2%	4.5%	4.1%	5.0%
CAN-GAP	9.6%	12.3%	11.5%	10.9%

Table 1: Comparative precision of lower bound LB and approximation solutions σ-*can* and σ-*bal*.

Table 2 provides now the specific results related to n = 10, which by the way, gives an estimation of the LAP(G) values which may derive from interval graph of this size:

INSTANCE NUMBER	**LB(G)**	**LAP(G)**	**CLAP(G)**	**CAN(G)**
1	10	12	12	13
2	8	8	8	8
3	13	16	17	19
4	12	13	14	15
5	12	13	13	14
6	10	11	11	11
7	15	15	17	18
8	13	15	15	17
9	11	11	11	12
10	9	10	10	10

Table 2: Values LAP(G), LB(G), CLAP(G) and CAN(G) related with a 10 instances group with Card(X) = 10.

VIII. CONCLUSION

This paper, with theoretical focus, proposes approximation results for the *Linear Arrangement* problem, in the case of interval graphs. Further research should be about the extension of our approaches to chordal graphs and circular graphs, as well as about the design of efficient exact algorithms.

***Abstract*—A concept of artificial supervisor of multi-task real-time object-oriented system is introduced. Next, a procedure for automatic creation of artificial supervisors is presented. The procedure is based on developmental genetic programming. As an input data, UML diagrams are used. A representative example of creation of a supervisor of building a house illustrates the procedure. The efficiency of the procedure from various points of view and comparison considerations are given.**

I. Introduction

A SYSTEM must meet user requirements and constraints. Besides specified functionalities, cost effectiveness and high performance are among the most important ones. Real-time (RT) systems are present in all areas of human life. Punctuality is an extra requirement for them. Sometimes punctuality requires very high performance. However, the higher performance the higher cost of the system. Usually the cost is limited.

Going into details, one can find RT systems in civil engineering, in traveling, in computer engineering, in banking, and so on. In the first case, a building enterprise is such a system. It owns resources, such as workers and building machinery, necessary to build a house according to the requirements of a client. These usually comprise functionalities of the house, its cost and a deadline. In the second case a human being is an RT system. He knows which means of transportation may use to meet his requirements. From among flights, trains, buses, rented cars, and even walking he selects a set, so that to reach a target on time and at affordable cost. An embedded computer system may be another example of RT system. A designer of such a system has to decide what of the tasks of the system is to allocate to what of its processing components, so that to get maximum of the performance and not to surpass the cost. In a bank an account may be operated in different ways. However, an owner of the account usually wants to get maximum profit with an acceptable risk in a specific time period. Summarizing, an RT system uses some hardware or software objects of its resources so that a specific goal is achieved, on time.

Multi-task system (MS) is a system where more than one task can be processed at the same time. A home computer is a familiar example of the MS. Common tasks are word processing, printing, communicating, and playing games. The system contains objects: hard drive, a monitor, a printer, a network adapter and an optical drive. Some of these objects are required for a subset of the tasks while others are required for all these tasks. The monitor and hard drive will always be in use whereas the printer is used only for printing, the network adapter is used for communicating, and the optical drive is used for reading stored materials. The enterprise is an example of RT MS, while a traveler is not.

Usually, RT systems should be optimized for cost vs. speed of operation (speed of reaching a goal or a target). Therefore, a building enterprise, and a traveler, and hardware/software system designer, and other RT systems have to be endowed with optimization engine. We will call these engines: artificial supervisors (AS) or artificial managers (AM) of resources. An AS should find an optimum use of supervised resources, taking into account the requirements and the constraints. This means that the AS decides what functionalities should be allocated to what resources and in which order these functionalities should be executed. Actually, it has to find a solution for a specific case of the well-known Resource-Constrained Project Scheduling Problem (RCPSP) which consists in rescheduling the project tasks (RT system tasks) efficiently using limited renewable resources (components/objects of the RT system) minimizing the maximal completion time of all activities [1].

The RCPSP is an NP-complete problem which is computationally very hard [2] [3]. Möhring [4] states that it is one of the hardest problems of Operational Research. Therefore, a skilled specialist with an assistance of the planner (Computer Aided System Engineering in case of the enterprise) might play a role of such an AS only for small systems containing a limited number of tasks and a moderate number of resources. No doubt, in case of real life systems, particularly RT MS, the AS must be a very powerful optimization engine.

The general RCPSP model cannot cover all situations that occur in practice. Therefore, many researchers have developed many variants and extensions of project scheduling problems, often using the standard RCPSP as a starting point [5].

978-83-60810-58-3/$25.00

Constructing an efficient AS for a given class of RCPSP problems is very difficult and time consuming. Moreover, a scheduling strategy that is optimal for one problem may not be efficient for others. Hence, instead of developing a general AS for all RT MS, in this paper, we propose a method that automatically generates a dedicated AS for the specific RT MS. The method is based on an idea derived from developmental genetic programming (DGP). It is universal and can be applied to optimization of RT MS of any kind. Our methodology is illustrated and evaluated with the help of a representative example.

Genetic programming (GP) is an extension of the genetic algorithm [6], in which the population consists of computer programs. In the DGP [7] [8], strategies that create solutions evolve, instead of computer programs. In this approach a genotype and a phenotype are distinguished. The genotype is a procedure that constructs a solution of the problem. It is composed of genes representing elementary functions, constructing the solution. The phenotype represents a target solution. During evolution, only genotypes are evolved, while genotype-to-phenotype mapping is used in the fitness computation, which is required for the genotype selection process. Next, all genotypes are rated according to an estimated quality of the corresponding phenotypes. The goal of the optimization is to find the procedure constructing the best solution. The idea is based on the theory from the molecular biology, concerning protein synthesis that produces proteins (phenotype) from the DNA (genotype). In our approach the AS corresponds to the genotype while the phenotype is the solution i.e. a makespan. First, the DGP is used to find the optimal solution, and the genotype constructing this solution is saved as the AS.

The method is universal, but an AS must be well-fitted to a particular RT MS. The RT MS is a micro-world with its own functionalities and resources. Therefore, a formal specification of the RT MS is an input data to the method. RT MS, where a number of resources have punctually to execute a number of tasks are good micro-worlds for object-oriented modeling. Objects may play a role of resources that execute tasks in real time for some costs. A widely accepted standard for modeling object-oriented systems (OOSs) is the Unified Modeling Language (UML) [9]. It shows how to write a system's blueprints, including conceptual things such as business processes and system functions. It encompasses OOSs of any kind, particularly real-time multi-task OOSs (RT MOOSs). Using the UML for modeling RT OOS has been a subject of many publications [10] [11] [12]. Hence, this will be applied here.

Related work is briefly described in section II. In section III the problem is stated. Section IV briefly shows how early UML models should be used as input data for the method, and section V explains how DGP can create the supervisors and the initial solutions. In section VI a computational experiment evaluating our approach is described. The experiment explains of how a supervisor of a simple RT MOOS (of building a house) is created. Finally, section VII contains conclusions.

II. Related Work

Genetic approach was proved as very efficient for solving RCPSP problems. Ones of the most efficient genetic algorithms for RCPSP are presented in [13] [14]. In [15] the method of improving the genetic algorithm for optimization of multi-task project scheduling was proposed. It was showed that the method is competitive in comparison with 11 other heuristic approaches. A method of solving a large scale RCPSP is presented in [16]. In this solution, a genetic algorithm is used and a method of encoding classical RCPSP problem in the chromosome is described. Results achieved by authors of [16] give a slight improvement, in comparison with other existing heuristics.

For the first time Developmental Genetic Programming was proposed by Koza, Bennet, Andre and Keane [17], to create electrical circuits. This methodology evolves circuit-construction tree, in which nodes correspond to functions defining the developmental process. The initial circuit consists of an embryo and a test fixture. The sample embryo is at least one modifiable wire while fixture is one or more unmodifiable wires or electrical components. The circuit is developed by progressively applying functions in the circuit-construction tree to the modifiable parts (wires and electronic components) of the embryonic circuit.

A similar methodology was used by Deniziak and Górski in the co-synthesis of embedded systems described by task graphs [18]. The system-construction tree is based on a task graph. Each node of the tree specifies an implementation of the corresponding task. The embryo is an allocation of the first task. First (initial) population is created randomly. Then after evolution, using crossover, mutation and reproduction, an optimal (or suboptimal) solution is found.

In [19] a list of 36 instances of human-competitive results produced by the GP is presented. A lot of them concern of synthesis of an analog electrical circuits, developing quantum algorithms, designing controllers. According to our best knowledge, there is no approach concerning optimization of object-oriented real-time multi-task systems using DGP methods.

III. Problem Statement

Let us assume that information about the functionalities of RT MOOS and resources available for implementation of these functionalities are specified with the help of UML early diagrams: use case, activity, and sequence. This is typical while designing OOS of any kind. To start the system a supervisor is needed, which allocates the functionalities into the resources in such a way that the cost will be minimal while all real-time constraints will be satisfied. Both, number of the functionalities and the number of resources, are large enough to exclude a human being as the supervisor. Therefore, an engine which optimizes supervising the system should be worked out. The engine will be named an artificial supervisor (AS), since it does what the supervisor should do.

An AS should work as follows:

1) it should work out a schedule for RT MOOS which would be optimal under current operational conditions, and
2) adjust the schedule, to keep its optimality, when the conditions have changed (some of the resources had failed, for example).

The goal of the research is to introduce a method of automatic generation of ASs from the diagrams. An approach based on an idea derived from developmental genetic programming is used.

The procedure consists of two steps. In the first one information included in the UML diagrams are transformed into a task graph and a library of objects working for the system. These are input data to the second step. In this step (Section V) the AS is created. To this end a universal method of evolution of a genotype of the AS is applied. Decision options, which may be contained in the genes of the AS, are defined and then the genotype is created developmentally, using DGP-like approach.

An example of the generation of a supervisor in a building enterprise is used to illustrate the method. The enterprise is an RT MOOS because its resources may be dealt with as objects of different kinds, human or technical, which work in real time and in multi-task mode of operation. A user of the RT MOOS specifies the functionalities of the house, a deadline of the implementation and cost constraints. In the case of a small building enterprise, a contractor assisted by a CASE tool (Computer Aided Software Engineering) can elaborate optimal or semi-optimal schedule of building the house. However, big consortia own a large number of resources and implement many different constructions. Hence, this duty must be waived from the contractor and placed onto an AS. Not the contractor, but the AS, which is engaged in building the house, should generate an optimal schedule for management of enterprise resources.

Summarizing, for each of the implementations an AS should be generated. The AS elaborates optimal schedule of the implementation. A procedure of generation of ASs is universal. However, to generate a specific AS (for building a housing estate or LNG terminal, or a bridge, or managing a bank account, and so on) it should be supplemented with data describing what should be supervised. This is done with the help of UML diagrams.

An AS should react to events that make the schedule non-optimal, such as failures of the resources, unexpected delays of task executions and so on. In such situations, any break in work could generate huge costs. Thus, changes in the schedule should be done in real-time, and as soon as possible.

IV. From UML Early Models to Library of Resources

The first step of the method consists in the generation of input data for DGP, which in turn will create an adequate supervisor. To this end UML early models of RT MOOS, which will be under optimization, are used. In case of building a house the models describe all activities of the supervisor that controls the whole process of the construction.

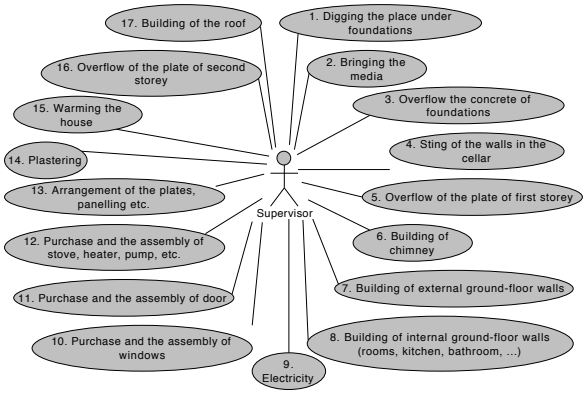

Fig. 1. Use case diagram for building a house

A. Functionalities and sequential constraints

Functionalities are described with the help of a UML use case diagram where a Supervisor is the main actor. It owns resources (objects) performing tasks in real-time and may face orders of task executions. Use case diagram describing building a house is given on Fig. 1. Actually, it maintains the enterprise which works as a real RT MOOS.

A task is an activity performed by a specific user of an RT MOOS. In the diagram, each of the use cases corresponds to one of such tasks, since a use case is an action performed by an object (objects) which aims to yield an observable goal for the user. Thus, each of the tasks has a use case that explains what the task is, and how it should function. Moreover, a use case may include statements about pre-conditions (required before the task began), post-conditions (valid when the task was successfully completed) and, if needed, exceptions.

The diagram on Fig. 1 contains 17 use cases (stages of a house building; numbered from 1 to 17 on Fig. 2) which should be scheduled for enterprise resources. Therefore, assignment of the use cases, to the resources, is a subject of optimization. However, the diagram may not say anything, that one of the cases must be used before another one. Digging foundations must precede their laying, and plastering must be done before warming a house, for example[1]. In general, an RT MOOS as an example of a multi-task system may have sequential constraints. Tasks should not be executed in arbitrary orders because some of the tasks need to be executed before others.

The Supervisor knows use case sequential constraints. This can be specified with the help of an extension and of an inclusion associations («extend» or «include» stereotypes [9]) and on pre- and post-conditions defined for the use cases (sequential dependencies [20]). As the summary, a UML

[1]Numerical prefixes are introduced to identify the use cases and will be used later on.

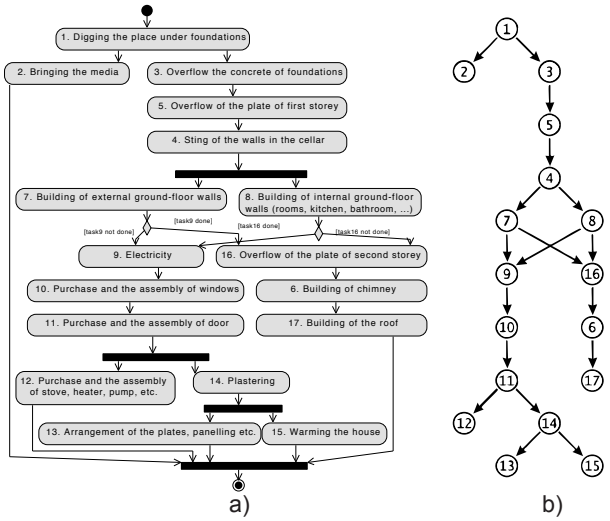

Fig. 2. Activity Diagram (a) and Task Graph (b) of the system.

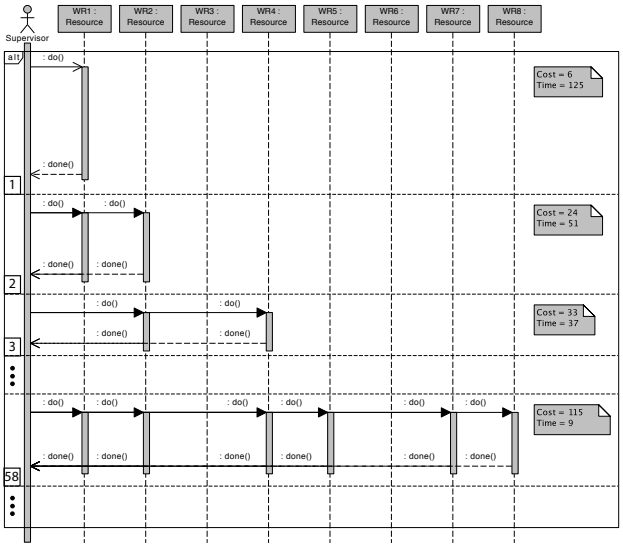

Fig. 3. Sequence diagram of Bringing the media use case.

activity diagram [9] for an RT MOOS can be defined, and then transferred into a task graph (TG) showing an execution of the tasks in a real-time. The constraints for the example are shown on Fig. 2a whereas their corresponding TG is shown on Fig. 2b[2].

B. Resources

The resource is an object required to execute a task. In general, it could be a human, a tool or any other object, which is reusable or renewable. If there are many resources of the same type, each of them should be presented as a separate resource.

In the example, two types of the resources are required for building a house. First are Workers. These are laborers like electricians, plasterers, and so on, that are able to execute some specific tasks. Also, a company, which could be used as an outsourcing, should be given as a resource. A worker could use the second type of the resources which are Tools. These are machines which could be used by workers during execution of tasks. Hardly ever one resource is able to complete a task itself. Thus resources are grouped into work teams, which will be described in the next subsection.

Not all resources are necessary for the execution of some tasks. This could be determined by the Supervisor with the help of the third kind of UML diagrams, namely sequence diagrams.

C. Scenarios of the resource cooperation

Inspired by real world, where most tasks are executed by a group of resources, a concept of a team is introduced. The team is a set of resources that are able to execute a task. Any task may be executed by more than one team. We assume that the execution cost and time of the task are known. One resource may belong to different teams, but teams having the same resources cannot be scheduled at the same time period.

A use case is refined into one or more sequence diagrams to show how the case might be implemented with the help of detailed actions. Therefore, each sequence of the actions defines an actual work-flow and reflects a sequence of decisions the supervisor should take to perform a single task. Every task is executed by teams (single worker team is also possible, but rarely). Different teams are able to finish their work faster or cheaper, using more or less resources. The sequence diagrams have to define these scenarios.

Fig. 3 shows an example how the supervisor might interact with objects participating in the construction of the building[3]. Moreover, the sequence diagrams show options (with time and cost of their implementations) available to the supervisor of the enterprise.

It is characteristic for a Supervisor that while traversing a task graph it determines step by step what should be done at that point and that its selections are usually optional. This means that it actually decides what functionalities of the RT MOOS should be assigned to what objects and in which order these functionalities should be executed. Its decisions should be optimal, taking into account costs and the time of execution. Therefore, the quality of the supervisor should be as high as possible.

D. Library of resources

Sequence diagrams specify how cooperating objects are organized in teams and how do they work. For example, Fig. 3 shows 4 teams. Each of the teams could bring media to a house under construction, but with different workload and costs. From sequence diagrams a table is derived which determines

[2]Automatic generation of TG from UML diagrams is possible but will not be discussed in the paper.

[3]Remaining 16 sequences are very similar.

TABLE I
A LIBRARY OF RESOURCES.

Task #	Team # (for the task #)	Time	Cost	Time * Cost	Members
1:	0	125	6	750	WR1
1:	1	51	24	1224	WR1, WR2
1:	2	37	33	1221	WR1, WR2
...	...	...	...	...	...
1:	58	9	115	1035	WR1, WR2, WR4, WR5, WR7, WR8
...	...	...	...	...	...
1:	62	82	183	15006	WR1, WR2, WR3, WR4, WR5, WR7, WR8
2:	0	57	62	3534	WR3
...	...	...	...	...	...
2:	3	41	82	3362	WR1, WR2, WR5
...	...	...	...	...	...
2:	62	10	189	1890	WR3, WR4, WR5, WR7, WR8
...	...	...	...	...	...

a binding of tasks with teams. For the example, this is given in Table I.

Columns "Time", "Cost" and "Members" of the table are filled in with data from sequence diagrams. Units of "Time" or "Cost" are inessential. It could be a day or an hour, dollar or euro. It is only important that all costs and all times are defined using the same units.

Column "Time * Cost" does not give any new information, but it is helpful to accelerate the time of the computations.

V. CREATION OF SUPERVISORS

The second step of the method consists of initiating and evolving genotypes, corresponding to the supervisors, with the help of DGP. It is assumed that the supervisor selects options defining the strategy of the allocation of resources. The way in which it does, it is a specific feature of its mind, and it is contained in its genotype. A supervisor with the best genotype (allocating the resources optimally) will be generated with the help of DGP. DGP evolves genotypes, while genotype-to-phenotype mapping is used in the fitness computation, which is required for the genotype selection process. It is possible, that one phenotype may be created from two different genotypes, because genotype-to-phenotype mapping always generates systems that meet the system requirements.

A genotype corresponding to the supervisor has a form of a tree engineering the system. A root of the tree specifies a construction of an embryonic system, while all other nodes correspond to functions which progressively build up the whole system. If the system is defined by a task graph, then an embryo is a system executing the first task from the task graph. Thus, the number of possible embryos equals the number of teams, in the library of resources, which are capable of executing the first task. Embryonic systems are selected randomly for each attempt to create an initial population of supervisors.

TABLE II
SUPERVISOR'S OPTIONS

Step	Option	P
1	a. The fastest team	0.16(6)
	b. The cheapest team	0.16(6)
	c. The lowest time * cost	0.16(6)
	d. Determination by second gene	0.16(6)
	e. The fastest starting team	0.16(6)
	f. The fastest ending team	0.16(6)
2	List scheduling	1

A. Supervisor's options

The supervisor undertakes the following two actions:

- resource allocation and task assignment, that send an appropriate team to execute a particular task and hence, allocate members of the team,
- task scheduling (only when more than one task is assigned to the same resource), that schedules the tasks assigned to the resources. When the resource is unavailable, the execution of the task is delayed as long as the resource is not released.

Initial population of supervisors consists of randomly generated genotypes. It selects one of the options given in part 1 of its decision table. Table II contains the options which the supervisor may choose. The last column in Table II shows a probability of the selection.

The first option prefers a team, which requires the smallest period of time to execute a task. Second one prefers a team, which brings the lowest cost increase. Third option prefers a team with the best ratio of the costs to the time of the execution. Fourth option works in a different way. It allows us to use "a little pushed" teams, what cannot be obtained as a result of the remaining options. The next option prefers a team, which could start an execution of the task as soon as possible (other teams might be busy). The last option prefers a team whose members could be the first to finish a task (be freed). For the second action only one option is available, namely the list scheduling method.

B. Genotype

The genotypes have forms of binary trees corresponding to various procedures of synthesis of phenotypes (target solutions). Every node has the same structure presented on Fig. 4

The first field *isLeaf* determines a role of the node in a tree. When it is true (the node is a leaf), the strategy for tasks is described in the field named *"strategy"*, which stores an option from Table II. In this case information from the other fields is omitted. When the node is not a leaf, a content of the field *"strategy"* is not important. In this case, *cutPos* contains a number describing which group of tasks should be scheduled by the left node and which one by the right node. Thus, *nextLeft* and *nextRight* must not be null pointers.

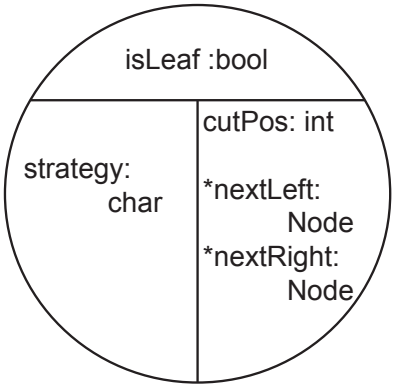

Fig. 4. A node of the genotype

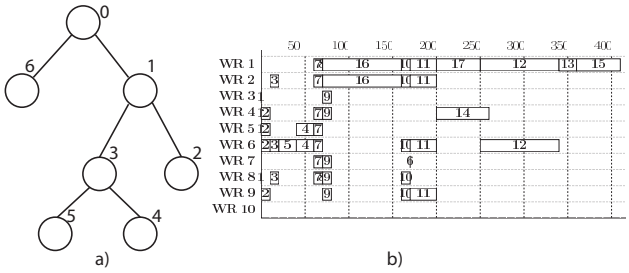

Fig. 5. A simple genotype (a) and the corresponding phenotype (b)

The simplest genotype consists of only one node, which is also a leaf and a root. A simple genotype and the corresponding phenotype are presented on Fig. 5.

During the evolution, a genotype grows but a size of the genotype tree is limited. If the tree exceeds the maximum size then too long branches are cut off. For example, if the maximum size is 6, every node on the sixth level which has a successor is changed into a leaf, and all its successors are destroyed.

An embryo of the tree could grow as an effect of genetic operators: mutation and crossover. An action associated with the mutation depends on the state of the node and is presented in the Table III.

The crossover is used to exchange information between two chromosomes. It is necessary to draw a point of cut a tree in both chromosomes. An example of the crossover is presented on Fig. 6

With every genotype an array is associated. Its size is equal to the number of tasks and contains indexes of teams. If for a task, strategy 'd' is chosen, the team with an index taken from the array is used. At the very beginning of the mutation, a place in the array is randomly chosen. Next a new index is randomly generated. During the crossover, parts of the arrays from both genotypes are swapped.

C. Genotype to phenotype mapping

The first step in a genotype-to-phenotype mapping is to assign strategies to tasks (that is teams from Table I to tasks

TABLE III
THE RULES OF MUTATIONS

Is a leaf?			
Yes		No	
Draw: switch leaf/node or not?			
Yes	No	Yes	No
Set *isLeaf* as FALSE. If *nextLeft* or *nextRight* is NULL - create a new leaf for it.	Draw new strategy	Set isLeaf as TRUE	Change value for a randomly chosen field: *cutPos*, *nextLeft* or *nextRight*

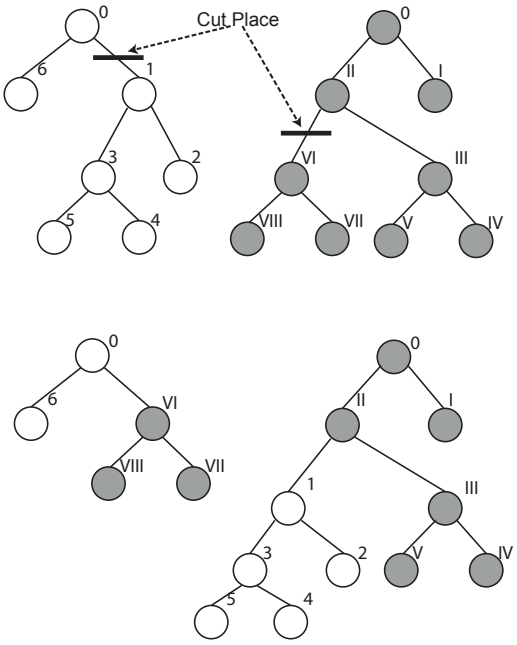

Fig. 6. An example of the crossover

from Fig. 2b, in the example). This step is illustrated on Fig. 7. Please note, that node 1 partitions tasks from 11 to 17 into two groups: from 11 to 18 and the rest. Because the first group is out of the range, in fact, there is only one group, which is taken by node 3.

In the second step all tasks without any predecessor, or with predecessors having already assigned teams, are being

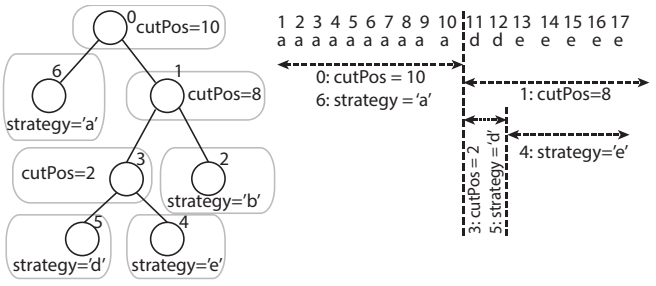

Fig. 7. The first step in genotype-to-phenotype mapping

searched for. For these tasks, teams are assigned according to their strategy. Then the step is repeated as long as there are tasks without assigned teams.

In the third step, the total cost of the solution could be calculated. For this purpose, the cost of each team from the resource library (Table I) is given.

D. Parameters of DGP

During the evolution, new populations of supervisors are created using genetic operations: reproduction, crossover (recombination) and mutation. After the genetic operations are performed on the current population, a new population replaces the current one. The number of individuals in each population is always equal:

$$\Pi = \alpha \prod_{i=1}^{n} s_i \tag{1}$$

where n is the number of tasks, s is the number of teams capable to solve specific problem and α is a constant between 0 and 1. If α is equal to 1, the population has as many individuals as many solutions of the problem exist. The evolution is controlled by parameters β, γ and δ, such that:

- $\Phi = \beta \cdot \Pi$ is the number of individuals created using the reproduction,
- $\Psi = \gamma \cdot \Pi$ is the number of individuals created using the crossover,
- $\Omega = \delta \cdot \Pi$ is the number of individuals created using the mutation and
- $\beta + \gamma + \delta = 1$

The last condition ensures that each of the created population will have the same number of individuals.

Finally, the selection of the best individuals by a tournament is chosen [21]. In this method, chromosomes (genotypes) are drawn with the same probability in quantity defined as a size of the tournament. From the drawn chromosomes the best one is taken. Hence, the tournament is repeated as many times as the number of chromosomes for a reproduction, crossover and mutation is required . A size of the tournament should not be too high, because the selection pressure is too strong and the evolution will be too greedy. It also could not be too low, because the time of finding any better result would be too long.

E. Fitness function

A fitness function determines the aim of DGP. In the presented approach, two options are possible. In the first one, the cheapest solution which has to be finished before a deadline is searched for. Such fitness function is applied when hard real time constraints have to be satisfied. In the second one, the DGP should find the fastest solution, which does not exceed a given budget. This case concerns systems with soft real-time requirements.

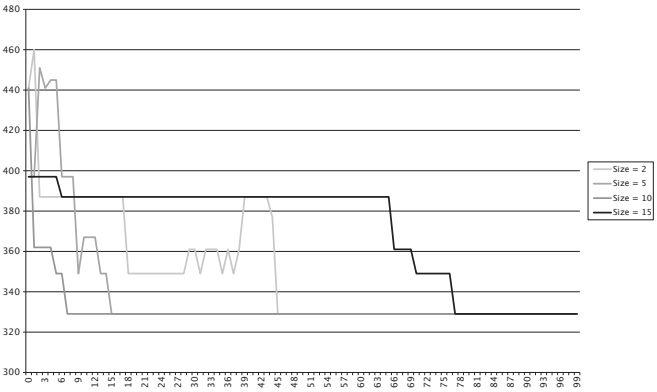

Fig. 8. Progress of the evolution for different tournament sizes

VI. Computational Experiments

High efficiency of the DGP may be achieved only when genetic parameters will be properly adjusted. The most important are the number of individuals created during reproduction, crossover, mutation and a size of the tournament. If their values are not chosen correctly, the DGP will find solutions far from the optimum or finding the best solution will take a lot of time.

The presented method was evaluated with the help of the example from Fig. 1. The deadline was equal 700 time units. During the experiments, the following values of genetic parameters were used:

- the evolution was stopped after 100 generations,
- each experiment was repeated 7 times, the mean of the best solutions received in each pass is given as the result,
- parameter α was equal $7 \cdot 10^{-30}$, thus the population size was equal 102.

First, the convergence of the DGP for different sizes of the tournament was explored. Tournament sizes equal 2, 5, 10 and 15 were examined (Fig. 8). We observed that the sizes 2 and 5 were too small. Very often the best solutions were skipped over, and not selected for further evolution. The best convergence was obtained for the size equal 10.

Next, we examined the influence of the crossover and the mutation on finding the best solution. For this purpose, an analysis of the best solutions achieved with different combination of parameters controlling the crossover and the mutation was performed. Fig. 9 presents the results obtained for different number of mutations. We may observe that for less than 10% of mutants in the population, the results are poor. The best result was obtained for 18% of the mutants. The number of mutants should not be too high. For more than 85% of the mutants the DGP usually produces also poor results. In this case, too much number of mutants probably disturbs the evolution. Fig. 10 presents results obtained for different numbers of individuals created using the crossover. The highest probability of obtaining the best results is when the crossover is applied for creation of at least 65% genotypes.

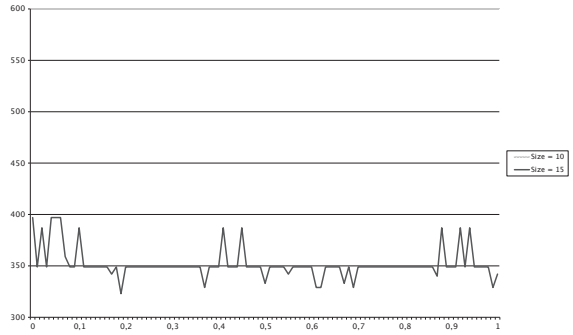

Fig. 9. The influence of δ

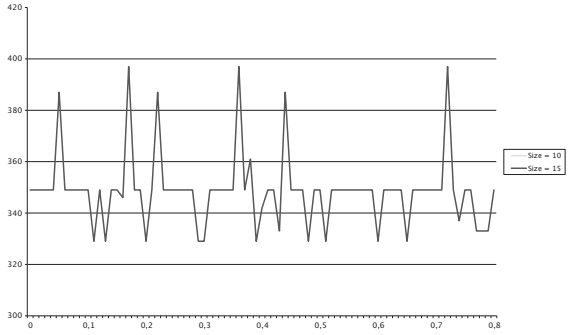

Fig. 10. The influence of γ

The results were also compared with greedy approach. The greedy algorithm assigns the cheapest teams to first tasks. However, if the deadline is to be exceeded, the algorithm assigns the fastest (usually the most expensive) teams to tasks at the end of the schedule as it is necessary to finish the work before the deadline. To the problem the greedy algorithm generates a solution which costs 1091 while the cost of the solution generated by the DGP is equal to 323. Thus, the result obtained with the help of our method is three times better.

To check whether our method led to global optimum or not, the entire space of the solutions was tested (Fig. 11). Out of $7.63 \cdot 10^{11}$ solutions, only 260 gave the best schedules, and a cost of the cheapest schedule was 323. So the answer is positive.

VII. Conclusions

A two-step procedure for automatic creation of supervisors of RT MOOS has been formulated. In the first step one has to specify functionalities of the system using early UML models (use case, activity, and sequence diagrams) and transform the models into a task graph and a library of resources of the system. In the second step one has to define decision options of a supervisor of the system and develop a genotype of the supervisor using DGP. An application of the procedure to RT MOOS, which was an enterprise of building houses, resulted in the creation of the best supervisor in acceptable time. It was evaluated from different points of view. Efficiency and precision were taken into account. Experiments showed

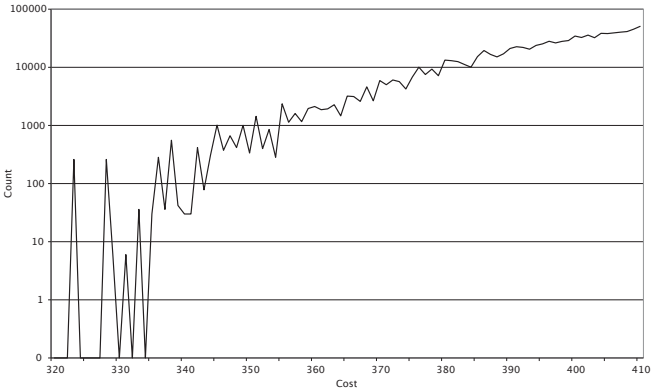

Fig. 11. The number of solutions to the problem for a given cost

that the supervisor can develop the best schedule, which corresponds to the global optimum.

Variant of the RCPSP presented in this paper is based on teams that are able to solve tasks. In general, a team is a group of workers and tools, but could also contain only one member. For different tasks, teams could contain different members, thus a team is able to start working when all of its members are idle. For this reason, it is possible, that choosing only the fastest teams do not yield the fastest solution. For the other hand, choosing only the cheapest teams could lead to the situation when the deadline of solution will be exceeded.

The influence of genetic parameters on the evolution of the genotype was also investigated. The most important parameter is δ, which defines the number of mutations. If it is too small or too large, DGP will have problems with escaping from local minima or it will behave too randomly. For the example presented in this paper, the best value for this parameter is about 20%.

The significant influence on the optimization has also a size of the tournament. If it is too small, DGP needs more time to find acceptable results. In the opposite case, if this value is too big, it leads DGP very quickly close to the global minimum, but has never achieved it. Actually, it stuck in local minima, because a variety of the population is decreasing.

The γ parameter corresponds to the number of crossovers. The crossover is responsible for a genotype tree development. Changing a genotype tree has also a bit similar effect of mutations, because after changing a position of the branch in the tree a new assignment of teams to tasks is achieved. Although this parameter has the smallest influence on results, it could be noticed that too high value of γ makes the solutions more random. If the value is too small, DGP need more time to achieve the optimal solution.

***Abstract*—Chess Rating System for Evolutionary algorithms (CRS4EAs) is a novel method for comparing evolutionary algorithms which evaluates and ranks algorithms regarding the formula from the Glicko-2 chess rating system. It was empirically shown that CRS4EAs can be compared to the standard method for comparing algorithms - null hypothesis significance testing. The following paper examines the applications of chess rating systems beyond Glicko-2. The results of 15 evolutionary algorithms on 20 minimisation problems obtained using the Glicko-2 system were empirically compared to the Elo rating system, Chessmetrics rating system, and German Evaluation Number (DWZ). The results of the experiment showed that Glicko-2 is the most appropriate choice for evaluating and ranking evolutionary algorithms. Whilst other three systems' benefits were mainly the simple formulae, the ratings in Glicko-2 are proven to be more reliable, the detected significant differences are supported by confidence intervals, the inflation or deflation of ratings is easily detected, and the weight of individual results is set dynamically.**

***Index Terms*—chess rating system, ranking, evolutionary algorithms comparison, Glicko-2, Elo, Chessmetrics**

I. Introduction

A METHOD for comparing the algorithms is needed for determing whether one algorithm performs better than the other. As numerous effective evolutionary algorithms are appearing, a comparison with only one algorithm is now insufficient. This fact leads to the need for determing which of the multiple algorithms is better than the other. Which of them is the best and which the worst? A well-established method for comparing the experimental results of multiple evolutionary algorithms is Null Hypothesis Significance Testing (NHST) [22]. Whilst there are many variants of NHST, there are still some pitfalls regarding statistics and its application [2], [7], [13], [21] that imply that this field still needs attention. A novel method the Chess Rating System for Evolutionary Algorithms (CRS4EAs) [30] suggests using a chess rating system for evaluating the results and ranking the algorithms. CRS4EAs treats (i) evolutionary algorithms as chess players, (ii) one comparison between two algorithms as one game, and (iii) execution and evaluation of pairwise comparisons between all algorithms participating in the experiment as a tournament. Just like the standard comparison of two algorithms, one game in CRS4EA can have three outcomes: the first algorithm is better (and therefore wins), the second algorithm is better (and therefore wins), or they perform equally regarding predefined accuracy ϵ (they play a draw). It has been empirically shown that CRS4EAs is comparable to NHST, and can be used as a comparative method for evolutionary algorithms [30]. A CRS4EAs method is used within an open-source framework Evolutionary Algorithms Rating System (EARS) [8], [9]. CRS4EAs and EARS were developed to provide fairer and easier to understand comparisons between evolutionary algorithms. All the experiments in EARS are executed for the same number of optimisation problems, the algorithms are written in the same programming language (Java), have the same termination criteria, are initialised with the same random seed, and executed under the same hardware configuration. Hence, some factors that could affect the final results of the experiment were excluded [30]. The CRS4EAs uses the Glicko-2 chess rating system [18], since it is one of the newest and it consists of many preferences that look promising. In the proposed paper the Glicko-2 rating system is compared to three other better-known and well-established rating systems: Elo, Chessmetrics, and German Evaluation Number (DWZ). In order to compare these four rating systems the experiment was conducted for 15 evolutionary algorithms covering 20 minimisation problems. The analysis showed that comparing evolutionary algorithms the Glicko-2 was the most appropriate choice. One downside to the Glicko-2 is its complicated formulae, for the understanding of which mathematical and statistical knowledge is needed. The differences amongst players are more straightforward in the other three systems, however they are unsupported by any reliable measurements - they are arbitrary. Otherwise, Glicko-2 was shown to be more reliable: the detected significant differences are supported by a confidence interval, straightforward measurement for rating reliability, the control of conservativity/liberty is more correct, the weightings of individual results are set dynamically, improvement through time is considered in final results, the inflation or deflation of ratings is easily detected, and the selective pairing is not an issue. This paper presents the reasons why the first choice for rating system used in CRS4EAs was the Glicko-2.

The paper is structured as follows. Section II summarises four more popular chess rating systems. The formulae used in these systems are adapted for EARS and are used during the experiment. The CRS4EAs method and the experiment are introduced in Section III, followed by a detailed analysis of the obtained results. Section IV concludes the paper.

II. BACKGROUND

Chess is a strategic game of two players with three possible outcomes: the first player can win, the first player can lose, or the players can play a draw. Usually, the absolute power of a chess player is described using a number that is called a 'rating'. A player's rating is updated after each tournament the player participates in and each chess organisation has its own rating system with formulae that evaluate its players. In this section the more common chess rating systems are introduced. All the players are represented on the leaderboard, from best to worst and although there are different formulae behind updating the players' ratings, all of them have two things in common: a player's rating is always a positive integer and the player with the highest rating value is expected to be better. A player joins the tournament with k opponents in which the ith player has a rating R_i, and plays m games.

A. Elo

The best-known chess rating system is the Elo rating system [10] where the expected score of the ith player against the jth player is calculated using the formula in Eq. 1.

$$E(R_i, R_j) = \frac{1}{1 + 10^{(R_j - R_i)/400}} \tag{1}$$

The expected score of the ith against the jth player is the probability of i defeating j. Hence, the sum of the expected scores of the ith and jth players (against each other) equals 1. The score the ith player gained against the jth player is denoted by $S_{i,j}$ and equals 1 if the ith player won, 0 if ith player lost, or 0.5 for a draw. All the ratings are updated at the end of a tournament using the formula from Eq. 2. The new rating of the ith player is denoted by R'_i.

$$R'_i = R_i + K \sum_{j=1}^{m} \big(S_{i,j} - E(R_i, R_j)\big) \tag{2}$$

The K-factor is a constant that affect the emphasis of the difference between the actual score and the expected score. The USCF (United States Chess Federation) rating system implements the K-factor by dividing 800 by the sum of effective number of games a player's rating is based on (N_e) and the number of games the player completed during a tournament (m) [17]. Even though, the Elo system is famous for its simplicity and wide-usage, it has a few drawbacks such as properly setting the K-factor, an inaccurate distribution model, or unreliable rating.

B. Chessmetrics

The chess statistician Jeff Sonas proposed the usage of a more dynamic K-factor in his own chess rating system called Chessmetrics [27], described as 'a weighted and padded simultaneous performance rating'. Chessmetrics uses the following formula (Eq. 3) for updating the rating of the ith player.

$$R'_i = 43 + \frac{R_{per} * m + 4 * \sum_{j=1}^{k} R_j/k + 2300 * 3}{m + 7} \tag{3}$$

R_{per} is the performance rating calculated as $\sum_{j=1}^{k} R_j/k + (\sum_{j=1}^{m} S_{i,j}/m - 0.5) * 850$ and with the meaning that each 10% increase in percentage score corresponds to an 85 point advantage in the ratings [27].

C. German Evaluation Number (DWZ)

The simplest and one of the first rating systems was the Ingo rating system [20] by Anton Hoesslinger (1948), which has influenced many other rating system, including the Deutsche Wertungszahl (DWZ) [6]. DWZ is similar to the Elo rating system of the FIDE (World Chess Federation) but has improved in its own way since 1990 when it was first introduced. The expected score in DWZ is calculated using the same formula as the expected score in the Elo system (Eq. 1), whilst the rating is updated using the formula in Eq. 4.

$$R'_i = R_i + \sum_{j=1}^{m} \frac{800}{D + m} \big(S_{i,j} - E(R_i, R_j)\big) \tag{4}$$

D is the development coefficient (Eq. 5), dependent on the fundamental value D_0 (Eq. 6), the acceleration factor a (Eq. 7), and the breaking value b (Eq. 8).

$$\begin{aligned} D &= a * D_0 + b \\ 5 \leq D &\leq \begin{cases} \min(30, 5i) & \text{if } b = 0 \\ 150 & \text{if } b > 0 \end{cases} \end{aligned} \tag{5}$$

$$D_0 = \big(\frac{R_i}{1000}\big)^4 + J \tag{6}$$

The coefficient J differs according to the different ages of the players - the older the player, the bigger the J. The acceleration factor a (Eq. 7) cannot be higher than 1 or lower than 0.5, and is calculated only if a player younger than 20 years achieved more points than expected, otherwise a equals 1. The breaking value b (Eq. 8) is computed only if the player with a rating under 1300 achieved less points than expected, otherwise b equals 0.

$$a = \frac{R_i}{2000} \tag{7}$$

$$b = e^{\frac{1300 - R_i}{150}} - 1 \tag{8}$$

D. Glicko-2

One of main concerns about the Elo system is the possibility of a player winning the game and losing rating points, or losing the game and gaining rating points. Problems with unreliable ratings show in those games between players with the same rating, when one of them has not played for years and the other plays constantly - they would lose and gain the same amount of points. A less reliable rating is expected for the player who has not played in years, and a more reliable rating for the player who plays constantly. It is expected that if the first player wins his rating would go up more than the rating of the second player goes down. Because anything cannot be said about the player's gaming behaviour or the reliability of his power, Glickman [14] introduced a new chess rating system. The Glicko system [15] introduces a new value that represents

the reliability of a player's power - rating deviation RD - which is similar to standard deviation regarding statistics. RD_i is set to 350 at the beginning of the first tournament and updated (just as rating) at the end of each tournament. It decreases with each tournament the ith player participates in and increases with each tournament ith player skips. The maximum value of RD is 350, whilst the minimum is set by an organisation implementing the system (Glickman suggests 30). Rating deviation tells how reliable the player's rating is - the lower the RD the more reliable the rating. In 2012 Glickman updated its system and presented the Glicko-2 rating system [18], which is based on Glicko but has another variable that presents the reliability of the player's strength - rating volatility σ_i. The volatility indicates the degree of expected fluctuation in a player's rating. If σ_i is low the player performs at a consistent level, whilst high σ_i indicates erratic performances. Firstly, the rating R and rating deviation RD have to be converted from Glicko to the Glicko-2 rating system (Eq. 9).

$$\mu = \frac{R - 1500}{173.7178} \text{ and } \phi = \frac{RD}{173.7178} \tag{9}$$

The estimated variance v of the player's rating based only on game outcomes is calculated using the formula in Eq. 10.

$$v = \left(\sum_{j=1}^{m} g(\phi_j)^2 E(\mu_i, \mu_j, \phi_i)(1 - E(\mu_i, \mu_j, \phi_i)) \right)^{-1} \tag{10}$$

The gravity factor g (Eq. 11) and the expected score E (Eq. 12) are calculated using the following formulae.

$$g(\phi) = \frac{1}{\sqrt{1 + 3\phi^2/\Pi^2}} \tag{11}$$

$$E(\mu, \mu_i, \phi_i) = \frac{1}{1 + 10^{-g(\phi_i)(\mu - \mu_i)}} \tag{12}$$

Next, the estimated improvement in rating Δ (Eq. 13) has to be calculated where the pre-period rating μ_i is compared to the performance rating μ_j based only on the game outcomes $S_{i,j}$.

$$\Delta = v \sum_{j=1}^{m} g(\phi_j)(S_{i,j} - E(\mu_i, \mu_j, \phi_i)) \tag{13}$$

A new rating volatility σ' is found when using the Illinois algorithm [5] for a function $f(x) = \frac{e^x(\Delta^2 - \phi^2 - v - e^x)}{2(\phi^2 + v + e^x)^2} - \frac{x - \ln(\sigma^2)}{\tau^2}$ with accuracy of up to 6 decimal places. This method is used for finding zeros and once the zero x_0 of this function is found, σ' is set to $e^{x_0/2}$ and the pre-rating period value ϕ^* (Eq. 14) is calculated.

$$\phi^* = \sqrt{\phi^2 + \sigma'^2} \tag{14}$$

New values for rating deviation ϕ' (Eq. 15) and rating μ' (Eq. 16) are set.

$$\phi' = \frac{1}{\sqrt{\frac{1}{(\phi^*)^2} + \frac{1}{v}}} \tag{15}$$

$$\mu' = \mu + \phi' \sum_{i=1}^{m} g(\phi_i)(S_i - E(\mu, \mu_i, \phi_i)) \tag{16}$$

Finally, the new rating R' and new rating deviation RD' are converted from the Glicko-2 to the Glicko system using the formulae in Eq. 17.

$$R' = 173.7178\mu' + 1500 \text{ and } RD' = 173.7178\phi' \tag{17}$$

All of these systems have their own advantages (Table I), however, Glicko-2 contains most of them despite its more complicated formula (in comparison with other systems).

TABLE I: Preferences a chess rating contains.

Preference	Elo	Chessmetrics	DWZ	Glicko-2
Simple formula	✔	✔	✔	
Player's age influence			✔	
Dynamic weight factor		✔	✔	✔
Control over selective pairing				✔
Time varying impact				✔
Bayesian approach				✔
Straightforward measurement of rating inflation and deflation				✔
Straightforward measurement of rating reliability				✔
Straightforward measurement of differences between ratings				✔

Our implementations of these four algorithms were used in the following experiment.

III. Experiment

This experiment was conducted using the novel method for comparing and ranking the evolutionary algorithms CRS4EAs [30]. The experiment in CRS4EAs is executed as any other experiment, however each outcome of each algorithm regarding every optimisation problem must be saved for further comparison. In the CRS4EAs the run-by-run comparison the roles of the chess players adopt evolutionary algorithms. Each outcome in every run for every optimisation problem of one algorithm is compared to the corresponding outcome of the other algorithm. Such a comparison is called one 'game'. If the difference between compared outcomes is less than the predefined ϵ, the final score of this game is a draw, otherwise the algorithm with the outcome closer to the optimum of the optimisation problem wins. With k algorithms ($k - 1$ opponents), N optimisation problems, and n runs, one algorithm plays $n * N * (k - 1)$ games during one tournament. Hence, in our tournament $n * N * k * (k - 1)/2$ games are played. The whole process is presented in the flowchart in Fig. 1. The chess rating system used in CRS4EAs is Glicko-2, however due to this being an experiment, other chess rating systems were implemented as well.

In the presented experiment our implementations of $k = 15$ evolutionary algorithms were compared for $N = 20$ optimisation problems over $n = 100$ runs. The simplest algorithm used in the experiment was the basic random search (RWSi) [24]. Next being Teaching Learning Based Optimization (TLBO) [3], [25]. There were two variants of evolutionary strategies (ES(1+1) and CMA-ES) [19], [26], 10 variants of the Differential Evolution [4], [23], [29], [31], and the Self-adaptive

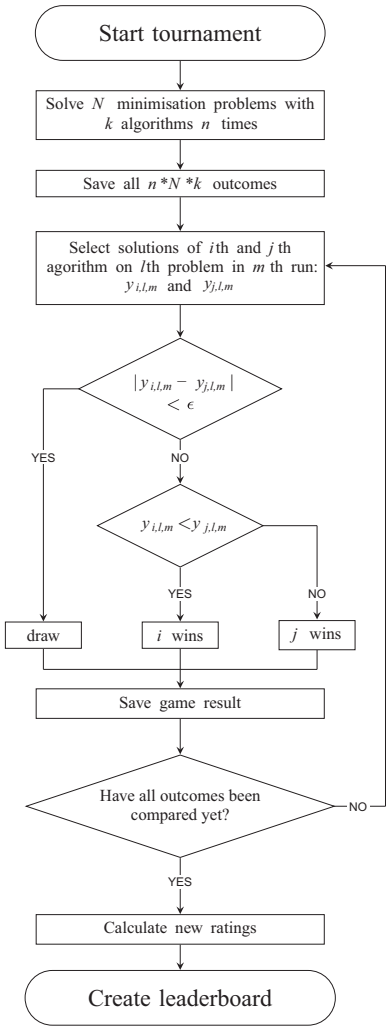

Fig. 1: Flowchart of experiment's execution in CRS4EAs.

Differential Evolution (jDE) [1]. The optimisation problems were from the Special Session and Competition on Large-Scale Global Optimization CEC 2010 [28]. The termination critera for each algorithm was maximum number of evaluations $Max\_FEs = 10^5$. The threshold for a draw was set at $\epsilon = 1.0e-06$, and the initial rating was set to 1500 for each rating system to provide a fairer comparison. Detailed descriptions of the algorithms and optimisation problems can be found in [30]. Other properties for the rating systems can be seen in Table II. R_{init} represents the initial rating for a new player, rating intervals and rating ranges present the values for detecting the differences in the powers of the algorithms, K is the K-factor in Elo, N_e is the number of games a player's rating is based on, m is the number of games the player completed during a tournament, J is the age coefficient from Chessmetrics, RD_{init} is the initial rating deviation for a new player, RD_{min} is the minimum rating deviation, and RD_{max} is the maximum rating deviation. Whilst Glicko-2 uses the straightforward values for detecting significant differences - R, RD, and rating interval - other systems do not consist of such preferences. Two algorithms are significantly different if their rating intervals do not overlap. In Glicko-2 the 99.7% rating (confidence) interval is defined by $[R-3RD, R+3RD]$. The rating range that distinguishes between the powers of two players in Elo equals 200 rating points. The minimum Elo rating can be 100 points, then the players are classified in categories: 100-199 points (J), 200-399 points (I), 400-599 points (H), 600-799 points (G), 800-999 points (F), 1000-1199 points (E), 1200-1399 points (D), 1400-1599 points (C), 1600-1799 points (B), 1800-1999 points (A), 2000-2199 points (expert), etc. The same is done for DWZ and Chessmetrics, but while DWZ uses the same categories as Elo, the Chessmetrics' categories differ by 100 points. However, it must be explicitly pointed out that this classification of categories is not a straighforward way of detecting significant differences as the confidence intervals in Glicko-2.

TABLE II: Properties for the chess ratings used during the experiment.

Chess rating system	Properties
Elo	$R_{init} = 1500$
	Rating range 200 points
	$K = \frac{800}{N_e+m}$
Chessmetrics	$R_{init} = 1500$
	Rating range 100 points
DWZ	$R_{init} = 1500$
	$J = 15$ for all players
	Rating range 200 points
Glicko-2	$R_{init} = 1500$
	$RD_{init} = 350$, $RD_{min} = 50$, $RD_{max} = 350$
	Rating interval $[R-3RD, R+3RD]$

The ratings evolutionary algorithms obtained for each rating system are presented on a group leaderboard in Table III. All the algorithms obtained minimum rating deviations of 50 points in the Glicko-2 system. Although, different formulae were used in different chess rating systems, the orders of the ratings were almost the same. The only rating system for which the order of algorithms was different was Elo where CMA-ES, DE/best/2/exp and DE/rand/1/exp go in reverse order. These three algorithms, however, are really close regarding rating points. In order to obtain a better picture the average ranking of the algorithms by data sets, i.e. Friedman ranking [11], [12] was added in the last column. A statistical analysis and comparison with NHST can be found in [30]. All the obtained ratings are displayed in Fig. 2 where distributions of ratings for each rating system are shown. Maximum and minimum overall rating values were obtained in Elo. These ratings were more scattered and there was a big gap (435 points) between the 7th algorithm DE/best/1/exp and the 8th algorithm DE/best/2/bin by dividing the algorithms into two groups: algorithms from 1 to 7 and algorithms from 7 to 15. The Chessmetrics and DWZ ratings seemed to be equally distributed, but the difference between the corresponding rating points varied between 20 to 59 points. The difference was bigger for better performing algorithms

TABLE III: Leaderboard with ratings the algorithms obtained using four different rating systems and the average ranking (AR) of the algorithms by data sets, i.e. Friedman ranking [11], [12].

i	Algorithm	Elo	Chessmetrics	DWZ	Glicko-2	AR
1	JDE/rand/1/bin	2014	1812	1753	1829	3.6
2	DE/rand/2/exp	1996	1772	1715	1779	3.425
3	CMA-ES	**1972**	1767	1711	1774	4.325
4	DE/best/2/exp	**1982**	1761	1705	1766	4.675
5	DE/rand/1/exp	**1985**	1758	1702	1762	4.325
6	DE/rand/2/bin	1940	1704	1651	1696	4.75
7	DE/best/1/exp	1890	1626	1578	1602	7.675
8	DE/best/2/bin	1455	1588	1542	1554	7.975
9	DE/rand-to-best/1/exp	1361	1575	1530	1540	7.05
10	DE/rand/1/bin	1221	1516	1475	1467	8.5
11	DE/rand-to-best/1/bin	1129	1375	1342	1294	10.8
12	TLBO	1078	1297	1268	1199	12.05
13	DE/best/1/bin	1057	1268	1241	1164	12.55
14	RWSi	1000	1178	1156	1054	13.7
15	ES(1+1)	983	1151	1131	1020	14.6

(59 for JDE/rand/1/bin) and smaller for worse performing algorithms (20 for ES(1+1)). The biggest gap in ratings for Glicko-2, DWZ, and Chessmetrics was between the 10th algorithm DE/rand/1/bin and the 11th algorithm DE/rand-to-best/1/bin. Algorithms DE/rand/2/exp ($i = 2$), CMA-ES ($i = 3$), DE/best/2/exp ($i = 4$), and DE/rand/1/exp ($i = 5$) were close in ratings for all four rating systems.

An interesting outlook regarding the results of a tournament is when examinating wins, losses, and draws (Table IV). This is not only useful in chess but also in comparison with evolutionary algorithms. The number of wins, losses, and draws can tell a lot about how one algorithm performed against another. For example, JDE/rand/1/bin was the overall best algorithm - it had the most wins and the least losses - but when comparing its performance with the performance of the worst algorithm ES(1+1) - with the least wins and the most losses - showed that ES(1+1) defeated JDE/rand/1/bin in 1 out of 2000 (=20*100) games. It could be concluded that the JDE/rand/1/bin performed with outliers as this is a phenomenon that is also detected with other worse algorithms: DE/rand-to-best/1/bin (2 outliers), TLBO (2 outliers), DE/best/1/bin (2 outliers), and RWSi (2 outliers). An interesting fact is that CMA-ES has more wins than DE/rand/2/exp but is ranked one place lower. This is due to the fact that CMA-ES also has more loses and less draws. However, as mentioned before the difference in ratings is small. Table IV also shows that the draws were less common in those games with low-ranked algorithms - even between the low-ranked algorithms themselves. The draws were fairly common in games between the first half of the algorithms, whilst in games with algorithms that were ranked lower than 8th place the draws hardly appeared. The most draws (1112) were played between DE/rand/2/exp and DE/rand/1/exp. DE/rand/2/exp, DE/rand/2/bin, and DE/rand-to-best/1/exp were the only three algorithms that won the absolute number of games (2000) against at least one opponent. DE/rand/2/exp won absolutely against TLBO, DE/best/1/bin, RWSi, and ES(1+1), DE/rand/2/bin against RWSi, and DE/rand-to-best/1/exp against ES(1+1).

The detected significant differences are shown in Fig. 3. As Chessmetrics has the lowest threshold for classifying players into groups (100 rating points), the highest distinctions (90) between players were detected within this system. Elo and DWZ had the same threshold (200 rating points), but more distinctions were detected in Elo, due to the fact that the obtained players' ratings in Elo had wider ranges. Chessmetrics detected 10 differences more than DWZ, 8 differences more than Elo, and there was no difference in those detected by DWZ or Elo and those Chessmtrics was not. DWZ detected 8 differences that Elo did not, and Elo detected 11 differences that DWZ did not. These differences are listed in Table V.

TABLE V: System marked with ✓ detected differences in the ratings of the listed algorithms, whilst the system marked with ✗ did not.

Chessmetrics ✓ DWZ ✗	Chessmetrics ✓ Elo ✗

DE/best/1/bin vs. RWSi	DE/best/1/exp vs. DE/rand/1/bin
	DE/best/2/bin vs. DE/rand-to-best/1/exp
	DE/best/2/bin vs. DE/rand/1/bin
	RWSi vs. ES(1+1)

It appears that Elo, Chessmetrics, and DWZ are more liberal, and the conservativity could be increased with a wider rating range between categories. However controlling the conservativity in such way would not be as efficient as in Glicko-2 where conservativity is controlled by setting the minimal rating deviation and choosing an appropriate confidence interval. In Glicko-2 the algorithms' ratings were compared pairwisely, whilst with the other three systems algorithms were classified into groups and then compared regarding them. Also, the significances of the differences detected within Elo, Chessmetrics, and DWZ are unknown, as there was no statistical tool for measuring them and the choice of rating range is arbitrary. On the other hand, Glicko-2 detected 50 significant differences that were made with 99.7% confidence and were comparable to NHST [30]. The tests of significance used for NHST analysis were the Friedman

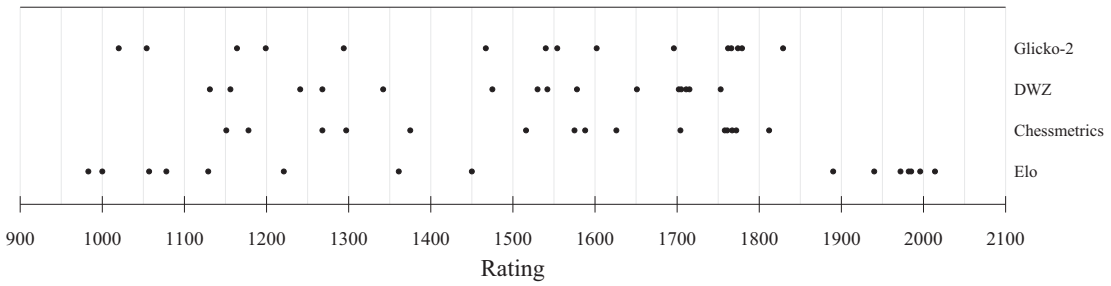

Fig. 2: Distributions of the ratings for all 4 rating systems.

TABLE IV: Wins (W), losses (L), and draws (D) algorithms obtained in tournaments against each other. When the number of losses is relatively small (e.g., < 75) the occurance of outliers is very likely.

and Nemenyi tests with critical difference $CD = 4.79$. The first implied that there are significant differences between algorithms, and the other found 43 significant differences that were similar to those found with Glicko-2 (Fig. 3e). The executed experiment therefore showed that the Glicko-2 rating system is more appropriate for comparison and ranking of evolutionary algorithms. It provides more reliable ratings and more evident way of detecting significant differences. Hence, the preferences of the Glicko-2 (Table I) do not only contribute in tournaments between chess players but also in comparison between evolutionary algorithms.

IV. Conclusion

This paper conducted a comparison of four chess rating systems for ranking evolutionary algorithms. All the rating systems were implemented within EARS software, executed as an experiment, and analysed using the CRS4EAs method. The experiment showed that the Glicko-2 rating system is the most appropriate for ranking evolutionary algorithms. The main reason lies in the detection of significant differences amongst players and the formation of a confidence interval that allows direct comparison with null hypothesis significance testing. The other three systems - Elo, Chessmetrics, and DWZ - use simpler methods for detecting differences between ratings. Players are classified into categories and the differences in powers depend on the category the player belongs to. A new method for detecting the differences between players could increase the efficiencies of these systems, if the proposed method were dynamic (similar to Glicko-2). Otherwise, the results obtained from small tournaments (with a small number of algorithms or a small number of optimisation problems) would be unreliable. The conservativity/liberty of the method can be more efficiently controlled within Glicko-2. Elo, Chessmetrics, or DWZ can be improved by using some factors that are important for chess players (e.g., a player's age or the colour of pieces), but are irrelevant when comparing evolutionary algorithms. The results in CRS4EAs can be examined by observing the number of wins, losses, and draws amongst different players. Using this approach the outliers can be detected and the number of draws can indicate which algorithms are more likely to play a draw. In this paper we have empirically shown that various chess rating systems can be used for comparison amongst evolutionary algorithms and their rankings. The rationale as to why Glicko-2 may be a better choice than other chess systems for comparing the evolutionary algorithms has also been discussed in details. In the future, we will continue using Glicko-2 for CRS4EAs, with more focus on tuning the parameters. Glicko-2 was proven to be more reliable and dynamic than other older systems.

***Abstract*—We have applied the methodology combining Bayesian inference with Genetic algorithm (GA) to the problem of the atmospheric contaminant source localization. The algorithms input data are the on-line arriving information about concentration of given substance registered by sensors' network. To achieve rapid-response event reconstructions the fast-running Gaussian plume dispersion model is adopted as the forward model. The proposed GA scan 5-dimensional parameters' space searching for the contaminant source coordinates (x,y), release strength (Q) and atmospheric transport dispersion coefficients. Based on the synthetic experiment data the GA parameters, best suitable for the contamination source localization algorithm performance were identified. We demonstrate that proposed GA configuration can successfully point out the parameters of abrupt contamination source. Results indicate the probability of a source to occur at a particular location with a particular release strength. We propose the termination criteria based on the probabilistic requirements regarding the parameters' value.**

I. Introduction

ACCIDENTAL atmospheric releases of hazardous material pose great risks to human health and the environment. In the event of an atmospheric release of chemical, but also radioactive biological materials, emergency responders need to quickly predict the current and future locations and concentrations of substance in the atmosphere. In this context it is valuable to develop the emergency system, which based on the concentration of dangerous substance by the sensors' network can inform about probable location of the release source. Moreover, the contamination source's location should be found as soon as possible. The most obvious way is to propose the simulation which gives the same substance point concentrations like registered by the sensors. However, to create the model realistically reproducing the real situation based only on the sparse point-concentration data is not trivial. This task requires specification of set of models' parameters, which depends on the applied model. The event reconstruction problem can be reformulated into a solution based on efficient sampling of an ensemble of simulations, guided by comparisons with data.

This work was supported by the Welcome Programme of the Foundation for Polish Science operated within the European Union Innovative Economy Operational Programme 2007-2013

A comprehensive literature review of past works on solutions of the inverse problem for atmospheric contaminant releases can be found in (e.g.[1]). The problem of the source term estimation was studied in literature grounded both on the deterministic and probabilistic approach. [2] implemented an algorithm based on integrating the adjoint of a linear dispersion model backward in time to solve a reconstruction problem. [3] introduced dynamic Bayesian modeling, and the Markov Chain Monte Carlo (MCMC) sampling approaches to reconstruct a contaminant source. The effectiveness of MCMC in the localization of the atmospheric contamination source based on the synthetic experiment data was presented in [4], [5]. The advantage of the Sequential Monte Carlo over the MCMC in the estimation of the probable values of the source coordinates was presented in [6].

The problem of finding the 'best fitted' model's parameters, for which a forward atmospheric dispersion model's output will reach agreement with real observations, can be considered as the optimization problem. Metaheuristics, such as genetic algorithms (GA), are broadly used to solve various optimization problems. GA was designed to imitate some of the processes that people can witness in natural environment [7]. By observing nature people noticed that many beings have evolved diametrically in the relatively short period of time. The concept of GA was to use the power of evolution to create a strong and universal tool reliable of solving optimization problems. The GAs are highly relevant for industrial applications, because they are capable of handling problems with non- linear constraints, multiple objectives, and dynamic components - properties that usually appear in the real-world problems (e.g. [8]). Since GA introduction and propagation the GA have been often used as an alternative to the conventional optimization methods and has been successfully applied in a variety of areas. For example it was used in control engineering [9], finding hardware bugs [11] and much more e.g. [10]. GA has been also used in

978-83-60810-58-3/$25.00

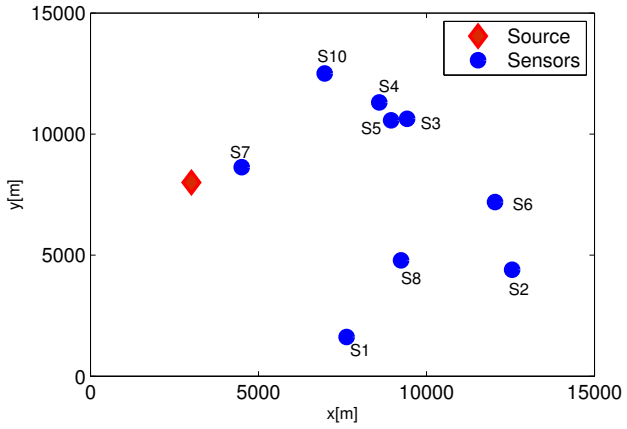

Fig. 1. Distribution of the sensors and the release source within the considered domain.

environmental sciences problem e.g. in the addressing air quality problem [12].

Application of the metaheuristic algorithms like GA requires defining the values of several algorithm components and parameters. These parameters have large impact on performance and efficiency of the algorithm (e.g., [13], [14], [15]). Therefore, it is important to estimate the algorithm's parameters best suitable for the considered optimization problem. The optimal values for the parameters depend mainly on: a) the problem; b) the domain of the problem to deal with; and c) computational time that can be spend for solving the problem. Usually, in the algorithm parameters tuning a compromise between solution quality and computational time should be achieved.

In this paper we apply the GA to the problem of localizing the abrupt atmospheric contamination source based on point-concentrations reported by the sensors network. Using the synthetic experiment data we demonstrate the efficient GA configuration best suitable for the algorithm performance.

A. Synthetic data

Our main goal is to conduct dynamic inference of an unknown atmospheric release. To test the proposed methods we require some concentration data. To satisfy this requirement we have performed the simulation with use of the atmospheric dispersion second-order Closure Integrated PUFF model (SCIPUFF) [16]. SCIPUFF is an ensemble mean dispersion model designed to compute the time-dependent field of expected concentrations resulting from one or more sources. The model solves the transport equations using a second-order closure scheme and treats releases as a collection of Gaussian puffs. In simulation we assumed that we have 10 sensors distributed over 15km x 15km area, the location of sensors was chosen randomly within the domain (Fig. 1). The atmospheric contamination source was located at $x = 3$ km, $y = 8$ km, $H = 25$ m within the domain. The simulated release was continuous with rate $Q = 8000 g/s$ and started one hour before first sensors measurements. The wind was directed along x axis with speed $5 m/s$. Further, in this paper we assume that the only algorithm input information we have, are reported every 15 minutes (in subsequent time steps) during 1.5 hour concentrations of dispersed substance registered by 10 sensors (Table I). We run algorithm searching for the source of contamination just after first information from sensors (t=1) and update the obtained probabilities with use of the developed algorithms by subsequent sensors registrations.

II. RECONSTRUCTION PROCEDURE

A. Bayesian inference

The Bayes' theorem, as applied to an emergency release problem, can be stated as follows:

$$P(M|D) \propto P(D|M)P(M) \tag{1}$$

where M represents possible model configurations or parameters and D are observed data. For our application, Bayes' theorem describes the conditional probability $P(M|D)$ of certain source parameters (model configuration M) given observed measurements of concentration at sensor locations (D). This conditional probability $P(M|D)$ is also known as *a posteriori* distribution and is related to the probability of the data conforming to a given model configuration $P(D|M)$, and to the possible model configurations $P(M)$, before taking into account the measurements. The probability $P(D|M)$, for fixed D, is called the *likelihood* function, while $P(M)$- *a priori* distribution [17]. To estimate the unknown source parameters M using (1), the posteriori distribution $P(M|D)$ must be sampled. $P(D|M)$ quantifies the likelihood of a set of measurements D given the source parameters M.

Value of likelihood for a sample is computed by running a forward dispersion model with the given source parameters M and comparison of the model predicted concentrations in the points of sensors location (within a considered domain) with actual observations D. The closer the predicted values are to the measured ones, the higher is the likelihood of the sampled source parameters.

As the sampling procedure we use an GA to obtain the posterior distribution $P(M|D)$ of the source term parameters given the concentration measurements at sensor locations. This way we completely replace the Bayesian formulation with a

sampling procedure to explore the model parameters' space and to obtain a probability distribution for the source location.

B. The likelihood function

A measure indicating the quality of the current GA population is expressed in terms of a likelihood function. This function compares the predicted from model and observed data at the sensor locations as:

$$\lambda(M) = -\frac{\sum_{i=1}^{N}[log(C_i^M) - log(C_i^E)]^2}{2\sigma_{rel}^2}, \quad (2)$$

where λ is the likelihood function, C_i^M are the predicted by the forward model concentrations at the sensor locations i, C_i^E are the sensor measurements, N is the number of sensors, σ_{rel}^2 is an error parameter which can be updated accordingly to the expected errors in the observations at given observational time interval, here fixed to 0.2.

C. Posterior distribution

The posterior probability distribution (1) is computed directly from the resulting GA generations and is estimated as:

$$P(M|D) = \frac{1}{n}\sum_{i=1}^{n}\delta(M_i - M), \quad (3)$$

which represents the probability of a particular model configuration M giving results that match the observations at sensor locations. Equation (3) is a sum over the entire GA generation. Thus $\delta(M_i - M) = 1$ when $M_i = M$, and 0 otherwise. If in the generation many chromosomes have the same configuration $P(M|D)$ increases through the summation increasing the probability for those contamination source parameters.

D. Forward dispersion model

A forward model is needed to calculate the concentration C_i^M at the points i of sensor locations for the tested set of model parameters M at each GA step. As a testing forward model we selected the fast-running Gaussian plume dispersion model (e.g. [18]).

The Gaussian plume dispersion model for uniform steady wind conditions can be written as follows:

$$C(x,y,z) = \frac{Q}{2\pi\sigma_y\sigma_z U} exp\left[-\frac{1}{2}\left(\frac{y}{\sigma_y}\right)^2\right] \times \quad (4)$$
$$\{exp\left[-\frac{1}{2}\left(\frac{z-H}{\sigma_z}\right)^2\right] + exp\left[-\frac{1}{2}\left(\frac{z+H}{\sigma_z}\right)^2\right]\}$$

where $C(x,y,z)$ is the concentration at a particular location, U is the wind speed directed along x axis, Q is the emission rate or the source strength and H is the height of the release; y and z are the distance along horizontal and vertical direction, respectively. In the equation (4) σ_y and σ_z are the standard deviation of concentration distribution in the crosswind and vertical direction. These two parameters are defined empirically for different stability conditions [19], [20]. In this case we restrict the diffusion to the stability class C (Pasquill type stability for rural area). In scanning algorithm we assumed

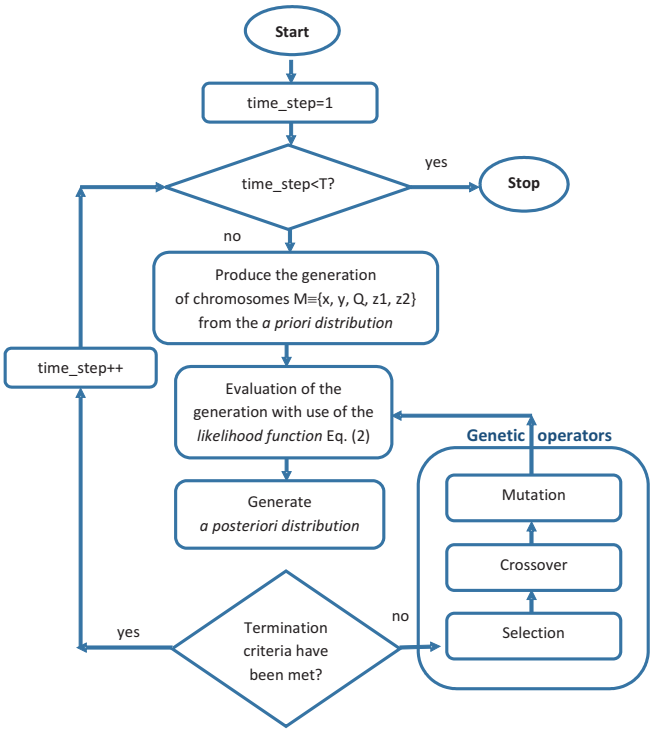

Fig. 2. Flow chart of the stochastic reconstruction procedure

that we do not know exact behavior of the plume and consider those coefficients as unknown. Thus, the parameters σ_y and σ_z are taken as: $\sigma_y = z_1 \cdot x \cdot (1 + x \cdot 4 \cdot 10^{-5})^{-0.5}, \sigma_z = z_2 \cdot x$ where values z_1 and z_2 are sampled by algorithm within interval $[0.001, 0.35]$.

To summarize, in this paper the searched model's parameter space is

$$M = (x, y, Q, z_1, z_2) \quad (5)$$

where x and y are coordinates of the release's source, Q release strength and z_1, z_2 are terms in the turbulent diffusion parametrization.

E. Genetic algorithm

The localization of the contamination source within the predefined domain requires the recognition of the atmospheric dispersion model parameters for which the model output at the sensors location meet the real data. In this context we can say that the problem can be seen as the optimization problem for which GA can be applied.

Fig. 2 presents the concept of GA's application in the Bayesian estimation of the unknown model parameters. The algorithm starts with the defining the initial population. The population is composed from the predefined number of chromosomes, $P(\tau) = x_1^\tau, \ldots, x_n^\tau$, for the generation τ, being initially randomly drawn from the admissible set of values. This set is explicitly defined by the space of explored parameters. GA chromosome is configured as binary value representing the real value of searched parameters. The quality

Algorithm 1 Rank Selection

```
ascSortMByLikelihoodFunction();
MProbabilityRange = 0;
FOR i=1 to N LOOP %N–population size
    M(i).rank = i-1; %M–chromosome
    probability = 2*(N-M(i).rank)/N*(N+1);
    MProbabilityRange += probability;
    M(i).probability = MProbabilityRange;
END LOOP
FOR i=1 to N LOOP
    randVal = drawNumberFrom0To1();
    FOR j=1 to N LOOP
        IF M(j).probability >= randVal
            newPopulation(i) = M(j);
            break;
        END IF
    END LOOP
END LOOP
```

Algorithm 2 Hard tournament selection

```
FOR i=1 to N LOOP
  FOR j=1 to TS LOOP
        tournamentGroup(j)=
                =drawSpecimenFromPopulation();
  END LOOP
  sortTournamentGroupByLikelihoodFunction();
  newPopulation(i) = getBestTournamentSpecimen();
END LOOP
```

of each chromosome in current population is evaluated based on the cost, or objective/likelihood function. Various objective functions can be applied; its form depends upon the problem being solved. We use the function presented by eq. (2). The 'improvement' of the current population can be done by the various genetic operators.

Information on the quality of population's chromosomes is used to perform selection. The portion of the population that is replaced in each generation is done based rank on the likelihood function (Eq.2) value obtained during the evaluation of the population (various in each algorithm iteration). Then, the crossover is performed. Crossover is process of replacing parents by their children in the current population. Children are created by blending of the parents at the randomly chosen crossover point. The number of crossovers that occurs within the population is determined by the crossover probability. Subsequently the current population is mutated. It changes the chromosome's features. By giving a chance of changing chromosome's individual bits mutation allows the algorithm to search for the entire solution's space and not to converge to local extremes. The number of mutations that occurs is determined by the mutation probability. After performing the selection crossover and mutation the new generation $(\tau + 1)$, being subject to the new evaluation, is established. After some number of generations the algorithm converges - it is expected that the best chromosome represents a near-optimum (reasonable) solution. The process stops when the termination criterion is fulfilled. The most common termination criterion is limited number of generations, but in this paper we present

Algorithm 3 Multi-point Crossover.

```
FOR i=1 to N LOOP %N–population size
    IF drawNumberFrom0To1() <= CP
      currentPopulation(i).isParrent(true);
    END IF
END LOOP

               + tmpZ2Bin2(CrossPoint+1);

  secondChildX = tmpXBin2(0,CrossPoint)+
               + tmpXBin1(CrossPoint+1);
  secondChildY = tmpYBin2(0,CrossPoint)+
               + tmpYBin1(CrossPoint+1);
  secondChildQ = tmpQBin2(0,CrossPoint)+
               + tmpQBin1(CrossPoint+1);
  secondChildZ1= tmpZ1Bin2(0,CrossPoint)+
               + tmpZ1Bin1(CrossPoint+1);
  secondChildZ2= tmpZ2Bin2(0,CrossPoint)+
               + tmpZ2Bin1(CrossPoint+1);

  firstChild = firstChildX+firstChildY+firstChildQ
             + firstChildZ1+firstChildZ2;
  secondChild= secondChildX+secondChildY+secondChildQ
             + secondChildZ1+secondChildZ2;

  currentPopulation(firstParent.getId())=firstChild;
  currentPopulation(secondParent.getId())=secondChild;
END LOOP
```

other possibility.

In this paper the scanned parameters space M is five-dimensional i.e. $M \equiv \{x, y, Q, z1, z2\}$. Correspondingly each population's chromosome $M(i)$ stores the following information:

- x, y - coordinates of contamination's source in [m],
- Q - strength of release in [g/s],
- $z1$, $z2$ - terms in the turbulent diffusion parametrization.

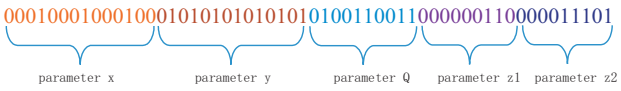

Fig. 3. Example of the chromosome representing the searched model's parameters

In the problem presented in this paper the parameters M are searched within the intervals $x \in \langle 0, 15000\rangle$, $y \in \langle 0, 15000\rangle$, $Q \in \langle 1, 8000\rangle$, $z1 \in \langle 0.001, 0.350\rangle$ and $z2 \in \langle 0.001, 0.350\rangle$. The parameters value precision P for parameters x,y equals $P_{x,y} = 1$ [m], for Q: $P_Q = 1$ [g/s], and $P_{z1} = P_{z2} = 0.001$. The example of the encoded chromosome presents Fig. 3.

1) Selection: There are many ways of dealing with GA selection e.g. roulette selection, rank selection, hard and soft tournament. For the problem presented in this paper the all mentioned methods were tested. The best results were achieved with selection based on rank and hard tournament selection. Results obtained applying these two selections are compared further in this paper. In the rank selection the better likelihood function results in the lower rank value leading to higher probability of being drawn to the next population. Pseudo code presents Algorithm 1. In the case of hard tournament selection of size 2, as the result of the tournament from each pair of the selected chromosomes one with the better objective function value passes to the next population. Pseudo code presents Algorithm 2.

2) Crossover: Similarly to the previous operator there are many ways of dealing with GA crossover e.g. single point crossover, multi point crossover, uniform crossover, arithmetic crossover. For a given problem the best results were achieved with by applying the multi-point crossover. Procedure begins with performing, for each chromosome, the test for being a parent according to the crossover probability CP. From the parents' population the unexploited pair is chosen, then one crossover point for each parameter encoded in the chromosome is drawn, i.e. five points for the problem presented. Parents are split at the crossover points for each encoded parameter, then (in term of each encoded parameter) bits are swap resulting in two children. Pseudo code presents Algorithm 3.

3) Mutation: The latter applied genetic operator is mutation. The most frequently used are uniform mutation and not-uniform mutation. For the given problem the best results were achieved with uniform mutation in which all chromosome's bits are mutated with the mutation probability MP. Pseudo code presents Algorithm 4.

In the reconstruction of the atmospheric contamination source the following GA configuration was applied:

- Size of population N=150;
- Selection:
  - rank selection,
  - hard tournament of size 2;
- Multi-point crossover with probability $CP = 0.75$, with 5 crossover points (5 is a number of searched parameters);
- Uniform mutation with probability $MP = 0.02$.

Algorithm 4 Uniform Mutation

```
FOR i=1 to N LOOP   %N–population size
  FOR j=1 to L LOOP %L–length of chromosome
                      %binary form
    IF drawNumberFrom0To1() <= MP
      currentPopulation(i).swapBitValue(j);
    END IF
  END LOOP
END LOOP
```

t=5	113	169 500
t=6	216	324 000
Summary	752	1 128 000

The size of population, crossover probability and mutation probability were selected based on the numerical tests presented in [21].

III. RESULTS

We assume that the concentration from the sensors arrives subsequently in six time steps (Table I). We start to search for the source location (x, y), release rate (Q) and model parameters z_1 and z_2 after first sensors' measurements. Thus, reconstruction algorithm is run with obtaining the first measurements from the sensors ($t = 1$ at Table I). We assume that initially we have no *a priori* information about the parameters' values. So, the initial value of each parameter is draw randomly from the predefined interval with use of the uniform distribution.

Then generation is evaluated with use of the likelihood function (Eq. 2). The subsequent generations are iteratively updated by the applied genetic operators until the stop criterion is met. Of course there arises question how to specify the termination criteria? The usual criterion applied in GA is fixed number of generations. For the problem presented in this paper the time of giving the answer is crucial, so the constant number of generations is not optimal. In the task of the estimation of the source of the atmospheric contamination the most important is to

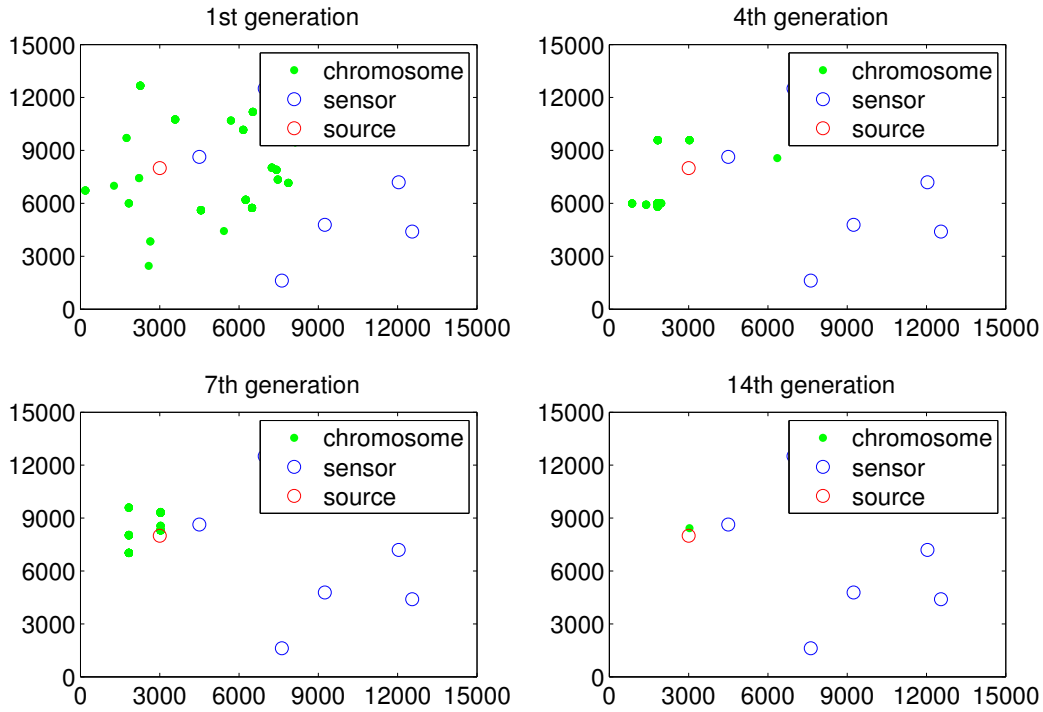

Fig. 4. Distribution of the x and y coordinates estimates during the GA runs for the given generation in 1st time step (rank selection).

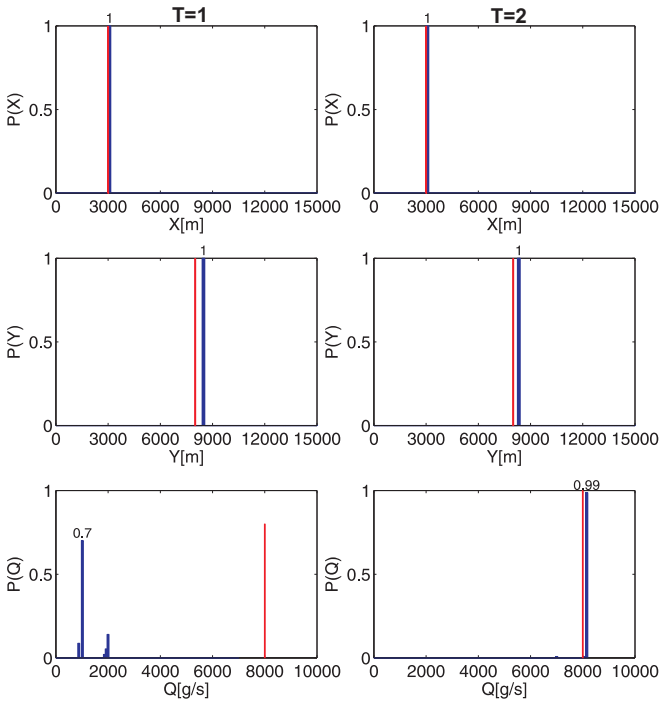

Fig. 5. Probability distributions of the models parameters x, y, and Q for the last generations in 1st and 2nd time step (rank selection). Vertical red lines represent the target value.

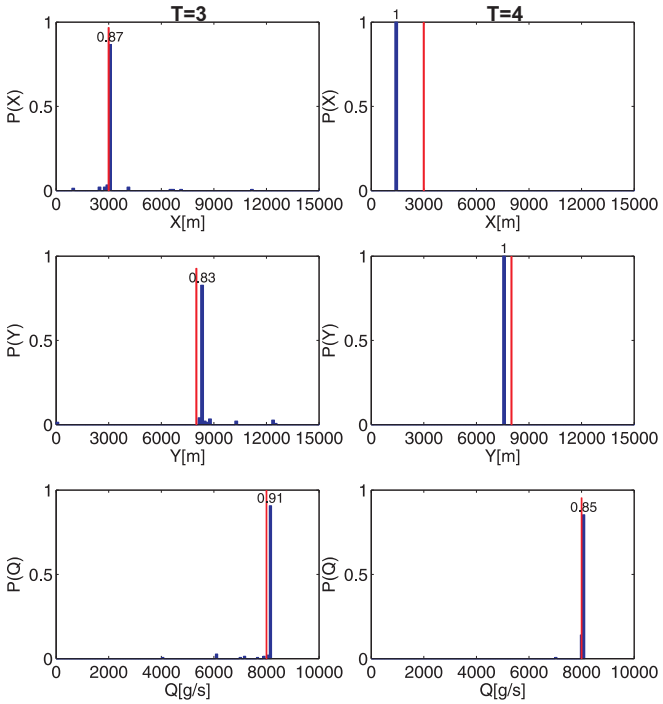

Fig. 6. Probability distributions of the models parameters x, y, and Q for the last generations in 3rd and 4th time step (rank selection). Vertical red lines represent the target value.

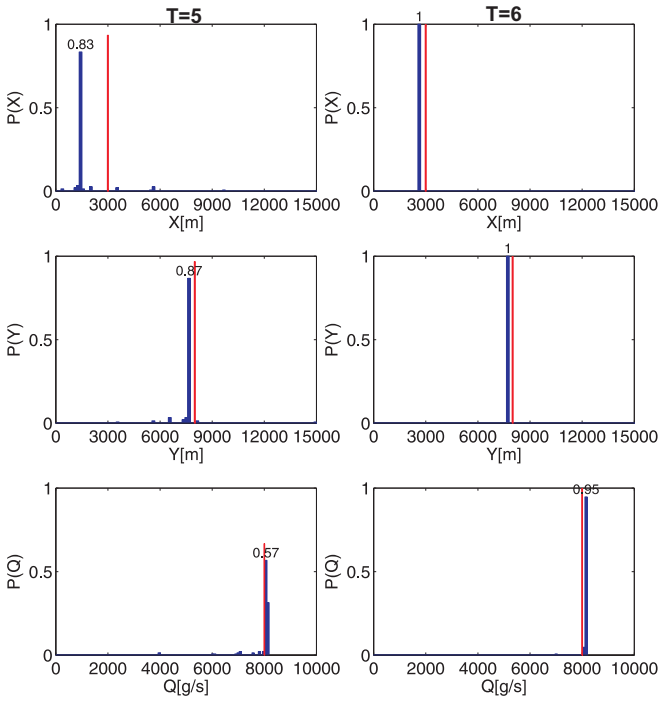

Fig. 7. Probability distributions of the models parameters x, y, and Q for the last generations in 5th and 6th time step (rank selection). Vertical red lines represent the target value.

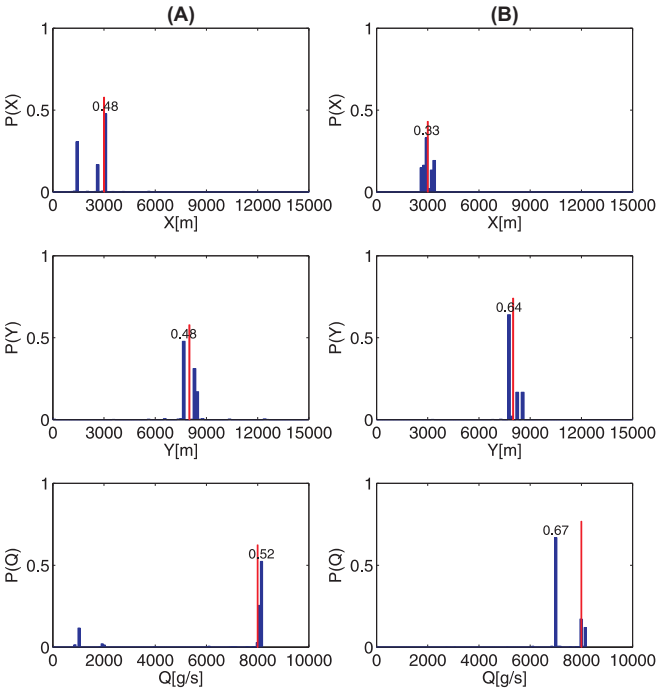

Fig. 8. Cumulative probability distributions of the models parameters x, y, and Q averaged over all time steps (A) rank selection, (B) hard tournament selection. Vertical red lines represent the target value.

estimate its location, to undertake the necessary action. Thus, crucial is assessment of the x and y coordinates of the source. Applying the Bayesian approach we can ask what probability of estimation of these parameters will be acceptable. So, after applying the last genetic operator, i.e. mutation, the histograms of x and y parameters encoded in the current chromosomes generation are evaluated. If many chromosomes have the same parameters configuration the probability of certain parameter's value increases. Consequently, the reconstruction algorithm is terminated when certain values of parameters x and y will be obtained with probability greater than 0.8. If this condition is fulfilled the *a posteriori* distributions of all parameters are calculated. Obtained *a posteriori* distributions are considered as the *a priori* distributions in the subsequent time step. Consequently, in the next time step, when new data from the sensors arrive the initial population is drawn uniformly from the *a priori* distribution i.e. *a posteriori* distribution from previous time step.

The number of generations required to fulfill the termination criterion in subsequent time steps for the rank selection is presented in Table II and for the hard tournament selection in Table III. Comparing the Tables it is obvious that the rank selection is much more effective. Fig. 4 illustrates the distribution of the estimated by the GA contamination source coordinates x and y in subsequent generations in the first time step. It is seen that at the beginning for the 1st generation the chromosomes are equally distributed within the scanned domain. However, the applied genetic operators improve population quality for further generations and the chromosomes gradually focus around the true source location. Finally, for 19th generation the estimated by the GA contamination source location approaches to the target location. Figs. 5, 6 and 7 present the a posteriori distributions for x, y and Q parameters obtained in the succeeding time steps. This distributions were obtained based on the chromosomes configurations in the last generation at given reconstruction algorithm iteration. Based on the searched parameters value, encoded in the final chromosomes population, the histogram for each parameter has been assessed. Obtained histograms shows which values of the parameters were the most frequent in the final generation, which directly is reflected in its probabilities.

Fig. 5 presents that the first sensors measurements allow to estimate the x and y parameters close to the target values, while the release strength Q is approached in the second time step. The probability distributions in subsequent time steps reflect how the sensor's data support or not the obtained distributions. The exact values of parameters differ in subsequent time steps. Below, as the estimated parameter value we provide the central value of the histogram bar with highest probability and as the error the half of the bar width. In the 6th time step the following parameters are estimated $P(x = 2625 \pm 75) = 1$, $P(y = 7725 \pm 75) = 1$ and $P(Q = 8120 \pm 40) = 0.95$. To effectively compare the results given by all proposed algorithms we have estimated the joint marginal distribution of x, y and Q parameters. Fig. 8ab present the *a posteriori* distribution averaged over all time steps for the GA algorithm

with rank selection and with the hard tournament selection, respectively. The algorithm applying rank selection as the most probable has pointed the parameters $P(x = 3075 \pm 75) = 0.48$, $P(y = 7725 \pm 75) = 0.48$ and $P(Q = 8120 \pm 40) = 0.52$, while the algorithm applying the hard tournament the parameters $P(x = 2925 \pm 75) = 0.33$, $P(y = 7725 \pm 75) = 0.64$ and $P(Q = 7000 \pm 40) = 0.67$. Fig. 9ab presents the probability distributions of the $z1$ and $z2$ parameters for the both selection methods. The algorithm applying rank selection returned the following values $P(z1 = 0.04375 \pm 0.00175) = 0.48$, $P(z2 = 0.00175 \pm 0.00175) = 0.79$ and algorithm applying the hard tournament $P(z1 = 0.05075 \pm 0.00175) = 0.48$, $P(z2 = 0.00175 \pm 0.00175) = 0.8$. We do not know the target values for these coefficient, as far the SCIPUFF model used to generate the synthetic concentration data do not allows to specify its directly. In the reconstruction procedure we could of course fix these coefficients according to the stability class pointed by the terrain and wind speed which in this case could be the stability class C for which $z1 = 0.22$ and $z2 = 0.2$. But our numerical tests showed that we obtain better results when we do not restrict the dispersion coefficients to the one given value. The 'freed' the dispersion coefficients in some acceptable interval assumption allows to better fit the Gaussian plum to the 'real' data.

Comparison of the obtained results leads to the conclusion that algorithms applying both selection methods return similar results for the x and y parameters, at the same time the algorithm using the hard tournament selection as the most probable denotes $Q = 7000$ which differs from the true release rate for $1000g/s$, while for the rank selection algorithm hits the target value. Consequently, we can pointed the algorithm applying the rank selection as more effective, as far it requires ~ 11 times less computational time than the hard tournament selection to return comparable results.

IV. Conclusion

We have presented a methodology to reconstruct a source causing an area of contamination, based on a set of measurements. The method combines Bayesian inference with the genetic algorithm and produces posterior probability distributions of the parameters describing the unknown source. Developed dynamic data-driven event reconstruction model couples data and pollutant dispersion simulations through Bayesian inference. This approach successfully provide the solution to the stated inverse problem i.e. having the downwind concentration measurement and knowledge of the wind field algorithm found the most probable location of the source and its strength.

We have proposed the termination criteria reflecting the probabilistic aspect of the obtained solution i.e. the GA is terminated when some of the searched parameters are pointed with satisfactorily probability. This approach allows to optimize the algorithm's computational time. We show that in the presented problem the rank selection is more efficient than the hard tournament selection.

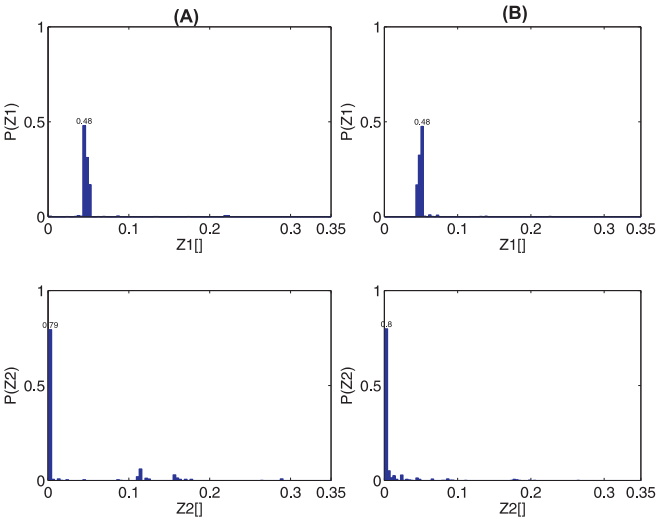

Fig. 9. Cumulative probability distributions of the models parameters $z1$ and $z2$ averaged over all time steps (A) rank selection, (B) hard tournament selection. Vertical red lines represent the value usually accepted in the Pasquili stability class C.

The probabilistic aspect of the solution optimally combines a probable answer with the uncertainties of the available data. Among several possible solutions, the Bayesian source reconstruction is solely able to find values of the model parameters that are more consistent with the currently available data.

***Abstract*—One of the main sources of inspiration for techniques applicable to complex search space and optimisation problems is nature. This paper proposes a new metaheuristic – Dispersive Flies Optimisation or DFO – whose inspiration is beckoned from the swarming behaviour of flies over food sources in nature. The simplicity of the algorithm, which is the implementation of one such paradigm for continuous optimisation, facilitates the analysis of its behaviour. A series of experimental trials confirms the promising performance of the optimiser over a set of benchmarks, as well as its competitiveness when compared against three other well-known population based algorithms (Particle Swarm Optimisation, Differential Evolution algorithm and Genetic Algorithm). The convergence-independent diversity of DFO algorithm makes it a potentially suitable candidate for dynamically changing environment. In addition to diversity, the performance of the newly introduced algorithm is investigated using the three performance measures of accuracy, efficiency and reliability and its outperformance is demonstrated in the paper.**

I. Introduction

THROUGHOUT the history nature has been an inexplicable source of inspiration for scientists and researchers. Observations, many of which made unintentionally, have been triggering the inquisitive minds for hundreds of years. The task of resolving problems and its often present nature in the minds of scientists boosts the impact of these observations, which in cases led to discoveries. Among others, researchers in mathematics, physics and natural sciences have had their fair share of 'observations-leading-to-discoveries'.

Observing the magnificently choreographed movements of birds, behaviour of ants foraging, convergence of honey bees in search for food source and so forth has led several researchers to propose (inspired vs. identical) models used to solve various optimisation problems. Genetic Algorithm [1], Particle Swarm Optimisation [2] and Ant Colony Optimisation [3] are only few such techniques belonging to the broader category of swarm intelligence; it investigates collective intelligence and aims at modelling intelligence by looking at individuals in a social context and monitoring their interactions with one another as well as their interactions with the environment.

The work presented here aims at proposing a novel nature-inspired algorithm based on the behaviours of flies hovering over food sources. This model – Dispersive Flies Optimisation or DFO – is first formulated mathematically and then a set of experiments is conducted to examine its performance when presented with various problems.

II. Flies in Nature

Flies are insects of the order *Diptera*, which comprises a large order, containing an estimated $240,000$ species of mosquitoes, gnats, midges and others [4]. Flies exist in various types each exhibiting distinctive behaviour in different environments. What most flies have in common is their swarming behaviour which depends on several factors.

Swarming have been described in [5] where a difference of shape between low swarms over dung and high swarms over other markers have been logged. High swarms fluctuated in height; vertical movements of the swarms of *Anopheles franciscanus* (Culicidae) are said to be correlated with female presence at swarms [6]. Height change in mosquito swarm induced by a clarinet note [7] and the human voice [8] may have evolved as responses to the flight tone of female mosquitoes [9].

Swarms of flies are associated with visual markers ranging in size from cowpies and stones to church steeples [10]. The criteria used by insects to select markers may be quite subtle; it was noted in [11] that certain objects are used repeatedly by the mosquito *Aedes cataphylla* while similar objects nearby are neglected.

As explained in [12], various swarms of flies usually "flying in relation to a more or less conspicuous element of the landscape, a lakeshore, a road, a treetop, below the tip of a branch, in an opening in the forest canopy, above a cow, an outstanding leaf", and so on according to species (e.g. [13], [14]). Depending on the species, the size of the swarm may consist of a single individual or tens or thousands, related to a discrete swarm marker; or even countless millions in the zonal swarms of lake shores.

Several elements play a role in *disturbing* the swarms of flies; for instance, the presence of a threat causes the swarms to disperse, leaving their current marker; they return to the marker immediately after the threat is over. However, during this period if they discover another marker which matches their criteria closer, they adopt the new marker.

III. Dispersive Flies Optimisation

Dispersive Flies Optimisation (DFO) is an algorithm inspired by the swarming behaviour of flies hovering over food sources. As detailed in section II, the swarming behaviour of flies is determined by several factors and that the presence of threat could disturb their convergence on the marker (or the

978-83-60810-58-3/$25.00

optimum value). Therefore, having considered the formation of the swarms over the marker, the breaking or weakening of the swarms is also noted in the proposed algorithm.

In other words, the swarming behaviour of the flies, in Dispersive Flies Optimisation, consist of two tightly connected mechanisms, one is the formation of the swarms and the other is its breaking or weakening. The algorithm and the mathematical formulation of the update equations are introduced below.

The position vectors of the population are defined as:

$$\vec{x}_i^t = \left[x_{i1}^t, x_{i2}^t, ..., x_{iD}^t\right], \qquad i = 1, 2, ..., NP \tag{1}$$

where t is the current time step, D is the dimension of the problem space and NP is the number of flies (population size).

In the first generation, when $t = 0$, the i^{th} vector's j^{th} component is initialised as:

$$x_{id}^0 = x_{min,d} + r\left(x_{max,d} - x_{min,d}\right) \tag{2}$$

where r is a random number drawn from a uniform distribution on the unit interval $U(0,1)$; x_{min} and x_{max} are the lower and upper initialisation bounds of the d^{th} dimension, respectively. Therefore, a population of flies are randomly initialised with a position for each flies in the search space.

On each iteration, the components of the position vectors are independently updated, taking into account the component's value, the corresponding value of the best neighbouring fly (consider ring topology) with the best fitness, and the value of the best fly in the whole swarm:

$$x_{id}^t = x_{nb,d}^{t-1} + \mathrm{U}(0,1) \times \left(x_{sb,d}^{t-1} - x_{id}^{t-1}\right) \tag{3}$$

where $x_{nb,d}^{t-1}$ is the value of the *n*eighbour's *b*est fly in the d^{th} dimension at time step $t-1$; $x_{sb,d}^{t-1}$ is the value of the *s*warm's *b*est fly in the d^{th} dimension at time step $t-1$; and $\mathrm{U}(0,1)$ is the uniform distribution between 0 and 1.

The algorithm is characterised by two principle components: a dynamic rule for updating flies position (assisted by a social neighbouring network that informs this update), and communication of the results of the best found fly to other flies.

As stated earlier, the swarm is disturbed for various reasons; one of the positive impacts of such disturbances is the displacement of the disturbed flies which may lead to discovering a better position. To consider this eventuality, an element of stochasticity is introduced to the update process. Based on this, individual components of flies' position vectors are reset if the random number, r, generated from a uniform distribution on the unit interval $U(0,1)$ is less than the *disturbance threshold* or *dt*. This guarantees a proportionate disturbance to the otherwise permanent stagnation over a likely local minima.

Algorithm 1 summarises the DFO algorithm[1].

The next section briefly presents three population-based algorithms which will be used to compare the performance of DFO, and then the results of a series of experiments conducted on DFO over a set of benchmark functions are reported.

IV. Population-Based Algorithms

The three algorithms introduced briefly in this section are variations of particle swarm optimisation (PSO), differential evolution algorithm (DE) and genetic algorithm (GA). One of the common features of these algorithms are the interactions between their population (i.e. information sharing), with the ultimate goal of finding the optima.

A. Particle Swarm Optimisation

Particle swarm optimisation (PSO) is population based optimization technique developed in 1995 by Kennedy and Eberhart [2]. It came about as a result of an attempt to graphically simulate the choreography of fish schooling or birds flying (e.g. pigeons, starlings, and shorebirds) in coordinated flocks that show strong synchronisation in turning, initiation of flights and landing, despite the fact that experimental researches to find leaders in such flocks failed [15].

A swarm in PSO algorithm comprises of a number of particles and each particle represents a point in a multi-dimensional problem space. The position of each particle, $\vec{x}$, is thus dependent on the particle's own experience and those of its neighbours. Each particle has a memory, containing the best position found so far during the course of the optimisation, which is called personal best or $\vec{p}$. Whereas the best position so far found throughout the population, or the local neighbourhood, is called neighbourhood best.

A standard particle swarm version, Clerc-Kennedy PSO (PSO-CK) or constriction PSO defines the position of each particle by adding a velocity to the current position. Here is the equation for updating the velocity and position of each particle:

$$v_{id}^t = \chi\left(v_{id}^{t-1} + c_1 r_1\left(p_{id} - x_{id}^{t-1}\right) + c_2 r_2\left(g_{id} - x_{id}^{t-1}\right)\right) \tag{4}$$

$$x_{id}^t = v_{id}^t + x_{id}^{t-1} \tag{5}$$

where χ which is the constriction factor is set to 0.72984 which is reported to be be working well in general [16]; v_{id}^{t-1} is the velocity of particle i in dimension d at time step $t-1$; $c_{1,2}$ are the learning factors (also referred to as acceleration constants) for personal best and neighbourhood best respectively (they are constant); $r_{1,2}$ are random numbers adding stochasticity to the algorithm and they are drawn from a uniform distribution on the unit interval $U(0,1)$; p_{id} is the personal best position of particle x_i in dimension d; and g_{id} is neighbourhood best. In the experiments reported in this work, local neighbourhood is used.

B. Differential Evolution Algorithm

Differential evolution (DE), an evolutionary algorithms (EAs), is a simple global numerical optimiser over continuous search spaces which was first introduced by Storn and Price [17].

DE is a population based stochastic algorithm, proposed to search for an optimum value in the feasible solution space. The parameter vectors of the population are defined as follows:

$$\vec{x}_i^g = \left[x_{i,1}^g, x_{i,2}^g, ..., x_{i,D}^g\right], i = 1, 2, ..., NP \tag{6}$$

where g is the current generation, D is the dimension of the problem space and NP is the population size. In the first generation, (when $g = 0$), the i^{th} vector's j^{th} component could be initialised as:

$$x_{i,j}^0 = x_{min,d} + r\left(x_{max,d} - x_{min,d}\right) \tag{7}$$

where r is a random number drawn from a uniform distribution on the unit interval $U(0,1)$, and x_{min}, x_{max} are the lower and upper bounds of the d^{th} dimension, respectively. The evolutionary process (mutation, crossover and selection) starts after the initialisation of the population.

1) Mutation: At each generation g, the mutation operation is applied to each member of the population x_i^g (target vector) resulting in the corresponding vector v_i^g (mutant vector). In this work, *DE/best/1* variation of mutation approaches is used:

$$v_i^g = x_{best}^g + F\left(x_{r_1}^g - x_{r_2}^g\right) \tag{8}$$

where r_1 and r_2 are different from i and are distinct random integers drawn from the range $[1, NP]$; In generation g, the vector with the best fitness value is x_{best}^g; and F is a positive control parameter for constricting the difference vectors and is set to 0.5.

2) Crossover: Crossover operation, improves population diversity through exchanging some components of v_i^g (mutant vector) with x_i^g (target vector) to generate u_i^g (trial vector). This process is led as follows:

$$u_{i,j}^g = \begin{cases} v_{i,j}^g, & \text{if } r \leq CR \text{ or } j = r_d \\ x_{i,j}^g, & \text{otherwise} \end{cases} \tag{9}$$

where r is a uniformly distributed random number drawn from the unit interval $U(0,1)$, r_d is randomly generated integer from the range $[1, D]$; this value guarantees that at least one component of the trial vector is different from the target vector. The value of CR, which is another control parameter and is set to 0.5, specifies the level of inheritance from v_i^g (mutant vector).

3) Selection: The selection operation decides whether x_i^g (target vector) or u_i^g (trial vector) would be able to to pass to the next generation $(g+1)$.In case of a minimisation problem, the vector with a smaller fitness value is admitted to the next generation:

$$x_i^{g+1} = \begin{cases} u_i^g, & \text{if } f\left(u_i^g\right) \leq f\left(x_i^g\right) \\ x_i^g, & \text{otherwise} \end{cases} \tag{10}$$

where $f(x)$ is the fitness function.

C. Genetic Algorithm

In this work, we use a real-valued Genetic Algorithm (GA) which has previously shown to work well on real-world problems [18], [19]. The GA works in the following way: the individuals are first randomly initialised and their fitness is evaluated through an objective function. Afterwards, in a iterative process, each individual has a probability of being exposed to recombination or mutation (or both). These probabilities are p_c and p_m respectively. The recombination operator used is arithmetic crossover and the mutation operator used is Cauchy mutation using an annealing scheme. At the end, in order to comb out the least fit individual, tournament selection [20] is utilised.

The reason behind using Cauchy mutation operator vs. the well-known Gaussian mutation operator is the thick tails of the Cauchy distribution that allows it to generate considerable changes, more frequently, compared to the Gaussian distribution. The Cauchy distribution is defined by:

$$C(x, \alpha, \beta) = \frac{1}{\beta\pi\left(1 + \left(\frac{x-\alpha}{\beta}\right)^2\right)} \tag{11}$$

where $\alpha \leq 0$, $\beta > 0$, $-\infty < x < \infty$ (α and β are parameters that affect the mean and spread of the distribution). As specified in [19], all of the solution parameters are subject to mutation and the variance is scaled with $0.1\times$ the range of the specific parameter in question.

In order to decrease the value of β as a function of the elapsed number of generations t, an annealing scheme was applied (α was set to 0):

$$\beta(t) = \frac{1}{1+t} \tag{12}$$

As for the arithmetic crossover, the offspring is generated as a weighted mean of each gene of the two parents:

$$\text{offspring}_i = r \times \text{parent1}_i + (1-r) \times \text{parent2}_i \tag{13}$$

where offspring_i is the i'th gene of the offspring, and parent1_i and parent2_i refer to the i'th gene of the two parents, respectively. The weight r is drawn from a uniform distribution on the unit interval $U(0,1)$.

In the experiments conducted in this paper, the probabilities of crossover and mutation of the individuals is set to $p_c = 0.7$ and $p_m = 0.9$ respectively. The tournament size of the tournament selection is set to two, and elitism with an elite size of one is deployed to maintain the best found solution in the population.

V. Experiments

This section presents a set of experiment investigating the performance of the newly introduced Dispersive Flies Optimisation (DFO) and discusses the results. Then, to understand whether disturbance plays an important role in the optimisation process, a *control* algorithm is presented DFO-c where no disturbance is inflicted upon the population of flies.

Recognising the lose of diversity as a common issue in all distribution based evolutionary optimisers (since dispersion reduces with convergence), the impact of disturbance on preserving the diversity of the population is also studied. Additionally, an optimal value for disturbance threshold, *dt*, is suggested. Afterwards the performance of DFO is compared against few other well-known population-based algorithms, namely Particle Swarm Optimisation (PSO), Differential Evolution (DE) and Genetic Algorithm (GA).

A. Experiment Setup

The benchmarks used in the experiments (see Table I) are divided in two sets, f_{1-14} and g_{1-14}; more details about these functions (e.g. global optima, mathematical formulas, etc.) are reported in [16] and [21]. The first set, f_{1-14}, have been used by several authors [22], [16], [23] and it contains the three classes of functions recommended by Yao *et al.* [24]: unimodal and high dimensional, multimodal and high dimensional, and low dimensional functions with few local minima. In order not to initialise the flies on or near a region in the search space known to have the global optimum, *region scaling* technique is used [25], which makes sure the flies are initialised at a corner of the search space where there are no optimal solutions.

The second test set, g_{1-14}, are the first fourteen functions of CEC 2005 test suite [21] and they present more challenging features of the common functions from the aforementioned test set (e.g. shifted by an arbitrary amount within the search space and/or rotated). This set has also been used for many researchers.

One hundred flies were used in the experiments and the termination criterion for the experiments is set to reaching $300,000$ function evaluations (FEs). There are 50 Monte Carlo simulations for each experiment and the results are averaged over these independent simulations. Apart from the disturbance threshold which is set to $dt = 0.001$, there are no adjustable parameters in DFO's update equation.

The aim of the experiments is to study and demonstrate the qualities of the newly introduced algorithm as a population based continuous optimiser. The behaviour of the DFO algorithm is compared against its control counterpart and some other population based algorithms (see Sections IV-A, IV-B and IV-C).

B. Performance measures and statistical analysis

In order to conduct the statistical analysis measuring the presence of any significant difference in the performance of the algorithms, Wilcoxon 1×1 non-parametric statistical test is deployed. The performance measures used in this paper are error, efficiency, reliability and diversity which are described below.

Error is defined by the quality of the best agent in terms of its closeness to the optimum position (if knowledge about the optimum position is known *a priori*, which is the case here). Another measure used is *efficiency* which is the number of function evaluations before reaching a specified error, and *reliability* is the percentage of trials where a specified error is reached. These performance measures are defined as below:

$$\text{Error} = |f(\vec{x}_g) - f(\vec{x}_o)| \quad (14)$$

$$\text{Efficiency} = \frac{1}{n}\sum_{i=1}^{n} \text{FEs} \quad (15)$$

$$\text{Reliability} = \frac{n^{'}}{n} \times 100 \quad (16)$$

where $\vec{x}_g$ is the best position found and $\vec{x}_o$ is the position of the known optimum solution; *n* is the number of trials in the experiment and $n^{'}$ is the number of successful trials, FEs is the number of function evaluations before reaching the specified error, which in these experiments, set to 10^{-8}.

In this work, *diversity*, which is the degree of convergence and divergence, is defined as a measure to study the population's behaviour with regard to exploration and exploitation. There are various approaches to measure diversity. The average distance around the population centre is shown [26] to be a robust measure in the presence of outliers and is defined as:

$$\text{Diversity} = \frac{1}{NP}\sum_{i=1}^{NP}\sqrt{\sum_{j=1}^{D}\left(x_i^j - \bar{x}^j\right)^2} \quad (17)$$

$$\bar{x}^j = \frac{1}{NP}\sum_{i=1}^{NP} x_i^j \quad (18)$$

where NP is the number of flies in the population, D is the dimensionality of the problem, x_i^j is the value of dimension j of agent i, and $\bar{x}^j$ is the average value of dimension j over all agents.

C. Performance of Dispersive Flies Optimisation

The error, efficiency and reliability results of DFO performance over the benchmarks are reported in Table II. The first five columns detail the error-related figures and the last column highlights the median efficiency along with the reliability (shown between brackets) of the algorithm in finding the optima. The algorithm exhibits a promising performance in optimising the presented problem set where half the benchmarks ($f_{1-2,5-11}$ and $g_{1-2,7,9}$) are optimised with the specified accuracy. The figures in the table are expanded in the following categories:

TABLE I
BENCHMARK FUNCTIONS

Fn	Name	Class	Dimension	Feasible Bounds
f_1	Sphere/Parabola	Unimodal	30	$(-100, 100)^D$

1) Unimodal, high dimensional ($f_{1,2}, g_{1-5}$): The algorithm optimises 57% of the benchmarks in this category; while both functions in the first set are optimised ($f_{1,2}$), only two out of five benchmarks in the second and more challenging set are optimised to the specified accuracy. All optimised benchmarks achieve 100% success.

2) Low dimensional and few local minima (f_{10-14}): In this category, 40% of the benchmarks are optimised, with 100% reliability for f_{10} and 32% for f_{11}. However, none of the Shekel functions (f_{12-14}) are optimised; Shekel is known to be a challenging function to optimise due to the presence of several broad sub-optimal minima; also the proximity of a small number of optima to the Shekel parameter $\vec{a}_i$ is another reason for the difficulty of optimising these set of functions.

3) Multimodal, high dimensional (f_{3-9}, g_{6-14}): The optimiser is able to optimise 50% of the benchmarks in this category (f_{5-9} and $g_{7,9}$), 71% of which achieve 100% success rate (all except f_7, g_7 with 28% and 10% success rates respectively). The optimiser exhibit a promising performance when dealing with the difficult Rosenbrock functions (f_3, g_6), reaching the error of 10^{-4} and 10^{-3} respectively. The algorithm performs exceptionally well in optimising the infamous Rastrigin functions, both common and shifted mode (i.e. f_5 and g_9), achieving 100% success rate; however it does show weakness in the more challenging g_{10} rotated version.

The success of the optimiser in optimising the notorious Rastrigin function in its common and shifted modes will be discussed in the context of DFO's dimension-to-dimension disturbance mechanism induced by the algorithm.

In order to provide a better understanding of the behaviour of the algorithm, in the next section, the disturbance is discarded and the diversity of the algorithm is studied.

D. Diversity in DFO

Most swarm intelligence and evolutionary techniques commence with exploration and, over time (i.e. function evaluations or iterations), lean towards exploitation. Maintaining the right balance between exploration and exploitation phases has proved to be difficult. The absence of the aforementioned balance leads to a weaker diversity when encountering a local minimum and thus the common problem of pre-mature convergence to a local minimum surfaces.

Similar to other swarm intelligence and evolutionary algorithms, DFO commences with exploration and over time, through its mechanism (i.e. gradual decrease in the distance between the members of the population and as such,

TABLE II
DFO – DISPERSIVE FLIES OPTIMISATION

each agent's local and global best positions), moves towards exploitation. However, having implemented the disturbance threshold, a dose of diversity (i.e. dt) is introduced in the population throughout the optimisation process, aiming to enhance the diversity of the algorithm.

Figure 1 illustrates the convergence of the population towards the optima and their diversities in three random trials over three benchmarks (i.e. $g_{1,7,9}$ chosen from the second set) as examples from unimodal and multimodal functions. The difference between the error and the diversity values demonstrates the algorithm's ability in exploration while converging to the optima whose fitness reach as low as 10^{-13} in g_1 and g_9.

Exploring the role of disturbance in increasing diversity, a control algorithm is proposed (DFO-c) where there is no disturbance ($dt = 0$) during the position update process.

The graphs in Fig. 2 illustrate the diversity of DFO-c populations in randomly chosen trials over three sample benchmarks (again $g_{1,7,9}$). The graphs illustrate that the diversity of the population in DFO-c is less than DFO, thus emphasising the impact of disturbance in injecting diversity which in turn facilitates the escape from local minima (e.g. as demonstrated in case of the highly multimodal Rastrigin functions f_5, g_9).

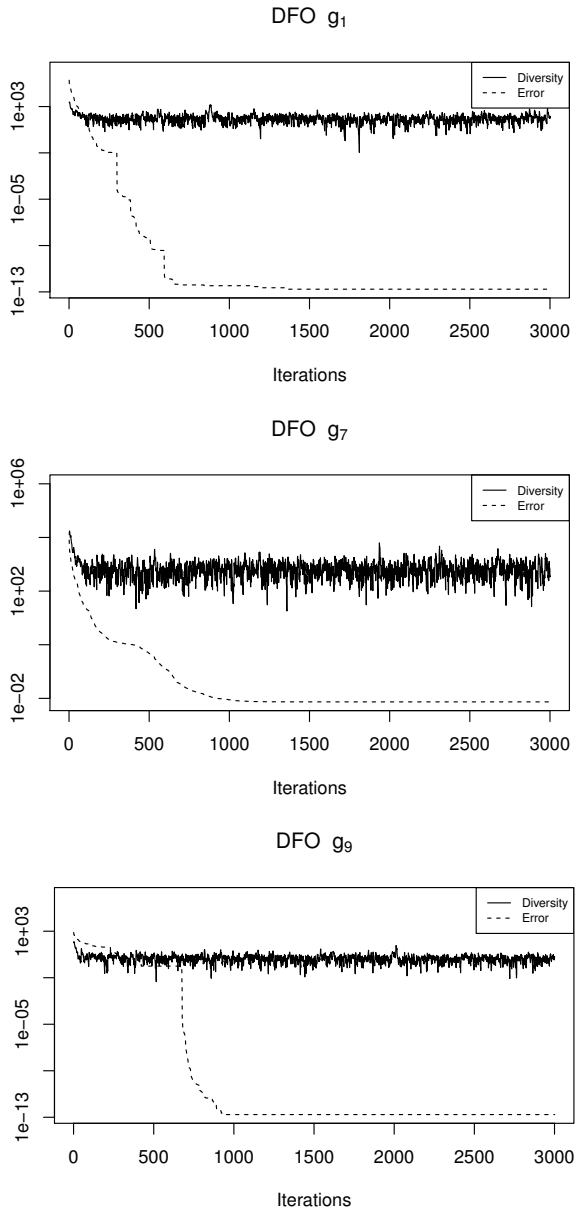

Fig. 1. DFO: diversity and error in $g_{1,7,9}$.

Note the gradual shrinkage of diversity in g_9 ($\approx 10^{-13}$) which is a clear indication of a premature convergence to a local minima with very poor chance of escape.

In order to compare the performance of DFO and its control counterpart, Table III presents the result of optimising the benchmarks using DFO-c. Additionally, a statistical analysis is conducted and the output is reported in Table IV where the performance is compared using the three aforementioned measures of error, efficiency and reliability (see Section V-B for the definitions of the measures). The results show that in 89% of cases (where there is a significant difference between the two algorithms), DFO is performing significantly better than its control counterpart (DFO-c) which is stripped from the

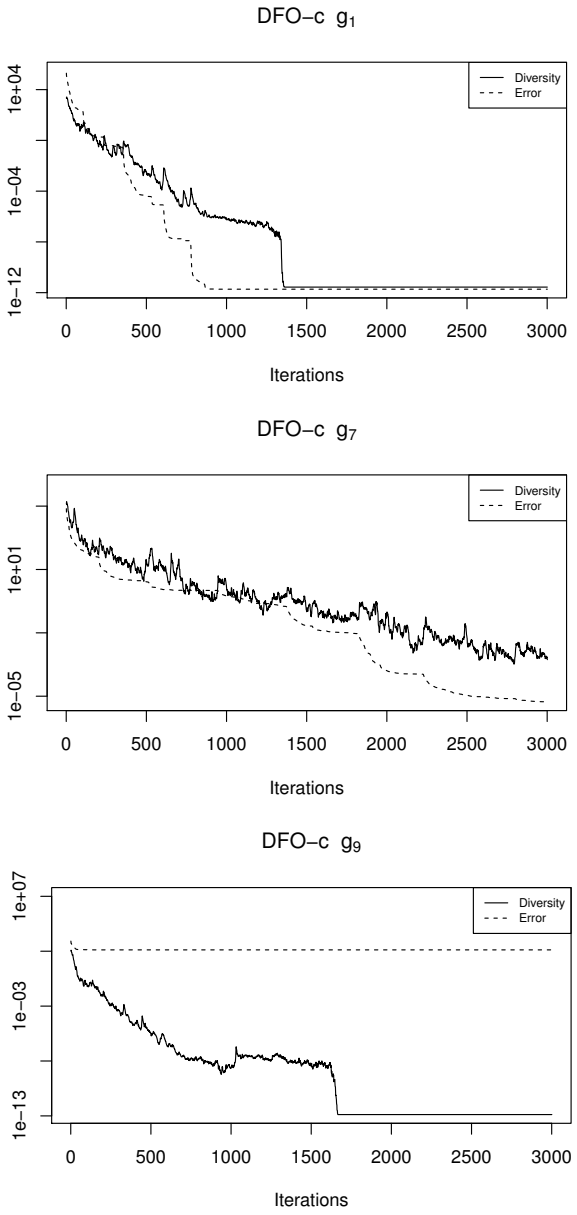

Fig. 2. DFO-c: diversity and error in $g_{1,7,9}$.

diversity inducing disturbance. Furthermore, in all multimodal functions (f_{3-9} and g_{6-12}), whenever there is a statistically significant difference between DFO and DFO-c, the former demonstrates significant outperformance over the later.

Following on the results from measuring error, Table IV also shows that in terms of efficiency and reliability measures, DFO is 79% more efficient than its control counterpart, and 92% more reliable.

E. Fine Tuning Disturbance Threshold

The role of disturbance in increasing the diversity of DFO population is discussed earlier (Section V-D). Also, the importance of disturbance is investigated on the optimisation capability of DFO by introducing a control algorithm which lacks the disturbance mechanism and the results demonstrate the positive impact of this mechanism.

The aim of this section is to recommend a value for the disturbance threshold, dt. The range of disturbance probabilities used in this experiment is between 1 to 10^{-9} and the values were chosen according to:

$$dt_n = 10^{-n}, \quad 0 \leq n \leq 9$$

Fig. 3 illustrates the performance of DFO using these dt probabilities. Both set of benchmarks (i.e. f_{1-14} and g_{1-14}) have been used to find a suitable value for the disturbance threshold. As the heat map highlights, the optimal range is $10^{-2} < dt < 10^{-4}$ and the overall recommended value of $dt = 10^{-3}$ is suggested as a good compromise.

F. Comparing DFO with other Population-Based Optimisers

Having presented the performance of the DFO algorithm (taking into account the three performance measures of error, efficiency and reliability, as well as the diversity of its population and the impact of disturbance on its behaviour), this section focuses on contrasting the introduced algorithm with few well-known optimisation algorithms. The three population

TABLE IV
COMPARING DFO AND DFO-C PERFORMANCE

Based on Wilcoxon 1×1 Non-Parametric Statistical Test, if the *error* difference between each pair of algorithms is significant at the 5% level, the pairs are marked. X–o shows DFO is significantly outperforming its counterpart algorithm; and o–X shows that the algorithm compared to DFO is significantly better than DFO. In terms of the *efficiency* and *reliability* measures, 1 – 0 (or 0 – 1) indicates that the left (or right) algorithm is more efficient/reliable. The figures, n – m, in the last row present a count of the number of X's or 1's in the respective columns.

algorithms deployed for this comparison are Differential Evolution (DE), Particle Swarm Optimisation (PSO) and Genetic Algorithm (GA). These algorithms are briefly described earlier in Sections IV-A, IV-B and IV-C. Generic versions of each algorithm are used against the generic version of Dispersive Flies Optimisation. In this comparison, only the second and the more challenging set of benchmarks, g_{1-14} are used. Table V presents the optimising results of the aforementioned algorithms, and as shown, the algorithms have optimised some of the benchmark to the specified accuracy, 10^{-8}. Table VI shows the result of the statistical analysis comparing DFO with the other three optimisers. Based on this comparison, whenever there is a significant difference between the performance of DFO and the other algorithms, DFO significantly outperforms DE, PSO and GA in 66.67%, 58.33% and 85.71% of the cases, respectively. Table VII summaries the efficiency results of the three optimisers with that of DFO; note that only the efficiency of functions reaching the specified error is given. As shown in the table, DFO, in the majority of cases, outperforms the other algorithms. In other words, although, when compared with DE, DFO only outperforms marginally (60%), it outperforms both PSO and GA in all cases (100%). The reliability comparison of DFO with the other optimisers is given in Table VIII. DFO is shown to be the most reliable algorithm in this comparison.

TABLE VI
COMPARING ERROR IN DFO WITH DE, PSO AND GA

Based on Wilcoxon 1×1 Non-Parametric Statistical Test, if the difference between each pair of algorithms is significant at the 5% level, the pairs are marked. X–o shows that the left algorithm is significantly better than the right one; and o–X shows that the right one is significantly better than the left. n – m in the row labeled Σ is a count of the number of X's in the columns above.

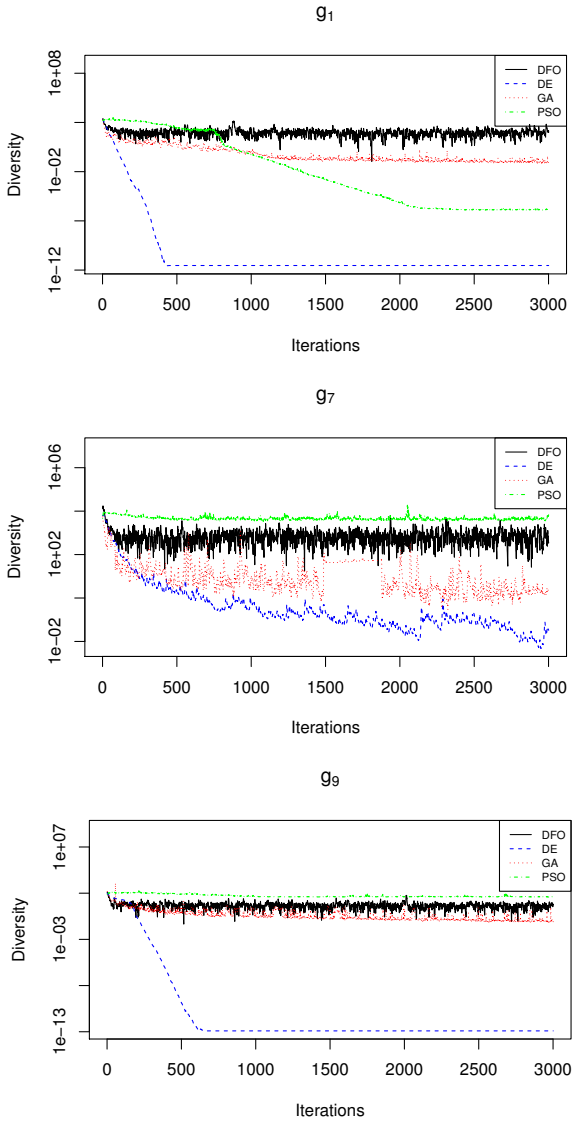

Fig. 4. Diversity of the population in DFO, DE, PSO and GA over three random trials in $g_{1,7 \text{ and } 9}$.

While DFO outperforms DE in 75% of cases, it show 100% outperformance when compared with PSO and GA. In order to compare the diversity of the DFO algorithm with the other three optimisers, three benchmarks were chosen from unimodal and multimodal categories ($g_{1,7,9}$). The result of this comparison is illustrated in Fig. 4. It is shown that DE has the least diversity in both uni- and multimodal functions. On the other hand, the diversity of the population in PSO decreases as the population converges towards an optimum (see g_1); however, when convergence does not occur (e.g. in $g_{7,9}$), PSO maintain its high diversity throughout the optimisation process. GA shows a similar pattern to that of PSO in multimodal functions, which is the gradual diversity decrease over time; however it maintains a higher diversity for the unimodal function than PSO (perhaps attributable to the difference in the fitness of the best positions found in both algorithms). In

terms of DFO, diversity is less convergence-dependent and more stable across all modalities.

VI. Conclusion

Dispersive Flies Optimisation (DFO), a simple numerical optimiser over continuous search spaces, is a population based stochastic algorithm, proposed to search for an optimum value in the feasible solution space; despite its simplicity, the algorithm's competitiveness over an exemplar set of benchmark functions is demonstrated.

As part of the study and in an experiment, a control algorithm is proposed to investigate the behaviour of the optimiser. In this experiment, the algorithm's induced disturbance mechanism shows the ability to maintain a stable and convergence-independent diversity throughout the optimisation process. Additionally, a suitable value is recommended for the *disturbance threshold* which is the only parameter in the update equations to be optimised. This parameter controls the level of diversity by injecting a component-wise disturbance (or restart) in the flies, aiming to preserve a balance between exploration and exploitation.

In addition to diversity, DFO's performance has been investigated using three other performance measures (i.e. error, efficiency and reliability). Using these measures, it is established that the newly introduced algorithm, outperforms few generic population based algorithms (i.e. differential evolution, particle swarm optimisation and genetic algorithm) in all of the aforementioned measures over the presented benchmarks. In other words, DFO is more efficient and reliable in 84.62% and 90% of the cases, respectively; furthermore, when there exists a statistically significant difference, DFO converges to better solutions in 71.05% of problem set.

A. Future Research

Much further research remains to be conducted on this simple new concept and paradigm. Among the possible future research are investigating the algorithm for an adaptive disturbance threshold, dt. Additionally, optimising multi-objective real world problems is yet to be researched; this would be a continuation of an earlier set of works on the deployment of population-based algorithms for detecting metastasis in bone scans and calcifications in mammographs [27]. At last, but not least, given the demonstrated stable and convergence-independent diversity of Dispersive Flies Optimisation (in the context of the presented benchmarks), another exciting future research is to investigate the performance of DFO in the context of dynamic optimisation problems.

Computer Science & Systems

CSS is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to more technical aspects of computer science and related disciplines. The CSNS area spans themes ranging from hardware issues close to the discipline of computer engineering via software issues tackled by the theory and applications of computer science and to communications issues of interest to distributed and network systems. Events that constitute CSNS are:

- CANA'14 - 7th Workshop on Computer Aspects of Numerical Algorithms
- MMAP'14 - 7th International Symposium on Multimedia Applications and Processing
- SCoDiS-LaSCoG'14 - 3nd Workshop on Scalable Computing in Distributed Systems and 8th Workshop on Large Scale Computations on Grids

7th Computer Aspects of Numerical Algorithms

NUMERICAL algorithms are widely used by scientists engaged in various areas. There is a special need of highly efficient and easy-to-use scalable tools for solving large scale problems. The workshop is devoted to numerical algorithms with the particular attention to the latest scientific trends in this area and to problems related to implementation of libraries of efficient numerical algorithms. The goal of the workshop is meeting of researchers from various institutes and exchanging of their experience, and integrations of scientific centers.

Topics

- Parallel numerical algorithms
- Novel data formats for dense and sparse matrices
- Libraries for numerical computations
- Numerical algorithms testing and benchmarking
- Analysis of rounding errors of numerical algorithms
- Languages, tools and environments for programming numerical algorithms
- Numerical algorithms on GPUs
- Paradigms of programming numerical algorithms
- Contemporary computer architectures
- Heterogeneous numerical algorithms
- Applications of numerical algorithms in science and technology

Event Chairs

Bylina, Beata, Maria Curie-Sklodowska University, Poland

Bylina, Jarosław, Maria Curie-Sklodowska University, Poland

Stpiczyński, Przemysław, Maria Curie-Sklodowska University, Poland

***Abstract*—In this paper we present an improvement of the algorithm based on recursive de Casteljau subdivision over an n-dimensional bounded domain (simplex or box). The modification consists of a novel end condition and a way of calculation the root in subdomain. Both innovations are based on linear approximation of polynomials in a system. This improvement results in that our approach takes almost half of the time of the standard approach: it can be stopped much earlier than using standard diameter condition and getting midpoint of a subdomain as a root.**

I. Introduction

SOLVERS of systems of algebraic equations are a very important part of today's CAD/CAM systems. Issues such as the numerical representation of curves and surfaces [1], physical contacts between objects, collision detection, representations of Voronoi diagrams of set-theoretic models [2] or formulation of configuration space of a robot in motion planning applications [3] are reduced to finding solutions of the systems of polynomial equations.

Finding roots of polynomials (one equation) is well researched. Unfortunately, the problem of solving systems of polynomial equations goes back to the ancient Greeks and Chinese and still there is no one good solving method. There are a number of algorithms invented over the years based on different approaches. For details, see section II. It is worth noticing that in many of applications, especially CAD/CAM, like collision detection or curves intersection, there is no need to find all solutions in $\mathbb{R}^n$ and problem is narrowed to a bounded domain, which can be approximated (bounded) by n-dimensional box or simplex. That is why algorithms which can be applied only to a specific domain are so desirable.

The method described in this paper is a multidimensional bisection algorithm that uses multivariate Bernstein representation of polynomials, de Casteljau subdivision and convex hull property. Brief review of the algorithm is presented in next sections, but for further details we refer readers to [4], [5].

First of all, the method can be applied to an n-dimensional box or simplex domain. Such domains are used in curves and surfaces representation, so the algorithm can be used naturally in CAD/CAM applications. The further advantages of the method are a numerical stability, finding all zeros in the domain and no need for entering a starting point. A major drawback is the exponential complexity $O(2^n)$ where n is a number of equations. However, a number of publications in recent years have proved that this algorithm is effective for surfaces or curves intersections, where a number of equations in the system is equal to one or two [6].

In addition, research on the use of graphics cards (CUDA technology) were conducted to improve the execution time of the algorithm [7].

Our contributions are twofold:

1) We show novel end condition in multidimensional bisection algorithm which is based on linear approximation of equations
2) We show a novel way of computing the root in multidimensional bisection algorithm which is based on solving a linear system of the linear approximations

In this paper we consider a unit n-simplex as a domain of a system of polynomial equations.

The paper is organized as follows: in Section II we discuss related work, in Section III we briefly introduce the theoretical background for a multidimensional bisection algorithm. After that we describe two geometrical interpretations in Section IV. In the Section V we discuss the details of our method (especially end condition and calculation of the root in subdomain). In the Section VI reader can find numerical results obtained for various sets of equations. Section VII provides conclusions drawn from the presented analysis.

II. Related Work

Current methods of solving systems of polynomial equations can be divided into three groups: symbolical, geometrical and numerical (in particular subdivision) solvers.

A. Symbolical/Algebraic solvers

Symbolical methods are based on resultants and Gröbner bases. Those methods eliminate variables and reduce problem to finding roots for univariate polynomial using rational univariate representation. Those methods, however, are efficient only for systems of three up to four polynomials of low degree, such as 2 or 3. After reducing those polynomials, we obtain one univariate polynomial of degree close to 15. As it was shown by Wilkinson [8], computing roots of polynomial of degree greater than 15 can be ill-conditioned. What is more, these methods are difficult to implement for computers that

978-83-60810-58-3/$25.00

use finite precision arithmetic and that also slows down the resulting algorithm. Symbolical methods should be considered a success in theoretical area, but practical impact is unclear. An example of such an approach is [9], [10].

B. Geometrical solvers

For some specific applications, particular methods have been developed. Those methods use geometrical formulation of a problem. For example, for curves and surface intersection or ray tracing the algorithms are based on subdivision. However, these methods have limited applications in the general case [11].

C. Numerical/Analytic solvers

Numerical methods are probably the most known. They can be classified into iterative methods and homotopy methods. The most popular iterative method is Newton's method and it works well locally and only if initial point is a good guess, which is difficult in solving systems of polynomial equations. Other methods are Newton like methods, minimization methods or Weierstrass method [12], [13].

Homotopic methods have a well-explored theoretical background. They are based on proceeding path in a complex space. Theoretically, every path should converge to an isolated solution. In practice, however, there are many issues as the paths are not geometrically isolated, which causes problems with robustness of the approach. Moreover, those methods are rather computationally demanding. Example of this approach is [14], [15], [16].

Subdivision methods use an exclusion criterion to remove a domain if it does not contain a root. These solvers are often used to isolate the real roots. Exclusion criteria are based on Taylor exclusion function [17], interval arithmetic [18], Turan test [19], Sturm method [20], Descartes rule [21]. In this paper we propose an improvement to subdivision algorithm, where excluding is based on properties of Bernstein representation of polynomials. More information about that method can be found in [4], [5], [7].

Interestingly, computing on GPU becomes more and more popular, recently there are attempts to calculate many numerical problems on GPU, in particular solving polynomial equations systems [7], [15], [22], [23].

III. Problem formulation and algorithm idea

Consider a set of n polynomial equations in n independent variables

$$\mathbf{p}(\mathbf{x}) = \mathbf{0} \tag{1}$$

where $\mathbf{p} = (p_1, p_2, \ldots, p_n)\colon S_1^n \to \mathbb{R}^n$ (S_1^n is a unit n-simplex). The problem is to calculate numerically, with a given accuracy ϵ, all real roots $\{\mathbf{x}_0\}$ of the system (1). The method can also be used when the number of equations is not equal to the number of variables, but it is not in the scope of this paper.

This algorithm uses a simplex (also known as barycentric) Bernstein representation of multivariate polynomials. Vectors of this basis are as follows (N - degree of Bernstein polynomial):

$$B^N_{(j_1,\ldots,j_n)}(x_1,\ldots,x_n) = \frac{N!}{j_0!\cdot j_1!\cdot\ldots\cdot j_n!}\cdot x_0^{j_0}\cdot x_1^{j_1}\cdot\ldots\cdot x_n^{j_n} \tag{2}$$

where

$$j_k \in \mathbb{N}\cup\{0\}, x_k \in [0,1]\wedge x_0+\cdots+x_n \le 1\wedge k\in\{1,\ldots,n\}$$

and

$$j_1+\cdots+j_n \le N, j_0 = N-(j_1+\cdots+j_n), x_0 = 1-(x_1+\cdots+x_n)$$

so each polynomial p_k, after conversion to Bernstein representation b_k is of the form

$$b_k(\mathbf{x}) = \sum_{(j_1,\ldots,j_n)\in\{(j_1,\ldots,j_n):j_1+\cdots+j_n\le N\}} b^{(k)}_{(j_1,\ldots,j_n)} B^N_{(j_1,\ldots,j_n)}(\mathbf{x}) \tag{3}$$

and $b^{(k)}_{(j_1,\ldots,j_n)}$ are called Bernstein coefficients. We will also use coefficients of the system:

$$\mathbf{b}_{(j_1,\ldots,j_n)} = \begin{bmatrix} b^{(1)}_{(j_1,\ldots,j_n)} \\ b^{(2)}_{(j_1,\ldots,j_n)} \\ \vdots \\ b^{(n)}_{(j_1,\ldots,j_n)} \end{bmatrix}_{n\times 1}$$

From that point we will refer to a system of polynomial equations in Bernstein basis as $\mathbf{b}(\mathbf{x})$, so we can rewrite the main problem as

$$\mathbf{b}(\mathbf{x}) = \mathbf{0} \tag{4}$$

Definition III.1 (Extreme coefficients of polynomial in Bernstein form)**.** Extreme coefficients of polynomial in Bernstein form are

$$I_e = \{(j_1,\ldots,j_n)\colon j_1+\cdots+j_n \le N$$
$$\wedge(\forall_{k\in\{1,\ldots,n\}} j_k = 0 \vee \exists_{k\in\{1,\ldots,n\}} j_k = N)\wedge j_k\in\mathbb{N}\cup\{0\}\}$$

In other words, extreme coefficients of polynomial b_k are $b^{(k)}_{0,\ldots,0}$, $b^{(k)}_{N,0,\ldots,0}$, …, $b^{(k)}_{0,0,\ldots,N}$.

Example III.1. *For polynomial b_k of three variables and second degree extreme coefficients are $b^{(k)}_{000}$,$b^{(k)}_{200}$,$b^{(k)}_{020}$,$b^{(k)}_{002}$.*

A pseudocode is listed in Algorithm 1. Firstly, we have to convert input polynomials from $p_1,\ldots,p_n$ to $b_1,\ldots,b_n$. An efficient, robust algorithm is presented e.g. in [24]. After that, we create two queues S and Q, the first with root of the system and second with areas (simplexes) to be processed.

Routine is that: get one subsimplex (in the very beginning it is the initial simplex, where our system is defined), which means get coefficients of polynomials in the system defined on that subsimplex. After that, perform root exclusion tests. The tests can exclude subdomain, where there is no root with 100% certainty. Therefore, all of those tests have 100% true negative ratio. However, tests differ in false positive ratio. The fastest

(b) Divided domain after applying the algorithm

Fig. 1: Algorithm idea, division of domain

Algorithm 1 Bisection algorithm to solve a system of polynomial equations

Require: Polynomials $b_1 \dots b_n$ in a system
Ensure: List of roots of the system
Initialize empty queue Q of n-tuples of polynomials;
Add $b_1 \dots b_n$ to Q
Initialize empty queue S of solutions;
while Q is not empty **do**
  Get n-tuple of $b_1 \dots b_n$ polynomials from Q
  Perform end condition test
  if End condition is true **then**
    Calculate root and add it to S queue
    CONTINUE;
  end if
  Divide $b_1 \dots b_n$ polynomials using de Casteljau method into $b_1^a \dots b_n^a$ and $b_1^b \dots b_n^b$ polynomials
  Perform tests (from fastest to slowest) and determine if every $b_1^a \dots b_k^a$ is suspected to have a root.
  if Every $b_1^a \dots b_n^a$ is suspected to have a root **then**
    Add $b_1^a \dots b_n^a$ into Q;
  end if
  Perform tests (from fastest to slowest) and determine if every $b_1^b \dots b_n^b$ is suspected to have a root.
  if Every $b_1^b \dots b_n^b$ is suspected to have a root **then**
    Add $b_1^b \dots b_n^b$ into Q;
  end if
end while
return S

test has the highest false positive ratio (the most subdomains are not excluded from consideration even though they should be). The slowest test has the lowest false positive ratio and is used only for those subdomains, which are not excluded by earlier tests. Details about the tests can be found in section V.

It should be stressed here that in general, de Casteljau division produces $n+1$ smaller simplexes from one input simplex. However, for simplicity and universality of the algorithm regardless of the number of equations, we make subdivision along one consecutive variable x_i, producing 2 smaller simplexes. Subdivision along the consecutive variable x_i has one more important advantage: we are assured that subdomains (diameter of subdomain) will be decreasing. More information about the diameter can be found in the section V. In other words, input simplex is a domain, and two output simplexes are subdomains, which added (in a set theory sense) are equal to input domain. Intersection of interiors of the subdomains is empty. Obtained polynomials, $b_1^a, \dots, b_n^a$ and $b_1^b, \dots, b_n^b$, are the same as input polynomials, but specified to new, smaller (scaled) unit simplex subdomain.

Subdomains not excluded from consideration are enqueued to Q.

Every subdomain dequeued from Q is tested for the end condition. If it is true, the root is calculated and enqueued in S. Thus the subdomain is excluded from consideration. The end condition and the root calculation are the centerpiece of this paper and will be discussed in section V.

When queue Q is empty, algorithm returns queue of solutions S.

In the Fig. 1 we can see an exemplary use of the algorithm. We have a two-dimensional domain (it means $n = 2$, so there are two polynomial equations in a system) and two roots x_0 and x_1 in the domain. The grey area represents a subdomain excluded by tests. We can see that the de Casteljau division is

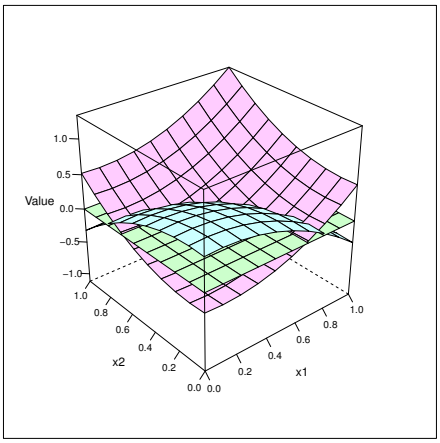

Fig. 2: Extended space representation for 2-dimensional box

performed along the longest edge of subsimplex, so diameters of the consecutive subsimplexes are getting smaller.

IV. Geometrical interpretations

Note that the problem can be geometrically interpreted in two ways.

A. Extended space representation

The extended space representation is used in the end condition and the root calculation. Consider a coordinate system with $n+1$ axes. n of them represent a domain. If we consider polynomial $p_k(\mathbf{x})$, the vector $\mathbf{x}$ has coordinates in those n axes. The $n+1$ axis is the value of the polynomial, so it is the value of $p_k(\mathbf{x})$. It implies that the polynomial $p_k(\mathbf{x})$ creates a surface in the coordinate system, where every point of that surface consists of n coordinates from domain (simplex) and last one which is value of the polynomial in that point.

Solving a system of polynomial equations (and equations in general) is finding points, where all of the surfaces have a zero value in the last, $n+1$, coordinate. The root is a point that consist of first n coordinates of such a point.

In the Fig. 2 we can see an example for n-dimensional box, where $n = 2$. One polynomial in the domain is pink, the second is blue, and value of zero is represented by a green plane.

B. n-dimensional mapping representation

The n-dimensional mapping representation can be applied to any system of functions. We can see the system as mapping $\mathbf{B}\colon S_1^n \to \mathbb{R}^n$. This function maps simplex S_1^n to $\mathbf{B}(S_1^n)$, so coordinate system has n axes.

This geometrical interpretation is used to understand tests that exclude subdomains from consideration. Those tests base on a Bernstein polynomial convex hull property, where coefficients $\mathbf{b}_{(j_1,\ldots,j_n)}$ of the system are the corners. More details can be found in [4].

Please note that:

$$(\mathbf{0} \in \mathbf{B}(S_1^n)) \Leftrightarrow ((\exists \mathbf{x}_0 \in S_1^n)\colon \mathbf{B}(\mathbf{x}_0) = \mathbf{0}) \tag{5}$$

Of course, even though this logical relationship is true, it is not very practical. It would be computationally demanding to check $\mathbf{0} \in \mathbf{B}(S_1^n)$. However, we can use the convex hull property of Bernstein polynomial:

$$(\exists \mathbf{x}_0 \in S_1^n\colon \mathbf{w}(\mathbf{x}_0) = \mathbf{0}) \Rightarrow (\mathbf{0} \in \operatorname{conv}(\{\mathbf{b}_{(j_1,\ldots,j_n)}\colon j_1 + \cdots + j_n \leq N\}) \tag{6}$$

Contraposition, however, of the above may be more convenient in practice:

$$(\mathbf{0} \notin \operatorname{conv}(\{\mathbf{b}_{(j_1,\ldots,j_n)}\colon j_1 + \cdots + j_n \leq N\}) \Rightarrow (\forall \mathbf{x}_0 \in S_1^n\colon \mathbf{w}(\mathbf{x}_0) \neq \mathbf{0}) \tag{7}$$

After obtaining certainty that the convex hull of the system of polynomial equations does not contain $\mathbf{0}$ point, we can see that we are able to exclude that system as it has no root. And if it contains $\mathbf{0}$, we can only suspect that a root is present in the system (because it is only in a convex hull).

We can see an example in the Fig. 3. It is a system of two polynomial equations of second degree. In Fig. 3a we can see a domain of the system and in the 3b there is the same system after mapping $\mathbf{B}(S_1^n)$. Coefficients of the system are marked as circles. Convex hull of the system is a green polygon. Vertices of red polygon are extreme coefficients of the system and they are marked as red circles. It is worth noticing that this system has two roots in the domain and both of them map to $\mathbf{0}$ in $\mathbf{B}(S_1^n)$.

Definition IV.1 (Hyperplane)**.** A hyperplane passing through the point h_0 and defined by a vector $\mathbf{p}$ is a set of points:

$$H^m(\mathbf{p}, \mathbf{h}_0) = \{\mathbf{h} \in \mathbb{R}^m\colon \mathbf{p}^T \cdot (\mathbf{h} - \mathbf{h}_0) = 0, \mathbf{h_0}, \mathbf{p} \in \mathbb{R}^m, \mathbf{p} \neq \mathbf{0}\} \tag{8}$$

where $\cdot$ is a dot product.

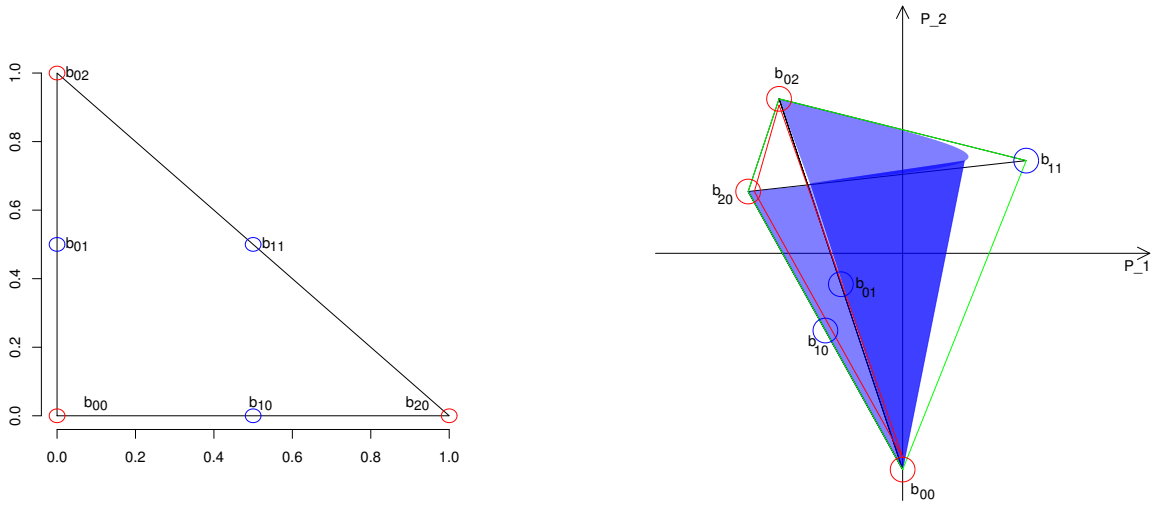
V. Algorithm details

All three described tests are based on hyperplanes. It can be proved that if we can find a hyperplane which separates the convex hull and $\mathbf{0}$, then convex hull does not include $\mathbf{0}$ point. More complicated tests use more interesting (and computationally damanding) hyperplanes.

As we wrote above, all three tests are based on finding a hyperplane that separates the convex hull and $\mathbf{0}$ point. Testing if all vertices of the convex hull are on one side of a hyperplane can be computed by checking a sign of dot product. More details about excluding tests can be found in [4].

A. Test of signs

This test checks hyperplanes $H^n(\mathbf{e}_i, \mathbf{0})$, where $\mathbf{e}_i$ is a base unit vector, for $i = 1, \ldots, n$. It can be performed as checking, if every polynomial in a system has coefficients of both signs, positive and negative. If at least one polynomial has all coefficients positive only or negative only, this test rejects that system as it does not have a root.



(a) S_1^n (b) $\mathbf{B}(S_1^n)$

Fig. 3: n-dimensional mapping representation

B. Test of midpoint

Let $M = \binom{n+N}{N}$ be a number of polynomial's coefficients. This equality can be proved by *Stars and bars* theorem, which can be found in [25].

Midpoint test (which should be performed as a second one) calculates a vector which is an average of Bernstein coefficients of set:

$$\mathbf{p_{mid}} = \frac{1}{M} \sum_{(j_1,\ldots,j_n)\in\{(j_1,\ldots,j_n):j_1+\cdots+j_n\leq N\}} \mathbf{b}_{(j_1,\ldots,j_n)}$$

Test verifies if all coefficients (points) are on one side of hyperplane $H^n(\mathbf{p_{mid}}, 0)$.

C. Test of hyperplanes

The last, most complex test is a side test. Hyperplanes in this test are determined by Bernstein coefficients of the system. We get every n linearly independent points from Bernstein coefficients $\mathbf{b}_{(j_1,\ldots,j_n)}$ and create a hyperplane H^n. Again, coefficients of the system are tested if they are on one side of the hyperplane (exclude) or not (further subdivision is needed).

There are two variants of this test. The first is that we get n linear independent points from extreme coefficients only. The second takes all coefficients into account. We have decided to implement the second variant in our work, as it tests more hyperplanes and can exclude more subdomains.

D. End condition and a root computation

The end condition used in literature is checking a diameter of the subdomain. A diameter, by definition, is the longest side of a simplex. If it is less than tolerance ϵ, algorithm assumes this area has a root and returns the midpoint of the simplex (adds it to the list of solutions). Such an approach can be found in [4], [5], [7].

We have found better approach, where a lower recursion level is needed. Using the de Casteljau division gives us smaller domains and we have observed that polynomials in these smaller domains are getting closer to linear functions.

We decided to check if polynomials on the subdomain are close enough to linear functions. If they are, then we change the problem to a system of linear equations (all polynomials on the subdomain are substituted to linear approximations) and solve it (find intersections of those approximations). Details are discussed below. In this part of the paper we should think of it according to the extended space representation, where every polynomial makes its own surface over the domain.

Definition V.1 (Control points of polynomial in Bernstein form)**.** Control point $\mathbf{b}^{(\mathbf{k})}_{(\mathbf{j_1},\ldots,\mathbf{j_n})}$ corresponding to a coefficient $b^{(k)}_{(j_1,\ldots,j_n)}$ of a polynomial b_k is a point (according to extended space representation) which first n coordinates are coordinates of the corresponding point of the domain (see Fig. 3a) and last $n+1$ coordinate is the value of coefficient $b^{(k)}_{(j_1,\ldots,j_n)}$.

Definition V.2 (Extreme control points of polynomial in Bernstein form)**.** Extreme control point $\mathbf{b}^{(\mathbf{k})}_{\mathbf{i_e}}$ $(i_e \in I_e)$ is a control point corresponding to an extreme coefficient $b^{(k)}_{i_e}$ of a polynomial b_k.

We can see an example in the Fig. 4. It is a surface created by polynomial according to extended space representation. Extreme control points are marked as red and the rest of control points are marked as blue.

After defining extreme control points, we can say that, after concluding that a polynomial is sufficiently linear on a subdomain, we can create a hyperplane passing through the extreme control points of the polynomial and the hyperplane will be an aformentioned linear approximiation of the equation.

The last thing we have to specify is a method to determine

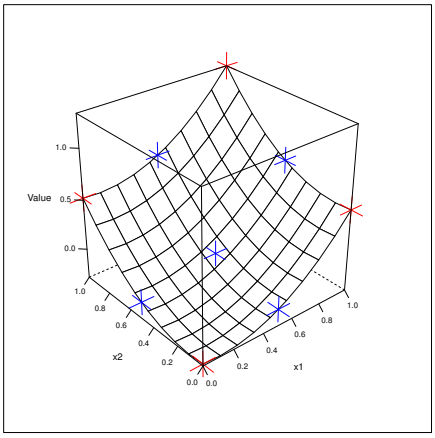


Fig. 4: Control points. Extreme control points are red.

when a polynomial is so similar to a linear function, that we can approximate the polynomial with the linear function with given error ϵ.

It should be stressed that there are $n+1$ extreme control points and we would denote them as ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{0}}^{(\mathbf{k})}$, ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{1}}^{(\mathbf{k})}$, ..., ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{n}}^{(\mathbf{k})}$ for polynomial b_k.

Definition V.3 (Thickness of a polynomial in Bernstein form)**.** Consider extreme control points ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{0}}^{(\mathbf{k})}$, ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{1}}^{(\mathbf{k})}$, ..., ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{n}}^{(\mathbf{k})}$ of polynomial b_k. Vectors ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{1}}^{(\mathbf{k})} - {}^{\mathbf{e}}\mathbf{b}_{\mathbf{0}}^{(\mathbf{k})}$, ..., ${}^{\mathbf{e}}\mathbf{b}_{\mathbf{n}}^{(\mathbf{k})} - {}^{\mathbf{e}}\mathbf{b}_{\mathbf{0}}^{(\mathbf{k})}$ span an n-dimensional subspace. For every control point $\mathbf{b}_{(\mathbf{j_1},\ldots,\mathbf{j_n})}^{(\mathbf{k})}$ (not only *extreme* control points) we can calculate the distance from the subspace by projecting $\mathbf{b}_{(\mathbf{j_1},\ldots,\mathbf{j_n})}^{(\mathbf{k})}$ on this subspace and computing the distance $d_{(j_1,\ldots,j_n)}^{(k)}$ from this point $\mathbf{b}_{(\mathbf{j_1},\ldots,\mathbf{j_n})}^{(\mathbf{k})}$ to its projection. *Thickness* of a polynomial b_k is $\max\{d_{(j_1,\ldots,j_n)}^{(k)} : j_1 + \cdots + j_n \leq N\}$.

E. Calculating thickness

Assume that we have vector $\mathbf{p} \in \mathbb{R}^{n+1}$ and subspace of n-dimensions U. We want to project $\mathbf{p}$ on U. It means $\mathbb{R}^{n+1} = U \oplus V$ where $\dim V = 1$. We say that V is the complementary (orthogonal) subspace to U. That means that $\mathbf{p}$ breaks up into:

$$\mathbf{p} = \mathrm{proj}(\mathbf{p}, U) + \mathrm{proj}(\mathbf{p}, V) \tag{9}$$

So to find $\mathrm{proj}(\mathbf{p}, U)$, we can simply find $\mathrm{proj}(\mathbf{p}, V)$, which is a projection onto a 1-dimensional subspace.

Assume that vectors $\{\mathbf{v}_1, \ldots, \mathbf{v}_n\}$ span U. We want to find vector $\mathbf{v}$ which is orthogonal to those vectors:

$$\begin{aligned} \mathbf{v} \cdot \mathbf{v}_1 &= 0 \\ \mathbf{v} \cdot \mathbf{v}_2 &= 0 \\ &\vdots \\ \mathbf{v} \cdot \mathbf{v}_n &= 0 \end{aligned}$$

We obtain linear system with n equations and $n+1$ unknowns. We have to add one constraint, e.g. $\mathbf{v}$ is unit vector or one of its coordinates is equal to 1. When we have $\mathbf{v}$, we get:

$$\mathrm{proj}(\mathbf{p}, V) = \frac{\mathbf{p} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}} \mathbf{v} \tag{10}$$

So

$$\mathrm{proj}(\mathbf{p}, U) = \mathbf{p} - \mathrm{proj}(\mathbf{p}, V) = \mathbf{p} - \frac{\mathbf{p} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}} \mathbf{v} \tag{11}$$

End condition is checking if thicknesses of all polynomials in system are less than ϵ. If so, linear approximations l_k of polynomials b_k are created and system of linear equations is solved. Solution of the linear system is taken as a root of the system of polynomial equations. If not, further subdivision is needed.

VI. Experimental results

The numerical experiments were performed on a PC with Intel Core i5-2500K CPU 3.30GHz and 8 GB of RAM. The goal of our research was to compare time and recursion level for different end conditions and root computation methods.

The input systems of equations differed in the number n of variables and equations (2 or 3) and the degree N (ranging from 1 to 20). Intersection of two or three curves or surfaces is a common case in CAD/CAM applications and that is why we limited our research to 2 or 3 equations.

Four cases were tested:

1) end condition was thickness of polynomials less than ϵ and root computation was solving a linear system of equations (our approach),
2) end condition was diameter of subdomain less than ϵ and root computation was returning midpoint of subdomain (standard approach),
3) end condition was diameter of subdomain less than ϵ and root computation was solving a linear system of equations,
4) end condition was thickness of polynomials less than ϵ and root computation was returning midpoint of subdomain.

Last two scenarios, which are mixture of our and standard approach, did not yield better results. In third case too many divisions were performed for given error ϵ, so time results were unsatisfactory. In fourth case too few divisions were performed, so accuracy of solutions was too small. Therefore results of genuine approaches are presented only.

We present results on Fig. 5–7. The tolerance ϵ for all tests was equal to 10^{-6}. It should be noted that all polynomials in a system were normalized so all coefficients were in set $[-1; 1]$. All polynomials in one tested system are of the same degree.

In Fig. 5 we can see maximal recursion level (number of de Casteljau divisions) needed to compute roots depending on the polynomials' degree. For standard approach it is constant number, because there is always the same number of divisions needed to obtain given diameter equal to ϵ of subdomain. Unlike standard approach, recursion level in our approach varies. Number of divisions depends on degree of polynomials. When polynomial is of higher degree, more recursions are required to get desirable linear approximation. When we use standard end condition, linear system is treated as always and many unnecessary subdivisions are performed.

It can be seen that obtaining the same thickness of hyperplane as diameter of subdomain (equal to ϵ) needs about half the number of recursions. What is more, a number of necessary recursions grows very slowly in degree of polynomials.

Nice feature of our approach is that, when a system of polynomial equations is in fact linear (all polynomials are polynomials of first degree), this case is detected in the first recursion level and system is solved by method dedicated for those systems.

In Fig. 6 we can see how much time it takes to compute roots depending on the polynomials' degree. As we can see, smaller number of recursion results in shorter time of computation. On average, our approach takes 60% time of the standard approach.

It can be seen that the method is good for polynomials of low degree. Detailed time of computation for those polynomials can be seen in Fig. 7. Unfortunately, for higher polynomials' degree time of computation becomes unacceptable: over 0.015 seconds for two equations (up to 0.05 for 20 degree) and over 0.5 seconds for three equations (up to 2.5 seconds for 20 degree).

We compared our approach with well-known application for computations, Mathematica. In Mathematica we used the function NSolve which is designed for numerical computation (Mathematica can perform symbol computations as well). We chose arguments "Reals" and "6", which means we are interested in real roots only and results should have 6 significant digits. What is more, in addition to the polynomial equations, we added inequalities such as $x \geq 0$ or $x + y \leq 1$.

Results of this comparison can be seen in Fig. 8. As we can see, the computation time of Mathematica is incomparable to our method so much we decided to plot it on a logarithmic scale. For example, for polynomials of fifth degree time of our method's computation is 0.0011 seconds, while Mathematica needs 0.0590 seconds. The time difference is even greater as a degree gets bigger and for degree of 16 execution times are 0.0190 and 4505 seconds, respectively.

Mathematica's function NSolve finds all roots in whole domain. We did not find method other than adding inequalities to bound domain. Adding inequalities means that NSolve finds all roots and after that it excludes those, which are not in domain. This is reflected at computation time. It is much worse than our approach. There is no sense using NSolve for polynomials of degree higher than five if we can bound domain in simplex.

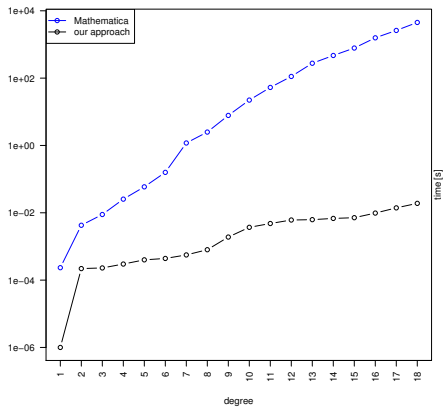

Fig. 8: Comparison of Mathematica and our approach computation time

We tried to use NSolve for a system of three polynomial equations, but a difference of computation time was even bigger. For example, for three polynomials of fifth degree time of execution NSolve was 976 seconds.

VII. Conclusion

In this paper a new algorithm isolating the roots of systems of polynomial equations has been introduced. An algorithm based on the general multivariate Bernstein representation and the systematic search of a given domain has been implemented.

The main objective of this research was verification of applicability of novel end condition and computation of root by linear approximations. It was shown that this novel approach is nearly two times faster than standard methods.

Main advantage of this method is finding all roots in the given domain. Many known methods base on Newton's method which can converge to the solution in another simplex [12], [13]. This implies that some solutions may be missed and some may be found several times. Other methods, e.g. symbolic or homotopic, find all roots in $\mathbb{R}^n$, from which we can choose those in a domain (n-dimensional box or simplex). Unfortunately, this approach unnecessarily increase computation time, especially when most roots are outside of the domain, because many solutions are calculated and after that they are excluded from final set of roots. What is more, our algorithm is one of the fastest methods when there are no roots, because it is detected in the very first step. The next case, for which this method is doing exceptionally well is system of linear equations. In first step *thickness* is equal to zero and system is solved (approximations l_k and polynomials p_k from the system are the same).

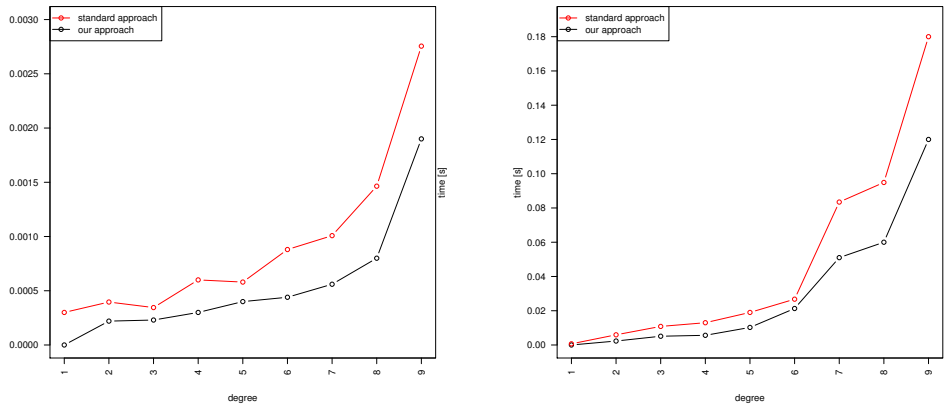
Fig. 6: Computation time depending on the polynomials' degree



(a) Computation time for two equations (b) Computation time for three equations

Fig. 7: Computation time depending on the polynomials' degree for 1–9 degrees

The algorithm has one interesting feature, when system has infinitely many solutions. If given ϵ is not too big, it can calculate some points which are roots of a system, and after connecting those points, we obtain a polyline, which approximates an infinite family of roots. A method for detecting this case in the beginning is needed.

The algorithm is at a disadvantage in the case where a root is in a corner or on a side of a subdomain. That causes many subdivisions and many simplexes to be considered because in many areas tests are passed. Detecting this case and evaluating only one simplex should be another area of exploration. However, it should be noted that a little perturbation of coefficients solves the problem.

A way for further development can be indicated. Some of the equations in the system can be close enough to linear function in earlier iterations of the algorithm than others. So we can substitute those equations to linear approximations. After that, one variable in the system (for one linear approximation) can be ousted. It would be very effective, because it would decrease the dimension of the problem. The algorithm has exponential computational complexity according to number of variables. That is why decreasing the number of variables is so important. One of the way to eliminate variables in a system of polynomial equations is using Gröbner basis.

Summarizing, this is an excellent method for surface intersections or for the visualization of curves and surfaces, because of finding all roots in a given domain. This is a well-conditioned numerical algorithm which can be useful for three to four equations [4]. It has some disadvantages like exponential computational complexity according to number of unknowns or vulnerability to roots in the corners or sides of a domain, but when we exclude those cases, it can be a powerful tool in computer graphics and computer-aided design.

***Abstract*—In this paper the authors evaluate in context of numerical calculations accuracy classical integer order and direct non-integer based order numerical algorithms of non-integer orders derivatives and integrals computations. Classical integer order based algorithm involves integer and fractional order differentiation and integration operators concatenation to obtain non-integer order. Riemann-Liouville and Caputo formulas are applied to obtain directly derivatives and integrals of non-integer orders. The following accuracy comparison analysis enables to answer the question, which algorithm of the two is burdened with lower computational error. The accuracy is estimated applying non-integer order derivatives and integrals computational formulas of some elementary functions available in the literature of the subject.**

I. Introduction

THERE are many formulas which can be applied to compute directly derivatives and integrals of non-integer orders [8], [9], [10], [11], [12], [14]. They include Riemann-Liouville non-integer (fractional) order integral/derivative and Caputo non-integer (fractional) derivative. However, non-integer order derivatives and integrals can be also computed applying integer and fractional order differentiation and integration operators concatenation. Classical integer order derivatives and integrals can be obtained applying well known numerical techniques. To calculate fractional order derivatives and integrals, Riemann-Liouville/Caputo formulas can be applied. The question, the authors want to answer is, which of the algorithms enables to obtain more accurate values of example non-integer derivatives and integrals of some elementary functions.

The paper is divided into the following parts: at the beginning the authors present details of the applied operators of non-integer (fractional) order differentiation and integration, followed by detailed description of the integer and fractional order differentiation and integration operators concatenation and the explanation of their practical numerical implementations. The final part of the paper include accuracy comparison analysis of example non-integer order derivatives and integrals of some elementary functions. The values assumed as exact for the accuracy comparison are calculated applying formulas of non-integer order derivatives and integrals available in the literature of the subject [11], [14].

II. Mathematical Preliminaries

Non-integer (fractional) order integration and differentiation operators include:

- Riemann-Liouville Fractional Order Integral

$$ {}_{t_0}^{RL}\mathrm{I}_t^{(\nu)} = \frac{1}{\Gamma(\nu)} \int_{t_0}^{t} \frac{f(\tau)}{(t-\tau)^{1-\nu}} d\tau \tag{1} $$

- Riemann-Liouville Fractional Order Derivative

$$ {}_{t_0}^{RL}\mathrm{D}_t^{(\nu)} f(t) = \frac{1}{\Gamma(n-\nu)} \left(\frac{d}{dt}\right)^n \int_{t_0}^{t} \frac{f(\tau)}{(t-\tau)^{1-\nu}} d\tau \tag{2} $$

- Caputo Fractional Derivative

$$ {}_0^{C}\mathrm{D}_t^{(\nu)} f(t) = \frac{1}{\Gamma(n-\nu)} \int_{0}^{t} \frac{f^{(n)}(\tau)}{(t-\tau)^{1-\nu}} d\tau \tag{3} $$

Formulas (2) and (3) are related by

$$ {}_{t_0}^{RL}D_t^{(\nu)} f(t) = {}_0^{C}D_t^{(\nu)} f(t) + \sum_{k=0}^{n-1} \frac{t^{k-\nu}}{\Gamma(k-\nu+1)} f^{(k)}(0) \tag{4} $$

where: $n-1 < \nu < n \in N = \{1, 2, ...\}$, $\nu \in R$ is the order of fractional integral/derivative, $f^{(n)}(\tau) = \frac{d^n f(\tau)}{d\tau^n}$ is the classical derivative of integer order, $\Gamma(x) = \int_0^\infty e^{-t} t^{x-1} dt$ is the gamma function and t satisfies the following conditions $-\infty < t_0 < t < \infty$, $\lfloor n \rfloor = n + \nu$.

III. Applied Methods of Integration and Differentiation

A. Applied Methods for Classical Integer Orders Derivatives and Integrals Computations

- Classical integer order derivatives are calculated applying well known numerical methods involving 5 point stencil Central Diffidences.
- Classical integrals of the integer orders are obtained applying well known and efficient methods of numerical integration:
  - Gauss-Kronrod Quadrature (denoted as **GKr**)
    - The method is a very efficient modification of well known Gauss-Legendre Rule. It uses so called the Gauss-Kronrod Pairs. For example the G30/K61 pair includes the nodes of the 30-point Gauss-Legendre Quadrature + 31 new ones and all 61 different coefficients.
    - The advantages of the method is its efficiency and high accuracy obtained with only some dozens of sampling points if applied to precisely selected type of integrand. The main disadvantages are: a complex method of nodes and weight calculations, high precision input data requirement and indept knowledge about the method application to actually obtain high accuracy results.
  - Midpoint Rule (denoted as **NCm**)
    - The method is a very efficient modification of the rectangular rule. In the midpoint rule the sample point is taken from the middle of each subinterval. This feature enable the application of the method to the integrands with singularities at the end point of the integration range.
    - The method can be applied to any integrand, because the weight function equals 1 and the nodes of quadrature are of equal width. The accuracy of calculations should theoretically increase while increasing the amount of subintervals, for which the integration range is divided into. However mechanical increase of the amount of subintervals often leads to small accuracy increase and big increase in computational complexity.

All further details regarding integer order derivatives and integrals methods of computations can be found in available literature of the subject [1], [2], [3], [4], [5]. There is only presented, on Figs 2-3 indicative accuracy of the applied methods.

B. Applied New Efficient High-accuracy Methods of Integration for Non-integer and Fractional Orders Derivatives and Integrals Computations

The integrands in formulas (1)-(3) are difficult to integrate due to singularity at the end of integration range. The difficulty rises as the order of calculated fractional order integral nears 0 and the order of fractional order derivative nears 1. This feature makes inefficient widely known methods of numerical integration in context of accuracy of calculations. Additionally some of the fractional orders derivatives and integrals, mentioned in last sentence are not possible to compute with satisfactory accuracy at all (relative error exceeding 90-100 %).

Generally the problems associated with singularities in numerical integration are the most difficult to solve. In such cases high accuracy results can only be obtained by application of dedicated methods, as for example weighted type quadratures. This type of quadratures, however can only be applied to precisely selected types of functions in unmodified form. It is forced by their association with the corresponding weights. To obtain high accuracy results, either the integrand must satisfy conditions of a particular quadrature application requirements or the quadrature must be adopted to a particular integrand. Choosing the second method, the authors of the paper developed precise modifications to the existing numerical methods of integration: Gauss-Jacobi Quadrature and Double Exponential Quadrature, which initially were developed for integer order integration only.

Modified version of Gauss-Jacobi Quadrature have adopted weight function for fractional order derivatives and integrals computations (the method is denoted in the paper as **GJ**). Double Exponential Quadrature (denoted as **DE**) [16], [17] on the other hand involves hyperbolic functions substitution in independent variable transformation in integrand and trapezoidal rule applied to the transformed integrand. Application of the methods enables to obtain high accuracy computations results of fractional order derivatives and integrals [6], [7].

Important remarks:

- In the case of the non-integer (fractional) order differentiation and integration operators (1)-(3), regardless if there is integral or derivative to calculate, we always apply the integration operator.
- The non-integer (fractional) order differentiation operators (1)-(3) unlike integer order differentiation operators, are non-local operators. They are not calculated applying the values of the neighbor function points, but from the whole range of differentiation. This can be beneficial in case of a physical process analysis, because we take into consideration its history from the beginning, however this feature increases significantly the complexity of numerical calculations. Higher complexity of calculations influences negatively the accuracy of input data for each part of calculations. Inaccuracies in input data are the classical cause for numerical calculations accuracy decrease.

C. Concatenation of Operators of Integer and Fractional Order Differentiation and Integration as a Obtain Method of Non-integer Order

Scientifically interesting calculation method of non-integer order derivatives and integrals computations is application of concatenation of integer and fractional order differentiation and integration operators.

The practical operations of concatenations are related with fractional and integer order operators. Some of them are trivial,

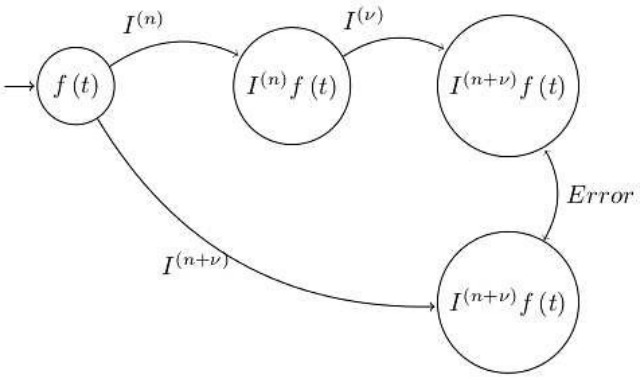

Fig. 1. Accuracy Estimation Based on Integer and Fractional Orders Integration Operators Concatenation

some require additional assumptions. There is always assumed the existence of the corresponding derivatives and integrals and that the operations of concatenation are always performed on the same definitive integration range.

Interesting concatenations combination of integer and fractional orders differentiation and integration in context of the paper's subject include:

- Fractional order derivative of integer order derivative

$$\mathrm{D}^{(\nu)}\left(\mathrm{D}^{(n)}f(t)\right)=\mathrm{D}^{(n+\nu)}f(t) \tag{5}$$

- Fractional order integral of integer order integral

$$\mathrm{I}^{(\nu)}\left(\mathrm{I}^{(n)}f(t)\right)=\mathrm{I}^{(n+\nu)}f(t) \tag{6}$$

where n is classical integer order derivative or integral, $\nu \geq 0$ and $t \geq 0$ (see Figure 1 for visualization).

Comprehensive mathematical calculations to the subject can be found in [14].

In the works of [9] and [10] discussed properties (5) and (6) are named *Law of Exponents*, because they relate to the operations performed on the exponents of the fractional and integer order operators (1)-(3). The *Law of Exponents* is generally true for the fractional integration operators. It is also valid for fractional order differentiation operators [14]. Still it is well known [10] and [9] in $\S IV.6$ *Law of Exponents*, that there exist functions for which fractional order differentiation operator (3) do not satisfy (5). However, the authors of the following paper focus only on functions, for which concatenations (5)-(6) are possible, in this case $f(t_0)=0$.

IV. Evaluation Details

The description of a general method of the fractional order differentiation and integration operators concatenation is presented in [10], [9]. It is expressed by the following formula

$$I^{(\nu)}\left[I^{(n)}f(t)\right]=\frac{1}{\Gamma(\nu)\cdot\Gamma(n)}\int_0^t(t-x)^{\nu-1}\cdot \cdot\left[\int_0^x f(y)\,dy\right]dx \tag{7}$$

We substitute $x=k*h$ in inner integral, where k is the amount of subintervals, which the integration range is divided into, and h is the width of each interval. As a result we obtain the values of the *inner* integral in h-spaced intervals. This values serve as input function $f(x)$ for the *outside* integral.

The integration methods applied in the following research require precisely sampled function's values in the nodes points and their synchronization with the corresponding weights. Sampling the function in equally spaced points and then interpolating the values of the function in the nodes points does not comply with its function sufficiently. There must be applied a different approach, which is presented as Algorithm 1.

Algorithm 1 Concatenation of integer and fractional order differentiation and integration operators. Nodes of a quadrature for $I^{(\nu)}$ as an integration step of $I^{(n)}$.

Step 1. Select fractional orders to concatenate $I^{(n)}$ and $I^{(\nu)}$. The $I^{(n)}$ is the *inner* integral and the $I^{(\nu)}$ is the *outer* one.

Step 2. Calculate quadrature nodes and weights for the $I^{(\nu)}$.

Step 3. Calculate $I^{(n)}$ applying as step the points of the nodes from *Step 2*.

Step 4. Calculate $I^{(\nu)}$ applying as inputting as $f(x)$ the values obtained in *Step 3*.

1) Arbitrary Precision in Numerical Calculations: To overcome the bottlenecks of the double precision computer arithmetic and to increase overall computations accuracy [18], two arbitrary precision programming libraries together with a C++ wrapper [22] are applied:

MPFR [21] is an arbitrary precision package for C language and is based on GMP [20].

MPFR supports arbitrary precision floating point variables. It also provides an exact rounding of all implemented operations and mathematical functions [19].

A. Testing Functions

The integrand in formulas (1)-(3) consists of two factors: the first factor, so called *core* and the second one, which is the actual function, of which there is non-integer (fractional) order derivative or integral to calculate.

The core has the biggest influence on the shape of the integrand and on the difficulty level of integration. In this respect, the actual function to integrate contributes only to a minimal extent.

Due to this, the authors decide it is enough to select two functions for testing purposes:

- Power function

$$f(t)=(t-t_0)^p,\ t_0=0,\ p=0.5\ ,t\in(0,1) \tag{8}$$

- Exponential function

$$f(t)=e^{at}\mathbf{I}(t),\ a=0.5,t\in(0,1) \tag{9}$$

B. Accuracy Estimation of Computations

Accuracy estimation is performed on the basis of the non-integer (fractional) order derivatives and integrals formulas (10)-(13) available in the literature of the subject [11], [14]. Due to the fact, that they are in fact computational formulas, there must be taken into consideration some calculations error, although very small.

Assuming $D^{(-\nu)} = I^{(\nu)}$.

- Power Function (8):
  - Fractional integral

$$ {}_{t_0}\mathrm{D}_t^{(-\nu)} f(t) = \frac{\Gamma(p+1)}{\Gamma(p+\nu+1)} (t-t_0)^{p+v}. \quad (10)$$

  - Fractional derivative

$$ {}_{t_0}\mathrm{D}_t^{(\nu)} f(t) = \frac{\Gamma(p+1)}{\Gamma(p+1-\nu)} (t-t_0)^{p-v}. \quad (11)$$

- Exponential Function (9):
  - Fractional integral

$$ {}_{t_0}\mathrm{D}_t^{(-\nu)} f(t) = t^{\nu} \sum_{k=0}^{N} \frac{(at)^k}{\Gamma(k+\nu+1)}. \quad (12)$$

  - Fractional derivative

$$ {}_{t_0}\mathrm{D}_t^{(\nu)} f(t) = t^{-\nu} \sum_{k=0}^{N} \frac{(at)^k}{\Gamma(k+1-\nu)}. \quad (13)$$

C. Accuracy Definition

In the whole paper the accuracy is expressed as relative error in % in context of integration range

$$ e_r^{(t)} = \left(1 - \frac{v_c}{v_e}\right) \cdot 100\% \quad (14)$$

where v_c denotes calculated value, v_e a value *assumed* as exact one and t_0, t is integration range.

V. Comparison Analysis

A. General remarks

The methods of numerical integration developed by the authors of the paper, to their best knowledge, are the only numerical methods of integration available at the moment, applying which it is possible to obtain high accuracy results calculating non-integer (fractional) derivatives and integrals:

- **GJ** method delivers high accuracy results with average accuracy above 10^{-80} mark. The order of the derivative and integral and integration range has no impact on accuracy. Actually, the method increases offered accuracy in cases, in which traditionally methods decrease it. The method requires 4-64 sampling points to reach average accuracy abilities. The type of integrated function influences only slightly the final results.
- **DE** is able to deliver 10^{-50} average accuracy level for fractional integrals of orders greater than 0.5 and fractional derivatives smaller that 0.5 with $600 - 1000$ sampling points. The methods is in general more dependable on range and type of the integrated function.

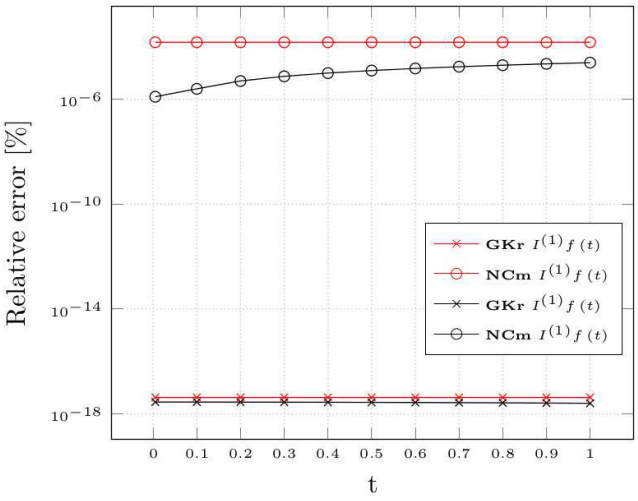

Fig. 2. Integer Order Integration results for function (8) in red and function (9) in black

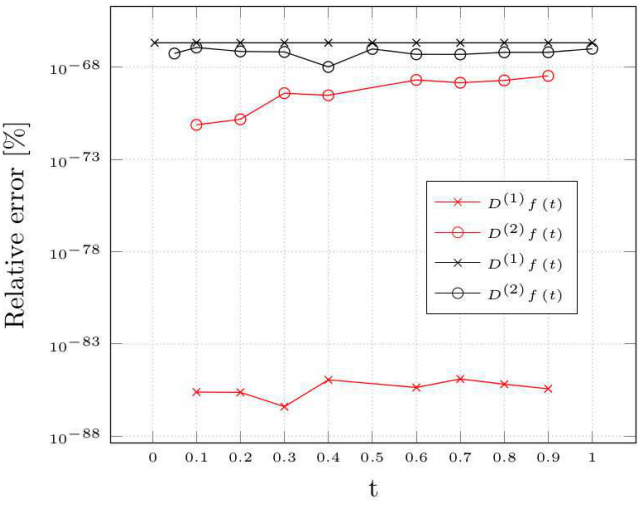

Fig. 3. Integer Order Differentiation results for function (8) in red and function (9) in black

B. Accuracy of integer order integration and differentiation

As it is presented on Fig. 2, GKr ensures enormous advantage over NCm in context of accuracy of integration. GKr achieves triple greater accuracy with only 61 sampling points. NCm was tested with 10000 sampling points. Further sampling points increase in case of GKr did not enable to obtain better results; actually, the accuracy deteriorated. In case of NCm, further accuracy increase was very slow with each 10000 sampling points added, that it did not justified the further experimentation.

Application of GKr is the optimal choice for integration operators concatenation.

Application of 5-point Central Differences to obtain 1^{st} and 2^{nd} derivative resulted with high accuracy, almost error free results (See Fig. 3). Further points increase did not bring any

accuracy increase.

Application of 5-point Central Differences is the optimal choice for differentiation operators concatenation.

C. Accuracy of non-integer order integration and differentiation

As it is presented on Figs 4-7 application of both developed methods of numerical integration GJ and DE to compute directly non-integer order derivatives and integrals enables to obtain highest possible results.

The accuracy of the integer and non-integer orders integration operators concatenation is limited to the accuracy possible to obtain applying integer order numerical integration methods, because it determines the accuracy of the input data for fractional order integration. For differentiation operators concatenation, the deteriorating amount of information about the integrated function during the operators concatenation affects the final accuracy. The loss of information understood in the sense of the input data accuracy decrease: during integer operator application the function is known in the entire range, i.e. it is available in the continuous form; during the fractional operator application the input function is available only in some earlier pre-calculated points, i.e. it is available in the discrete form only.

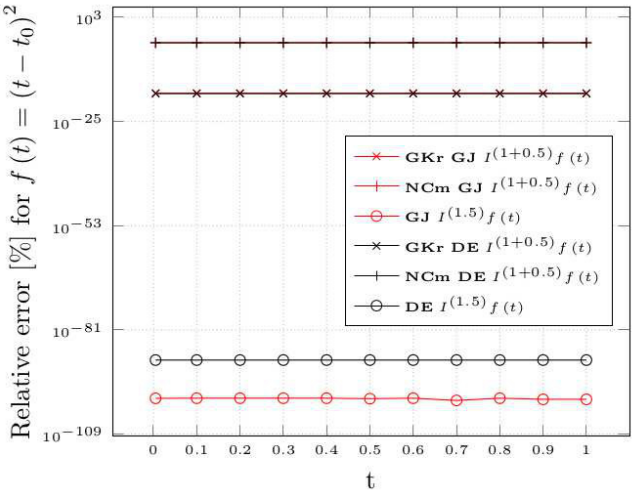

Fig. 4. Non-integer Order Integration Results for function (8). GKr and NCm applied to compute integer orders, GJ and DE to compute fractional and non-integer order

VI. Conclusion

The purpose of the following research was to evaluate in context of computations accuracy two algorithms of non-integer order derivatives and integrals computations: direct numerical calculation of non-integer order derivatives and integrals and the non-integer orders of derivatives and integrals obtained by the application of concatenation of the integer and fractional orders operators of integration and differentiation.

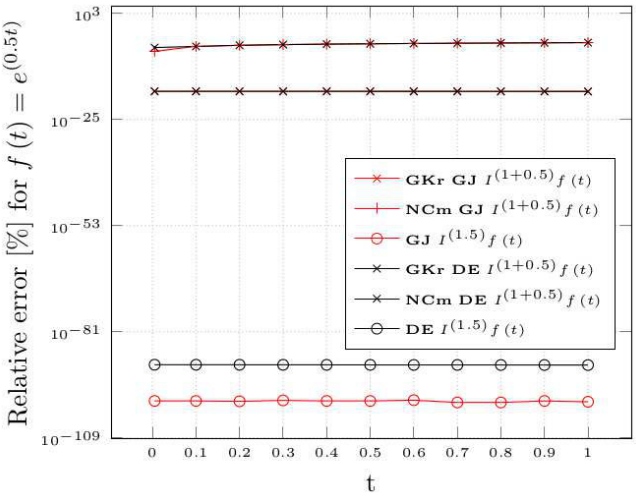

Fig. 5. Non-integer Order Integration Results for function (9) GKr and NCm applied to compute integer orders, GJ and DE to compute fractional and non-integer order

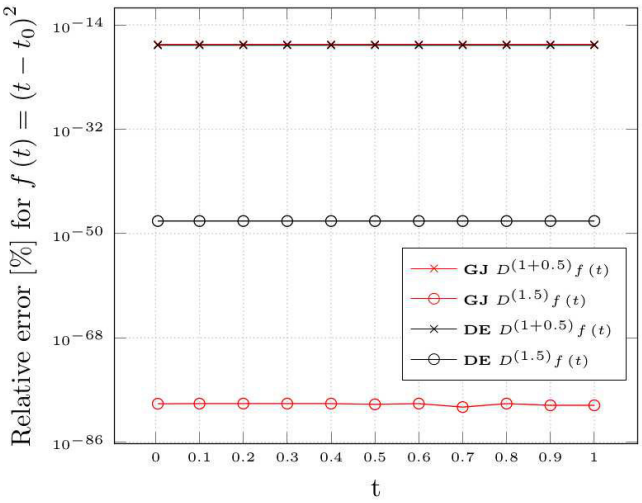

Fig. 6. Non-integer Order Differentiation Results for function (8)

There is no doubt, that direct calculation of non-integer orders derivatives and integrals applying both numerical methods, GJ and DE, developed by the authors of the paper for non-integer and fractional order derivatives and integrals computations applying formulas (1)-(3) are the methods to favorite if one want to obtain high accuracy results. The methods are efficient and their accuracy does not depend on order of the calculated derivative and integral or the integration range.

APPENDIX

Below there are presented the main ideas behind two new numerical methods of integration developed by the authors of the paper for non-integer (fractional) order derivatives and integrals computations mentioned in the paper.

A. Double Exponential Formula

The Double Exponential (**DE**) formula joins two applied techniques: the double exponential transformation applied to the initial integrand and the trapezoidal rule applied to the transformed integrand.

General idea standing behind the DE transformation which was proposed by Schwartz [15] and become known as the Tanh rule (since $x = tanh(t)$) is as follows:

Let us consider the integral

$$I = \int_a^b f(x)\, dx$$

where $f(x)$ is integrable on interval (a, b). The function $f(x)$ may have singularity $x = a$, $x = b$ or at both.

First we apply the following variable transformation

$$x = \phi(t),\ \phi(-\infty) = a,\ \phi(\infty) = b.$$

We obtain

$$I = \int_{-\infty}^{\infty} f(\phi(t))\, \phi'(t)\, dt.$$

It is important that $\phi(t)$ possess the property such as $\phi'(t)$ decreases its values to 0 at at least double exponential as $t \to \pm\infty$, i.e.

$$\left|\phi'(t)\right| \to exp(-c\, exp(|t|)) \tag{15}$$

where c is some constant.

After that, it is best to apply the trapezoidal formula with an equal mesh size to the transformed integrand expression [23], i.e.

$$I = h \sum_{n=-\infty}^{\infty} f(\phi(nh))\, \phi'(nh)$$

where nh is sampling step.

Due to the property (15) truncation of the summation process can be done at some arbitrary chosen $n = -N_-$ and $n = +N_+$, i.e.

$$I = h \sum_{n=-N_-}^{N_+} f(\phi(nh))\, \phi'(nh), \tag{16}$$

$N = N_- + N_+ + 1$, where N states the amount of sampling points of the function.

Since $\phi'(nh)$ as well as the whole expression $f(\phi(nh))\, \phi'(nh)$ converges to 0 at exponential rate at

large $|n|$, the quadrature formula (16) is called the Double Exponential [16], [17].

Due to truncation of the summation process (16) at some arbitrary chosen $n = N_-,\ n = N_+$, function $f(x)$ can have singularities at $x = a$ and/or $x = b$ as long as it is integrable over the integration range.

There should be taken two kinds of errors into consideration when implementing the DE formula: discretization error, because we use the trapezoidal rule to approximate an integral and truncation error, because we truncate infinite sum at some N.The optimal strategy is to make both errors equal [17].

The subinterval width h, which defines the evaluation step and the number of sample points are key values in such strategy. The source [17] suggest the following value of h for DE formula

$$h \sim \frac{log\,(2\pi N\omega/c)}{N},$$

where c is some constant to be taken, usually 1 or $\pi/2$ and ω is the distance to the nearest singularity of the integrand.

Correct selection of a function (17)-(19) with optimal properties enables to control the level of convergence of the whole transformed expression (16). The rate of convergence has enormous impact on accuracy, i.e. to rapid convergence decreases the accuracy [16].

The authors test three different transformations and selected (18) because of it optimal convergence rate for the purpose of the research, which is also suggested by the literature of the subject [17], [16].

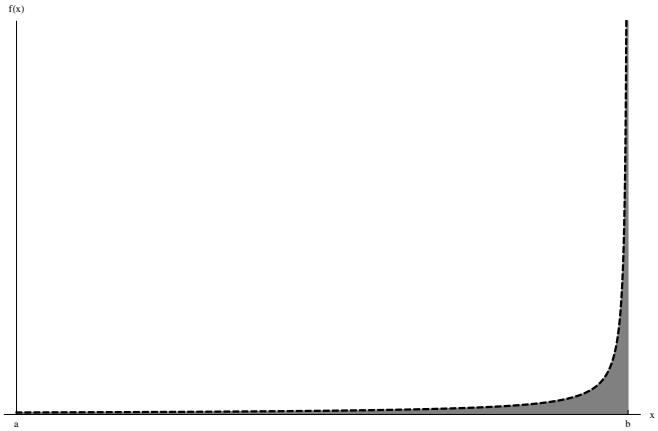

Fig. 8. Graph of the original *core* integrand in the formulas (1)-(3)

The transformations expressions are as follows:

$$x = \phi(t) = \\ = tanh\, t^p,\ \phi^{'}(t) = \frac{pt^{p-1}}{cosh^2 t^p},\ p = 1, 3, 5, \ldots \quad (17)$$

$$x = \phi(t) = \\ = tanh\,(\phi/2\ sinh\,(t)),\ \phi^{'}(t) = \frac{\phi/2\ cosh\ t}{cosh^2 sinh\,(t)} \quad (18)$$

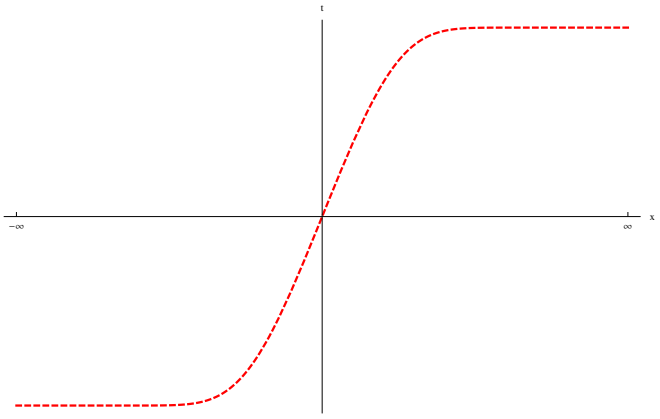

Fig. 9. Graph of the transforming expression (18)

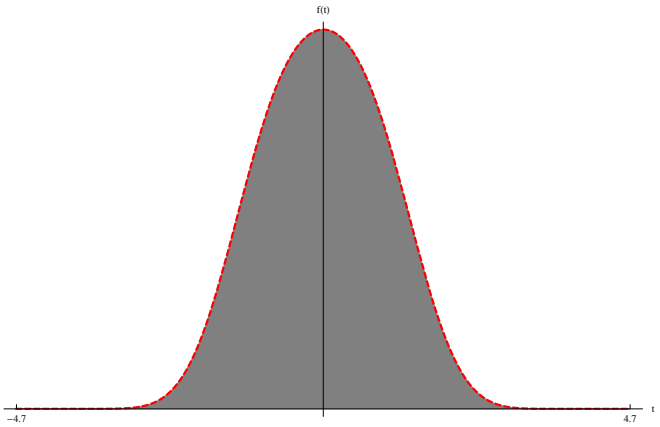

Fig. 10. Graph of the transformed *core* integrand (20) and the range applied in computations

$$x = \phi(t) = tanh\left(\phi/2\ sinh\left(t^3\right)\right),$$
$$\phi^{'}(t) = \frac{3\pi/2\ t^2\ \phi/2\ cosh\ t^3}{cosh^2 sinh\,(t^2)} \quad (19)$$

Applying the transformation (18) to the formulas (1)-(3) according the formula (16), we obtain the following trapezoidal form

$$S = h\sum_{i=1}^{N} f\left(\frac{b-a}{2}\ x_i + \frac{b+a}{2}\right) w_i \quad (20)$$

where

$$x_i = f\,(tanh\,(\pi/2\ sinh\,(t_i)))$$

are the nodes and

$$w_i = \frac{cosh\,(t_i)}{cosh^2\ \pi/2\ sinh\ t_i} \cdot \frac{b-a}{2}$$

are the weights of the Double Exponential Quadrature.

Additionally $t_i = -t_a + (i-1)\cdot h,\ i = 0, 1, 2, 3, \cdots N - 1, h = \frac{2t_a}{N-1}$ are the new integration range and the width of one trapezoidal subinterval. The selection of the value t_a parameter decides how near the singularity we integrate.

There is presented the visualization of the DE transformation on Figs 8-10.

B. Gauss-Jacobi Quadrature with Adopted Weight Function

A weight function, which enables to eliminate definite integration range endpoints singularities is Jacobi weight (21) [1], [2], [3], [4].

$$p(x) = (1-x)^{\lambda}(1+x)^{\beta},\ \lambda,\beta > -1. \tag{21}$$

A quadrature formula with the weight (21) assumes the form

$$\int_{-1}^{1}(1-x)^{\lambda}(1+x)^{\beta}\cdot f(x)\,dx \cong \cong \sum_{k=1}^{n} A_k \cdot f(x_k). \tag{22}$$

The nodes x_i are zeros of the Jacobi polynomial $J_n(x;\lambda,\beta)$.

The Jacobi Polynomial can be determined by applying Rodrigues formula

$$J_n(x;\lambda,\beta) = = \frac{(-1)^n}{2n\cdot n!}(1-x)^{-\lambda}(1+x)^{-\beta}\cdot \cdot \frac{d^n}{dx^n}\left[(1-x)^{\lambda+n}(1+x)^{\beta+n}\right] \tag{23}$$

The weights A_k can be computed applying the following formula

$$A_k = 2^{\lambda+\beta+1}\frac{\Gamma(\lambda+n+1)\Gamma(\beta+n+1)}{n!\Gamma(\lambda+\beta+n+1)}\cdot \cdot \frac{1}{(1-x_k^2)\left[J_n^{(\lambda,\beta)'}x_k\right]^2} \tag{24}$$

The remainder of the Gauss-Jacobi Quadrature is expressed as

$$R = \frac{2^{\lambda+\beta+2n+1}}{\lambda+\beta+2n+1}\cdot \cdot \frac{\Gamma(\lambda+n+1)\Gamma(\beta+n+1)\Gamma(\lambda+\beta+n+1)}{\Gamma^2(\lambda+\beta+2n+1)}\cdot \cdot \frac{n!}{2n}\cdot f^{2n}(\xi), \xi\in\langle -1,1\rangle \tag{25}$$

Now the transformation of the weight function. Substituting $\lambda = 1-\alpha, \beta = 0$ in (22) we obtain

$$\int_{-1}^{1}\frac{\phi(x)}{(1-x)^{1-\alpha}}dx \tag{26}$$

which coincides with *the core* integrand in the formulas (1)–(3).

To change the integration range from $[-1,1]$ to arbitrary chosen $[t_0,t]$ formula (26) must be transformed as follows

$$\left(\frac{t-t_0}{2}\right)^{\nu}\cdot\int_{-1}^{1}\frac{\phi(u)}{(1-u)^{1-\alpha}}du \tag{27}$$

where

$$\phi(u) = f\left(\left(\frac{t-t_0}{2}\right)u + \left(\frac{t-t_0}{2}\right)\right)$$

Applying formulas (26)-(27) we can express the formula (1) as

$${}^{RL}\mathrm{I}^{(\nu)} = \frac{1}{\Gamma(\nu)}\left(\frac{t-t_0}{2}\right)^{\nu}\int_{t_0}^{t}\frac{f(u)}{(t-u)^{1-\alpha}}du.$$

To calculate non-integer (fractional) order derivatives applying formula (3) we proceed the similar way

$$\left(\frac{t-t_0}{2}\right)^{n-\nu}\int_{-1}^{1}\frac{\phi(u)}{(1-u)^{1-\alpha}}du$$

where

$$\phi(u) = f\left(\left(\frac{t-t_0}{2}\right)u + \left(\frac{t-t_0}{2}\right)\right).$$

The formula (3) assumes the following form

$${}^{C}\mathrm{D}^{(\nu)} = \frac{1}{\Gamma(n-\nu)}\left(\frac{t-t_0}{2}\right)^{n-\nu}\int_{t_0}^{t}\frac{\left(\frac{d}{dt}\right)^n}{(t-u)^{n-\alpha-1}}du. \tag{28}$$

The formula (28) seems to have similar form as (3). The most difficult part in context of numerical integration, however is calculated applying a method which guarantees multiple times higher accuracy, applying the Jacobi polynomials.

***Abstract*—In the paper the authors present the WZ factorization in MATLAB. MATLAB is an environment for matrix computations, therefore in the paper there are presented both the sequential WZ factorization and a block-wise version of the WZ factorization (called here VWZ). Both the algorithms were implemented and their performance was investigated. For random dense square matrices with the dominant diagonal we report the execution time of the WZ factorization in MATLAB and we investigate the accuracy of such solutions. Additionally, the results (time and accuracy) for our WZ implementations were compared to the similar ones based on the LU factorization.**

Keywords: linear system, WZ factorization, LU factorization, matrix factorization, matrix computations

I. Introduction

IN THE international academic circles MATLAB is accepted as a reliable and convinient software for numerical computations. Particularly, it is used for linear algebra computations. Nowadays, there are a lot of papers devoted to the use of MATLAB in mathematics (linear systems [7], least-squares problems [9]; function approximation [12]; eigenvalues [2], [11] — and many others). In this paper we use MATLAB to solve linear systems.

Solution of linear systems of the form:

$$\mathbf{A}\mathbf{x} = \mathbf{b}, \qquad \text{where} \quad \mathbf{A} \in \mathbb{R}^{n\times n}, \quad \mathbf{b} \in \mathbb{R}^{n}, \qquad (1)$$

is an important and common problem in engineering and scientific computations. One of the direct methods of solving a dense linear system (1) is to factorize the matrix $\mathbf{A}$ into some simpler matrices — it is its decomposition into factor matrices (that is, factorization) of a simpler structure — and then solving simpler linear systems. The most known factorization is the LU factorization. MATLAB provides many ways to solve linear systems, one of them is based on the LU factorization: `[L,U]=lu(A)`. This method is powerful and simple to use.

In [7] an object-oriented method is presented, which is is a meta-algorithm that selects the best factorization method for a particular matrix, whether sparse or dense — allowing the reuse of its factorization for subsequent systems.

In this work we study another form of the factorization, namely the WZ factorization and investigate both the accuracy of the computations and their time. In [4], [5] we showed that there are matrices for which applying the incomplete WZ preconditioning gives better results than the incomplete LU factorization.

The aim of the paper is to analyze the potential of implementations of the WZ factorization in a high-level language (as it is the case of MATLAB). We implement the WZ factorization and compare its performance to a MATLAB function implementing the LU factorization, namely: `[L,U]=lu(A)` — and to the authors' own MATLAB implementation of the LU factorization.

The content of the paper is following. In Section II we describe the idea of the WZ factorization [8], [13] and the way the matrix $\mathbf{A}$ is factorized to a product of matrices $\mathbf{W}$ and $\mathbf{Z}$ — such a factorization exists for every nonsingular matrix (with pivoting) what was shown in [8]. Section III provides information about some modifications of the original WZ algorithm — in a way to decrease the number of loops and to make as much as possible computations in blocks — and this will allow us to use MATLAB efficiently. In Section IV we present the results of our experiments. We analyzed the time of WZ factorization. We study the influence of the size of the matrix on the achieved numerical accuracy. We compare the WZ factorization to the LU factorization. Section V is a summary of our experiments.

II. WZ Factorization (WZ)

Here we describe shortly the WZ factorization usage to solve (1). The WZ factorization is described in [8], [10]. Let us assume that the $\mathbf{A}$ is a square nonsingular matrix of an even size (it is somewhat easier to obtain formulas for even sizes than for odd ones). We are to find matrices $\mathbf{W}$ and $\mathbf{Z}$ that fulfill $\mathbf{WZ} = \mathbf{A}$ and the matrices $\mathbf{W}$ and $\mathbf{Z}$ consist of the rows $\mathbf{w}_i^T$ and $\mathbf{z}_i^T$ shown in Figure 1, respectively.

After the factorization we can solve two linear systems:

$$\mathbf{W}\mathbf{y} = \mathbf{b},$$

$$\mathbf{Z}\mathbf{x} = \mathbf{y}$$

(where $\mathbf{c}$ is an auxiliary intermediate vector) instead of one (1).

Figure 2 shows an example of a matrix nad its WZ factors.

In this paper we are interested only in obtaining the matrices $\mathbf{Z}$ and $\mathbf{W}$. The first part of the algorithm consists in setting

This work was partially supported within the project N N516 479640 of the Ministry of Science and Higher Education of the Polish Republic (MNiSW) "Modele dynamiki transmisji, sterowania, zatłoczeniem i jakością usług w Internecie".

$$

Fig. 2. A matrix $\mathbf{A}$ and its factors $\mathbf{W}$ and $\mathbf{Z}$

succesive parts of columns of the matrix $\mathbf{A}$ to zeros. In the first step we do that with the elements in columns 1st and nth — from the 2nd row to the $n-1$st row. Next we update the matrix $\mathbf{A}$.

More formally we can describe the first step of the algoritm the following way.

1) For every $i = 2, \ldots, n-1$ we compute w_{i1} and w_{in} from the system:

$$
\begin{cases} a_{11}w_{i1} + a_{n1}w_{in} = -a_{i1} \\ a_{1n}w_{i1} + a_{nn}w_{in} = -a_{in} \end{cases}
$$

and we put them in a matrix of the form:

$$
\mathbf{W}^{(1)} = \begin{bmatrix} 1 & 0 & \cdots & 0 & 0 \\ w_{21} & 1 & \ddots & \vdots & w_{2n} \\ \vdots & 0 & \ddots & 0 & \vdots \\ w_{n-1,1} & \vdots & \ddots & 1 & w_{n-1,n} \\ 0 & 0 & \cdots & 0 & 1 \end{bmatrix}.
$$

2) We compute:

$$
\mathbf{A}^{(1)} = \mathbf{W}^{(1)}\mathbf{A}.
$$

After the first step we get a matrix of the form:

$$
\mathbf{A}^{(1)} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1,n-1} & a_{1n} \\ 0 & a_{22}^{(1)} & \cdots & a_{2,n-1}^{(1)} & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ 0 & a_{n-1,2}^{(1)} & \cdots & a_{n-1,n-1}^{(1)} & 0 \\ a_{n1} & a_{n2} & \cdots & a_{n,n-1} & a_{nn} \end{bmatrix},
$$

where (for $i, j = 2, \ldots, n-1$):

$$
a_{ij}^{(1)} = a_{ij} + w_{i1}a_{1j} + w_{in}a_{nj}.
$$

Then, we proceed analogously — but for the inner square matrices — $\mathbf{A}^{(1)}$ of size $n-2$ and so on.

So, the whole algorithm is following.

For $k = 1, 2, \ldots, \frac{n}{2} - 1$:

1) For every $i = k+1, \ldots, n-k$ we compute w_{ik} and $w_{i,n-k+1}$ from the system:

$$\begin{cases} a_{kk}^{(k-1)} w_{ik} & + & a_{n-k+1,k}^{(k-1)} w_{i,n-k+1} \\ & = & -a_{ik}^{(k-1)} \\ a_{k,n-k+1}^{(k-1)} w_{ik} & + & a_{n-k+1,n-k+1}^{(k-1)} w_{i,n-k+1} \\ & = & -a_{i,n-k+1}^{(k-1)} \end{cases}$$

and we put them in a matrix of the form shown in Figure 3.

2) We compute:

$$\mathbf{A}^{(k)} = \mathbf{W}^{(k)} \mathbf{A}^{(k-1)}$$

(where obviously $\mathbf{A}^{(0)} = \mathbf{A}$).

After $\frac{n}{2} - 1$ such steps we get the matrix

$$\mathbf{Z} = \mathbf{A}^{(\frac{n}{2}-1)}$$

.

Moreover, we know that:

$$\mathbf{W}^{(\frac{n}{2}-1)} \cdot \ldots \cdot \mathbf{W}^{(1)} \cdot \mathbf{A} = \mathbf{Z}$$

so we get:

$$\mathbf{A} = \left(\mathbf{W}^{(1)}\right)^{-1} \cdot \ldots \cdot \left(\mathbf{W}^{(\frac{n}{2}-1)}\right)^{-1} \cdot \mathbf{Z} = \mathbf{W}\mathbf{Z}$$

Figure 4 shows the same algorithm implemented in MATLAB.

III. Vector WZ Factorization (VWZ)

Now we describe a matrix-vector algorithm for the WZ factorization of the matrix $\mathbf{A}$ which is originally presented in [6].

This is a sequential algorithm where we grouped and ordered the scalar operations anew, into matrix-vector operations. We are showing the algorithm without pivoting, working only for matrices for which such a WZ factorization is executable (for example, for matrices with a dominant diagonal.

Let us write the matrices $\mathbf{A}$, $\mathbf{W}$, $\mathbf{Z}$ as block matrices. We can get equations presented in Figure 5.

In Figure 5, $\widehat{\mathbf{W}}$ and $\widehat{\mathbf{Z}}$ are square matrices of the same structure as the matrices $\mathbf{W}$ and $\mathbf{Z}$, respectively; $\widehat{\mathbf{A}}$ is a full square matrix; $\widehat{\mathbf{W}}$, $\widehat{\mathbf{Z}}$ and $\widehat{\mathbf{A}}$ are of the size 2 less than the size of $\mathbf{W}$, $\mathbf{Z}$ and $\mathbf{A}$; vectors $\mathbf{a}_{1*}^T$, $\mathbf{a}_{n*}^T$, $\mathbf{z}_{1*}^T$, $\mathbf{z}_{n*}^T$ are row vectors; vectors $\mathbf{a}_{*1}$, $\mathbf{a}_{*n}$, $\mathbf{w}_{*1}$, $\mathbf{w}_{*n}$ are column vectors.

From the comparison of the corresponding elements in Figure 5 we get:

$$\begin{array}{ll} a_{11} = z_{11}; & a_{1n} = z_{1n}; \\ a_{n1} = z_{n1}; & a_{nn} = z_{nn} \end{array}$$

$$\mathbf{a}_{1*}^T = \mathbf{z}_{1*}^T; \quad \mathbf{a}_{n*}^T = \mathbf{z}_{n*}^T$$

$$\begin{cases} \mathbf{a}_{*1} & = & \mathbf{w}_{*1} z_{11} & + & \mathbf{w}_{*n} z_{n1} \\ \mathbf{a}_{*n} & = & \mathbf{w}_{*1} z_{1n} & + & \mathbf{w}_{*n} z_{nn} \end{cases} \tag{2}$$

$$\widehat{\mathbf{A}} = \mathbf{w}_{*1}\mathbf{z}_{1*}^T + \widehat{\mathbf{W}}\widehat{\mathbf{Z}} + \mathbf{w}_{*n}\mathbf{z}_{n*}^T$$

From (2) we can describe our algorithm for finding $\mathbf{W}$ and $\mathbf{Z}$ as following:

1) let the first row of the matrix $\mathbf{Z}$ be the first row of the matrix $\mathbf{A}$;
2) let the last row of the matrix $\mathbf{Z}$ be the last row of the matrix $\mathbf{A}$;
3) compute the vectors $\mathbf{w}_{*1}$ and $\mathbf{w}_{*n}$ from:

$$\begin{aligned} \mathbf{w}_{*1} &= \alpha \mathbf{a}_{*n} - \beta \mathbf{a}_{*1}, \\ \mathbf{w}_{*n} &= \gamma \mathbf{a}_{*1} - \delta \mathbf{a}_{*n}, \end{aligned}$$

where

$$\begin{aligned} \alpha &= \frac{z_{n1}}{z_{1n}z_{n1} - z_{11}z_{nn}}, \\ \beta &= \frac{z_{nn}}{z_{1n}z_{n1} - z_{11}z_{nn}}, \\ \gamma &= \frac{z_{1n}}{z_{1n}z_{n1} - z_{11}z_{nn}}, \\ \delta &= \frac{z_{11}}{z_{1n}z_{n1} - z_{11}z_{nn}}; \end{aligned}$$

4) update the inner part of the matrix $\mathbf{A}$ (the matrix without its first and last row and column):

$$\widehat{\mathbf{A}}^{\text{new}} = \widehat{\mathbf{W}}\widehat{\mathbf{Z}} = \widehat{\mathbf{A}} - \mathbf{w}_{*1}\mathbf{z}_{1*}^T - \mathbf{w}_{*n}\mathbf{z}_{n*}^T;$$

5) if the size of the matrix $\widehat{\mathbf{A}}^{\text{new}}$ is 3 or more, then start over from 1., but with $\mathbf{A} = \widehat{\mathbf{A}}^{\text{new}}$, $\mathbf{W} = \widehat{\mathbf{W}}$ and $\mathbf{Z} = \widehat{\mathbf{Z}}$ (so all three matrices become smaller and smaller and the algorithm comes eventually to the end).

Figure 6 shows this algorithm implemented in MATLAB.

IV. Numerical Experiments

In this section we tested the time and the absolute accuracy of the WZ factorization. Our intention was to investigate the WZ factorization and compare our implementation (done in MATLAB, which is a high-level language) of the WZ factorization with the LU factorization.

The input matrices are generated (by the authors). They are random matrices with a dominant diagonal of even sizes (500, 1000, 1500 and so on, up to 3000 or 4000).

The MATLAB implementation was compiled and tested under MS Windows on workstations with an AMD processor and an Intel processor. Table I shows details of specification of the hardware used in the experiment. To measure the performance time standard MATLAB functions were used — `tic` and `toc`. We measured the difference between $\mathbf{A}$ and $\mathbf{WZ}$ by absolute error $||\mathbf{A} - \mathbf{WZ}||_2$ — to compute the norm there was used a standard MTLAB function: `norm`. The implementations were tested in MATLAB R2008 and MATLAB R2010.

Figures 8, 9, 10 and 11 show the performance time (in seconds) of the WZ factorization on the AMD processor and the Intel processor, implemented in MATLAB R2008 and MATLAB R2010. Additionally, we compared the WZ

$$\mathbf{W}^{(k)} = \begin{bmatrix} 1 & & & & & & & \\ & \ddots & & & & & & \\ & & 1 & & & & & \\ & & w_{k+1,k} & \ddots & & w_{k+1,n-k+1} & & \\ & & \vdots & & \ddots & \vdots & & \\ & & w_{n-k,k} & & & w_{n-k,n-k+1} & & \\ & & & & & 1 & & \\ & & & & & & \ddots & \\ & & & & & & & 1 \end{bmatrix}$$

TABLE I
HARDWARE USED IN EXPERIMENTS

#	CPU	Memory
1	AMD FX-8120 3.1 GHz	16 GB
2	Intel Core 2 Duo 2.53 GHz	4 GB

factorization (both in its sequential — Figure 4 — and vector — Figure 6 — versions) with a standard MATLAB LU factorization function, namely `lu`, which uses the subroutine DGETRF from LAPACK [1], and also with the simple LU implementation (shown in Figure 7).

Results show that the vector WZ factorization (VWZ) is much faster than the sequential WZ factorization in both tested MATLAB versions and on both architectures.

However, on the older processor (Intel Core is here the case) the sequentials algorithms perform better than on the newer (AMD) — and the block algorithms (VWA and the standard MATLAB function `lu`) perform better on the newer one. It is caused by the differences in architectues — newer ones prefer block algorithms because of their stronger inner parallelism.

Tables II, III, IV and V illustrate the accuracy (given as the norms $||\mathbf{A} - \mathbf{WZ}||_2$ and $||\mathbf{A} - \mathbf{LU}||_2$) of the WZ and LU factorizations in MATLAB. The first column shows the norm for the sequential WZ factorization (from Figure 4); the second — the vector WZ factorization (VWZ, from Figure 6); the third presents the norm for the sequential LU factorization (from Figure 7); the fourth — the norm for the standard MATLAB function `lu`.

Based on the results, we can state that different implementations give quite similar accuracies. However, the sizes of the matrix influences the accuracy (it worsens when the size grows).

Tables VI, VII, VIII, IX, illustrate the speedup for the VWZ and LU factorizations in MATLAB (both R2008 and R2010) relative to the sequential WZ factorization. The first column shows the speedup of VWZ, the second — the speedup of the LU factorization and the third — the speed of the standard MATLAB function `lu` — all relative to the sequential WZ factorization.

Based on these results, we can conclude that various implementations of the WZ factorization give different performance. Namely, VWZ is even about 4 times faster then the sequential WZ (on the AMD processor; on the Intel processor the speedup is only about 2). The LU factorization implemented by the authors is the slowest of all the tested implementations. However, the standard MATLAB function `lu` is the fastest — this function implements a block LU factorization, which makes the processor architecture is better utilized.

V. CONCLUSION

In this paper we did some performance analysis of a MATLAB implementations of the WZ factorization. We examined a sequential implementation of the WZ factorization. We also implemented in MATLAB a vector version of the WZ factorization (VWZ) — to avoid loops. We compared these implementations with two versions of the LU factorization — our MATLAB implementation and a standard MATLAB function `[L,U]=lu(A)`.

From the results we can conclude that the reduction of the number of nested loops in the original WZ factorization increased the speed even four times. The sequential WZ factorization is faster than the sequential LU factorization. Of course, the fastest of the implementation is the built-in MATLAB function `lu` — which utilizes LAPACK block factorization [1].

The implementation and the architecture had no impact on the accuracy of the factorization — the accuracy depended only on the size of the matrix what is quite self-evident.

The version of MATLAB has no significant influence on neither the performance time nor the speedup — only the architecture and the size of the matrix count.

VI. FUTURE WORK

To accelerate the WZ factorization, it would be desirable to build a block algorithm for the WZ factorization and to utilize parallelism — especially for the machines with many processing units.

***Abstract*—In this paper we present two algorithms for performing sparse matrix-dense vector multiplication (known as SpMV operation). We show parallel (*multicore*) version of algorithm, which can be efficiently implemented on the contemporary multicore architectures. Next, we show distributed (so-called *multinodal*) version targeted at high performance clusters. Both versions are thoroughly tested using different architectures, compiler tools and sparse matrices of different sizes. Considered matrices comes from The University of Florida Sparse Matrix Collection. The performance of the algorithms is compared to the performance of SpMV routine from widely used Intel Math Kernel Library.**

Keywords: sparse matrix-dense vector multiplication, SpMV operation, parallel matrix-vector multiplication, multicore platforms, computer cluster.

I. Introduction

IN THIS paper we consider multiplication of a sparse matrix by a dense vector, which is called SpMV operation. This operation is fundamental part of many numerical algorithms [4], [8]. In particular SpMV is used for iterative solving of systems of linear equations, e.g. in projective GMRES method or CG method.

Given a $n \times n$ square, sparse matrix $\mathbf{A}$ and a dense vector $\mathbf{x}$ of dimension n we define operation SpMV as

$$\mathbf{y} \leftarrow \mathbf{A}\mathbf{x}.$$

Let us denote ith row of matrix $\mathbf{A}$ by $\mathbf{A}(i, 1 : n)$. Then, to compute ith element of vector $\mathbf{y}$, we have to compute the dot product of $\mathbf{A}(i, 1 : n)$ and $\mathbf{x}$ vectors. So the whole operation of computing $\mathbf{y}$ vector can be easy parallelized, since the computations of all resulting elements are independent. Hence SpMV operation can be treated as n distinct tasks, which have ith row of $\mathbf{A}$ and $\mathbf{x}$ as a input data and produce ith element of $\mathbf{y}$. Note that $\mathbf{x}$ is shared between all computing tasks.

In the paper [11] authors focus on SpMV operation in the case of multicore platforms. They survey some low level optimization techniques related to hardware properties, while using CSR format for storing sparse matrices. All techniques are then benchmarked on a few multicore environments.

In the article [12] authors show a new format suitable for multicore architectures, which they call *Compressed Sparse Block* (*CSB*). It allows effective storage and efficient computations. It also uses special optimizations in the case of multiplication of banded matrices.

The aim of this paper is to present our research on the efficient implementation of a sparse matrix by a dense vector multiplication with the use of contemporary parallel multicore and distributed computer architectures to gain high performance at low cost.

We propose a parallel SpMV algorithm based on modified SPARSKIT library routine [9] targeted at multicore platforms. We investigate the performance of this algorithm using various architectures, compilers and a few sparse matrices, which arises in real life problems. These matrices comes from The University of Florida Sparse Matrix Collection [3]. We include optimized SpMV routine from Intel Math Kernel Library [5] in the comparison.

Next we introduce a distributed algorithm for computing SpMV on computer clusters consisting of multiple nodes. Our universal approach allows to use any existing SpMV implementation locally within one node. For performance comparison we use the same set of sparse matrices as previously.

The paper is structured as follows. Section II describes data structures suitable for representing sparse matrices and their usability for the implementation of SpMV operation. Next section contains short description of standard, sequential SpMV algorithm. In Section IV we present multicore version of existing SPARSKIT SpMV routine. The description of SpMV algorithm for distributed environments is included in Section V. Then we present some numerical results and concluding remarks in sections VI and VII respectively.

II. Storage formats for sparse matrices

Special data structures and algorithms are used for storing sparse matrices (for efficient memory usage) and performing basic mathematical operations. The survey of many storage formats can be found in [8]. Note, that the same formats are used in algorithms designed for sequential and parallel architectures. However, due to different properties of these architectures, different formats may be preferred in each case.

$$data = \begin{bmatrix} -4 & 1 & -1 & 8 & 5 & -1 & 31 & 21 & -1 & -8 \end{bmatrix}$$
$$col = \begin{bmatrix} 0 & 4 & 1 & 3 & 3 & 0 & 1 & 3 & 4 & 4 \end{bmatrix}$$
$$row = \begin{bmatrix} 0 & 0 & 1 & 1 & 2 & 3 & 3 & 3 & 3 & 4 \end{bmatrix}$$

Fig. 2. Matrix from Fig. 1 stored in COO format

Below we shortly present three widely used formats for storage of sparse matrices. Fig. 1 shows square, sparse matrix of dimension 5 stored in dense format, which, from the programmers point of view, is equivalent to using one two-dimensional array.

A. Coordinate Format (COO)

The simplest and the most flexible format for storing any sparse matrix is so-called *Coordinate Format* or *COO* for short. In this format, only nonzero values are stored, together with rows and columns indexes. Technically, it uses three one-dimensional arrays:

- $data$ for storing nonzero elements,
- col for storing indexes of columns of nonzero elements in the original matrix,
- row for storing indexes of rows of nonzero elements in the original matrix.

On Fig. 2 we see COO storage scheme for the matrix from Fig. 1. Unfortunately, there are some disadvantages of this format, namely it is not memory and computationally efficient (especially in the case of SpMV operation). Note that MATLAB software uses this format [6].

B. Matrix Market Format (MM)

The University of Florida Sparse Matrix Collection [3] is large repository of sparse matrices, which comes from real life applications. It uses Matrix Market format (*MM*) for storing sparse matrices. This format is based on COO with some optimizations added, e.g. it can store only the half of the matrix, in case it is symmetric [7].

C. Compressed Sparse Row Format (CSR)

Another way to store sparse matrix is to use *Compressed Sparse Row* format (*CSR*). As in the case of COO, only the nonzero elements are stored and their columns indexes, while the rows indexes are kept in somewhat different way. There are also three one-dimensional arrays used:

- $data$ which keeps nonzero elements,
- col which keeps indexes of columns of nonzero elements in the original matrix,

$$data = \begin{bmatrix} -4 & 1 & -1 & 8 & 5 & -1 & 31 & 21 & -1 & -8 \end{bmatrix}$$
$$col = \begin{bmatrix} 0 & 4 & 1 & 3 & 3 & 0 & 1 & 3 & 4 & 4 \end{bmatrix}$$
$$ptr = \begin{bmatrix} 0 & 2 & 4 & 5 & 9 & 10 \end{bmatrix}$$

Fig. 3. Matrix from Fig. 1 stored in CSR format

```
      do 100 i = 1,n
         t = 0.0d0
         do 99 k=ptr(i), ptr(i+1)-1
            t = t + data(k)*x(col(k))
 99      continue
         y(i) = t
100   continue
```

Fig. 4. Standard implementation of SpMV for CSR storage

- ptr which keeps indexes of the beginnings of the consecutive rows in $data$ array.

Fig. 3 shows sparse matrix stored in CSR format.

III. Sequential SpMV algorithm

CSR is the most common format used, when dealing with applications containing many SpMV operations. Basic, sequential implementation of SpMV is presented on Fig. 4. We assume that `data`, `col` and `ptr` arrays keeps a sparse matrix in CSR format, while `x` is given vector and `y` is the result of the operation.

IV. Multicore SpMV algorithm

SPARSKIT [9] is Fortran library for dealing with sparse matrices. It provides several formats for storing matrices (including CSR) and routines for performing fundamental mathematical operations. There is SpMV routine in this library for matrices stored in the CSR format, however it is strictly sequential, hence it doesn't take advantage of contemporary parallel architectures. We used OpenMP [10] directives for simple and effective parallelization (use of all present CPU cores) of available source code. The modified source code using `omp parallel do` directive is presented on Fig. 5. We will refer to this algorithm as the *multicore algorithm*.

V. Multinodal SpMV algorithm

In this section we present distributed version of SpMV for clusters consisting of multicore nodes, which we will call the *multinodal algorithm*.

Assume that $\mathbf{A} \in \mathbf{R}^{n \times n}$ matrix is divided into p^2 blocks (with possible different dimensions)

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_{00} & \cdots & \mathbf{A}_{0,p-1} \\ \vdots & \ddots & \vdots \\ \mathbf{A}_{p-1,0} & \cdots & \mathbf{A}_{p-1,p-1} \end{bmatrix},$$

```
      subroutine pamux (n, x, y, a,ja,ia)
      real*8  x(*), y(*), a(*)
      integer n, ja(*), ia(*)
      real*8 t
      integer i, k
!$omp parallel do private(t,k)
      do 100 i = 1,n
         t = 0.0d0
         do 99 k=ia(i), ia(i+1)-1
            t = t + a(k)*x(ja(k))
 99      continue
         y(i) = t
100   continue
!$omp end parallel do
      return
      end subroutine pamux
```

Fig. 5. Implementation of SPARSKIT SpMV routine using OpenMP

where $\mathbf{A}_{ij} \in \mathbf{R}^{n_i \times n_j}$ and $\sum_{i=0}^{p-1} n_i = n$. Vectors $\mathbf{x}$ and $\mathbf{y}$ are also divided into p blocks, where $\mathbf{x}_i, \mathbf{y}_i \in \mathbf{R}^{n_i}$. Then

$$\begin{bmatrix} \mathbf{y}_0 \\ \vdots \\ \mathbf{y}_{p-1} \end{bmatrix} \leftarrow \begin{bmatrix} \mathbf{A}_{00} & \dots & \mathbf{A}_{0,p-1} \\ \vdots & \ddots & \vdots \\ \mathbf{A}_{p-1,0} & \dots & \mathbf{A}_{p-1,p-1} \end{bmatrix} \begin{bmatrix} \mathbf{x}_0 \\ \vdots \\ \mathbf{x}_{p-1} \end{bmatrix}$$

and

$$\mathbf{y}_i \leftarrow \sum_{j=0}^{p-1} \mathbf{A}_{ij}\mathbf{x}_j, \qquad i = 0, \dots, p-1. \tag{1}$$

Algorithm 1 describes the multiplication of sparse matrix by dense vector using computer cluster, which has at least p^2 distinct CPUs. The matrix is appropriately distributed between the grid of $p \times p$ tasks denoted by P_{ij}, $0 \le i, j < p$. Algorithm comprises the following steps:

1) sending the data from the first column of tasks to "diagonal" tasks,
2) broadcasting the data columnwise,
3) performing actual computations,
4) performing global reduction.

We assume that each computing task is running on different CPU, however there can be more than one CPU installed in one cluster node.

On figure 6 we see the grid of tasks in the case of dimension 2×2. The grid in the case of 4×4 dimension, together with communication scheme is presented on Fig. 7.

To implement Algorithm 1 we used routines from BLACS (Basic Linear Algebra Communication Subprograms) [1] and MKL (Intel Math Kernel Library) [5] libraries. BLACS routines were used for organizing task grid and transferring data between tasks, while optimized multicore `mkl_dcsrgem` from MKL was used for performing SpMV. The most important part of Fortran implementation of this algorithm is presented on Fig. 8. We used the following variables in the implementation:

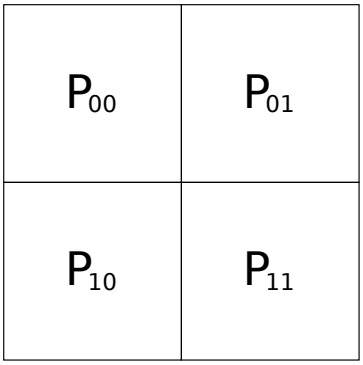

Fig. 6. Task grid of dimension 2×2

- `proc_row`, `proc_col` are coordinates of current task in the task grid,
- arrays `data`, `col`, `ptr` store block $\mathbf{A}_{\texttt{proc\_row,proc\_col}}$ of sparse matrix in CSR format,
- arrays `x` and `y` keep vectors $\mathbf{x}$ and $\mathbf{y}$ respectively,
- `nrows` and `ncols` denotes the number of rows and the number of columns of the $\mathbf{A}_{\texttt{proc\_row,proc\_col}}$ block,
- `context` describes appropriate BLACS context.

Note, that this algorithm is not tied to `mkl_dcsrgem` routine. Instead, it can use implementation from Section IV or any other available code.

VI. Numerical experiments

In this section we review the tests of our SpMV implementations for multicore (Section IV) and distributed (Section V) systems.

A. Data

We used several sparse matrices from The University of Florida Sparse Matrix Collection [3]. All matrices were downloaded in the Matrix Market format and then were converted to CSR format, which was used in all numerical experiments. We present the results for 4 matrices: parabolic_fem, bmw3_2, torso1, nd24k. Detailed parameters are shown in Table I, where we have:

- n is the number of rows and columns,
- nz is the number of nonzero elements,
- $d = nz/n$ denotes the density of the matrix.

Fig. 9 shows the sparsity patterns of these matrices.

Considered matrices were first read from the files and then distributed between all running MPI tasks using BLACS `dgesd2d` routine. We used simple distribution scheme, in which we divided the matrices into the blocks of almost the same sizes.

Note, that instead of reading data from files it is possible to generate matrices locally in each node.

B. Test environment

We used two hardware platforms for testing: E5-2660 and X5650. Their specifications are presented in Table II.

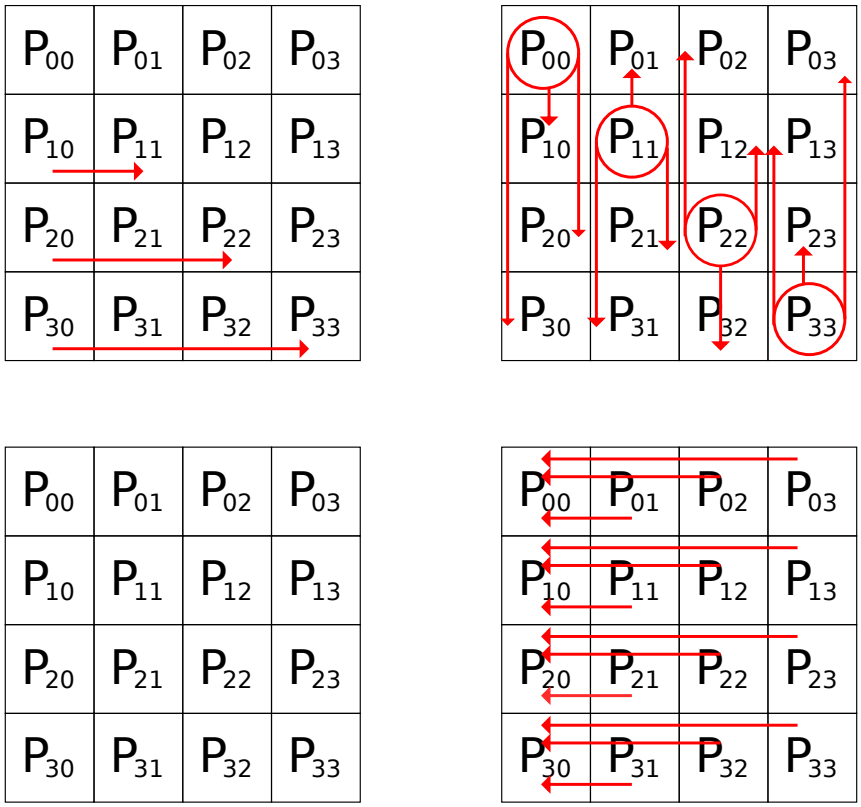

Fig. 7. Communication scheme for the 4×4 task grid: 1) sending the data from the first column of tasks to "diagonal" tasks (top left), 2) broadcasting the data columnwise (top right), 3) performing actual computations (no communication, bottom left), 4) performing global reduction (bottom right)

```
! step 1) sending the data to "diagonal" tasks
   if ((proc_col.eq.0).and.(proc_row.ne.0)) then
      call dgesd2d(context, nrows, 1, y, 1, proc_row, proc_row)
   else
      if ((proc_row.eq.proc_col).and.(proc_row.ne.0)) then
         call dgerv2d(context, nrows, 1, x, 1, proc_row, 0)
      end if
   end if

! step 2) broadcasting the data columnwise
   if (proc_row.eq.pcol) then
      call dgebs2d(context, 'C', ' ', ncols, 1, x, 1)
   else
      call dgebr2d(context, 'C', ' ', ncols, 1, x, 1, proc_col, proc_col)
   end if

! step 3) performing actual computations
   call mkl_dcsrgemv('N', nrows, data, col, ptr, x, y)

! step 4) performing global reduction
   call dgsum2d(context, 'R', ' ', nrows, 1, y, 1, proc_row, 0)
```

nd24k	72000	28715634	398.83	non-symmetric

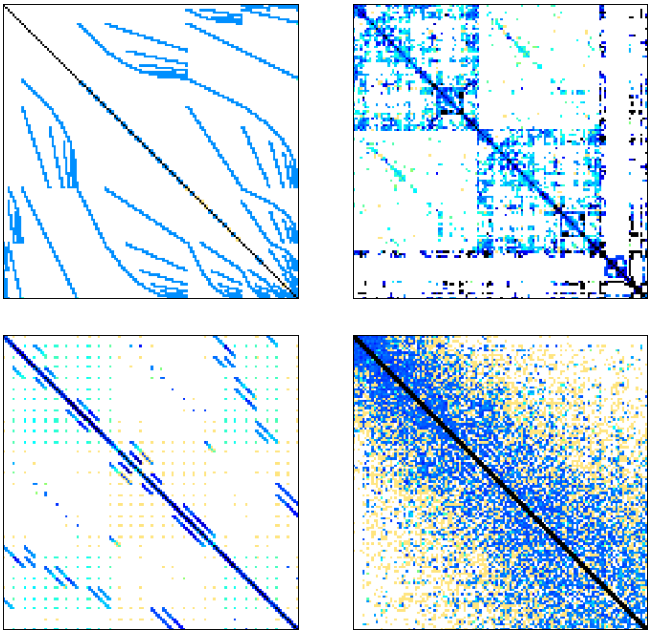

Fig. 9. Sparsity patterns of parabolic_fem (top left), bmw3_2 (top right), torso1 (bottom left) and nd24k (bottom right) matrices

Our algorithms were implemented in Fortran 95 using appropriate parallel and numerical libraries (OpenMP, MPI, SPARSKIT, MKL). Two Fortran compilers, namely `ifort` by Intel and `pgfortran` by The Portland Group, were used for compiling source codes with compiler flags, which are shown in Table III.

For time measurement we used the following routines:

- `omp_get_wtime()` for the multicore version,
- `MPI_Wtime()` in the multinodal case.

C. Results for multicore algorithm

On figures 10, 11, 12 and 13 we see the performance (in Gflops) of the multicore version of SpMV multiplication. The performance is shown for two platforms (X5650, E5-2660), two compilers (Intel, pgi), and we also include the performance chart of SpMV routine from Intel MKL library optimized for multicore CPUs (denoted by mkl).

Using obtained results we conclude that:

- For small number of running threads the performance is similar in each case.
- For growing number of threads E5-2660 architecture outperforms X5650, due to its older architecture. We were expecting this result.
- Compiler version has negligible impact on the performance of the algorithms, however there is a drop in the performance in the case of `pgfortran` dealing with large number of threads.
- Simple SPARSKIT implementation with OpenMP directives (Fig. 5) gives as good performance as the optimized MKL version of SpMV.

TABLE IV
PERFORMANCE (GFLOPS) OF THE MULTINODAL SPMV ALGORITHM

matrix	1 task	4 tasks	16 tasks
parabolic_fem	1.91	0.31	0.41
bmw3_2	2.69	2.02	3.05
torso1	3.12	4.49	8.25
nd24k	3.31	4.39	12.00

D. Results for multinodal algorithm

Table IV shows the performance of our multinodal SpMV implementation (Algorithm 1). In the column denoted by "1 task" we see the performance of the multicore version compiled by `ifort` with MKL support and running on X5650 system. Multinodal version was compiled using `mpiifort` compiler and was running on cluster consisting of 2 or 8 X5650 nodes, connected using 40Gbit/s Infiniband. To optimize the workload of each node we used the following number of MPI tasks:

- 4 tasks were running on 2 nodes with 4 CPUs (as in Fig. 6),
- 16 tasks were running on 8 nodes with 16 CPUs (as in Fig. 7).

Each MPI task was using multithreaded version of SpMV from MKL.

Looking at Table IV we see, that:

- there are cases, when the algorithm achieves very high scalability (e.g. nd24k matrix)
- for some matrices (e.g. parabolic_fem), the performance decreases,

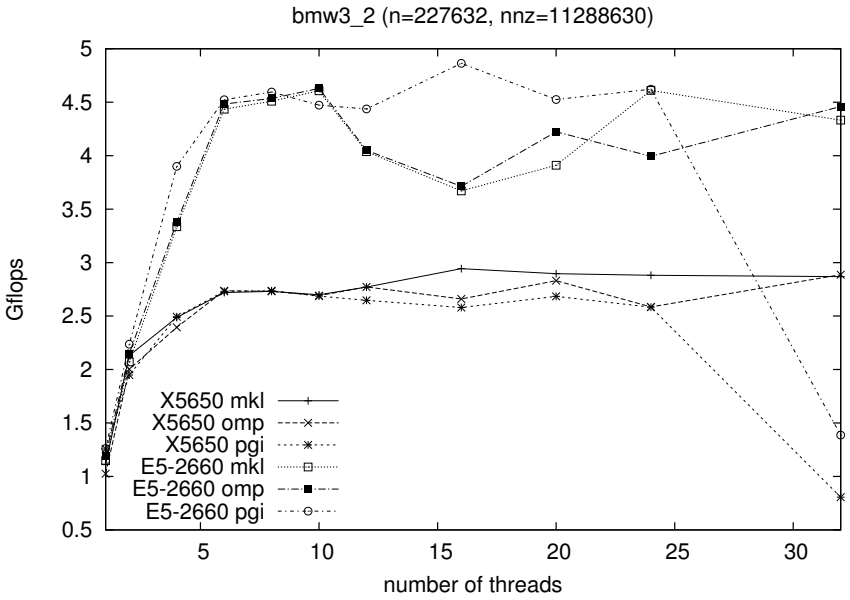

Fig. 11. The performance of SpMV operation for bmw3_2 matrix

- the scalability of the algorithm is related to the distribution scheme and to the matrix properties, especially to its density — sparser the matrix, worse the scalability. Table V shows the division of torso1 and parabolic_fem matrices in the case of 4 tasks. We see, that the densities of the resulting blocks are smaller than the densities of whole matrices (showed in the Table I). Notice, that for parabolic_fem matrix there is a block with no nonzero elements, hence one of the nodes stay idle. The situation is even worse, when we consider 16 tasks division. Looking at Table VI we see, that there are 6 empty blocks for parabolic_fem matrix and the densities of the rest of them are very low.

VII. Conclusion and future work

In this work we investigated the parallelization of SpMV operation, an important and highly-demanding numerical kernel used in many numerical methods. We compared various implementations, namely routine from MKL library, OpenMP parallelized SPARSKIT version compiled using two compilers and two architectures and our own distributed version. The results show, that the most important factor of achieving high performance is hardware architecture together with the distribution pattern and the properties of sparse matrices. It is worth to note, that it is possible to further optimize multinodal implementation (Algorithm 1) by distributing blocks of matrices between nodes taking into account the original matrix density to obtain balanced workload of each MPI task.

Another way to speed up computations is to use GPU cards or MIC architecture accelerators instead of CPUs.

***Abstract*—This work presents a parallel implementation of the Parareal method using Portable Extensible Toolkit for Scientific Computation (PETSc). An optimal control problem of a parabolic partial differential equation with known boundary conditions and initial state is solved, where the minimized cost function relates the controller v usage and the approximation of the solution y to an optimal known function y^*, measured by $\|y\|$ and $\|y^*\|$, respectively. The equations that model the process are discretized in space using Finite Elements and in time using Finite Differences. After the discretizations, the problem is transformed to a large linear system of algebraic equations, that is solved by the Conjugate Gradient method. A Parareal preconditioner is implemented to speed up the convergence of the Conjugate Gradient.**

The main advantage in using the Parareal approach is to speed up the resolution time, when comparing to implementations that use only the Conjugate Gradient or GMRES methods. The implementation developed in this work offers a parallelization relative efficiency for the strong scaling of approximately 70% each time the process count doubles. For weak scaling, 75% each time the process count doubles for a constant solution size per process and 96% each time the process count doubles for a constant data size per process.

I. Introduction

MANY challenges of engineering design, such as heat dissipation, electromagnetic inversion, diffraction tomography among others, can be modeled as a parabolic optimal control problem [1]. The problem to be solved is [2, 3]:

$$\begin{cases} minimize & J(y,v) \\ s.t. & \nabla_t y = \Delta_x y + v\,, \end{cases} \tag{1}$$

with [3]

$$J(y,v) = \frac{\alpha}{2}\int_\Omega\int_{t_0}^{t_f} \|y-y^*\|_2^2 dtdx + \frac{\beta}{2}\int_\Omega \|y(t_f)-y^*(t_f)\|_2^2 dx + \frac{\gamma}{2}\int_\Omega\int_{t_0}^{t_f}\|v\|_2^2 dtdx\,, \tag{2}$$

where y^* is the optimal condition for the function y, α is the weight for the general approximation of the function y, β is the weight for the approximation at the final instant of the function y and γ gives the cost of the controller usage.

The finite elements discretization using the Galerkin method yields the following state equation [4, 5]:

$$M\dot{\underline{z}} = K\underline{z} + B\underline{u} \tag{3}$$

where $\underline{z} \in \mathbb{R}^{\hat{q}}$ is the nodal representation of y, $\underline{u} \in \mathbb{R}^{\hat{p}}$ is the nodal representation of v, M is the mass matrix, K is the stiffness matrix and B is the coupling matrix. Using this discretization, the cost function (2) becomes:

$$J_h(\underline{z},\underline{u}) = \frac{\alpha}{2}\int_{t_0}^{t_f}(\underline{z}-\underline{z}^*)^T M(\underline{z}-\underline{z}^*)\,dt + \frac{\beta}{2}\left\{[\underline{z}(t_f)-\underline{z}^*(t_f)]^T M[\underline{z}(t_f)-\underline{z}^*(t_f)]\right\} + \frac{\gamma}{2}\int_{t_0}^{t_f}\underline{u}^T R\underline{u}\,dt \tag{4}$$

where $\underline{z}^*$ is the nodal representation of y^* and R is the controller's mass matrix.

The finite differences discretization, using a time interval τ with $\hat{l}$ time instants, is based on equation [4]:

$$F_1\underline{z}(i+1) = F_0\underline{z}(i) + \tau B\underline{u}(i+1);\ \text{for } 0 < i < \hat{l} \quad \text{and } \underline{z}(0) = y_0 \tag{5}$$

where $F_0, F_1 \in \mathbb{R}^{\hat{q}\times\hat{q}}$ are matrices defined by $F_0 = M$ and $F_1 = M + \tau K$. The arrangement of equation (3) for all times yield:

$$\mathbf{Ez} + \mathbf{Nu} = \mathbf{f}_3 \tag{6}$$

where $\mathbf{z} \in R^{\hat{l}\hat{q}}$ and $\mathbf{u} \in R^{\hat{l}\hat{p}}$. With a similar argument, equation (4) has the following form:

$$J_h^\tau(\mathbf{z},\mathbf{u}) = \frac{1}{2}(\mathbf{z}-\mathbf{z}^*)^T\mathbf{Q}(\mathbf{z}-\mathbf{z}^*) + \frac{1}{2}\mathbf{u}^T\mathbf{G}\mathbf{u} + (\mathbf{z}-\mathbf{z}^*)^T\mathbf{g}. \tag{7}$$

Using Lagrange multipliers [6] for minimizing equation (7) subject to equality constraint (6) and imposing first order optimality conditions [7, 8, 9], the following KKT system [3] with saddle point form [10] is obtained [2, 4, 11]:

$$\begin{bmatrix} \mathbf{Q} & 0 & \mathbf{E}^T \\ 0 & \mathbf{G} & \mathbf{N}^T \\ \mathbf{E} & \mathbf{N} & 0 \end{bmatrix}\begin{bmatrix} \mathbf{z} \\ \mathbf{u} \\ \mathbf{q} \end{bmatrix} = \begin{bmatrix} \mathbf{f}_1 \\ \mathbf{0} \\ \mathbf{f}_3 \end{bmatrix} \tag{8}$$

978-83-60810-58-3/$25.00

A. Schur's Equation

In order to simplify the linear system (8), the variables $\mathbf{z}$ and $\mathbf{q}$ are solved in terms of the control variable $\mathbf{u}$ [12, 4, 10, 13]. Making $\mathbf{z} = \mathbf{E}^{-1}\mathbf{f}_3 - \mathbf{E}^{-1}\mathbf{N}\mathbf{u}$, $\mathbf{q} = \mathbf{E}^{-T}\mathbf{f}_1 - \mathbf{E}^{-T}\mathbf{Q}\mathbf{z}$, and substituting on the final equation from (8), gives [13, 14, 15]:

$$\mathbf{H}\mathbf{u} = \mathbf{f} \tag{9}$$

where $\mathbf{H} = \mathbf{G} + \mathbf{N}^T\mathbf{E}^{-T}\mathbf{Q}\mathbf{E}^{-1}\mathbf{N}$ and $\mathbf{f} = \mathbf{N}^T\mathbf{E}^{-T}(\mathbf{Q}\mathbf{E}^{-1}\mathbf{f}_3 - \mathbf{f}_1)$. [1]

Doing this, the reduced Schur Complement [16, 14] Doing this, the equation system (8) is reduced. This expression is known as the Schur complement for equation (8) [16].

From this point on, the problem to solve is (9), a linear equation system, lets say $Ax = b$ for a general form, where the matrix A (in this case matrix $\mathbf{H}$ from equation (9)) is symmetric positive definite [10, 7, 4].

II. Mathematical Solution Formulation

A. Conjugate Gradient

The Conjugate Gradient method is used to solve a generic equation $Ax = b$ where $A \in \mathbb{R}^{\tilde{n}\times\tilde{n}}$ is symmetric positive definite and $b \in \mathbb{R}^{\tilde{n}}$.

On this work, the iterative algorithm defined in [17] is applied to the input matrix A and vector b, with error tolerance ε, initial guess x_0 and iteration limit for convergence max_i, as follows:

Algorithm 1 Conjugate Gradient

Input: $A, b, \varepsilon, x_0, max_i$
Output: x

1: $r_0 \leftarrow b - Ax_0$
2: $p_0 \leftarrow r_0$
3: $i \leftarrow 0$
4: **while** $r_{i+1} \geq \varepsilon \wedge i < max_i$ **do**
5: $\quad \alpha_i \leftarrow \frac{r_i^T r_i}{p_i^T A p_i}$ ▷ In our implementation, Ap_i is calculated by Algorithm 2
6: $\quad x_{i+1} \leftarrow x_i + \alpha_i p_i$
7: $\quad r_{i+1} \leftarrow r_i - \alpha_i A p_i$ ▷ In our implementation, Ap_i is calculated by Algorithm 2
8: $\quad \beta_i \leftarrow \frac{r_{i+1}^T r_i}{r_i^T r_i}$
9: $\quad p_{i+1} \leftarrow r_{i+1} + \beta_i p_i$
10: $\quad i \leftarrow i + 1$
11: **end while**
12: **if** $r_{i+1} < \epsilon$ **then**
13: $\quad$ **return** x_i ▷ Convergent
14: **else**
15: $\quad$ **return** $n.c.$ ▷ Not convergent
16: **end if**

[1] Recall that $\mathbf{u}, \mathbf{b} \in \mathbb{R}^{\hat{l}\hat{p}}$, $\mathbf{H}, \mathbf{G} \in \mathbb{R}^{\hat{l}\hat{p}\times\hat{l}\hat{p}}$, $\mathbf{N} \in \mathbb{R}^{\hat{l}\hat{q}\times\hat{l}\hat{p}}$ and $\mathbf{E}, \mathbf{Q} \in \mathbb{R}^{\hat{l}\hat{q}\times\hat{l}\hat{q}}$.

B. Using the Conjugate Gradient

In order to use Algorithm 1, the input matrix $\mathbf{H}$ must be previously computed, which requires a great computational work [5]. To avoid building matrix $\mathbf{H}$, steps 5) and 7) from Algorithm 1 are performed using Algorithm 2.

Let $\mathbf{s}$ be a generic input vector, and matrices $\mathbf{G}, \mathbf{N}, \mathbf{E}$ and $\mathbf{Q}$ as defined in Section I. The value of the product $\mathbf{H}\mathbf{s}$ is found using only matrix-vector operations, to avoid matrix-matrix operations that require more computational resources [18]. Algorithm 2 describes these matrix-vector operations [7].

Algorithm 2 Matrix-Vector Product $\mathbf{H}\mathbf{s}$

Input: $\mathbf{G}, \mathbf{N}, \mathbf{E}, \mathbf{Q}, \mathbf{s}$
Output: $\mathbf{x}$ ▷ $\mathbf{x} = \mathbf{H}\mathbf{s} = \mathbf{G}\mathbf{s} + \mathbf{N}^T\mathbf{E}^{-T}\mathbf{Q}\mathbf{E}^{-1}\mathbf{N}\mathbf{s}$

1: $\mathbf{s}_1 \leftarrow \mathbf{G}\mathbf{s}$
2: $\mathbf{s}_2 \leftarrow \mathbf{N}\mathbf{s}$
3: $\mathbf{s}_3 \leftarrow \mathbf{E}^{-1}\mathbf{s}_2$ ▷ $\mathbf{E}\mathbf{s}_3 = \mathbf{N}\mathbf{s}$, in our implementation, solved by Algorithm 4
4: $\mathbf{s}_4 \leftarrow \mathbf{Q}\mathbf{s}_3$ ▷ $\mathbf{s}_4 = \mathbf{Q}\mathbf{E}^{-1}\mathbf{s}_2$
5: $\mathbf{s}_5 \leftarrow \mathbf{E}^{-T}\mathbf{s}_4$ ▷ $\mathbf{E}^T\mathbf{s}_5 = \mathbf{Q}\mathbf{s}_3$, in our implementation, solved by Algorithm 4
6: $\mathbf{x} \leftarrow \mathbf{s}_1 + \mathbf{N}^T\mathbf{s}_5$ ▷ $\mathbf{x} = \mathbf{G}\mathbf{s} + \mathbf{N}^T\mathbf{s}_5$

The direct implementation of Algorithm 2 can be unviable since steps 3) and 5) require inverse matrices [7]. To avoid this, the steps 3) and 5) from the Algorithm 2 can be solved using an inner Conjugate Gradient. This step will have a high computational cost because it will be done for each iteration of the outer Conjugate Gradient.

The idea is to replace steps 3) and 5) from Algorithm 2 using the Parareal method [7].

C. Parareal

The Parareal method [19, 9] is an iterative method used to solve a time dependant equation, based on a time domain decomposition $[t_0, t_f]$ in $\hat{k}$ *coarse* time intervals, each of size $\Delta T = (t_f - t_0)/\hat{k}$, with $T_0 = t_0$ and $T_k = t_0 + k\Delta T$ for $1 \leq k \leq \hat{k}$. This sets the solution for each instant T_k with $1 \leq k \leq \hat{k}$ using the *multiple-shooting* technique [20, 21] that requires the parallel resolution of the equation $\mathbf{z} = \mathbf{E}^{-1}\mathbf{b}$ for each (T_{k-1}, T_k) subinterval. To accelerate each multiple-shooting iteration, the residual equations are preconditioned by a coarse time grid discretization, with a time interval ΔT [7].

An approximation $\mathbf{E}_n^{-1}$ for $\mathbf{E}^{-1}$, is based on n Richardson's iterations [22], through the Parareal algorithm, where the Richardson's algorithm is used as an external iteration for a Schur's complement problem [7, 16, 23]. The matrix $\mathbf{E}_n$ is used to approximate the solution $\mathbf{z}$ by $\mathbf{z}_n = \mathbf{E}_n^{-1}\mathbf{b}$, and the main interest is that $\mathbf{z}_n = \mathbf{E}_n^{-1}\mathbf{b}$ and $\mathbf{z}_n \to \mathbf{z}$ as $n \to \infty$, in practical situations n is bounded [4].

Let $\hat{m} = (T_k - T_{k-1})/\tau$, $j_{k-1} = (T_{k-1} - T_0)/\tau$ and Z_k be the solution for the instant T_k, defined by solving from time T_{k-1} to T_k using the Finite Difference discretization scheme on the fine grid [24] (for each time instant, of size τ) with initial values Z_{k-1} in T_{k-1} and right hand side vector

$\mathbf{b} = [\underline{b}(j_{k-1}+1)^T, \ldots, \underline{b}(j_{k-1}+\hat{m})^T]^T$. The solution of each coarse interval is given by:

$$F_1 \otimes Z_k = F_0^{\Delta} \otimes Z_{k-1} + S_k \tag{10}$$

where, $\otimes$ represents the Kronecker product [25], $F_0^{\Delta} = (F_0 F_1^{-1})^{\hat{m}-1} F_0 \in \mathbb{R}^{\hat{q}\times\hat{q}}$, $Z_0 = 0$, the matrices F_0 y F_1 as set in (5) and

$$S_k = \sum_{m=1}^{\hat{m}} (F_1^{-1}F_0)^{\hat{m}-m}[F_0 Z_{k-1} - \underline{b}(j_{k-1}+m)] \tag{11}$$

Imposing continuity, $F_1 \otimes Z_k - F_0^{\Delta} \otimes Z_{k-1} - S_k = 0$ on the instants T_k, for $1 \le k \le \hat{k}$, the system $\mathbf{CZ} = \mathbf{S}$ is obtained [9, 7]:

$$\underbrace{\begin{bmatrix} F_1 & & & \\ -F_0^{\Delta} & F_1 & & \\ & \ddots & \ddots & \\ & & -F_0^{\Delta} & F_1 \end{bmatrix}}_{\mathbf{C}} \underbrace{\begin{bmatrix} Z_1 \\ Z_2 \\ \vdots \\ Z_{\hat{k}} \end{bmatrix}}_{\mathbf{Z}} = \underbrace{\begin{bmatrix} S_1 \\ S_2 \\ \vdots \\ S_{\hat{k}} \end{bmatrix}}_{\mathbf{S}} \tag{12}$$

The case where the coarse solution in T_k with initial data $Z_{k-1} \in \mathbb{R}^{\hat{q}}$ in T_{k-1} is obtained after using a Finite Differences step for the coarse time interval $G_1 Z_k = G_0 Z_{k-1}$ is considered, where the matrices $G_1 = (M + K\Delta T)$ and $G_0 = M \in \mathbb{R}^{\hat{q}\times\hat{q}}$ are defined.

A coarse grid propagator based on G_0 and G_1 is used in the Parareal algorithm to precondition (12) [9]. The coarse grid propagation system $\mathbf{Z}^{i+1} = \mathbf{Z}^i + \mathbf{E}_g^{-1}\mathbf{R}^i$ is defined as:

$$\underbrace{\begin{bmatrix} Z_1^{i+1} \\ Z_2^{i+1} \\ \vdots \\ Z_{\hat{k}}^{i+1} \end{bmatrix}}_{\mathbf{Z}^{i+1}} = \underbrace{\begin{bmatrix} Z_1^{i} \\ Z_2^{i} \\ \vdots \\ Z_{\hat{k}}^{i} \end{bmatrix}}_{\mathbf{Z}^{i}} + \underbrace{\begin{bmatrix} G_1 & & & \\ -G_0 & G_1 & & \\ & \ddots & \ddots & \\ & & -G_0 & G_1 \end{bmatrix}^{-1}}_{\mathbf{E}_g^{-1}} \underbrace{\begin{bmatrix} R_1^{i} \\ R_2^{i} \\ \vdots \\ R_{\hat{k}}^{i} \end{bmatrix}}_{\mathbf{R}^{i}} \tag{13}$$

for $0 \le i \le (n-1)$, where the residue $\mathbf{R}^i = \left[{R_1^i}^T, \ldots, {R_{\hat{k}}^i}^T\right] \in \mathbb{R}^{\hat{k}\hat{q}}$ in (13) is defined as $\mathbf{R}^i = \mathbf{S} - \mathbf{CZ}^i$, where $\mathbf{Z}^i = \left[{Z_1^i}^T, \ldots, {Z_{\hat{k}}^i}^T\right]^T \in \mathbb{R}^{\hat{k}\hat{q}}$ and $\mathbf{Z}^0 = [0^T, \ldots, 0^T]^T$. Each R_j^i vector stands for the i-th iteration of the residue, on the T_j time instant. Likewise, each Z_j^i vector stands for the i-th iteration of the solution, on the T_j time instant.

Now, $\mathbf{z}_n = \mathbf{E}_n^{-1}\mathbf{b}$ is defined. Let $\mathbf{z}_n$ be the nodal representation of a piecewise linear function $\underline{z}^n$ in the time dimension with respect to the fine space discretization parameterized by τ in $[t_0, t_f]$. Because $\mathbf{z}_n \in \mathbb{R}^{(\hat{l}+\hat{k}-1)\hat{q}}$ is continuous in each coarse subinterval $[T_{k-1}, T_k]$, the function $\underline{z}^n$ can be discontinuous on the points T_k, with $1 \le k \le \hat{k}-1$. On each $[T_{k-1}, T_k]$ subinterval, $\underline{z}^n$ is defined by solving from the instant T_{k-1} to the instant T_k using the Finite Differences scheme with fine time intervals τ and initial data Z_{k-1}^n in T_{k-1}. The equation that describes the solution on the fine intervals, starting from a coarse interval is:

$$F_1 \underline{z}^n(i+1) = F_0 \underline{z}^n(i) - \underline{b}(i+1); \text{ for } T_{k-1} \le t < T_k; \text{ y } \underline{z}^n(T_{k-1}) = Z_{k-1}^n. \tag{14}$$

The vector $\mathbf{z}_n$ is obtained computing (14) for $2 \le k \le \hat{k}$. With this algorithm the steps 3) and 5) from Algorithm 2 can be solved, and therefore it can find the product $\mathbf{Hs}$. In the program, the input vector $\mathbf{s}$ for Algorithm 2 will be each vector p_k from Algorithm 1, used on the outer iteration of the Conjugate Gradient.

III. Implementation

The user defines the spatial discretization size $\hat{q}$, the fine time discretization size $\hat{l}$, the coarse time discretization size $\hat{k}$, the initial condition y_0 and the target solution y^*.

To help the convergence rate of the outer Conjugate Gradient, an initial guess $\mathbf{u}_0$ is found through:

$$\mathbf{u}_0 = \mathbf{N}\mathbf{E}^{-T}\mathbf{Q}\mathbf{E}^{-1}\mathbf{f}_3 - \mathbf{N}^T\mathbf{E}^{-T}\mathbf{f}_1\,. \tag{15}$$

The program implemented on this work uses the `main` structure of Algorithm 3.

Algorithm 3 Main

Input: $\hat{q}, \hat{l}, \hat{k}, \hat{m}, y_0, y^*$
Output: $\mathbf{u}$

1: $[M, K, B] = finiteElements(\hat{q}, y_0, y^*)$ ▷ Call to the function that does the space discretization, as described in Section I
2: $[\mathbf{E}, \mathbf{Q}, \mathbf{N}, \mathbf{b}] = fineGrid(M, K, B, \hat{l})$ ▷ Call to the function that does the fine time discretization, as described in Section I
3: $[\mathbf{C}, \mathbf{E}_g] = coarseGrid(M, K, \hat{k}, \hat{m})$ ▷ Call to the function that does the coarse time discretization, as described in Section II-C
4: $[\mathbf{u}_0] = preconditioner(\mathbf{G}, \mathbf{E}, \mathbf{Q}, \mathbf{N}, \mathbf{b})$ ▷ Call to a function that calculates (15)
5: $[\mathbf{u}] = cg(\varepsilon, \mathbf{u}_0, max_i, \hat{k}, \hat{m}, \mathbf{G}, \mathbf{E}, \mathbf{Q}, \mathbf{N}, \mathbf{b}, \mathbf{C}, \mathbf{E}_g)$ ▷ Call to Algorithm 1

With the defined problem data, the finite elements matrices are generated. Next, the matrices of the time discretization are built, and the system (8) can be formulated. The matrices from the time discretization are considered as the fine grid matrices, because they have every time instant from the problem. Afterward, the coarse grid matrices are generated from the finite elements matrices. The coarse grid matrices are needed for the application of the Parareal method, as shown in equations (12) and (13).

With all the matrices created, the Conjugate Gradient method is executed to resolve $\mathbf{Hu} = \mathbf{b}$. On each Conjugate Gradient's iteration i, the product $\mathbf{H}p_i$ must be computed as described in Algorithm 1. To perform the product of matrix $\mathbf{H}$ by a vector, the Algorithm 2 is called. The steps 3) and 5) form Algorithm 2 are solved using the Parareal method. When the product $\mathbf{H}p_i$ is computed, the outer Conjugated Gradient's execution resumes.

For instance, to appreciate the benefits of the Parareal method, consider a space discretization grid with $\hat{q} = 2{\times}2 = 4$ elements, a fine time discretization with $\hat{l} = 10000$ time instants and a coarse time discretization with $\hat{k} = 10$ time instants. As a consequence, each process gets $\hat{m} = 1000$ time instants of the fine grid. For this example, the solution of the system $\mathbf{Ez} = \mathbf{b}$ involves $4 \cdot 10 \cdot 1000 \times 4 \cdot 10 \cdot 1000$ equations and variables, while the approximation $\mathbf{E}_n\mathbf{z}_n = \mathbf{b}$ is a linear system of only $4 \cdot 10 \times 4 \cdot 10$ equations and variables.

IV. Algorithms

The pseudocode of the function used for the Parareal method (Algorithm 4) and its dependences are presented next, given that its implementation is the main contribution of this work. Besides, Algorithm 4 shows how the message passing is managed to maintain a low communication cost among the parallel processes.

The first pseudocode presented corresponds to the Parareal method. The same naming conventions as in Section II-C are used. The input parameters for the `Parareal` function are: the vector $b = \mathbf{b}$, the matrix $E_g = \mathbf{E}_g$, the matrix $C = \mathbf{C}$, the vector of the initial approximated solution Z_0, the coarse intervals count $\hat{k}$, the fine intervals by coarse interval count $\hat{m}$ and the error tolerance ε.

The output of the `Parareal` function is an approximation to $z = \mathbf{z} \leftarrow \mathbf{E}^{-1}\mathbf{b}$ as described on Section II-C. Algorithm 4 calls the functions `fineSolver` (Algorithm 5) and `marching` (Algorithm 6) to be next described in this section.

Algorithm 4 Parareal

Input: $b, E_g, C, \hat{k}, \hat{m}, Z_0, \varepsilon$
Output: y
1: $S \leftarrow fineSolver(b, \hat{k}, \hat{m})$ ▷ Call to Algorithm 5
2: $Z \leftarrow Z_0$
3: $R \leftarrow S$ ▷ $\mathbf{R}^1 \leftarrow \mathbf{S} - \mathbf{CZ}^0$, communication of S^k to the next process
4: **while** $\|r_i\| > \varepsilon$ **do**
5: $coarse \leftarrow E_g^{-1}R$ ▷ $aux \leftarrow \mathbf{E}_g^{-1}\mathbf{R}^i$
6: $Z \leftarrow Z + coarse$ ▷ $\mathbf{Z}^{i+1} \leftarrow \mathbf{Z}^i + aux$
7: $R \leftarrow S - C \times Z$ ▷ $\mathbf{R}^{i+1} \leftarrow \mathbf{S} - \mathbf{CZ}^i$
8: **end while**
9: $y \leftarrow marching(b, x_{i-1}, \hat{k}, \hat{m})$ ▷ Call to Algorithm 6
10: **return** y

Algorithm 5 shows how the jumps vector $\mathbf{S}$ is generated according to equation (11), that saves only the final elements of the coarse time interval.

Algorithm 5 fineSolver

Input: $b, \hat{k}, \hat{m}$
Output: S
1: **for all** $k < \hat{k}$ **do** ▷ parallel loop, distributed in $\hat{k}$ processes
2: $s \leftarrow \vec{0}$
3: **for all** $i < \hat{m}$ **do** ▷ local loop, calculated on each process
4: $s \leftarrow F_1^{-1}(F_0 s - b(k,i))$ ▷ Equation (10)
5: **end for**
6: $S(k) = s$
7: **end for**
8: **return** S

With this information the iterative loop of the Parareal algorithm is performed, the loop computes vector $\mathbf{Z}^i$ iteratively, as indicated in equation (13), until the solution of the coarse grid $\mathbf{Z}^n$ is found, when the required tolerance is reached.

After finding the coarse solution, the function `marching` is called, so that each process can extend its initial coarse solution to their own fine time intervals $\underline{z}^n$. Joining the solution of every process, the approximated general solution $\mathbf{z}_n$ is found.

Algorithm 6 marching

Input: $b, coarse, \hat{k}, \hat{m}$
Output: y
1: **for all** $k < \hat{k}$ **do** ▷ parallel loop, distributed in $\hat{k}$ processes
2: $z \leftarrow coarse(k)$
3: **for all** $i < \hat{m}$ **do** ▷ local loop, calculated on each process
4: $z \leftarrow F_1^{-1}(F_0 z - b(i,k))$ ▷ Equation (14)
5: $y(k,i) = z_i$
6: **end for**
7: **end for**
8: **return** y

The functions `fineSolver` and `marching` are similar, because both solve the problem on the coarse time intervals. The `fineSolver` function finds its fine grid solution to calculate the final coarse instants (used as a preconditioner for the Parareal). The function `marching` finds the fine grid solution given an initial condition $\mathbf{Z}^n$ (the coarse grid solution), to complete the global solution.

As it was mentioned previously, some special attention is needed when a process requires some data that belongs to another process. The algorithms were designed to reduce the data communication between processes. With the proposed solution, the data communication between processes is needed only on the `Parareal` function, when the coarse data grid is propagated according to equation (13). Next, the experimental results of the implementation are presented.

V. Numerical experiments

The results of the experiments using the implementation of the Parareal method are presented in this Section. The experiments are based on the reference paper [7], used for validation.

The hardware used is a cluster of four Dell PowerEdge R710 nodes, with 2 processors of 4 cores Intel Xeon E5530 of 2.4GHz, Intel 5530 chipset, 8GB DDR3 of 1066 MHz RAM memory, connected in a Giga-Ethernet (1Gbps) LAN, as shown in Figure 1.

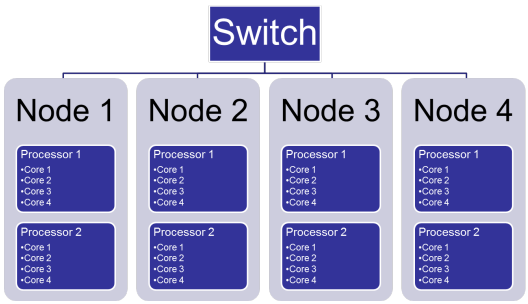

Fig. 1. Experimental platform

In this set of experiments, there are at most 4 nodes used and, for simplicity, only the first processor of each node is used. Therefore, only 4 cores per node are used.

A. Definitions

The optimal control problem to be solved for the experiments is given by the following 2D heat equation:

$$\begin{cases} z_t - z_{xx} = v, & x \in \Omega, \quad 0 < t \\ z(t,0) = 0, & x \in \partial\Omega, \quad 0 \leq t \\ z(0,x) = 0, & x \in \partial\Omega\,, \end{cases} \tag{16}$$

where $\Omega = [0,1] \times [0,1]$. The selected target function is $y^*(x_1,x_2) = x_1(1-x_1)e^{-x_1}x_2(1-x_2)e^{-x_2}$ for $t \in [0,1]$. The selected problem, the problem sizes and considerations are used as in the reference paper [7].

As naming conventions for the experiments, pCG(n,p) represents the execution of the modified Conjugate Gradient, using the Parareal method, for n nodes, each with p parallel processes. In all the experiments, a single process is run in each core. Times values are shown in seconds for all tables.

For each comparative table all tests are remade, so there may be some time differences in different tables that run the same setup of pCG(n,p). Those differences are unavoidable [26], but the variations are small in general, so they are acceptable anyway.

It should be mentioned that in the conducted experiments, the peak FLOPS / average FLOPS ratio [27] was not larger than 1.06 in any experiment.

B. Validation

The implementation of the pCG(n,p) of this work is compared to the reference work (IFOM) [7]. As [7] is a theoretical work about Parareal, there is no execution time; on the contrary, there are only data about the required iterations needed for the resolution of the problems. The values of Table I are given in the format $iter_e(iter_i)$, where $iter_e$ is the external iteration count (Conjugate Gradient) and $iter_i$ is the inner iteration count (Parareal).

TABLE I
Comparision of iterations of [7]'s implementation and our implementation pCG(n,p), for inner tolerance values ε_i, outer tolerance $\varepsilon_o = 10^{-6}$, $\alpha = 1$, $\beta = 12$, $\gamma = 10^{-5}$, inner grid size 13×13, $\tau = 1/512$, $\hat{k} = 32$, $\Delta T/\tau = 16$ and $n.c.$ means that the system does not converge in 100 iterations.

ε_i	IFOM	pCG$(1,p)$		
		$p=1$	$p=2$	$p=4$
10^{-12}	16(586)	16(586)	16(580)	16(578)
10^{-10}	17(510)	17(510)	17(502)	17(504)
10^{-8}	18(442)	18(442)	18(414)	18(424)
10^{-7}	18(362)	18(362)	18(364)	20(404)
10^{-6}	21(338)	21(338)	21(342)	19(340)
10^{-5}	24(274)	24(274)	24(280)	n.c.
10^{-4}	28(220)	28(220)	63(312)	43(258)

Table I shows that the iteration count obtained through the implementation of pCG$(1,1)$ is consistent with the theoretical results expected from [7]. Some other tests were also made, which compare the solutions u_{IFOM} of IFOM and u_{pCG} of pCG(n,p), and the error $\epsilon = \|u_{IFOM} - u_{pCG}\|/\|u_{IFOM}\|$ was smaller than 10^{-6} on all the cases. Furthermore, checking the execution of the Parareal solver on pCG$(1,1)$, the error of each iteration's result was less than 10^{-6}.

C. Efficiency

The following concepts are used for the efficiency analysis of the implementation. *Strong Scaling* is defined as the variation of the resolution time as the number of processes changes, while having a fixed problem size[2] [28]. *Weak Scaling* is defined as the variation of the resolution time as the number of processes changes, while having a fixed problem size per process[3] and therefore, the problem size is proportional to the number of processes [28].

The product $c = n \cdot p$ represents the total processes used, remembering that n is the amount of nodes used and p is the amount of processes run per node. Considering the strong scaling, an increase in the number of processes c, decreases the problem size in each process. Conversely, considering the weak scaling, an increase in the number of processes c, increases the total problem size.

A well recognized metric used to describe the scaling of a program is the parallelism efficiency. The absolute efficiency of the parallelism is:

$$e_c = \frac{t_s}{ct_c} \tag{17}$$

[2]Related to the Amdahl's Law[29].
[3]Related to the Gustafson's Law [30].

where e_c is the absolute efficiency of the parallelism in c processes, t_s is the execution time of the best known serial solution and t_c is the execution time of the program using c processes [28]. In this analysis, the best known serial solution is the one developed on this work, so the equality $t_s = t_1$ is used.

Another metric proposed in this work is the relative efficiency when the number of processes doubles ϵ_c, this is defined as:

$$\epsilon_c = \begin{cases} (e_c)^{1/log_2 c}, & c > 1 \\ 1, & c = 1 \end{cases} \quad (18)$$

The only values used for the experiments were $\epsilon_1 = 1$, $\epsilon_2 = e_2$, $\epsilon_4 = (e_4)^{1/2}$, $\epsilon_8 = (e_8)^{1/3}$ and $\epsilon_{16} = (e_{16})^{1/4}$.

1) Strong scaling: The absolute efficiency for the strong scaling is calculated as:

$$e_c = \frac{time(\text{pCG}(1,1))}{c \cdot time(\text{pCG}(n,p))}. \quad (19)$$

The problem size for the first test is $\hat{q} = 13{\times}13$ and $\hat{l} = 512$, as it is used in [7]. To illustrate the problem size for this configuration, the dimension of matrix $\mathbf{G}$ is 199680×199680 and the dimension of matrix $\mathbf{E}$ is 86528×86528.

TABLE II
TIMES OF PCG$(1,p)$, FOR DIFFERENT INNER TOLERANCE ε_i VALUES, OUTER TOLERANCE $\varepsilon_e = 10^{-6}$, $\alpha = 1$, $\beta = 12$, $\gamma = 10^{-5}$, INNER GRID SIZE 13×13, $\tau = 1/512$, $\hat{k} = 32$ AND *n.c.* MEANS THAT THE SYSTEM DOES NOT CONVERGE IN 100 ITERATIONS.

ε_i	pCG$(1,p)$		
	$p=1$	$p=2$	$p=4$
10^{-12}	9.075293	5.867213	4.406441
10^{-10}	9.0619	5.964406	4.398958
10^{-8}	8.99508	5.988965	4.353884
10^{-7}	8.826598	5.693643	4.540562
10^{-6}	9.293346	6.345327	4.236906
10^{-5}	9.908053	6.485624	n.c.
10^{-4}	10.695609	14.248947	7.465788

Table II shows the execution times of the experiments presented in Table I. Fixing the values of p, it can be noticed that the time values do not differ greatly until an inner tolerance of 10^{-5}. When the required precision of the inner solver (Parareal) is increased, the inner iterations count increases, while the outer iterations count (Conjugate Gradient) decreases. Although there are less iterations needed for the low precision cases, the external iterations count increase leads to greater execution times. For a case with inner tolerance of 10^{-5}, the algorithm does not converge. At the same time, for lower precision cases the convergence rate of the outer Conjugate Gradient is lowered.

The inner tolerance value of 10^{-6} is used as a reference, because it is coherent with the outer tolerance value of 10^{-6}. Therefore the base tolerance value of 10^{-6} is chosen for the following tests.

To build Table III, the absolute efficiency e_c of the parallelism is calculated from the data of Table II, following (19).

TABLE III
EFFICIENCY OF PCG$(1,p)$, FOR DIFFERENT INNER TOLERANCE ε_i VALUES, OUTER TOLERANCE $\varepsilon_e = 10^{-6}$, $\alpha = 1$, $\beta = 12$, $\gamma = 10^{-5}$, INNER GRID SIZE 13×13, $\tau = 1/512$, $\hat{k} = 32$ AND *n.c.* MEANS THAT THE SYSTEM DOES NOT CONVERGE IN 100 ITERATIONS.

ε_i	pCG$(1,p)$		
	$p=1$	$p=2$	$p=4$
10^{-12}	1	0.77339	0.51489
10^{-10}	1	0.75966	0.51500
10^{-8}	1	0.75097	0.51650
10^{-7}	1	0.77513	0.48599
10^{-6}	1	0.73230	0.54836
10^{-5}	1	0.76384	n.c.
10^{-4}	1	0.37531	0.35815

The efficiency values from Table III show that the average relative efficiency for a single cluster node is approximately $\epsilon = 0.73$ each time the number of processes doubles.

The next step is to calculate the efficiency for multiple cluster nodes. In order to have a viable test, the spatial grid must be larger. The total execution times and the relative efficiency ϵ are calculated with a grid of $\hat{q} = 19{\times}19$. Figure 2 is obtained using the average efficiency of the different inner tolerances $\varepsilon_i = \{10^{-12}, 10^{-10}, 10^{-8}, 10^{-7}, 10^{-6}, 10^{-5}, 10^{-4}\}$.

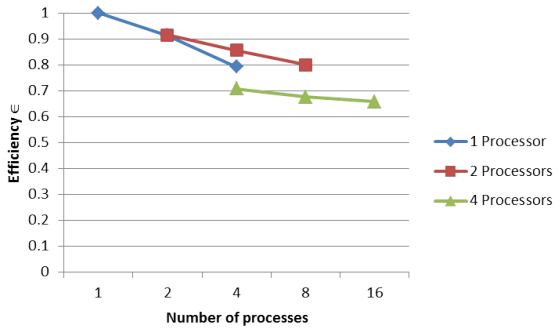

Fig. 2. Average strong scaling (Total time)

The average strong scaling shown in Figure 2 is approximately $\epsilon = 0.7$ each time the number of processes doubles. Considering only the times of the solver (without taking into account the time used to build the matrices and the execution of the external Conjugate Gradient preconditioner), the main contribution of this work can be noticed. The Figure 3 shows the times of the Parareal solver.

On this test, the average relative efficiency on a single cluster node is approximately $\epsilon = 0.79$, that is higher than the one calculated on Table III. This indicates that the strong scaling efficiency increases as the problem size grows.

The next test for the strong scaling is for a big sized problem, that cannot be solved in a single cluster node, and that is near the size limit that two nodes can solve.

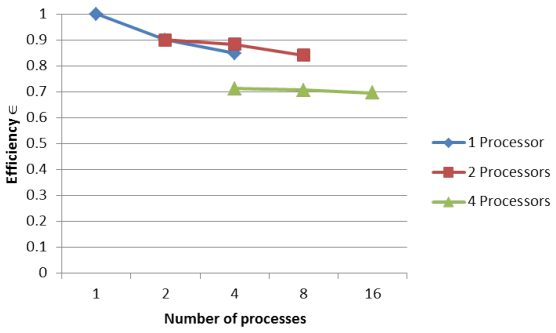

Fig. 3. Average strong scaling (considering only the solver)

TABLE V
EFFICIENCY OF PCG$(1,p)$, INNER TOLERANCE $\varepsilon_i = 10^{-6}$ VALUES, OUTER TOLERANCE $\varepsilon_e = 10^{-6}$, $\alpha = 1$, $\beta = 12$, $\gamma = 10^{-5}$, INNER GRID SIZE 19×19, $\hat{l} = 8192$, AND *o.o.m.r.* MEANS THAT THE SYSTEM RUNS OUT OF MEMORY DURING THE RESOLUTION OF THE PROBLEM.

$\hat{k}$	pCG(n,p)					
	$n=2$			$n=4$		
	$p=1$	$p=2$	$p=4$	$p=1$	$p=2$	$p=4$
512	o.o.m.r.	o.o.m.r.	o.o.m.r.	1	0.96257	0.55323
256	1	0.80291	0.49520	0.54950	0.53390	0.32647
128	1	0.97602	0.43423	0.53439	0.51296	0.31407
64	1	0.87475	0.43981	0.54046	0.50359	0.30965
32	1	0.89704	0.42091	0.51832	0.48340	0.29379
16	1	0.82382	0.44782	0.44917	0.42319	0.25103

The values $\hat{q} = 19 \times 19$ and $\hat{l} = 8192$ are chosen. With these values, the size of matrix $\mathbf{E}$ is 2957312×2957312 (approximately $3 \cdot 10^6 \times 3 \cdot 10^6 = 9 \cdot 10^{12}$ elements) and the size of matrix $\mathbf{G}$ is 6537216×6537216 (approximately $6.54 \cdot 10^6 \times 6.54 \cdot 10^6 \approx 4.3 \cdot 10^{13}$ elements).

TABLE IV
TIMES OF PCG$(1,p)$, INNER TOLERANCE $\varepsilon_i = 10^{-6}$ VALUES, OUTER TOLERANCE $\varepsilon_e = 10^{-6}$, $\alpha = 1$, $\beta = 12$, $\gamma = 10^{-5}$, INNER GRID SIZE 19×19, $\hat{l} = 8192$, AND *o.o.m.r.* MEANS THAT THE SYSTEM RUNS OUT OF MEMORY DURING THE RESOLUTION OF THE PROBLEM.

$\hat{k}$	pCG(n,p)					
	$n=2$			$n=4$		
	$p=1$	$p=2$	$p=4$	$p=1$	$p=2$	$p=4$
512	o.o.m.r.	o.o.m.r.	o.o.m.r.	506.84255	263.27448	229.03597
256	958.6446	596.9837	483.9645	436.1471	224.44206	183.52355
128	919.7547	471.1759	529.52744	430.2823	224.12969	183.02848
64	926.5926	529.6313	526.7008	428.6131	229.998	187.0255
32	939.2415	523.5229	557.8653	453.0177	242.8749	199.8105
16	922.1194	559.6586	514.7818	513.2409	272.3714	229.5808

It is not possible to compute the efficiency in a classic sense for Table IV, given that there is no serial solution that can solve the proposed problem cases as the system runs out of memory when the matrices are built in a single node. Therefore, to obtain the efficiency, the base execution time may be considered as the one that solves the problem with the least amount of cluster nodes, and the least amount of cores of each node. In the tests shown in Table IV, for $\hat{k} = 512$ and $\hat{m} = 16$ the base case will be pCG$(4,1)$ and for all the other tested conditions of $\hat{k}$ and $\hat{m}$, it will be pCG$(2,1)$.

Considering the data of Table V, the average relative efficiency can be established as $\epsilon = 0.7$ each time the number of processes doubles.

From the data presented, the general strong scaling obtained is approximately $\epsilon = 0.7$ each time the number of processes doubles.

As a noteworthy detail to keep in mind, in general, the efficiency decays faster when the number of nodes increases than when the number of processes per node increases. This occurs because the LAN's connection to the new nodes adds latency to the computations and has a lower data transfer rate than the local bus on each node. In general, the LAN's data transfer rate is not enough to keep the same efficiency in processes on different nodes as compared to processes on a same node. There is also a bus bandwidth from the central memory in each node that limits the efficiency of increasing the number of processes per node, as adding more processes will decrease the bandwidth available for each process after a certain point. The limit will depend on the equipment specifications.

2) Weak scaling: The efficiency for the weak scaling is computed as:

$$e_c = \frac{time(\text{pCG}(1,1))}{time(\text{pCG}(n,p))}. \tag{20}$$

Given that the total problem size grows as the number of used processes c does, there is no need to multiply the denominator by $c = n \cdot p$.

To compute the weak scaling, the problem size per process must be fixed. As a first experimental option, the number of elements from vector $\mathbf{u}$ can be fixed; this is, the size of the solution found by each process $\hat{q} \cdot \hat{m}$ is constant and the number of coarse intervals $\hat{k}$ is shifted to obtain several configurations. Let $\hat{q} = 19 \times 19$, $\hat{m} = 32$ be the fixed size per process, when the total execution times are measured, the relative efficiency ϵ is computed. Figure 4 shows the average of the relative efficiency for the coarse instants per node $\hat{k}/n = \{1, 2, 4, 8, 16\}$.

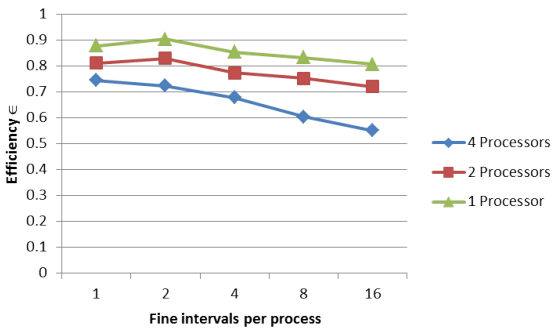

Fig. 4. Average weak scaling (Total time)

The average weak scaling form Figure 4 is approximately $\epsilon = 0.75$ each time the number of processes doubles. Considering only the execution time of the function pCG(n,p), the

weak scaling is approximately $\epsilon = 0.85$ each time the number of processes doubles, with an increasing efficiency as the problem size increases, as it can be observed in Figure 5 (this is a meaningful improvement with respect to the efficiency of the whole program, when the scaling efficiency drops to $\epsilon = 0.29$ for the pCG$(4, 4)$ with $\hat{k} = 256$).

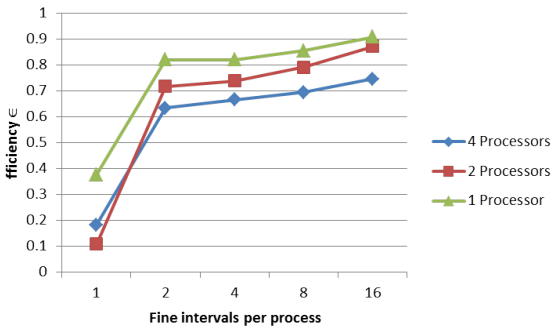

Fig. 5. Average weak scaling (considering only the solver)

The problem with the pCG's preconditioner is that it uses standard PETSc operations to solve the inverse of matrix $\mathbf{E}$. In particular for the test pCG$(4, 4)$ with $\hat{k} = 256$, the time to build the matrices is 9.21 seconds, 332 seconds for the preconditioner and 48.7 seconds for the pCG function. This clearly shows that solving a single time the inverse of matrix $\mathbf{E}$ by the standard means is much slower than the multiple solutions done by the pCG function.

The problem with the first consideration for the fixed problem size is that the matrices involved on the problem have their size squared compared to the solution vector. Then, as a second experimental option, the fixed data size per process is the size of the matrices stored on each process. With this approach, and setting the parameters $\hat{q} = 19 \times 19$ and $\hat{m} = 32$, each execution time is measured, then the relative efficiency ϵ is computed. The average of the relative efficiency for the coarse instants per node $\hat{k}/n = \{1, 2, 4, 8, 16\}$ is shown in Figure 6.

A detail to have in mind is that to allow the size of the matrices to be constant, on all the tests, the only possible combinations of n and p are those that make $c = n \cdot p$ a perfect square. This occurs because $\hat{k}$ must be divisible by c and the matrices's sizes are proportional to the square of $\hat{k}$. Therefore, the number of elementes of matrix $\mathbf{E}$, $size(\mathbf{E})$ will be set as reference.

Most iterative Krylov subspace methods have a computational complexity of $\mathcal{O}(sol_s \cdot iter)$ where sol_s is the solution size and $iter$ the number of iterations needed for the convergence of the algorithm [31]. The number of iterations using the Conjugate Gradient method is bounded by $1 \leq iter \leq sol_s$ because it can be used as a direct method [32]. The first experimental option tests the lower $iter$ bound and the second experimental option tests the upper $iter$ bound, because the number of iterations needed for the convergence is unknown before the execution of the solver.

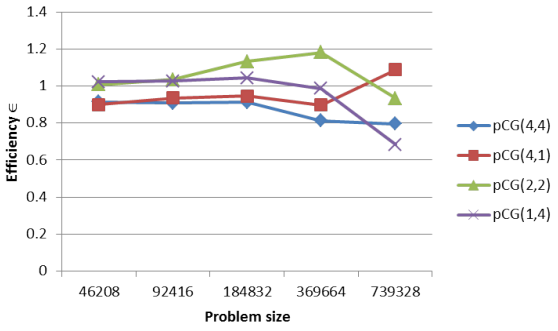

Fig. 6. Average weak scaling (Total time)

Because the number of iterations the solver used to converge in each experiment is greater than 1 and less than $\hat{lp}$ (equal to sol_s), the first experimental option will give a scaling less than 1, and the second experiment can give a scaling greater than 1. This can be seen in Figure 6, where in some cases the scaling is greater than 1.

On average, for the second experimental option, the relative efficiency of the weak scaling is approximately $\epsilon = 0.96$ each time the number of processes doubles.

The same process as in the first experimental option is used for the solver time, Figure 7 shows the weak scaling of the pCG function.

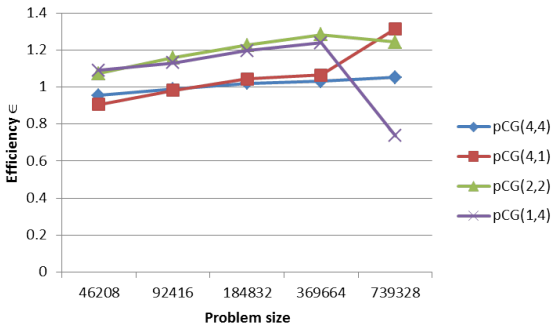

Fig. 7. Average weak scaling (considering only the solver)

It can be noticed in Figure 7 that most of the resolution times (not considering the preconditioner) scale on a supraliear way. In this context, the average relative efficiency is approximately $\epsilon = 1.09$ each time the number of processes doubles.

On both weak scaling considerations, the efficiency lost as the number of nodes increases is greater than the efficiency lost as the number of cores used per node increases. This is expected as it was analyzed on the strong scaling, due to the data transfer among cores on a single node is faster than the transfer among cores on different nodes, because the data has to travel through the switch holding the LAN.

The analysis continues comparing the problem resolution using or not the Parareal method.

D. Parareal vs No Parareal

To solve the external Conjugate Gradient, the steps 3) and 5) from Algorithm 2 must be solved by some iterative method. Three options to solve those steps are compared, *a*) the Parareal implementation done for this work *b*) the PETSc's implementation of the Conjugate Gradient, and *c*) the PETSc's implementation of GMRES.

The parameters used for the test are $\hat{q} = 9 \times 9$, $\hat{l} = 256$, $\hat{m} = 16$, while the values $\hat{k} = \{16, 32\}$ are considered. The Conjugate Gradient did not converge for any test case from this set, therefore only the Parareal and GMRES methods are compared.

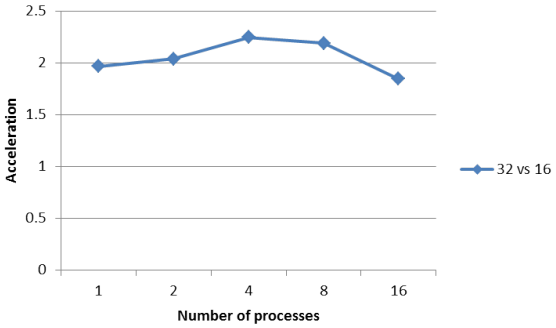

Fig. 8. Acceleration of Parareal vs GMRES (Total time)

The quotient from the resolution time of the GMRES and the the Parareal methods gives the speed-up for the cases $\hat{k} = 16$ and $\hat{k} = 32$. Then, the quotient from the cases $\hat{k} = 32$ and $\hat{k} = 16$ yield the acceleration obtained as the problem size doubles. This is presented in Figures 8 and 9.

Figures 8 and 9 show that the execution of the Parareal takes less time than the execution of the GMRES for every problem size tested, since the acceleration is higher than 1 for every case. Indeed, when the problem size increases the quotient from the execution time of the GMRES and the execution time from the Parareal increases with an average of 2 when the solution size doubles.

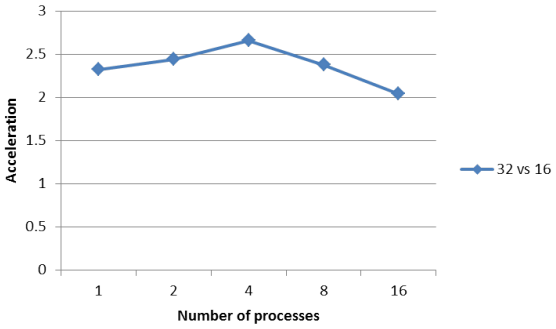

Fig. 9. Acceleration of the Parareal vs GMRES (Solver only)

As hinted, a considerable time difference was expected, after analysing the strong scaling tests, and for that reason the problem sizes for the test were small. The acceleration shown in Figures 8 and 9 are from linear systems where the size of matrix $\mathbf{E}$ are 20736×20736 (when $\hat{k} = 16$) and 41472×41472 (when $\hat{k} = 32$) respectively.

The main time load for the preconditioner of the external Conjugate Gradient is the solution of a system $\mathbf{E}x = b$. With the execution time of the preconditioner ($t_{precond}$), the resolution time of the system using GMRES (t_{GMRES}) can be estimaded by $t_{precond} \cdot iter_{cg} \approx t_{GMRES}$, where $iter_{cg}$ is the iterations needed for the convergence of the pCG (even if it uses the Parareal, as the iteration count for the external Conjugate Gradient is stable for every inner method tested).

The time approximation variation var (of the approximated value versus the measured value) found from the tests of this section, calculated by $var = |t_{GMRES} - t_{precond} \cdot iter_{cg}|/t_{GMRES}$, is at most 20%.

To emphasize the time reduction achieved using the Parareal method, the time of pCG$(4, 4)$ with $\hat{q} = 19 \times 19$ and $\hat{l} = 8196$ is analyzed. In this case, building the matrices takes 9.21 seconds, the external preconditioner takes 332 seconds and the pCG function takes 48.7 seconds (with 16 iterations). Solving this pCG$(4, 4)$ case with the GMRES solver would take $332 \cdot 16 - 48.7 = 5263$ seconds more (almost one hour and a half compared to 49 seconds when using the Parareal).

E. Parallelization suitability

When the strong scaling was analyzed, it was found that an increase in the problem size would give a better parallelization efficiency on each node.

Extending that idea, on a sufficiently small problem the cost of creating new processes and the communication costs among the processes would be higher than the time benefit obtained with the parallelization. The parallelization is convenient when the solution of the pCG(1,1) takes longer than every other analyzed solution of pCG(n, p). The tests are done with grid sizes that gives problem sizes of approximately twice as big each time.

Table VI is used to find the convenient problem size for the parallelization on a single node.

TABLE VI
TIMES OF PCG(n, p), OUTER TOLERANCE $\varepsilon_e = 10^{-6}$, INNER TOLERANCE $\varepsilon_i = 10^{-6}$, $\alpha = 1$, $\beta = 12$, $\gamma = 10^{-5}$, $\hat{l} = 512$ AND $\hat{k} = 32$.

$\hat{q}$	pCG(n, p)		
	$n = 1$		
	$p = 1$	$p = 2$	$p = 4$
4×4	1.6396871	2.6615668	2.7016241
7×7	2.434376	2.5144259	2.447761
9×9	3.673742	3.319042	2.524157

The convenient minimum problem size on a single node for matrix $\mathbf{E}$ is 41472×41472 elements ($\hat{q} = 9 \times 9$ and $\hat{l} = 512$). In a similar fasion, multiple nodes are analyzed on Table VII.

Table VII shows that, in general, the parallelization is suitable starting on a matrix $\mathbf{E}$ of 86528×86528 elements ($\hat{q} = 13 \times 13$ and $\hat{l} = 512$).

TABLE VII
TIMES OF PCG(n,p), OUTER TOLERANCE $\varepsilon_e = 10^{-6}$, INNER TOLERANCE $\varepsilon_i = 10^{-6}$, $\alpha = 1$, $\beta = 12$, $\gamma = 10^{-5}$, $\hat{l} = 512$ AND $\hat{k} = 32$.

$\hat{q}$	pCG(n,p)					
	$n=2$			$n=4$		
	$p=1$	$p=2$	$p=4$	$p=1$	$p=2$	$p=4$
7×7	3.012665	2.7350261	2.472511	3.914736	3.915797	3.9322839
9×9	3.723882	2.760471	2.400935	3.842674	3.819844	4.711632
13×13	6.70257	4.045551	2.946394	6.058765	4.413698	4.337244

VI. CONCLUSIONS

- The experiments of Section V-D shows that the execution of the program using the Parareal method is considerably faster than executions that use the CG or GMRES methods. Not only it does perform better, but it accelerates for larger problem sizes.
- The experiments of Section V-C present a relative efficiency of around $\epsilon = 0.7$ each time the number of processes doubles for the strong scaling. At the same time, for the weak scaling, the relative efficiency is $\epsilon = 0.75$ each time the number of processes doubles for a constant solution size per process, and $\epsilon = 0.96$ each time the number of processes doubles for a constant data size per process.
- The experiments of Section V-C find that for the used hardware (described in Section V), the parallelization begins to be convenient for solution size of 40000 elements.

In summary, this paper presented a parallel efficient alternative in PETSc to solve a parabolic optimal control problem using the Parareal mthod. Experimental results above summarized demonstrate the advantages of this proposal over classical methods as the Conjugate Gradient and GMRES ones in a computing cluster.

***Abstract*—Computational kernel of the three-dimensional variational data assimilation (3D-Var) problem is a linear system, generally solved by means of an iterative method. The most costly part of each iterative step is a matrix-vector product with a very large covariance matrix having Gaussian correlation structure. This operation may be interpreted as a Gaussian convolution, that is a very expensive numerical kernel. Recursive Filters (RFs) are a well known way to approximate the Gaussian convolution and are intensively applied in the meteorology, in the oceanography and in forecast models. In this paper, we deal with an oceanographic 3D-Var data assimilation scheme, named OceanVar, where the linear system is solved by using the Conjugate Gradient (GC) method by replacing, at each step, the Gaussian convolution with RFs. Here we give theoretical issues on the discrete convolution approximation with a first order (1st-RF) and a third order (3rd-RF) recursive filters. Numerical experiments confirm given error bounds and show the benefits, in terms of accuracy and performance, of the 3-rd RF.**

I. Introduction

In recent years, Gaussian filters have assumed a central role in image filtering and techniques for accurate measurement [26]. The implementation of the Gaussian filter in one or more dimensions has typically been done as a convolution with a Gaussian kernel, that leads to a high computational cost in its practical application. Computational efforts to reduce the Gaussian convolution complexity are discussed in [16], [24]. More advantages may be gained by employing a *spatially recursive filter*, carefully constructed to mimic the Gaussian convolution operator.

Recursive filters (RFs) are an efficient way of achieving a long impulse response, without having to perform a long convolution. Initially developed in the context of time series analysis [5], they are extensively used as computational kernels for numerical weather analysis, forecasts [17], [20], [25], digital image processing [8], [23]. Recursive filters with higher order accuracy are very able to accurately approximate a Gaussian convolution, but they require more operations.

In this paper, we investigate how the RF mimics the Gaussian convolution in the context of variational data assimilation analysis. Variational data assimilation (Var-DA) is popularly used to combine observations with a model forecast in order to produce a *best* estimate of the current state of a system and enable accurate prediction of future states. Here we deal with the three-dimensional data assimilation scheme (3D-Var), where the estimate minimizes a weighted nonlinear least-squares measure of the error between the model forecast and the available observations. The numerical problem is to minimize a cost function by means of an iterative optimization algorithm. The most costly part of each step is the multiplication of some grid-space vector by a covariance matrix that defines the error on the forecast model and observations. More precisely, in 3D-Var problem this operation may be interpreted as the convolution of a covariance function of background error with the given forcing terms.

Here we deal with numerical aspects of an oceanographic 3D-Var scheme, in the real scenario of OceanVar. Ocean data assimilation is a crucial task in operational oceanography and the computational kernel of OceanVar software is a linear system resolution by means of the Conjugate Gradient (GC) method, where the iteration matrix is relate to an errors covariance matrix, having a Gaussian correlation structure.

In [9], it is shown that a computational advantage can be gained by employing a first order RF that mimics the required Gaussian convolution. Instead, we use the 3rd-RF to compute numerically the Gaussian convolution, as how far is only used in signal processing [27], but only recently used in the field of Var-DA problems.

In this paper we highlight the main sources of error, introduced by these new numerical operators. We also investigate the real benefits, obtained by using 1-st and 3rd-RFs, through a careful error analysis. Theoretical aspects are confirmed by some numerical experiments. Finally, we report results in the case study of the OceanVar software.

The rest of the paper is organized as follows. In the next section we recall the three-dimensional variational data assimilation problem and we remark some properties on the

978-83-60810-58-3/$25.00

conditioning for this problem. Besides, we describe our case study: the OceanVar problem and its numerical solution with CG method. In section III, we introduce the n-th order recursive filter and how it can be applied to approximate the discrete Gaussian convolution. In section IV, we estimate the effective error, introduced at each iteration of the CG method, by using 1st-RF and 3rd-RF instead of the Gaussian convolution. In section V, we report some experiments to confirm our theoretical study, while the section VI concludes the paper.

II. Mathematical Background

The aim of a generic variational problem (VAR problem) is to find a best estimate x, given a previous estimate x_b and a measured value y. With these notations, the VAR problem is based on the following regularized constrained least-squared problem:

$$\min_x J(x)$$

where x is defined in a grid domain D. The objective function $J(x)$ is defined as follows:

$$J(x) = \|y - \mathcal{H}(x)\|^2 + \lambda R(x, x_b) \tag{1}$$

where measured data are compared with the solution obtained from a nonlinear model given by $\mathcal{H}(x)$.
In (1), we can recognize a quadratic data-fidelity term, the first term and the general regularization term (or penalty term), the second one. When $\lambda = 1$ and the regularization term can be write as:

$$R(x, x_b) = \|x - x_b\|^2$$

we deal with a three-dimensional variational data assimilation problem (3D-Var DA problem). The purpose is to find an optimal estimate for a vector of states x_t (called the analysis) of a generic system S, at each time $t \in T = \{0, .., n\}$ given:

- a prior estimate vector x_t^b (called the background) achieved by numerical solution of a forecasting model $\mathcal{L}_{t-1,t}(x_{t-1}) = x_t^b$, with error $\delta x_t = x_t^b - x_t$;
- a vector y_t of observations, related to the nonlinear model by δy_t that is an effective measurement error:

$$y_t = H(x_t) + \delta y_t.$$

At each time t, the errors δx_t in the background and the errors δy_t in the observations are assumed to be random with mean zero and covariance matrices $\mathbf{B}$ and $\mathbf{R}$, respectively. More precisely, the covariance $\mathbf{R} =< \delta y_t, \delta y_t^T >$ of observational error is assumed to be diagonal, (observational errors statistically independent). The covariance $\mathbf{B} =< \delta x_t, \delta x_t^T >$ of background error is never assumed to be diagonal as justified in the follow. To minimize, with respect to x_t and for each $t \in T$, the problem becomes:

$$\min_{x_t \in D} J(x_t) = \min_{x_t \in D} \{\frac{1}{2}\|y_t - H(x_t)\|^2_{\mathbf{R}} + \frac{1}{2}\|x_t - x_t^b\|^2_{\mathbf{B}}\} \tag{2}$$

In explicit form, the functional cost of (2) problem can be written as:

$$\begin{aligned} J(x_t) = \tfrac{1}{2}(y_t - H(x_t))^T\mathbf{R}^{-1}(y_t - H(x_t)) + \\ + \tfrac{1}{2}(x_t - x_t^b)^T\mathbf{B}^{-1}(x_t - x_t^b) \end{aligned} \tag{3}$$

It is often numerically convenient to approximate the effects on $H(x_t)$ of small increments of x_t, using the linearization of H. For small increments δx_t, follows [18], it is:

$$H(x_t) \simeq H(x_t^b) + \mathbf{H}\delta x_t$$

where the linear operator $\mathbf{H}$ is the matrix obtained by the first order approximation of the Jacobian of H evaluated at x_t^b.
Now let $d_t = y_t - H(x_t^b)$ be the *misfit*. Then the function J in (3) takes the following form in the increment space:

$$J(\delta x_t) = \tfrac{1}{2}(d_t - \mathbf{H}\delta x_t)^T\mathbf{R}^{-1}(d_t - \mathbf{H}\delta x_t) + \tfrac{1}{2}\delta x_t^T\mathbf{B}^{-1}\delta x_t \tag{4}$$

At this point, at each time t, the minimum of (4) is obtained by requiring $\nabla J = 0$. This gives rise to the linear system:

$$(\mathbf{B}^{-1} + \mathbf{H}^T\mathbf{R}^{-1}\mathbf{H})\delta x_t = \mathbf{H}^T\mathbf{R}^{-1}d_t$$

or equivalently:

$$(I + \mathbf{B}\mathbf{H}^T\mathbf{R}^{-1}\mathbf{H})\delta x_t = \mathbf{B}\mathbf{H}^T\mathbf{R}^{-1}d_t \tag{5}$$

For each time $t = 0, ..., n$, iterative methods, able to converge toward a practical solution, are needed to solve the linear system (5). However this problem, so as formulated, is generally very ill conditioned. More precisely, by following [15], and assuming that

$$\mathbf{\Psi} = \mathbf{H}^T\mathbf{R}^{-1}\mathbf{H} \tag{6}$$

is a diagonal matrix, it can be proved that the conditioning of $I + \mathbf{B}\mathbf{\Psi}$ is strictly related to the conditioning of the matrix $\mathbf{B}$ (the covariance matrix). In general, the matrix $\mathbf{B}$ is a block-diagonal matrix, where each block is related to a single state of vector x_t and it is ill conditioned.
This assertion is exposed in [14] starting from the expression of $\mathbf{B}$ for one-state vectors as:

$$\mathbf{B} = \sigma_b^2\mathbf{C}$$

where σ_b^2 is the background error variance and $\mathbf{C}$ is a matrix that denotes the correlation structure of the background error. Assuming that the correlation structure of matrix $\mathbf{C}$ is homogeneous and depends only on the distance between states and not on positions, an expression of $\mathbf{C}$ as a symmetric matrix with a circulant form is given; i. e. as a Toeplitz matrix. By means of a spectral analysis of its eigenvalues, the ill-conditioning of the matrix $\mathbf{C}$ is checked. As in [7], it follows that $\mathbf{B}$ is ill-conditioned and the matrix $I + \mathbf{B}\mathbf{\Psi}$, of the linear system (5), too. A well-known technique for improving the convergence of iterative methods for solving linear systems is to *preconditioning* the system and thus reduce the condition number of the problem.
In order to precondition the system in (5), it is assumed that $\mathbf{B}$ can be written in the form $\mathbf{B} = \mathbf{V}\mathbf{V}^T$, where $\mathbf{V} = \mathbf{B}^{1/2}$ is the square root of the background error covariance matrix $\mathbf{B}$.

Because $\mathbf{B}$ is symmetric Gaussian, $\mathbf{V}$ is uniquely defined as the symmetric ($\mathbf{V^T} = \mathbf{V}$) Gaussian matrix such that $\mathbf{V^2} = \mathbf{B}$. As explained in [18], the cost function (4) becomes:

$$J(\delta x_t) = \tfrac{1}{2}(d_t - \mathbf{H}\delta x_t)^T \mathbf{R}^{-1}(d_t - \mathbf{H}\delta x_t) + \tfrac{1}{2}\delta x_t^T (\mathbf{V}\mathbf{V^T})^{-1}\delta x_t$$
$$= \tfrac{1}{2}(d_t - \mathbf{H}\delta x_t)^T \mathbf{R}^{-1}(d_t - \mathbf{H}\delta x_t) + \tfrac{1}{2}\delta x_t^T (\mathbf{V^T})^{-1}\mathbf{V}^{-1}\delta x_t$$

Now, by using a new control variable v_t, defined as $v_t = \mathbf{V}^{-1}\delta x_t$, at each time $t \in T$ and observing that $\delta x_t = \mathbf{V}v_t$ we obtain a new cost function:

$$\widetilde{J}(v_t) = \frac{1}{2}(d_t - \mathbf{H}\mathbf{V}v_t)^T \mathbf{R}^{-1}(d_t - \mathbf{H}\mathbf{V}v_t) + \frac{1}{2}v_t^T v_t. \quad (7)$$

Equation (7) is said the *dual problem* of equation (4). Finally, to minimize the cost function $\widetilde{J}(v_t)$ in (7) leads to the new linear system:

$$(I + \mathbf{V}\mathbf{\Psi}\mathbf{V})v_t = \mathbf{V}\mathbf{H}^T\mathbf{R}^{-1}d_t \quad (8)$$

Upper and lower bounds on the condition number of the matrix $I + \mathbf{V}\mathbf{\Psi}\mathbf{V}$ are shown in [14]. In particular it holds that:

$$\mu(I + \mathbf{V}\mathbf{\Psi}\mathbf{V}) << \mu(I + \mathbf{B}\mathbf{\Psi}).$$

Moreover, under some special assumptions, it can be proved that $I + \mathbf{V}\mathbf{\Psi}\mathbf{V}$ is very well-conditioned ($\mu(I + \mathbf{V}\mathbf{\Psi}\mathbf{V}) < 4$).

The OceanVar model

As described in [9], at each time $t \in T$, OceanVar software implements an oceanographic three-dimensional variational DA scheme (3D Var-DA) to produce forecasts of ocean currents for the Mediterranean Sea. The computational kernel is based on the resolution of the linear system defined in (8). To solve it, the Conjugate Gradient (CG) method is used and a basic outline is described in **Algorithm 1**.

Algorithm 1 CG Algorithm

1: $k = 0$; $\mathbf{x}_0$, the initial guess;
2: $\mathbf{r}_0 = \mathbf{b} - \mathbf{A}\mathbf{x}_0$;
3: $\rho_\mathbf{0} = \mathbf{r_0}$;
4: **while** $\left(\|\mathbf{r}_k\|/\|\mathbf{b}\| > \epsilon \ .and. \ k \leq n\right)$ **do**
5: $\mathbf{q}_k = \mathbf{A}\rho_k$;
6: $\alpha_k = (\mathbf{r}_k, \mathbf{r}_k)/(\rho_k, \mathbf{q}_k)$; $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k\rho_\mathbf{k}$;
7: $\mathbf{r}_{k+1} = \mathbf{r}_k - \alpha_k\mathbf{q}_k$; $\beta_k = (\mathbf{r}_{k+1}, \mathbf{r}_{k+1})/(\mathbf{r}_k, \mathbf{r}_k)$;
8: $\rho_{k+1} = \mathbf{r}_{k+1} + \beta_k\rho_k$; $k = k + 1$;
9: **end while**

We focus our attention on step 5.: at each iterative step, a matrix-vector product $\mathbf{A}\,\rho_k$ is required, where

$$\mathbf{A} = \mathbf{I} + \mathbf{V}\mathbf{\Psi}\mathbf{V},$$

$\rho_\mathbf{k}$ is the residual at step k and $\mathbf{\Psi}$ depends on the number of observations and is characterized by a bounded norm (see [15] for details). More precisely, we look to the matrix-vector product

$$\mathbf{q}_k = (I + \mathbf{V}\mathbf{\Psi}\mathbf{V})\rho_\mathbf{k}$$

which can be schematized as shown in **Algorithm 2**.

Algorithm 2 $(I + \mathbf{V}\mathbf{\Psi}\mathbf{V})\rho_k$ Algorithm

1: $z_1 = \mathbf{V}\rho_k$;
2: $z_2 = \mathbf{\Psi}z_1$;
3: $z_3 = \mathbf{V}z_2$;
4: $\mathbf{q}_k = \rho_k + z_3$;

The steps 1. and 3. in **Algorithm 2** consist in a matrix-vector product. These products, as detailed in next section, can be considered discrete Gaussian convolutions and the matrix $\mathbf{V}$, for one-dimensional state vectors, has Gaussian structure. Even for state vectors defined on two (or more) dimensions, the matrix $\mathbf{V}$ can be represented as product of two (or more) Gaussian matrices. Since a single matrix-vector product of this form becomes prohibitively expensive if carried out explicitly, a computational advantage is gained by employing Gaussian RFs to mimic the required Gaussian convolution operators.
In the previous OceanVar scheme, it was implemented a 1st-RF algorithm, as described in [21], [20]. Here, we study the 3rd-RF introduction, based on [27], [23].
The aim of the following sections is to precisely reveal how the n-th order recursive filters are defined and, through the error analysis, to investigate on their effect in terms of error estimate and perfomences.

III. Gaussian recursive filters

In this section we describe Gaussian recursive filters as approximations of the discrete Gaussian convolution used in steps 1. and 3. of **Algorithm 2**. Let denote by

$$g(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{x^2}{2\sigma^2}\right)$$

the normalized Gaussian function and by $\mathbf{V}$ the square matrix whose entries are given by

$$\mathbf{V}_{i,j} = g(i-j) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(i-j)^2}{2\sigma^2}\right). \quad (9)$$

Now let be $s^0 = (s_1^0, \ldots, s_m^0)^T$ a vector; the discrete Gaussian convolution of s^0 is a new vector $s = (s_1, \ldots, s_m)^T$ defined by means of the matrix-vector product

$$s = \mathbf{V} \otimes s^0 \equiv \mathbf{V}\ s^0. \quad (10)$$

The discrete Gaussian convolution can be considered as a discrete representation of the continuous Gaussian convolution. As is well known, the continuous Gaussian convolution of a function s^0 with the normalized Gaussian function g is a new function s defined as follows:

$$s(x) = [g \otimes s^0](x) = \int_{-\infty}^{+\infty} g(x-\tau)s^0(\tau)d\tau. \quad (11)$$

Discrete and continuous Gaussian convolutions are strictly related. This fact could be seen as follows. Let assume that

$$I = \{x_1 < x_2 < \ldots < x_{m+1}\}$$

is a grid of evaluation points and let set for $i = 1, \ldots, m$

$$s_i \equiv s(x_i), \qquad s_i^0 \equiv s^0(x_i) \quad \text{and} \quad \Delta x_i = x_{i+1} - x_i = 1.$$

By assuming that s^0 is 0 outside of $[x_1, x_{m+1}]$ and by discretizing the integral (11) with a rectangular rule, we obtain

$$s_i = \int_{-\infty}^{+\infty} g(x_i-\tau)s^0(\tau)d\tau = \int_{x_1}^{x_{m+1}} g(x_i-\tau)s^0(\tau)d\tau = \\ = \sum_{j=1}^{m}\int_{x_j}^{x_{j+1}} g(x_i-\tau)s^0(\tau)d\tau \approx \sum_{j=1}^{m}\Delta x_j g(x_i-x_j)s_j^0 = \\ = \sum_{j=1}^{m} g(i-j)s_j^0 = \sum_{j=1}^{m}\mathbf{V}_{i,j}s_j^0 = (\mathbf{V}s^0)_i. \quad (12)$$

An optimal way for approximating the values s_i is given by Gaussian recursive filters. The n-order RF filter computes the vector $s^K = (s_1^K, \ldots, s_m^K)^T$ as follows:

$$\begin{cases} p_i^k = \beta_i s_i^{k-1} + \sum_{j=1}^{n}\alpha_{i,j}p_{i-j}^k \quad i = 1, \ldots, m \\ s_i^k = \beta_i p_i^k + \sum_{j=1}^{n}\alpha_{i,j}s_{i+j}^k \quad i = m, \ldots, 1 \end{cases}. \quad (13)$$

The iteration counter k goes from 1 to K, where K is the total number of filter iterations. Observe that values $p_1^k, \ldots p_n^k$ are computed taking in the sums terms $\alpha_{i,j}p_{i-j}^k$ provided that $i-j \geq 1$. Analogously values $s_m^k, \ldots s_{m-n+1}^k$ are computed taking in the sums terms $\alpha_{i,j}s_{i+j}^k$ provided that $i+j \leq m$. The values $\alpha_{i,j}$ and β_i, at each grid point x_i, are often called *smoothing coefficients* and they obey to the constraint

$$\beta_i = 1 - \sum_{j=1}^{n}\alpha_{i,j}.$$

In this paper we deal with first-order and third-order RFs. The first-order RF expression ($n = 1$) becomes:

$$\begin{cases} p_1^k = \beta_1 s_1^{k-1}, \\ p_i^k = \beta_i s_i^{k-1} + \alpha_i p_{i-1}^k \quad i = 2, \ldots, m \\ s_m^k = \beta_m p_m^k, \\ s_i^k = \beta_i p_i^k + \alpha_i s_{i+1}^k \qquad i = m-1, \ldots, 1. \end{cases} \quad (14)$$

If R_i is the correlation radius at x_i, by setting

$$\sigma_i = \frac{R_i}{\Delta x_i} \quad \text{and} \quad E_i = \frac{K\Delta x_i^2}{R_i^2} = \frac{K}{\sigma_i^2},$$

coefficients α_i e β_i are given by [21]:

$$\alpha_i = 1 + E_i - \sqrt{E_i(E_i+2)}, \qquad \beta_i = \sqrt{E_i(E_i+2)} - E_i. \quad (15)$$

The third-order RF expression ($n = 3$) becomes:

$$\begin{cases} p_i^k = \beta_i s_i^{k-1} + \sum_{j=1}^{3}\alpha_{i,j}p_{i-j}^k \quad i = 1, ..., m \\ s_i^k = \beta_i p_i^k + \sum_{j=1}^{3}\alpha_{i,j}s_{i+j}^k \quad i = m, \ldots, 1. \end{cases} \quad (16)$$

Third-order RF coefficients $\alpha_{i,1}, \alpha_{i,2}, \alpha_{i,3}$ and β_i, for one only filter iteration ($K = 1$), are computed in [11]. If

$$a_i = 3.738128 + 5.788982\sigma_i + 3.382473\sigma_i^2 + \sigma_i^3.$$

the coefficients expressions are:

$$\alpha_{i,1} = (5.788982\sigma_i + 6.764946\sigma_i^2 + 3\sigma_i^3)/a_i$$
$$\alpha_{i,2} = -(3.382473\sigma_i^2 + 3\sigma_i^3)/a_i$$
$$\alpha_{i,3} = \sigma_i^3/a_i$$
$$\beta_i = 1 - (\alpha_{i,1} + \alpha_{i,2} + \alpha_{i,3}) = 3.738128/a_i.$$

In [23] the use of a value $q = q(\sigma_i)$ instead of σ_i is proposed. The q value is:

$$q(\sigma_i) = \begin{cases} 0.98711\sigma_i - 0.96330 & \text{if} \quad \sigma_i > 2.5 \\ 3.97156 - 4.14554\sqrt{1 - 0.26891\sigma_i} & \text{oth.} \end{cases} \quad (17)$$

In order to understand how Gaussian RFs approximate the discrete Gaussian convolution it is useful to represent them in terms of matrix formulation. As explained in [5], the n-order recursive filter computes s^K from s^0 as the solution of the linear system

$$(LU)^K s^K = s^0, \quad (18)$$

where matrices L and U are respectively lower and upper band triangular with nonzero entries

$$U_{i,i} = L_{i,i} = \frac{1}{\beta_i}, \qquad L_{i,i-j} = U_{i,i+j} = -\frac{\alpha_{i,j}}{\beta_i}. \quad (19)$$

By formally inverting the linear system (18) it results

$$s^K = \mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}\, s^0, \quad (20)$$

where $\mathbf{F}_{\mathbf{n}}^{(\mathbf{K})} \equiv (LU)^{-K}$. A direct expression of $\mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}$ and its norm could be obtained, for instance, for the first order recursive filter in the homogenus case ($\sigma_i = \sigma$). However, in the following, it will be shown that $\mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}$ has always bounded norm, i.e.

$$\|\mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}\|_\infty \leq 1. \quad (21)$$

Observe that $\mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}$ is the matrix operator that substitutes the Gaussian operator $\mathbf{V}$ in (10), then a measure of how well s^K approximates s can be derived in terms of the operator distance

$$\|\mathbf{V} - \mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}\|_\infty.$$

Ideally one would expect that $\|\mathbf{V} - \mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}\|$ goes to 0 (and $s^K \to s$) as K approaches to ∞, yet this does not happen due to the presence of edge effects. In the next sections we show the numerical behaviour of the distance $\|\mathbf{V} - \mathbf{F}_{\mathbf{n}}^{(\mathbf{K})}\|$ for some case study and we will show its effects in the CG algorithm.

IV. RF ERROR ANALYSIS

Here we are interested to analyze the error introduced on the matrix-vector operation at step 5. of **Algorithm 1**, when the Gaussian RF is used instead of the discrete Gaussian convolution. As previously explained, in terms of matrices, this is equivalent to change the matrix operator, then **Algorithm 2** can be rewritten as shown in **Algorithm 3**.

Now we are able to give the main result of this paper: indeed the following theorem furnishes an upper bound for the error

Algorithm 3 $(I + \mathbf{F_n^{(K)}}\mathbf{\Psi}\mathbf{F_n^{(K)}})\widetilde{\rho}_k$ Algorithm

1: $\widetilde{z}_1 = \mathbf{F_n^{(K)}}\widetilde{\rho}_k$;
2: $\widetilde{z}_2 = \mathbf{\Psi}\widetilde{z}_1$;
3: $\widetilde{z}_3 = \mathbf{F_n^{(K)}}\widetilde{z}_2$;
4: $\widetilde{\mathbf{q}}_k = \widetilde{\rho}_k + \widetilde{z}_3$;

$\mathbf{q}_k - \widetilde{\mathbf{q}}_k$, made at each single iteration k of the CG (**Algorithm 1**). This bound involves the operator norms

$$\|\mathbf{F_n^{(K)}}\|_\infty, \quad \|\mathbf{\Psi}\|_\infty, \quad \|\mathbf{V}\|_\infty,$$

the distance $\|\mathbf{V} - \mathbf{F_n^{(K)}}\|_\infty$ and the error $\rho_k - \widetilde{\rho}_k$ accumulated on ρ_k at previous iterations.

Theorem 4.1: Let be ρ_k, $\widetilde{\rho}_k$, $\mathbf{q}_k$, $\widetilde{\mathbf{q}}_k$ as in **Algorithm 2** and **Algorithm 3**. Let be $\|\cdot\| = \|\cdot\|_\infty$ and let denote by

$$e_k = \rho_k - \widetilde{\rho}_k$$

the difference between values ρ_k and $\widetilde{\rho}_k$. Then it holds

$$\|\mathbf{q}_k - \widetilde{\mathbf{q}}_k\| \leq (1 + \|\mathbf{V}\|\cdot\|\mathbf{\Psi}\|\cdot\|\mathbf{V}\|)\cdot\|e_k\| + \\ + \|\mathbf{F_n^{(K)}} - \mathbf{V}\|\cdot\|\mathbf{\Psi}\|\cdot\big(\|\mathbf{V}\| + \|\mathbf{F_n^{(K)}}\|\big)\cdot\|\widetilde{\rho}_k\|. \quad (22)$$

Proof: A direct proof follows by using the values z_i and $\widetilde{z}_i$ introduced in Algorithm 2 and in Algorithm 3. It holds:

$$\|z_1 - \widetilde{z}_1\| = \|\mathbf{V}\rho_k - \mathbf{F_n^{(K)}}\widetilde{\rho}_k\| = \|\mathbf{V}\rho_k - \mathbf{V}\widetilde{\rho}_k + \mathbf{V}\widetilde{\rho}_k - \mathbf{F_n^{(K)}}\widetilde{\rho}_k\| \leq \\ \leq \|\mathbf{V}\rho_k - \mathbf{V}\widetilde{\rho}_k\| + \|\mathbf{V}\widetilde{\rho}_k - \mathbf{F_n^{(K)}}\widetilde{\rho}_k\| \leq \\ \leq \|\mathbf{V}\|\cdot\|e_k\| + \|\mathbf{V} - \mathbf{F_n^{(K)}}\|\cdot\|\widetilde{\rho}_k\|.$$

Then, for the difference $z_2 - \widetilde{z}_2$, we get the bound

$$\|z_2 - \widetilde{z}_2\| = \|\mathbf{\Psi}z_1 - \mathbf{\Psi}\widetilde{z}_1\| \leq \|\mathbf{\Psi}\|\cdot\|z_1 - \widetilde{z}_1\| \leq \\ \leq \|\mathbf{\Psi}\|\cdot\|\mathbf{V}\|\cdot\|e_k\| + \|\mathbf{\Psi}\|\cdot\|\mathbf{V} - \mathbf{F_n^{(K)}}\|\cdot\|\widetilde{\rho}_k\|.$$

Hence, for the difference $z_3 - \widetilde{z}_3$, we obtain

$$\|z_3 - \widetilde{z}_3\| = \|\mathbf{V}z_2 - \mathbf{F_n^{(K)}}\widetilde{z}_2\| = \|\mathbf{V}z_2 - \mathbf{V}\widetilde{z}_2 + \mathbf{V}\widetilde{z}_2 - \mathbf{F_n^{(K)}}\widetilde{z}_2\| \leq \\ \leq \|\mathbf{V}\|\cdot\|z_2 - \widetilde{z}_2\| + \|\mathbf{V} - \mathbf{F_n^{(K)}}\|\cdot\|\widetilde{z}_2\| \leq \\ \leq \|\mathbf{V}\|\cdot\|z_2 - \widetilde{z}_2\| + \|\mathbf{V} - \mathbf{F_n^{(K)}}\|\cdot\|\mathbf{\Psi}\|\cdot\|\mathbf{F_n^{(K)}}\|\cdot\|\widetilde{\rho}_k\| \leq \\ \leq \|\mathbf{V}\|\cdot\|\mathbf{\Psi}\|\cdot\|\mathbf{V}\|\cdot\|e_k\| + \|\mathbf{V}\|\cdot\|\mathbf{\Psi}\|\cdot\|\mathbf{V} - \mathbf{F_n^{(K)}}\|\cdot\|\widetilde{\rho}_k\| \\ + \|\mathbf{V} - \mathbf{F_n^{(K)}}\|\cdot\|\mathbf{\Psi}\|\cdot\|\mathbf{F_n^{(K)}}\|\cdot\|\widetilde{\rho}_k\| = \\ \|\mathbf{V}\|\cdot\|\mathbf{\Psi}\|\cdot\|\mathbf{V}\|\cdot\|e_k\| + \|\mathbf{V} - \mathbf{F_n^{(K)}}\|\cdot\|\mathbf{\Psi}\|\big(\|\mathbf{V}\| + \|\mathbf{F_n^{(K)}}\|\big)\cdot\|\widetilde{\rho}_k\|$$

In the second-last inequality we used the fact that

$$\|\widetilde{z}_2\| = \|\mathbf{\Psi}\widetilde{z}_1\| = \|\mathbf{\Psi}\mathbf{F_n^{(K)}}\widetilde{\rho}_k\| \leq \|\mathbf{\Psi}\|\cdot\|\mathbf{F_n^{(K)}}\|\cdot\|\widetilde{\rho}_k\|.$$

Finally, observing that

$$\|\mathbf{q}_k - \widetilde{\mathbf{q}}_k\| = \|\rho_k + z_3 - (\widetilde{\rho}_k + \widetilde{z}_3)\| \leq \\ \leq \|\rho_k - \widetilde{\rho}_k\| + \|z_3 - \widetilde{z}_3\| = \|e_k\| + \|z_3 - \widetilde{z}_3\|,$$

and taking the upper bound of $\|z_3 - \widetilde{z}_3\|$, the thesis is proved. ◇

Previous theorem shows that, at each iteration of the CG algorithm, the error bound on the computed value $\mathbf{q_k}$ at step 5., is characterized by two main terms: the first term can be considered as the contribution of the standard forward error analysis and it is not significant, if $\|e_k\|$ is small; the second term highlights the effect of the introduction of the RF. More in detail, at each iteration step, the computed value $\mathbf{q_k}$ is biased by a quantity proportional to three factors:

- the distance between the original operator (the Gaussian operator $\mathbf{V}$) and its approximation (the operator $\mathbf{F_n^{(K)}}$);
- the norm of $\mathbf{\Psi}$;
- the sum of the operator norms $\|\mathbf{F_n^{(K)}}\|$ and $\|\mathbf{V}\|$.

Table 1: Operator norms

σ	$\|\|\mathbf{F_1^{(1)}}\|\|_\infty$	$\|\|\mathbf{F_3^{(1)}}\|\|_\infty$
5	0.9920	0.9897
20	0.9012	0.8537
50	0.9489	0.8950

As shown in (21) the norm $\mathbf{\Psi}$ is bounded. Besides, the norm of $\mathbf{V}$ is always less or equal to one (because it comes from the discretization of the of the continuous Gaussian convolution). The norm of $\mathbf{F_n^{(K)}}$ is bounded by one too. This fact can be seen by observing the Table 1, where we consider several tests by varying data distributions in the homogeneous case ($\sigma_i = \sigma$), for 1st-RF and 3rd-RF. Starting from these considerations, the error estimate of *Theorem 4.1* can be specialized as:

$$\|\mathbf{q}_k - \widetilde{\mathbf{q}}_k\| \leq (1 + \|\mathbf{\Psi}\|)\,\|e_k\| + 2\|\mathbf{F_n^{(K)}} - \mathbf{V}\|\cdot\|\mathbf{\Psi}\|\|\widetilde{\rho}_k\|. \quad (23)$$

V. Experimental Results

In this section we report some experiments to confirm the discussed theoretical results. In the first part, we deal with the approximations of the discrete operator $\mathbf{V}$ with the first order and of the third order $\mathbf{F_1^{(K)}}$ and $\mathbf{F_3^{(1)}}$ respectively. In the last subsection, we analyze the improving in the performance and in the accuracy terms of the third order RF applied to the case study.

A. 1st-RF and 3rd-RF operators

In the following experiments, we construct the operators $\mathbf{V}$, $\mathbf{F_1^{(1)}}$, $\mathbf{F_1^{(50)}}$ and $\mathbf{F_3^{(1)}}$ in the case of $m = 601$ samples of a random vector $\mathbf{s^0}$. We assume that $\mathbf{s^0}$ comes from a uniform grid with homogeneous condition $\sigma_i = \sigma = 15$. In Figure 1, it is highlighted that the involved discrete operators have different structures. In particular, a first qualitative remark is that the operator $\mathbf{F_1^{(1)}}$ is a poor approximation of $\mathbf{V}$. Conversely, the operator $\mathbf{F_1^{(50)}}$ (Figure 2 on the top) is very close to $\mathbf{V}$ but, as for $\mathbf{F_1^{(1)}}$, there are significant differences with $\mathbf{V}$ in the bottom left and in the top right corners. These dissimilarities in the edges, by a numerical point of view, give some kind of artifacts in the computed convolutions, that determine a vector $\mathbf{s}$ with components, in the initial and final positions, that decay to zero.

Figure 2 bottom shows that the operator $\mathbf{F_3^{(1)}}$ is closer then $\mathbf{F_1^{(1)}}$ and $\mathbf{F_1^{(50)}}$ to the discrete convolution $\mathbf{V}$. In particular, this recursive filter is able to reproduce $\mathbf{V}$ more accurately in the bottom left corner, but unfortunately it does not give good

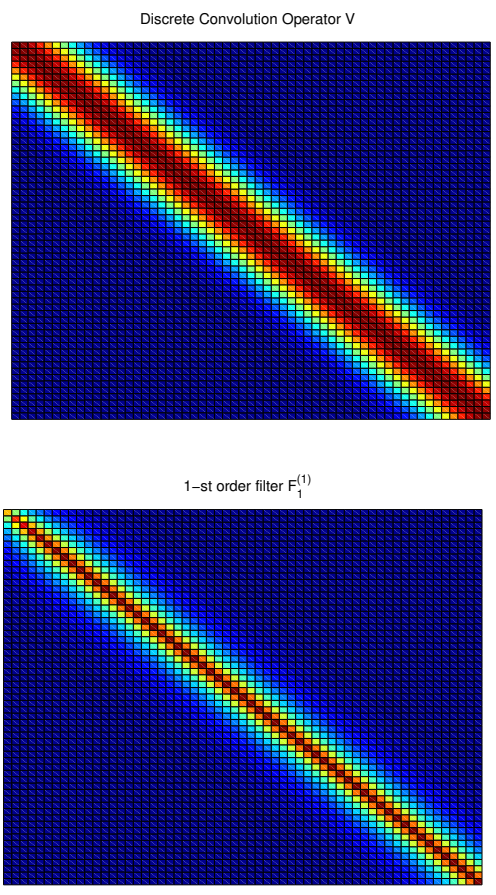

Fig. 1. **Top**. Discrete Gaussian convolution operator $\mathbf{V}$. **Bottom**. 1-st order recursive filter operator F_1

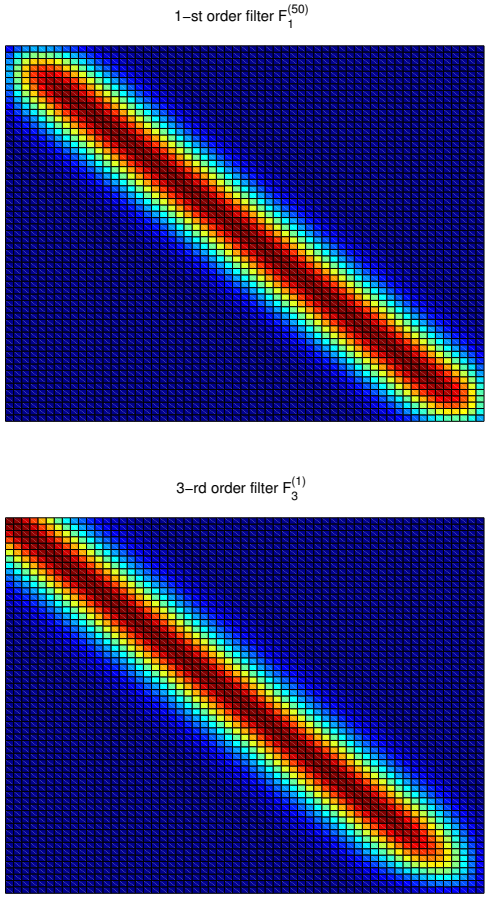

Fig. 2. **Top**. 1-st order recursive filter operator $F_1^{(50)}$ with 50 iterations. **Bottom**. 3-rd order recursive filter operator $F_3^{(1)}$

results on top right corner. In Table 2, for random distributions with homogeneous condition ($\sigma_i = \sigma$), we underline the edge effects by measuring the norms between the discrete convolution $\mathbf{V}$ and the RF filters. Although the $||\mathbf{F_n^{(K)}} - \mathbf{V}||_\infty$ ideally goes to zero as k goes to $+\infty$, this does not happen in practice as observed below.

Table 2: Distance metrics

σ	$\|\|\mathbf{F_1^{(1)}} - \mathbf{V}\|\|_\infty$	$\|\|\mathbf{F_1^{(50)}} - \mathbf{V}\|\|_\infty$	$\|\|\mathbf{F_3^{(1)}} - \mathbf{V}\|\|_\infty$
5	0.2977	0.3800	0.5346
10	0.3895	0.4397	0.5890
25	0.4533	0.4758	0.6221
50	0.4686	0.4809	0.6125

In order to bring out these considerations, we show the application of $\mathbf{V}$, $\mathbf{F_1^{(K)}}$ and $\mathbf{F_3^{(1)}}$ to a periodic signal $\mathbf{s^0}$. We choose $m = 252$ samples of the cos function in $[-2\pi, 2\pi]$ and we perform simulations by using the 1-st RF with $1, 5$ and 50 iterations and 3-rd RF with one iteration. In Figure 3 it is shown the computed Gaussian convolution and the poor approximation of $\mathbf{V}s^0$ on the right side of the test interval, due to the edge effects. A nice result is that our $\mathbf{F_3^{(1)}}$ convolution operator gives better results on the left side of the domain.

Finally, we give some considerations about the accuracy of the studied Gaussian RF schemes, when they are applied to the Dirac rectangular impulse

$$s^0 = (0, \ldots, 0, 1, 0, \ldots).$$

We choose a one-dimensional grid of $m = 301$ points, a constant correlation radius $R = 120, km$, a constant grid space $\Delta x = 6\, km$ and $\sigma = R/\Delta x = 20$. In the numerical experiments to avoid the edge effects, we only consider $\bar{m} = 221$ central values of s^K, i.e.

$$\bar{s}^K = (s^K_{2\sigma}, s^K_{2\sigma+1}, \ldots, s^K_{m-2\sigma-1}, s^K_{m-2\sigma}).$$

Similarly, in Table 3 we measure the operator distances we use $||\bar{\mathbf{F}}_\mathbf{1}^{(1)} - \bar{\mathbf{V}}||_\infty$ and $||\bar{\mathbf{F}}_\mathbf{3}^{(1)} - \bar{\mathbf{V}}||_\infty$, where $\bar{V}$, $\bar{F}_1^{(1)}$ and $\bar{F}_3^{(1)}$ indicate the submatrices obtained, neglecting first and last $2\sigma - 1$ rows and columns.

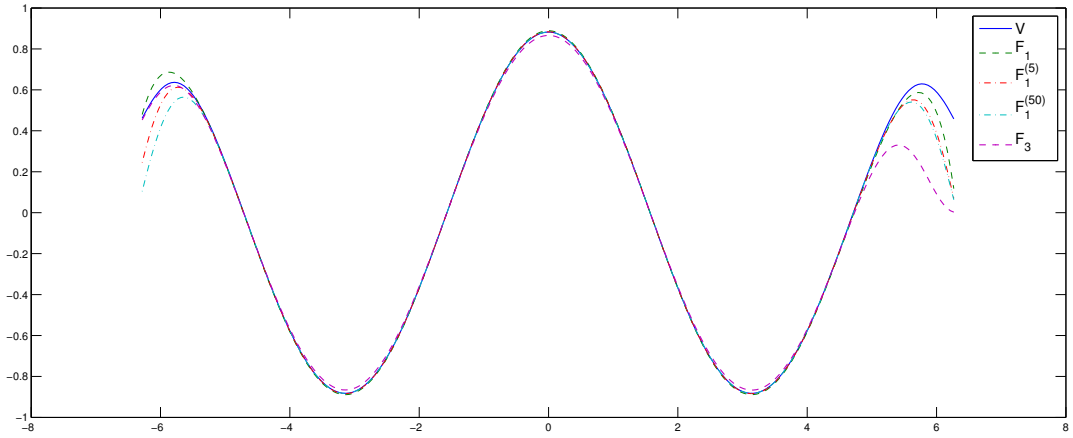

Fig. 3. Discrete convolution $\mathbf{V}$ and Gaussian recursive filtering $\mathbf{F_1^{(K)}}$ with $1, 5, 50$ iterations and $\mathbf{F_3^{(1)}}$ applied to $n = 252$ samples of the periodic function $s^0 = \cos(x)$ in $[-2\pi, 2\pi]$.

Table 3: Convergence history

K	$\|\|\bar{\mathbf{F}}_\mathbf{1}^{(\mathbf{K})} - \bar{\mathbf{V}}\|\|_\infty$	$\|\|\bar{\mathbf{F}}_\mathbf{3}^{(\mathbf{K})} - \bar{\mathbf{V}}\|\|_\infty$
1	0.211	**0.0424**
2	0.13	–
5	0.078	–
50	0.048	–
100	0.0429	–
500	0.0414	–

These case studies show that , neglecting the edge effects, the 3-rd RF filter is more accurate the the 1st-RF order with few iterations. This fact is evident by observing the results in Figure 4 and the operator norms in Table 3. Finally, we remark that the 1-st order RF has to use 100 iteration in order to obtain the same accuracy of the 3-rd order RF. This is a very interesting numerical feature of the third order filter.

B. A case study: Ocean Var

The theoretical considerations of the previous sections are useful to understand the accuracy improvement in the real experiments on Ocean Var. The preconditioned CG is a numerical kernel intensively used in the model minimizations. Implementing a more accurate convolution operators gives benefits on the convergence of GC and on the overall data assimilation scheme [11] . Here we report experimental results of the 3rd-RF in a Global Ocean implementation of OceanVar that follows [22], [12]. These results are extensively discussed in the report [11]. In real scenarios [4], [10], scientific libraries and high performance computing environments are needed. The case study simulations were carried-out on an IBM cluster using 64 processors. The model resolution was about $1/4$ degree and the horizontal grid was tripolar, as described in [19]. This configuration of the model was used at CMCC for global ocean physical reanalyses applications (see [13]). The model has 50 vertical depth levels. The three-dimensional

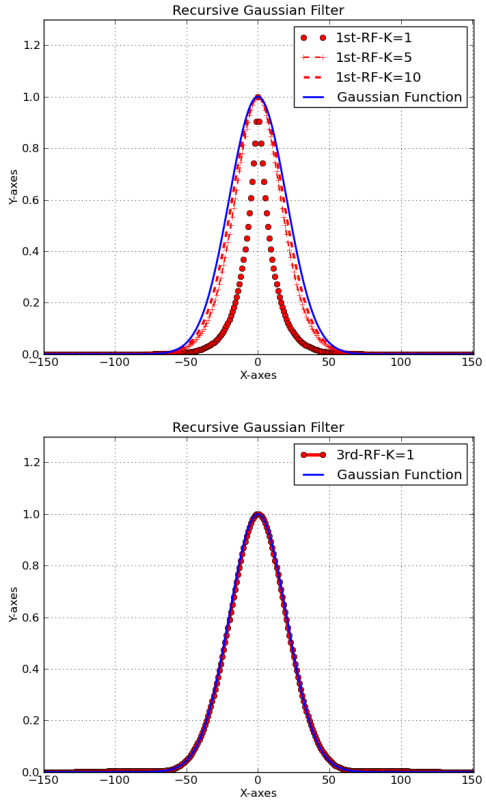

Fig. 4. **Top**. The discrete Gaussian convolution $\mathbf{V}s^0$ (blue) and $\mathbf{F_1^{(K)}}s^0$ for $K = 1, 5, 10$ (red). **Bottom** The discrete Gaussian convolution $\mathbf{V}s^0$ (blue) and $\mathbf{F_3^{(1)}}s^0$ (red).

model grid consists of 736141000 grid-points. The comparison between the 1st-RF and 3rd-RF was carried out for a realistic case study, where all in-situ observations of temperature and

salinity from Expendable bathythermographs (XBTs), Conductivity, Temperature, Depth (CTDs) Sensors, Argo floats and Tropical mooring arrays were assimilated. The observational profiles are collected, quality-checked and distributed by [3]. The global application of the recursive filter accounts for spatially varying and season-dependent correlation length-scales (CLSs). Correlation length-scale were calculated by applying the approximation given in [2] to a dataset of monthly anomalies with respect to the monthly climatology, with inter-annual trends removed.

The obtained performances of a 3Dvar application that uses the 1st-RF with 1, 5 and 10 iterations and the 3rd-RF are shown in Figure 5 with a zoom in the same area of Western Pacific Area as in Figure 5, for the temperature at 100 m of depth. The Figure also displays the differences between the 3rd-RF and the 1st-RF with either 1 or 10 iterations. The patterns of the increments are closely similar, although increments for the case of 1st-RF (K=1) are generally sharper in the case of both short (e.g. off Japan) or long (e.g. off Indonesian region) CLSs. The panels of the differences reveal also that the differences between 3rd-RF and the 1st-RF (K=10) are very small, suggesting once again that the same accuracy of the 3rd-RF can be achieved only with a large number of iterations for the first order recursive filter. Finally, in [12] was also observed that the 3rd-RF compared to the 1st-RF (K=5) and the 1st-RF (K=10) reduces the wall clock time of the software respectively of about 27% and 48%.

VI. Conclusions

Recursive Filters (RFs) are a well known way to approximate the Gaussian convolution and are intensively applied in the meteorology, in the oceanography and in forecast models. In this paper, we deal with the oceanographic 3D-Var scheme OceanVar. The computational kernel of the OceanVar software is a linear system solved by means of the Conjugate Gradient (GC) method. The iteration matrix is related to an error covariance matrix, with a Gaussian correlation structure. In other words, at each iteration, a Gaussian convolution is required. Generally, this convolution is approximated by a first order RF. In this work, we introduced a 3rd-RF filter and we investigated about the main sources of error due to the use of 1st-RF and 3rd-RF operators. Moreover, we studied how these errors influence the CG algorithm and we showed that the third order operator is more accurate than the first order one. Finally, theoretical issues were confirmed by some numerical experiments and by the reported results in the case study of the OceanVar software.

***Abstract*—In the article a new approach for solving complex and highly nonlinear differential-algebraic equations (DAEs) was presented. An important kind of applications of DAE systems is modeling of biotechnological processes, which can have a very different course. An efficient solving of equations describing biotechnological industrial inlets results in better optimization of the processes and has a positive impact on the environment. Some of the mentioned processes were characterized by a highly nonlinear dynamics. To obtain the trajectories of the state numerically, the backward differentiation formula was used in the presented method. As a result, a large-scale system of nonlinear algebraic equations was obtained. To solve a such system, the inexact Newton matrix-free approach was proposed. The new algorithm was tested on a mathematical model of a fed-batch fermentor for penicillin production. The numerical simulations were executed in MATLAB using Wroclaw Center for Networking and Supercomputing.**

Keywords*—inexact Newton methods, matrix-free methods, DAE systems, system of nonlinear equations.

I. Introduction

NOWADAYS, biotechnological processes are widely used in many real-life industrial plants. They can be often met in food industry, production of medicines and in many other sectors of industry, especially, when biodegradable components have to be used for the protection of the environment [16], [21].

Very often, the mathematical models of the bioprocesses have highly nonlinear dynamics. Technological and resources constraints on both the state and the control variables are also frequently present. Hence, a commonly used way to describe complex processes are both nonlinear ordinary differential equations and differential-algebraic equations [3], [4].

In recent years, many efforts have been devoted to the model-based optimization of processes in biotechnology and bioengineering. An example of a problem which has received major attention is the dynamic optimization of fed-batch bioreactors [17]. Dynamic optimization allows the computation of the optimal operating policies for these units to ensure the maximization of a predefined performance index. The performance index reflects a productivity or an economical index derived from both the operation profile and the final concentrations [22].

The development of information technology, robust numerical methods and computing capacity, enables to obtain optimal operating policies of the complex biotechnological processes. An efficient solving of the differential-algebraic systems enables the use of optimization strategies, what can improve a process flow significantly [5], [10].

In this work, the general problem of solving dynamical models of bioprocesses described by nonlinear differential-algebraic equations was considered. A solution strategy based on the matrix-free inexact Newton method was presented.

The article consists of 5 sections. The problem of solving complex and highly nonlinear differential-algebraic equations (DAEs) will be introduced in the next section. In the 3*rd* section the matrix-free Newton-Krylov method will be presented. The inexact Newton method will be discussed in the 4*th* section. The inexact Newton matrix-free approach will be tested on the fed-batch fermentor for penicillin production. The numerical results will be presented in the 5*th* section.

II. Statement of the problem

In general, real-life biotechnological systems with dynamics and conservation laws can be described in a *fully-implicit* form

$$\mathcal{B}\Big(\dot{y}(t), y(t), z(t), u(t), p, t\Big) = 0. \tag{1}$$

Here $y(t) \in \mathcal{R}^{n_y}$ represents the differential state trajectory, whereas $z(t) \in \mathcal{R}^{n_z}$ denotes the algebraic state trajectory, $u(t) \in \mathcal{R}^{n_u}$ a vector representing control function and $p \in \mathcal{R}^{n_p}$ indicates a vector of parameters constant in the time. Then, the nonlinear vector-valued function is considered

$$\mathcal{B} : \mathcal{R}^{n_y \times n_z \times n_u \times 1} \rightarrow \mathcal{R}^{n_\mathcal{B}}. \tag{2}$$

On the other hand, when only dynamical features of the systems are pondered, the ordinary differential equations are enough

$$\dot{y}(t) = \mathcal{G}\big(y(t), u(t), p, t\big). \tag{3}$$

Hence, some interesting relations between variables and their physical interpretations can be lost [6].

The first general technique for the numerical solution of the *fully-implicit* DAEs was the backward differential formula. The idea of this technique was that the derivative $\dot{y}(t)$ could be approximated by a linear combination of the solution $y(t)$ at the current mesh point and at several previous mesh points [19].

Previously, the backward differential formula was defined for the differential equations systems coupled to the algebraic

978-83-60810-58-3/$25.00

equations. The application of this method was soon extended to any fully-implicit system of the differential-algebraic equations.

The first order backward differential formula has been considered as the simplest method for solving differential-algebraic systems [14]. It consists of replacing the derivative in eq. (1) by the backward difference quotient

$$F\Big(\frac{y_{n+1}-y_n}{h}, y_{n+1}, z_{n+1}, t_{n+1}\Big) = 0. \tag{4}$$

where $h = t_{n+1} - t_n$.

This procedure results in system of nonlinear equations for y_{n+1} at each step. To obtain the solution from time t_n to time t_{n+1}, the system of equations (4) should be solved.

There are two main assumptions to solve the system (4). The initial value $y(t_0)$ is known and t (time) is the independent variable.

In practical applications, if the time interval, in which the system has to be considered, is known, it can be scaled to the interval $[0, 1]$.

The presented methodology leads to the following equation

$$F(\chi) = 0. \tag{5}$$

This equation is very general and often found in scientific and engineering computing areas. It was assumed, that the function F is considered, where $F : \mathcal{R}^n \to \mathcal{R}^n$ is a nonlinear mapping with the following properties:

(1) There exists a point $\chi^* \in \mathcal{R}^n$ with $F(\chi^*) = 0$.

(2) F is continuously differentiable in a neighborhood of χ^*.

(3) The Jacobian matrix $F'(\chi^*) \equiv \mathcal{J}(\chi^*)$ is nonsingular and for

$$F(\chi) = [F_1, F_2, \cdots, F_n] \tag{6}$$

and

$$\chi \in \mathcal{R}^n, \tag{7}$$

the (i, j)th element (ith row, jth column) of the Jacobian matrix is calculated as

$$\mathcal{J}_{i,j} = \frac{\partial F_i(\chi)}{\partial \chi_j}. \tag{8}$$

There have been a lot of methods for solving the nonlinear equations (5). The most popular and important are both the Newton and different variations of the inexact Newton methods [18].

III. Matrix-free Newton-Krylov method

The matrix-free Newton-Krylov method stands the iterative approach consisting of some nested levels, generally, from two to four. The name of the method come from the primary levels, which are *the Newton correction step* and the loop building up *the Krylov subspace*, out of which each Newton correction is computed [15].

In some applications two additional levels are present. There is *a preconditioner* in the interior to the Krylov loop, and, outside of the Newton loop, *a globalization method* is often required.

A. Newton method

The Newton iteration for $F(\chi) = 0$ derives from a multivariate Taylor expansion about a current point χ_k

$$F(\chi_{k+1}) = F(\chi_k) + F'(\chi_k)(\chi_{k+1} - \chi_k) + \cdots. \tag{9}$$

Neglecting the terms of the higher-order curvature and setting the left-hand side to zero yields a strict Newton method. It is as an iterative process of solving the sequence of the linear systems

$$\mathcal{J}(\chi_k)\delta\chi_k = -F(\chi_k), \tag{10}$$

to obtain $\delta\chi_k$ and to determine

$$\chi_{k+1} = \chi_k + \delta\chi_k, \qquad k = 0, 1, \cdots, \tag{11}$$

where the starting point χ_0 is given, $F'(\chi)$ is a vector-valued function of nonlinear residuals, $\mathcal{J}(\chi)$ is the Jacobian matrix associated with $F'(\chi)$, χ stands the state vector to be found, and k is a nonlinear iteration index.

The Newton iteration is terminated based on a required decrease in the norm of the nonlinear residual

$$\frac{\|F(\chi_k)\|}{\|F(\chi_0)\|} < \Delta_{res}, \tag{12}$$

and a sufficiently small Newton update

$$\frac{\|\delta\chi_k\|}{\|\chi_k\|} < \Delta_{update}. \tag{13}$$

In a scalar example, there is a one-to-one mapping between grid points and rows in the Jacobian. But forming each element of $\mathcal{J}$ requires taking analytic or discrete derivatives of the system of equations with respect to χ. This can be both time consuming and possible source of error for many problems in control and optimization of the biotechnological processes.

B. Krylov method

Krylov subspace methods are approaches for solving large-scale linear systems. They are projection or generalized projection methods for solving

$$A\chi = b, \tag{14}$$

using the Krylov subspace $\mathcal{K}_j$ defined as

$$\mathcal{K}_j = span(r_0, Ar_0, A^2r_0, \cdots, A^{j-1}r_0), \tag{15}$$

where $r_0 = b - A\chi_0$.

These methods require only matrix-vector products, not the individual elements of the matrix A, to perform the iteration. This is the key to their use with the Newton method.

C. Matrix-free Newton-Krylov methods

In the matrix-free Newton–Krylov approach, a Krylov method is used to solve the linear system of equation given by eq. (10). For the Newton step, an initial linear residual r_0 is defined, and an initial guess $\delta\chi_0$ is given

$$r_0 = -F(\chi) - \mathcal{J}(\chi)\delta\chi_0. \tag{16}$$

The nonlinear iteration index k has been omitted, because the Krylov iteration is performed at a fixed k. Let j be the Krylov iteration index. Since the Krylov solution is a Newton correction, and a locally optimal move was just made in the direction of the previous Newton correction, the initial iterate for the Krylov iteration for $\delta\chi_0$ is typically zero. This is asymptotically a reasonable guess in the context of the Newton step, as the converged value for $\delta\chi_0$ should approach zero in late Newton iterations.

When the Generalized Minimal RESidual method (GMRES) is used, in the jth iteration $\|\mathcal{J}\delta\chi_j + F(\chi)\|_2$ is minimized within a subspace of small dimension, relative to the number of unknowns, in a least-square sense [20]. $\delta\chi_j$ is drawn from the subspace spanned by the Krylov vectors, $\{r_0, \mathcal{J}r_0, \mathcal{J}^2 r_0, \cdots, \mathcal{J}^{j-1}r_0\}$, and can be written as

$$\delta\chi_j = \sum_{i=0}^{j-1} \beta_i \mathcal{J}^i r_0, \tag{17}$$

where the scalars β_i minimize the residual.

Upon examining eq. (17) one can see, that GMRES requires the Jacobian only in the form of the matrix-vector products, which may be approximated by

$$\mathcal{J}v \approx [F(\chi + \varepsilon v) - F(\chi)]/\varepsilon, \tag{18}$$

where ε is a small perturbation.

Equation (18) is a first order Taylor series expansion approximation to the product of the Jacobian $\mathcal{J}$ and a vector v.

In a simple case, when the two coupled nonlinear equations are considered $F_1 = (\chi_1, \chi_2) = 0, F_2 = (\chi_1, \chi_2) = 0$, the Jacobian matrix takes a form

$$\mathcal{J} = \begin{bmatrix} \frac{\partial F_1}{\partial \chi_1} & \frac{\partial F_1}{\partial \chi_2} \\ \\ \frac{\partial F_2}{\partial \chi_1} & \frac{\partial F_2}{\partial \chi_2} \end{bmatrix}. \tag{19}$$

The matrix-free Newton-Krylov method does not require the formation of this matrix. Instead, a result vector, that approximates this matrix multiplied by a vector, was formed.

$$\frac{F(\chi + \varepsilon v) - F(\chi)}{\varepsilon} = \begin{bmatrix} \frac{F_1(\chi_1+\varepsilon v_1, \chi_2+\varepsilon v_2) - F_1(\chi_1,\chi_2)}{\varepsilon} \\ \\ \frac{F_2(\chi_1+\varepsilon v_1, \chi_2+\varepsilon v_2) - F_2(\chi_1,\chi_2)}{\varepsilon} \end{bmatrix}. \tag{20}$$

Approximation of $F(\chi+\varepsilon v)$ with a first order Taylor series expansion about χ takes a form

$$F'(\chi_1, \chi_2) \approx \begin{bmatrix} \frac{F_1(\chi_1,\chi_2) + \varepsilon v_1 \frac{\partial F_1}{\partial \chi_1} + \varepsilon v_2 \frac{\partial F_1}{\partial \chi_2} - F_1(\chi_1,\chi_2)}{\varepsilon} \\ \\ \frac{F_2(\chi_1,\chi_2) + \varepsilon v_1 \frac{\partial F_2}{\partial \chi_1} + \varepsilon v_2 \frac{\partial F_2}{\partial \chi_2} - F_2(\chi_1,\chi_2)}{\varepsilon} \end{bmatrix}, \tag{21}$$

which simplifies

$$\mathcal{J}v = \begin{bmatrix} v_1 \frac{\partial F_1}{\partial \chi_1} + v_2 \frac{\partial F_1}{\partial \chi_2} \\ \\ v_1 \frac{\partial F_2}{\partial \chi_1} + v_2 \frac{\partial F_2}{\partial \chi_2} \end{bmatrix}. \tag{22}$$

The error in this approximation is proportional to ε.

The most attractive advantages of the matrix-free approach is a Newton-like nonlinear convergence without costs of forming and storing the true Jacobian. In practice, one forms a matrix for preconditioning purposes. However, the matrices employed in preconditioning can be simpler than true Jacobian of the problem, so the algorithm is properly said to be *Jacobian-free* [15].

Since the use of an iterative technique to solve eq. (10) does not require the exact solution of the linear system, the resulting algorithm is categorized as *the inexact Newton method*.

IV. Inexact Newton method

The Newton method is attractive because its quadratically rate of convergence from any sufficiently good initial point. But the computational cost can be expensive, especially, when the size of the problem is very large. In each iteration step the Newton equation

$$F(\chi_k) + \mathcal{J}(\chi_k)\delta\chi_k = 0 \tag{23}$$

should to be solved. Here χ_k denotes the current iterate, and $\mathcal{J}(\chi_k)$ is the Jacobian matrix of $F(x)$ at point χ_k. The solution $\delta\chi_k^N$ of the Newton equation is known as the Newton correction or the Newton step. Once the Newton step is obtained, the next iterate is given by

$$\chi_{k+1} = \chi_k + \delta\chi_k^N. \tag{24}$$

The inexact Newton method is a generalization of the Newton method [8], [12]. It is any method, which for given an initial guess χ_0, generates a sequence χ_k of approximations to χ^* as in Algorithm 1.

ALGORITHM 1. The inexact Newton method
1. Given $\chi_0 \in \mathcal{R}^n$
2. For $k = 0, 1, 2, \cdots$ until χ_k converges
   2.1 Choose some $\eta_k \in [0, 1)$
   2.2 Inexactly solve the Newton equation (10) and obtain a step $\delta\chi_k$, such that
   $\|F(\chi_k) + \mathcal{J}(\chi_k)\delta\chi_k\| \le \eta_k \|F(\chi_k)\|$. $(\star)$
   2.3 Let $\chi_{k+1} = \chi_k + \delta\chi_k$.

In the Algorithm 1, η_k is the forcing term in the kth iteration, $\delta\chi_k$ is the inexact Newton step and $(\star)$ is the inexact Newton condition.

In each iteration step of the inexact Newton method, a real number $\eta_k \in [0, 1)$ should be chosen. Then the inexact

Newton step $\delta\chi_k$ was obtained by solving the Newton equation approximately.

Since $F(\chi_k) + \mathcal{J}(\chi_k)\delta\chi_k$ is both residual of the Newton equations and the local linear model of $F(\chi)$ at χ_k, the inexact Newton condition ($\star$) reflects both the reduction in the norm of the local linear model and certain accuracy in solving the Newton equations. In this way, the role of forcing terms is to control the accuracy degree of solving the Newton equations. In particular, if $\eta_k = 0$ for all k, then the inexact Newton method is reduced into the Newton method.

The inexact Newton method, like the Newton method, is locally convergent.

Theorem 1 ([8]): Assume that $F : \mathcal{R}^n \to \mathcal{R}^n$ is continuously differentiable, $\chi^* \in \mathcal{R}^n$ such that $\mathcal{J}(\chi^*)$ is nonsingular. Let $0 < \eta_{max} < \beta < 1$ be the given constants. If the forcing terms η_k in the inexact Newton method satisfy $\eta_k \leq \eta_{max} < \beta < 1$ for all k, then there exists $\varepsilon > 0$, such that for any $\chi_0 \in N_\varepsilon(\chi^*) \equiv \{\chi : \|\chi - \chi^*\| < \varepsilon\}$, the sequence $\{\chi_k\}$ generated by the inexact Newton method converges to χ^*, and

$$\|\chi_{k+1} - \chi^*\|_* \leq \beta\|\chi_k - \chi^*\|_*, \tag{25}$$

where $\|v\|_* = \|\mathcal{J}(\chi^*)v\|$.

If the forcing terms $\{\eta_k\}$ in the inexact Newton method are uniformly strict less than 1, then by Theorem 1, the method is locally convergent. The following result states the convergence rate of the inexact Newton method.

Theorem 2 ([8]): Assume that $F : \mathcal{R}^n \to \mathcal{R}^n$ is continuously differentiable, $\chi^* \in \mathcal{R}^n$ such that $\mathcal{J}(\chi^*)$ is nonsingular. If the sequence $\{\chi_k\}$ generated by the inexact Newton method converges to χ^*, then

(1) χ_k converges to χ^* superlinearly when $\eta_k \to 0$;

(2) χ_k converges to χ^* quadratically if $\eta_k = \mathcal{O}(\|F(\chi_k)\|)$ and $\mathcal{J}(\chi)$ is Lipschitz continuous at χ^*.

Theorem 2 indicates, that the convergence rate of the inexact Newton method is determined by the choice of the forcing terms.

Various ways for selection the forcing terms have been widely discussed and tested in [1] and [13].

V. Case study

As the case study a fed-batch reactor for the production of penicillin [2] was considered. The objective was to maximize the amount of penicillin using the feed rate as the control variable. The duration of the process was specified at 120 hours.

The mathematical statement of the dynamical optimization problem is as follows.

Find $u(t)$ and t_f over $t \in [t_0, t_f]$ to maximize

$$J = x_2(t_f) \cdot x_4(t_f) \tag{26}$$

subject to differential-algebraic system

$$\frac{dx_1}{dt} = h_1 x_1 - u\left(\frac{x_1}{500x_4}\right), \tag{27}$$

$$\frac{dx_2}{dt} = h_2 x_1 - 0.01x_2 - u\left(\frac{x_2}{500x_4}\right), \tag{28}$$

$$\frac{dx_3}{dt} = -h_1\frac{x_1}{0.47} - h_2\frac{x_1}{1.2} - x_1\frac{0.029x_3}{0.0001 + x_3} + \frac{u}{x_4}\left(1 - \frac{x_3}{500}\right), \tag{29}$$

$$\frac{dx_4}{dt} = \frac{u}{500}, \tag{30}$$

$$h_1 = 0.11\left(\frac{x_3}{0.006x_1 + x_3}\right), \tag{31}$$

$$h_2 = 0.0055\left(\frac{x_3}{0.0001 + x_3(1 + 10x_3)}\right), \tag{32}$$

where x_1, x_2 and x_3 are the biomass, penicillin and substrate concentration (g/L), and x_4 is the volume (L). The initial conditions are

$$x(t_0) = [1.5 \quad 0 \quad 0 \quad 7]^T. \tag{33}$$

There are several path constraints for state variables

$$0 \leq x_1 \leq 40, \tag{34}$$

$$0 \leq x_2 \leq 25, \tag{35}$$

$$0 \leq x_3 \leq 10. \tag{36}$$

The upper and lower bounds on the control variable (feed rate of substrate) are

$$0 \leq u \leq 50. \tag{37}$$

The control problem of the fed-batch fermentor for penicillin production was solved with the matrix-free inexact Newton method, presented in the article.

At first, the overall time domain was divided into 1200 equidistant intervals. The resulting model consisted of 7200 nonlinear algebraic equations and the same number of variables and it was of the form

$$x_{1,n+1} - x_{1,n} - \Delta t\Big(h_{1,n+1}x_{1,n+1} - u\frac{x_{1,n+1}}{500x_{4,n+1}}\Big) = 0, \tag{38}$$

$$\vdots$$

$$x_{4,n+1} - x_{4,n} - \Delta t\frac{u}{500} = 0, \tag{39}$$

$$h_{1,n+1} - \Delta t\Big(0.11 \times \frac{x_{3,n+1}}{0.006x_{1,n+1} + x_{3,n+1}}\Big) = 0, \tag{40}$$

$$h_{2,n+1} - \Delta t\Big(0.0055 \times \frac{x_{3,n+1}}{0.0001 + x_{3,n+1}(1 + 10x_{3,n+1})}\Big) = 0, \tag{41}$$

for $\quad n = 0, 1, \cdots, 1200.$

The initial conditions were known only for the first stage $n = 0$. In this way, there are 7200 decision variables connected with initial values for both differential and algebraic state variables. There is one variable, which is the assumed value of the feed rate and represents the control variable.

The initial values for the decision variables were as follows

$$\chi_{1,x_{1,1}}, \cdots, \chi_{1200,x_{1,1200}} = 1.5, \tag{42}$$

$$\chi_{1201,x_{2,1}}, \cdots, \chi_{2400,x_{2,1200}} = 0.0, \tag{43}$$

$$\chi_{2401,x_{3,1}}, \cdots, \chi_{3600,x_{3,1200}} = 0.0, \tag{44}$$

$$\chi_{3601,x_{4,1}}, \cdots, \chi_{4800,x_{4,1200}} = 7.0, \tag{45}$$

$$\chi_{4801,h_{1,1}}, \cdots, \chi_{6000,h_{1,1200}} = 10.0, \tag{46}$$

$$\chi_{6001,h_{2,1}}, \cdots, \chi_{7200,h_{2,1200}} = 10.0, \tag{47}$$

In the simulations the following rule choice of the forcing terms was used

$$\eta = \min\left\{\frac{1}{k_{iter}+2}, \|F(\chi_{iter})\|\right\}, \tag{48}$$

where $iter$ denotes the number of the previously iterate [9].

For the constant control function u, the final value of the objective function was $81.1943g$. The obtained value of the control function was $u_{const} = 12.5000$. The assumed duration of the whole process was adjusted to 120 hours. Simulations were performed with the accuracy $\Delta_{res} = \Delta_{update} = 10^{-6}$. There are the optimal trajectories of both the biomass and penicillin concentrations in the Fig. 1.

In the simulation for solving the Newton equation (10), the Generalized Minimal RESidual method (GMRES) was used. In GMRES, the Arnoldi basis vector form the trial subspace out of which the solution was constructed. One matrix-vector product was required per iteration to create each new trial vector, and the iterations are terminated based on a by-product estimate of the residual that does not require explicit construction of intermediate residual vector of solutions. It was a major beneficial feature of the algorithm.

In the case study, the Jacobian matrix in the Newton equation consisted on more than $50 \cdot 10^6$ cells. It means, that the matrix-vector product would be impossible to obtain by ordinary methods.

The first proposition was to use the sparsity of the matrix, especially for the storage and speed-up of the computations. In the Jacobian matrix only 0.048% elements has another value than zero. The second proposition is the Jacobian-free approach.

These two remarks, enables us to solve the fed batch fermentor for penicillin production described by the nonlinear differential-algebraic equations.

The numerical simulations were executed in MATLAB using Wroclaw Center for Networking and Supercomputing

VI. Conclusion

In this paper the new approach for solving the nonlinear differential-algebraic equations in the *fully-implicit* form was presented. The method consists of two main remarks. The first, that the Newton equation can be solved inexactly. The appropriate choice of the forcing terms to obtain the well behaved inexact Newton method preserve locally the superlinearly convergence rate. The second remark is that, the matrix-free approach enables us to consider a large-scale systems

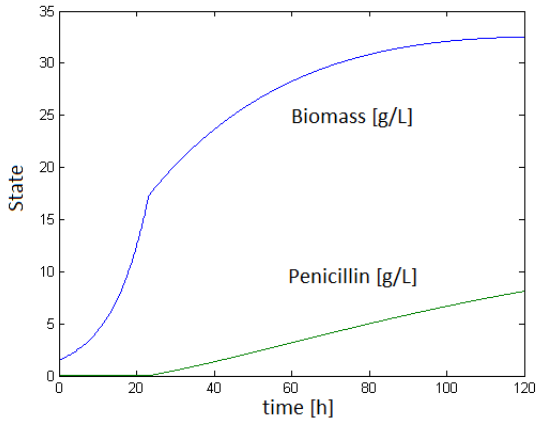

Fig. 1. The optimal trajectories of both the biomass and penicillin concentrations.

with thousands of variables. The sparse representation of the Jacobian matrix and a function, which calculate the matrix-vector product effectively, makes large-scale computations possible.

The algorithm was tested on the nonlinear DAE system, which described the fed batch fermentor for penicillin production. The discretized large-scale model consisted on 7200 nonlinear algebraic equations and the same number of variables.

The presented approach can be applied in real-life industrial plants, to optimize and control the biotechnological processes [7], [23]. The high degree of utilization of resources ensures a high profit and negligible waste.

At the next step, the new preconditioned Jacobian-free algorithms, which could solve large-scale optimization problems efficiently, will be studied and adjusted for new challenges in solving the dynamical optimization problems [11].

***Abstract*—In the present article we describe the implementation of the finite element numerical integration algorithm for the Xeon Phi coprocessor. The coprocessor is an extension of the idea of the many-core specialized unit for calculations and, by assumption, its performance has to be competitive with the current families of GPUs. Its main advantage is the built-in set of 512-bit vector registers and the ease of transferring existing codes from normal x86 architectures. However, the differences between standard x86 architectures and Xeon Phi do not guarantee performance portability. We choose an alternative approach and, instead of porting standard multithreaded code, we adapt to Xeon Phi previously developed OpenCL algorithms for finite element numerical integration. The algorithm is tested for standard FEM approximations of selected problems. The obtained timing results allow to compare the performance of the OpenCL kernels executed on the Xeon Phi and the contemporary GPUs.**

I. Motivation

IN RECENT years there has been a noticeable increase of popularity of programming with the use of graphic cards. Their computing power allows for significant acceleration of calculations for properly implemented programs. However, there is a price to be paid, in the form of complex programming model with a complicated memory organization [1], [2]. Huge performance of GPUs can be seriously limited due to data transfers between different memory levels. Therefore, an important step is to design an algorithm that takes into account characteristics of memory access mechanisms for a particular architecture.

The development of multi-core architectures has resulted in many interesting ideas for further evolution of hardware for scientific and technical calculations. GPUs are an example of massively multi-core microprocessors with the large number of relatively simple cores equipped with small amount of memory. Another development trend in microprocessor architecture is to increase the amount and width of vector execution units within a single processor, clearly visible in recent general purpose cores [3]. The other idea was to combine the architecture of a general purpose processor with SIMD units encountered in graphics cards. The first example which achieved a fairly considerable popularity is the CellBE architecture used in Sony Playstation 3 consoles and successfully adapted to the scientific purposes as PowerXCell 8i processor [4]. In our previous studies, we focused on the development of an algorithm for the finite element numerical integration on the aforementioned processors which resulted in the development of highly efficient implementations for higher order elements of the Discontinous Galerkin approximation [5]. At the same time authors developed a version for the graphic card which was then successfully redesigned to use a standard approximation of the finite element method [6]. The resulting version of the algorithm has been tested on different types of graphic cards and the results of these tests will soon be presented in [7]. Both mentioned architectures can be considered as predecessors of the new Intel Xeon Phi architecture. This architecture combines large number of cores with wide vector units in each core. Opposite to standard GPUs, coprocessor cores are less numerous and their complexity lies in between standard, general purpose cores and simple GPU cores. As in GPUs, Xeon Phi shares the same way of memory organization and therefore all codes developed for graphic cards should be easily adapted to coprocessor architecture, but as in all types of such architectures, data movement between different levels of memory may become an issue of primary importance [8]. With the introduction of Intel Xeon Phi numerical coprocessors, there is a need to test the previously developed algorithms on the new architecture and verify whether the widely advertised adaptability of existing codes also applies to the transition from GPU to coprocessor.

II. Numerical Integration Algorithm

Numerical integration algorithm is one of the most important parts of the finite element method codes. FEM assumes the division of the whole computational domain into elements for which the integrals, corresponding to pairs of element basis functions, are calculated and the results are collected in local, element stiffness matrices. Local load vectors are also obtained through integration of corresponding terms. Final structure of the formula to calculate the example entry to the element stiffness matrix depends on the form of the weak statement for the considered problem and can look as (1).

This work is developed within the project DEC-2011/01/B/ST6/00674 financed by Polish National Science Centre

$$A^e_{i_s j_s} = \int_{\Omega_e} \sum_{i_D, j_D} C^{i_D j_D} \frac{\partial \phi_{i_s}}{x_{i_D}} \frac{\partial \phi_{j_s}}{x_{j_D}} d\Omega \quad (1)$$

In the formula above, $C^{i_D j_D}$ are coefficients that depend on the problem with $i_D, j_D = 0,1,2,3$ and ϕ_{i_s}, ϕ_{j_s} are global basis functions.

In order to calculate the integrals we need to perform the change of variables, which means that the integration is made for a particular type of reference element. The transformation from the reference element to the real element is denoted by $x(\xi)$. For a reference element we use shape functions instead of global basis functions and apply one of the forms of quadrature. In our case, we used one of the most popular Gaussian quadrature. This quadrature allows for the transformation of the integral to the sum over integration points within the reference domain. Number of integration points is dependent on the required accuracy of the calculations and the type of the reference element. For N_Q integration points with coordinates ξ^Q and weights w^Q we can transform the integral (1) to the sum (2).

$$A^e_{i_S j_S} = \sum_{i_Q}^{N_Q} \sum_{i_D, j_D} C^{i_D j_D} \frac{\partial \hat{\phi}_{i_S}}{\partial \xi^Q} \frac{\partial \xi^Q}{x_{i_D}} \frac{\partial \hat{\phi}_{j_S}}{\partial \xi^Q} \frac{\partial \xi^Q}{x_{j_D}} det\, \boldsymbol{J}_{T_e} w^Q \quad (2)$$

Where $\hat{\phi}_{i_s}$ and $\hat{\phi}_{j_s}$ are shape functions and $\boldsymbol{J}_{T_e}$ is the Jacobian matrix of transformation $x(\xi)$.

Performance of numerical integration algorithm depends greatly on the problem being solved (weak formulation) and the approximation method employed. With the use of standard linear approximation the time of the creation of element stiffness matrix is relatively small. From the computational point of view, numerical integration algorithm consists of multiple independent calculations for each element. For this reason, the computational cost increases with growing number of elements. Calculated integrals correspond to the different terms in the weak formulation of the problem for which there is a need to define the matrix of coefficients for integration. Therefore, for the various problems we obtain different combinations of integration components for partial integrals of the test functions.

The problem dependent contribution mainly consists of the set of coefficient for numerical integration. Besides standard i_D and j_D indices that corresponds to the different spatial derivatives for test and trial functions, there can be also second pair of indices i_E, j_E. This indices are introduced, because for vector problems, the same approximation can be used for different unknowns in the solved system of partial differential equations (PDEs). Hence, for each combination of i_D and j_D there may be a small matrix of coefficients with the N_E dimension equal to the number of equations in solved system of PDEs. Moreover, in the most general cases there may be different values of coefficients at each integration point. Hence for the generic numerical integration algorithm array of coefficient should be considered in a form $C^{i_Q i_D j_D i_E j_E}$. The problem dependent indices indicate that element stiffness matrix entry is also dependent on the problem solved. Hence, we can define full equation for our computations, with the definition of $\frac{\partial \hat{\phi}_i}{\partial \xi}$ as $\psi^{i_Q i_D i_S}$ and $det\, \boldsymbol{J}_{T_e} w^Q$ as vol^{i_Q} (3)

$$A^e_{i_E j_E i_S j_S} = \sum_{i_Q}^{N_Q} \sum_{i_S, j_S}^{N_S} \sum_{i_E, j_E}^{N_E} \sum_{i_D, j_D}^{N_D} C^{i_Q i_D j_D i_E j_E} \psi^{i_Q i_D i_S} \psi^{j_Q j_D j_S} vol^{i_Q} \quad (3)$$

The corresponding right hand side vector is calculated using the formula (4)

$$b^e_{i_E i_S} = \sum_{i_Q}^{N_Q} \sum_{i_S}^{N_S} \sum_{i_E}^{N_E} \sum_{i_D}^{N_D} D^{i_Q i_D i_E} \psi^{i_Q i_D i_S} vol^{i_Q} \quad (4)$$

As the conclusion of the numerical integration problem definition we provide the algorithm for computing stiffness matrices and load vectors for a set of elements of the same type and the order of approximation :

1: read quadrature data ξ_Q and weights w_Q for the reference element of particular type.
2: **for** $e=1$ **to** N_e **do**
3: read problem dependent coefficients common for all integration points (e.g. material data, previous iterations (or time steps) degrees of freedom etc.)
4: read element geometry data for $x(\xi)$ transformation
5: initialize element stiffness matrix $A^e_{i_E j_E i_S j_S}$ and element load vector $b^e_{i_E i_S}$
6: **for** $i_Q=1$ **to** N_Q **do**
7: read or calculate(on a basis of the coordination of the integration points) values of shape functions and their derivatives with respect to their local coordinates for a given integration point.
8: read or calculate jacobian matrix, its determinant and inverse.
9: calculate vol^{i_Q}
10: using the jacobian matrix calculate derivatives of shape functions $\hat{\phi}_{i_Q}$ with respect to the global coordinates for a given integration point
11: basing on the values of unknowns obtained through the use of $\hat{\phi}_{i_Q}$ calculate the C^{i_Q} and D^{i_Q} coefficients for a given quadrature point
12: **for** $i_S=1$ **to** N_S **do**
13: **for** $j_S=1$ **to** N_S **do**
14: **for** $i_E=1$ **to** N_E **do**
15: **for** $j_E=1$ **to** N_E **do**
16: **for** $i_D=0$ **to** N_D **do**

```
17:            for jD=0 to ND do
18:              Ae[iS][jS][iE][jE]+=
                                  C[iQ][iE][jE][iD][jD]×
                                  ψ[iQ][iS][iD]×
                                  ψ[jQ][jS][jD]×vol[iQ]
19:            end for (jD)
20:          end for (iD)
21:          if iS=jS && iE=jE then
22:            for iD=0 to ND do
23:              be[iS][iE]+=D[iQ][iE][iD]×ψ[iQ][iS][iD]
24:          end for (jE)
25:        end for (iE)
26:      end for (jS)
27:    end for (iS)
28:  end for (iQ)
29: end for (e)
```

As we see from algorithm above, we can either read or compute most of the necessary components for numerical integration. This leads us to the conclusion that we can steer the amount of data sent from the memory and the amount of computations, depending on the available hardware resources and the problem solved.

In our case, we focused on the problem of convection-diffusion for N_E = 0 in two cases - one with simple Laplace equation, where the coefficient matrix C is sparse and coefficients appear only on the main diagonal in the case of $i_D = j_D$ (3 coefficients for stiffness matrices, one for the right hand side (RHS) vector) and a second with enhanced convection-diffusion problem for the full sixteen coefficients for stiffness matrix and four for RHS vector. Furthermore, for solving the Laplace task all coefficient were the same for all Gaussian integration points for stiffness matrix and different for the RHS vector. In the second, convection-diffusion task, all coefficients were constant for all Gauss points. For our reference elements we use prisms with 6 degrees of freedom. Our assumptions are illustrated by the data in Table I.

TABLE I.
NUMBER OF PARAMETERS FOR NUMERICAL INTEGRATION OF PRISMATIC ELEMENT

N_Q		6
N_S		6
N_geo_dofs		6
Nr_coeff_SM	**Laplace**	3
Nr_coeff_LV		6
Nr_coeff_SM	**Convection-diffusion**	16
Nr_coeff_LV		4

For optimization of the data transfer we need to decide which coefficients should be computed on the host system side and which on the accelerator side. This depends on the available resources and the type of the solved problem. Amount of data to send/store for one element can be observed in Table II.

For the GPU implementation the most important part is a proper way of data transfer organization and utilization of a limited resources. In order to port the code to the Xeon Phi coprocessor we need to reorganize the code, based on the experience gained when implementing the numerical integration for the PowerXCell 8i architecture.

III. INTEL XEON PHI

With the development of multi-core architectures and a simultaneous trend of using the graphics cards for the calculation, an idea came up to combine several different architectures in a single hardware unit whose individual elements would be responsible for processing different type of code fragments. The first device of this type – mentioned earlier PowerXCell 8i processor was unveiled by IBM and was equipped with two core with IBM Power architecture (Power Processing Element) and a few specialized SIMD cores (Synergistic Processing Elements). Its hybrid design allowed for sending to SPE a pieces of code for which you can apply the SIMD paradigm in order to speed up calculations [9]. Truncated version of this processor has been successfully applied for commercial purposes in Sony Playstation 3 consoles and its scientific version was part of the Roadrunner computer which in 2008 exceeded the petaflops performance barrier [10]. PowerXCell 8i processor was a very big step in the development of architecture and despite the discontinuation of its production it has become a base used by other manufacturers for a hardware development for high-performance computing. At the same time Intel was working on its

line of graphics cards codenamed Larabee trying to eliminate the main disadvantage in programming CellBE or GPU architectures, which is complicated programming model. The main features of this architecture was the use of a very wide vector units (512bit), texture units taken from the GPU, the coherence memory hierarchy and compatibility with x86 architecture [11]. On the basis of this project Intel Many Integrated Core (MIC) architecture was developed, which was successfully applied in Intel Xeon Phi coprocessors [12]. These coprocessors are sold as a PCI-express cards (Fig 1.) and are equipped with its own operating system based on Linux, and depending on the version 57-61 cores with hard-

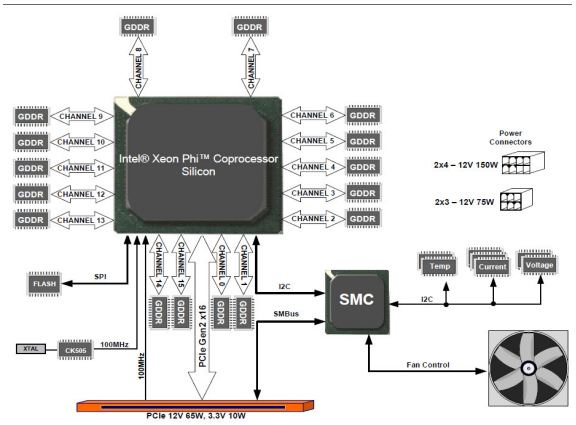

Fig 1. Xeon Phi coprocessor board schematic [13]

ware multithreading support (4 threads per core).

For testing purposes, we used 5110P coprocessor equipped with 8GB of RAM and 60 cores with a speed of 1GHz. However, in order to function properly, a single coprocessor core and 2GB of memory are reserved for the internal operating system which results in a 236 available threads and 6GB of memory for performing the calculations [14]. MIC Architecture cores design is based mainly on the Pentium architecture but it is enhanced with 512-bit vector units. The x86 compatible architecture theoretically allows for easy transfer of existing code to be used on the coprocessor with a significant increase in performance. Fig 2. shows the internal structure of the single coprocessor core.

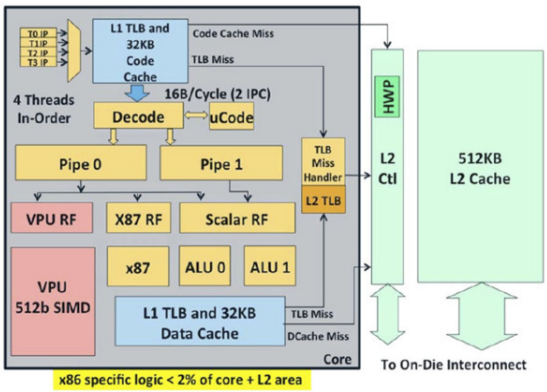

Fig 2. Single coprocessor core [15]

Every core is connected to the ultra fast interface, and thanks to a coherent cache memory, the data between cores

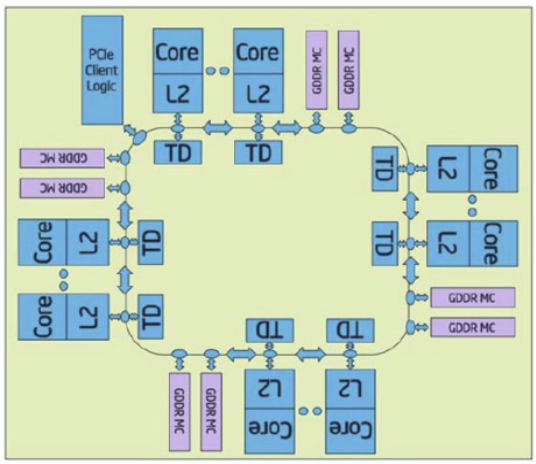

Fig 3. Xeon Phi microarchitecture [15]

are exchanged almost immediately (Fig. 3).

IV. OpenCL Programming Model

OpenCL is a software development platform that supports many kinds of available hardware, from standard CPUs, through hybrid architectures to the GPUs [16]. In recent years this platform has gained popularity due to its portability and similarity to the previously used CUDA programming model developed by Nvidia [17]. OpenCL code is compiled and run for a given platform, representing the environment for code execution. Each platform is equipped with sets of devices of three types: CPU, GPU or Accelerator. For one host system there could be many platforms installed, varying on the vendor and supported devices. Host system runs standard code and manages the execution of an OpenCL code on device. OpenCL code is called a kernel and is written in a slightly modified C language, with the special extensions to manage different types of devices. Each device in the platform is composed of compute units, that are further divided into processing elements. Individual threads are running on processing elements with capabilities depending on the architecture of device. In OpenCL nomenclature all threads are called work items and they are grouped into work groups. This allows for direct hardware mapping for different architectures. OpenCL programming model is shown on Fig. 4. Threads within a single work group execute concurrently and can be synchronized using fast system calls. Moreover, they can share some of the data in their fast shared memory, called local memory in OpenCL nomenclature. Different work-groups are scheduled independently and have

their own resources. OpenCL execution model specifies a

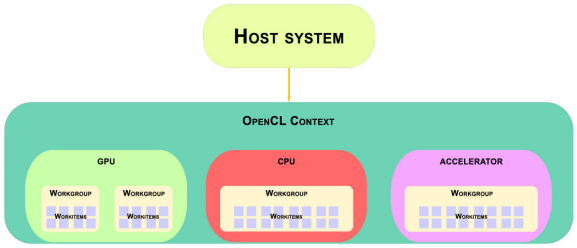

Fig 4. OpenCL programming model

set of events that has to occur in order to run a kernel.

The first phase includes initialization of the OpenCL platform, data structures and checking the available devices. Then the kernel code has to be prepared (read or compile) for running on the devices. Because of the ability of passing arguments to kernels, the space for them has to be allocated on device, before executing a kernel. Host is also responsible for preparing and allocating the space needed for variables and arrays in different types of memory that are explicitly available to programmers. All memory transactions are performed by sending a request to the OpenCL management layer. Then the requests are realized asynchronously to the host code. The same strategy is used to request kernel execution or transfer of data, back from device memory to the host memory [18].

In OpenCL the programmers have several types of memory regions explicitly available to use. Each of memory objects can be created in OpenCL memory model with different mappings to hardware resources. Individual variables defined inside kernel belong to private memory. Each thread has its own copy of each variable, and they can be stored in scalar or vector registers. Other memory regions can be assigned through specific qualifiers. Typical memory regions are divided into three types – global, constant and local. Global memory stores variables that are visible to all threads executing the kernel. Constant memory is also available for all threads but it is only accessible for reading. Variables stored in fast local memory are shared by threads in a single work-group. Because of the portability of created code OpenCL contains procedures that allows for adapting to different platforms and devices [19]. The code can query the environment to get information about many available resources. For our case we compare the available resources of all three types of devices – CPU, GPU and Accelerator. The results are presented in Table III. As we notice CPU and a Xeon Phi cards share the same amount of local and constant memory which indicates the same origins of this architectures. The Tesla K20m card used for testing our GPU implementations of numerical integration has bigger local memory size but less compute units. Hence, one can conclude that it should be slower than the other devices, but OpenCL hardware layer does not provide information on deeper division of compute units into processing elements. OpenCL in both, CPU and Intel MIC architectures treat their cores as a single compute unit but it ignores all CUDA or STREAM cores in GPUs. Our reference Tesla K20m card is equipped with 13 compute units with the Kepler architecture [20] that indicates that we have a massive amount of 192 processing elements per one compute unit, giving total 2496 cores available [21]. Despite of that all three architectures are treated as a direct opponents in the domain of high performance computing. This happens because each of these architectures has its own unique characteristics that allow for direct

TABLE III.
COMPARISON OF DIFFERENT TYPES OF DEVICES AVAILABLE IN OPENCL

cache line size (B)	64	128	0
number of compute units	24	13	236

comparison between them (e.g. architecture of cores, clock speed, vector registers etc.). This determines also, that in order to fully exploit possibilities of the hardware, all existing algorithms should be adapted separately for each of the architectures. The task of numerical integration becomes non-trivial and therefore very interesting from the performance point of view.

V. Numerical Integration on Intel Xeon Phi

For our tests we use ModFEM code - a computational framework developed for solving various scientific and engineering problems by the adaptive finite element method [22]. Due to its modular structure it allows to test different levels of the FEM. Therefore, we can easily separate the numerical integration algorithm and make a parallel versions for different architectures.

For numerical integration algorithm we have several levels of parallelism available. The chosen way of parallelisation will depend on the size of data and the number of calculations in the solved problem. Therefore, we can choose which loop from algorithm 1 should be divided. On first level we can parallelize the outermost loop over elements. Then, we can divide the loop over integration points and subsequently two inner loops over shape functions. In our previous works [5],[6] we have tested several strategies for higher order finite elements. Because of the quite big sizes of computed matrices in the problems described above, we have tested division of the inner loops over shape functions, and also a loop over Gaussian integration points. In the current case we decided to test standard approximation module. Therefore, our stiffness matrices and load vectors are quite small as we can see in Tables I and II. Hence, as the method of parallelization the most natural way of parallelizing the loop over elements is selected.

As it was mentioned above we decided to test two cases for our implementation – small Laplace and big Convection-Diffusion problem. Moreover, we have tested this problems with the use of double precision and single precision variables to check the differences between DP and SP hardware units. For our tests on graphic cards we have tried two versions of kernels – one with the stiffness matrix and load vector stored in registers and the second with the matrices stored in shared memory. In this article we will reference to them by using acronyms REG_ONE_EL for register and SHM_ONE_EL for shared memory version. Both versions has their own advantages and disadvantages. The first one allows for using very fast registers, and it saves local (shared) memory for other data, but with the limited number of registers available it can easily cause register spilling and therefore lose the efficiency of the algorithm. The second version allows for saving fast registers, but it uses a slower shared memory. Our ONE_EL versions assume that the whole element is computed by the one work-group, although one work-group can (and should) of course compute more than one element. At a first stage, host code has to compute all necessary sizes of data and thus, all needed divisions of the loops. For our reference platform we use a system equipped with NVIDIA Tesla K20m GPU, whose parameters are presented in Table III. The main difference that we must assume during the transformation of the GPU algorithm for the Xeon Phi implementation, is the size of warp/wavefront. This size (equals 32 for NVIDIA or 64 for AMD) indicates the minimal size of work-group that should be used on a given device. Due to the hardware division of every compute unit of Tesla GPU, we must also provide proper (high enough) ratio of compute unit occupancy. According to [23], Intel Xeon Phi fully utilizes its vector registers when the work-group size is set to 16. This allows for the most optimal automatic vectorization that can fully use the advantages of a very wide vector registers to store variables and use vector computations on the hardware units. Other difference lay in the use of the shared memory, because all OpenCL memory levels are mapped into Xeon Phi global memory. Hence, the use of shared and constant memory should be minimized and all possible data should be declared locally to allow proper vectorization. Of course, in the case of such a complicated algorithm there is no possibility to fit all data in registers, so we must find a proper way of preparing and storing the data. For these reasons, in opposite to GPUs SHM and REG versions that assumes only stiffness matrix allocation, we have considered more complex options for Xeon Phi.

For our tests we use a computational domain with 782336 prismatic elements. Because of the minimal work-group size that should be used for a certain architecture this indicates that we have to compute data of 785408 elements on Xeon Phi and 798720 on GPU, which in this second case is 16384 elements more than our computational domain size. While this amount seems to be very large, in fact it is only 2% more calculations and it is absolutely necessary for the proper mapping to the hardware. Due to the fact that one work-group has to compute 64 elements at once, we must divide the number of elements per compute unit by this size, so we will receive 832 work-groups that will work on 960 elements. For our Xeon Phi accelerator we have accordingly 236 work-groups with 208 elements to compute. Therefore, for GPU we have a total number of 53248 threads, while for Xeon Phi there are only 3776 threads. All precomputed values needed for calculations are shown in Table IV.

After calculations of all necessary divisions, the space needed for calculation is computed, and the data preparation phase begins. At this stage all needed buffers on the kernel side are prepared and the necessary data are computed. For our algorithm we need the following data:

- execution parameters – all values earlier computed on the host side that may be necessary for our computations – e.g. the number of elements per kernel and per work-group. This data can be stored in constant memory because we do

not need to change it. For Xeon Phi case where constatnt memory is a part of global we can assume direct read from the global memory.

TABLE IV.
PARAMETERS FOR NUMERICAL INTEGRATION OF PRISMATIC ELEMENT

	Xeon Phi	Tesla K20m
number of elements to compute	782336	782336
number of elements for kernel	785408	798720
compute units	236	13
number of elements per CU	3328	61440
number of elements per wg	208	960
wg size	16	64
number of work groups	236	832

- Gauss points data – all necessary Gaussian integration points data – their coordinates and associated weights can also be stored in constant memory or read from global in Xeon Phi case.
- Values of the shape functions and their derivatives on a reference element – needed for all Jacobian calculations and obtained in the same way as previous data.
- Geometric data (coordinates) for all elements – stored in global memory of the device. Here we can assume several different cases – we can copy it to local memory for each element separately (main method for REG version), copy it in coalesced way for all elements in work group (main method for SHM version) or use it directly form global memory (Xeon Phi).
- Problem dependent coefficients – send to global memory for all elements. Here we can repeat the methods from the geometric data above but for Xeon Phi we also decided to copy it directly to the registers to speed up the calculations.

After preparing the data above we can start our computations. Firstly if we are using shared and constant memory we must read all necessary execution parameters, Gauss data and values of the reference shape functions. At this stage for SHM version we have to declare local arrays for stiffness matrix and load vector. After preparation we are entering the outer loop over elements processed by a thread. According to the Table IV for Xeon Phi it is 208 elements per work-group of size 16 which indicates that each thread has to compute 13 elements, while for Tesla it will be 960 elements per work-group of size 64, that results in 15 elements per single iteration. Inside this loop we are reading all geometrical and coefficient data for one element. As it was mentioned above for SHM version we can organize this data for so-called coalescent access which theoretically enable higher performance of data transfer allowing for simultaneously read all data by all threads within one work-group. For Xeon Phi we can use global memory directly. Because of the use of the local memory on GPU after reading this data we need to establish a synchronization point with the use of a barrier, which can slow the flow of calculations a little bit in opposite to Xeon Phi and its direct global memory access. The next step includes defining (for REG and PHI versions) and zero the local stiffness matrix and load vector. Afterwards, we are entering the loop over Gauss points where we have to compute the Jacobian transformation matrix and its inverse on the basis of the previously obtained Gauss and geometrical data. After this calculations we are entering the innermost loops over the shape functions. After computing the values of shape functions and their derivatives for a real element based on their values for the reference element and earlier computed Jacobian matrix, we can compute a final entry to the stiffness matrix and load vector according to the algorithm 1. For SHM version we need to compute the right offset for storing the computed matrix in local memory. After computations for each Gauss points we can send the data to the device global memory. After all computations, the data stored are read back to the host system memory where they can be checked and used for further FEM computations. The amount of data send to and received from device global memory is shown in Table V.

TABLE V.
AMOUNT OF DATA SEND FOR NUMERICAL INTEGRATION

Device	Problem	Variable types	In data size [MB]	Out data size [MB]
Xeon Phi	**Laplace**	**double**	169,65	263,89
		float	84,82	131,95
	Conv-diff	**double**	238,76	263,89
		float	119,38	131,95
Tesla K20m	**Laplace**	**double**	172,52	268,37
		float	86,26	134,19
	Conv-diff	**double**	242,81	268,37
		float	121,41	134,19

VI. TESTS RESULTS

For the best comparison we use the same SHM and REG algorithms for our tests on Xeon Phi. Moreover, basing on our experiments and the [23] we have prepared the more optimal version with the direct global memory use and maximization of the register usage which we refer as PHI. The performance results obtained are presented in tables VI and VII. For simplifying the comparison between our

Xeon Phi card and a reference Nvidia Tesla K20m we provide corresponding figures.

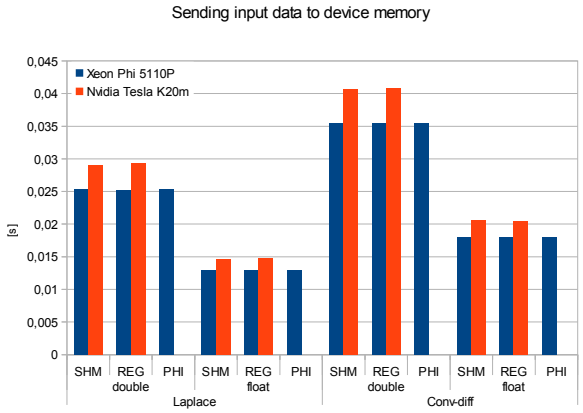

Fig 5. Sending input data to device memory

As we see from Fig. 5 the time for sending the data of comparable sizes are almost the same for Xeon Phi and Nvidia Tesla, but in all cases Xeon seems to be slightly better than Tesla.

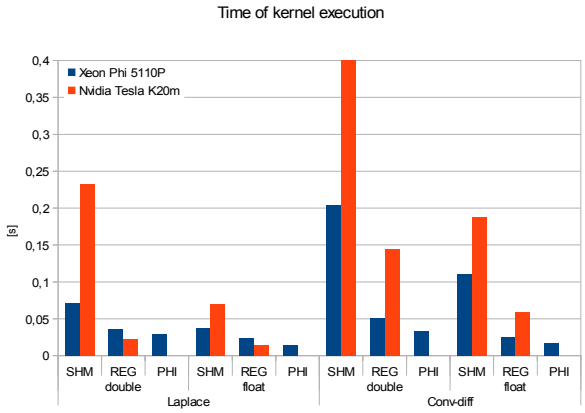

Fig 6. Time of kernel execution

Time of kernel execution (Fig. 6) shows more differences depending on the tested problem and used algorithm. A version with the use of shared memory turns out to be non optimal in our cases, but Xeon Phi is a much more faster than the Tesla card. What is more interesting we can see that the REG version with stiffness matrix stored in registers is slightly more faster than the PHI version for a small Laplace problem. All this advantage is lost when we use more complicated Convection-diffusion problem. This may indicate that Xeon Phi need quite big amount of data to fully utilize its vector registers and take advantage of it.

TABLE VII.
TEST RESULTS FOR TESLA K20M

Problem	Variable types	Kernel version	Sending Input Data to device memory		Executing kernel [s]	Copying Output Data from device memory	
			[s]	[GB/s]		[s]	[GB/s]
Laplace	double	SHM	0,029054	5,938045	0,232612	0,094975	2,82569
		REG	0,029334	5,881336	0,022464	0,164163	1,634778
	float	SHM	0,014627	5,897442	0,069616	0,142744	0,94004
		REG	0,014691	5,871696	0,013967	0,047422	2,829597
Conv-diff	double	SHM	0,040705	5,965142	0,80109	0,509872	0,526347
		REG	0,040874	5,940472	0,144406	0,094887	2,82831
	float	SHM	0,020599	5,893718	0,188041	0,046696	2,873589
		REG	0,020489	5,925403	0,058719	0,04689	2,861695

Unfortunately, all this gained performance is lost during the copying the output data back from the accelerator to the host memory (Fig. 7). As we see on Xeon Phi the organization of the global memory has no impact on the obtained results, in opposite to the Tesla card.

Table VIII shows the obtained results in Gflops – basing on that we can see that our algorithm reaches almost 15% of theoretical peak for both double and single precision according to [24]. This can lead us to the conclusion that there is a certain margin of performance that can be used for further optimization.

VII. CONCLUSIONS AND FUTURE WORK

As we have shown in this article Intel Xeon Phi could be an efficient and easy to use hardware for the finite element calculations. However, it needs quite big changes in actually developed GPU codes. In our further work we will try to manually vectorize the calculations and change the data retrieving algorithm to be more efficient. The first method will allow for comparing the automatic vectorization option of the compiler and check if it fully utilizes very wide 512-bit vector registers. Second method will allow to catch up with the Tesla GPU speed of data transfer and will let to make a full comparison of the competitive architectures.

***Abstract*—Practical realizations of 3D forward/inverse separable discrete transforms, such as Fourier transform, cosine/sine transform, etc. are frequently the principal limiters that prevent many practical applications from scaling to a large number of processors. Specifically, existing approaches, which are based primarily on 1D or 2D data decompositions, prevent the 3D transforms from effectively scaling to the maximum (possible / available) number of computer nodes. Recently, a novel, highly scalable, approach to realize forward/inverse 3D transforms has been proposed. It is based on a 3D decomposition of data and geared towards a torus network of computer nodes. The proposed algorithms requires compute-and-roll time-steps, where each step consists of an execution of multiple GEMM operations and concurrent movement of cubical data blocks between nearest-neighbor nodes (directly using the logical arrangements of the nodes within the torus). The proposed 3D orbital algorithms gracefully avoids the, required, 3D data transposition. The aim of this paper is to present a preliminary experimental performance study of the proposed implementation on two different high-performance computer architectures.**

I. Introduction

THREE-DIMENSIONAL (3D) discrete transforms (DT) such as Fourier transform, cosine/sine transform, Hartley transform, Walsh-Hadamard transform, etc., are known to play a fundamental role in many application areas, such as spectral analysis, digital filtering, signal and image processing, data compression, medical diagnostics, etc. Continuously increasing demands for high speed computing, in a constantly increasing number of many real-world applications, have stimulated the development of a number of "fast algorithms," such as the Fast Fourier Transform (FFT), characterized by dramatic reduction of arithmetic complexity. However, further reduction of execution (wall-clock) time is possible only by overlapping these arithmetic operations, i.e. using parallel implementation.

There exists three different approaches to parallel implementation of the 3D forward/inverse discrete transforms. Two of them are particularly well suited for the Fourier transform.

The first one is the 1D or "slab" decomposition of the initial 3D data. In this approach, $N \times N \times N$ data is divided into 2D slabs of size $N \times N \times b$, where $b = N/P$ and P is the number of computer nodes. The scalability of the slab-based approach, or the maximum number of nodes that can be used concurrently, is limited by the number of data elements along a single dimension of the 3D transform.

The second approach is the 2D or "pencil" decomposition, of a 3D $N \times N \times N$ initial data, among a 2D array of $P \times P$ computer nodes. Here, the initial cube is divided into a 1D "pencil" of size $N \times b \times b$, and is assigned to each node (as above, $b = N/P$). This approach increases the maximum number of nodes than can be effectively used in computations, from N to N^2. Parallel 3D FFT implementation with a 2D data decomposition has been discussed, among others, in [1], [3], [4].

In both of these, so-called, "transposed" approaches, the computational part and the inter-node communication part are separated. Moreover, a computational part inside each node is implemented by using either 2D or 1D fast (recursive) algorithm for a "slab"-based or a "pencil"-based decomposition, respectively, *without* any inter-node communication. However, upon completion of each computational part, in order to support contiguity of memory accesses, a transposition of the 3D data array is required, to put data of appropriate dimension(s) into each node. Here, at least one or two transpositions would be needed for the 1D or 2D data decomposition-based approaches, respectively. Each of such transpositions of

978-83-60810-58-3/$25.00

3D data is typically implemented by a global "all-to-all" inter-node, message-passing communication.

The last approach is the 3D or "cube" decomposition, which was recently proposed in [5]. The 3D or "cubic" decomposition of an $N \times N \times N$ initial data among $P \times P \times P$ computer nodes, allows a 3D data "cube" of size $b \times b \times b$ to be assigned to each computer node. It is easy to realize that, here, the theoretical scalability is further improved from N^2 to N^3. In this approach, blocked GEMM-based algorithms are used to compute the basic one-dimensional N-size transform, not on a single but on the $P = N/b$ cyclically interconnected (for data reuse) nodes of a 3D torus network. In this way, the proposed algorithm *integrates* local intra-node computation with a nearest-neighbour inter-node communication, at each step of the three-dimensional processing. It is important to observe that the proposed algorithm, with its 3D data decomposition, and the torus-oriented communication scheme, *completely eliminates global communication*. In addition, computation and local communication can be overlapped. Finally, note that in the considered approach, the 3D transform is represented as three chained sets of cubical tensor-by-matrix or matrix-by-tensor multiplications, which are executed in a 3D torus network of computer nodes by the fastest and extremely scalable orbital algorithms.

Te main contribution of this paper is to experimentally evaluate the performance of the latter algorithm. To do this, we have implemented overlapping of computation and communication for the 3D data decomposition and used GEMM kernels available on selected computers. The experimental performance of the 3D Discrete Cosine Transform (DCT) and Discrete Fourier Transform (DFT), with the 3D data decomposition, has been evaluated on a Linux cluster and on the Blue Gene/P supercomputer.

II. 3D Separable Transform

Let us start by introducing basic definitions concerning 3D separable transforms. Let $X = [x(n_1, n_2, n_3)]$, $0 \le n_1, n_2, n_3 < N$, be an $N \times N \times N$ cubical grid of input data, or a three-way data tensor. A separable forward 3D transform of X is another cubical grid of an $N \times N \times N$ data or a three-way tensor $\dddot{X} = [\dddot{x}(k_1, k_2, k_3)]$, where for all $0 \le k_1, k_2, k_3 < N$:

$$\dddot{x}(k_1, k_2, k_3) = \sum_{n_3=0}^{N-1} \sum_{n_2=0}^{N-1} \sum_{n_1=0}^{N-1} x(n_1, n_2, n_3) \cdot c(n_1, k_1) \cdot c(n_2, k_2) \cdot c(n_3, k_3) \quad (1)$$

A separable inverse, or backward, 3D transform of a three-way tensor $\dddot{X} = [\dddot{x}(k_1, k_2, k_3)]$ is expressed as:

$$x(n_1, n_2, n_3) = \sum_{k_3=0}^{N-1} \sum_{k_2=0}^{N-1} \sum_{k_1=0}^{N-1} \dddot{x}(k_1, k_2, k_3) \cdot c(n_1, k_1) \cdot c(n_2, k_2) \cdot c(n_3, k_3) \quad (2)$$

where $0 \le n_1, n_2, n_3 < N$ and $X = [x(n_1, n_2, n_3)]$ is an output $N \times N \times N$ cubical tensor.

We will use the notations from [5] to describe the proposed parallel algorithm. First, we divide the input data $X = [x(n_1, n_2, n_3)]$ into $P_1 \times P_2 \times P_3$ data rectangular cuboid, where each cuboid $X(N_1, N_2, N_3), 0 \le N_i < P_i$, has the size of $b_1 \times b_2 \times b_3$, i.e. $b_i = N/P_i$. Then, the forward 3D transform can be expressed as a block version of the multi-linear matrix multiplication:

$$\dddot{X}(K_1, K_2, K_3) = \sum_{N_3=0}^{P_3-1} \sum_{N_2=0}^{P_2-1} \sum_{N_1=0}^{P_1-1} X(N_1, N_2, N_3) \times C(N_1, K_1) \times C(N_2, K_2) \times C(N_3, K_3), \quad (3)$$

where $0 \le K_i < P_i$ and $C(N_s, K_s), s = 1, 2, 3$, is the (N_s, K_s)-th block of the transform matrix C.

Due to the separability of the linear transforms, the 3D transform can be split into three data dependent sets of 1D transforms. At the *first stage*, the 1D transform of $X(N_1, N_2, :)$ is performed for all (N_1, N_2) pairs, as a block tensor-by-matrix multiplication:

$$\dot{X}(N_1, N_2, K_3) = \sum_{N_3=0}^{P_3-1} X(N_1, N_2, N_3) \times C(N_3, K_3).$$

At the *second stage*, the 1D transform of $\dot{X}(:, N_2, K_3)$ is implemented for all (N_2, K_3) pairs, as the second block tensor-by-matrix multiplication:

$$\ddot{X}(K_1, N_2, K_3) = \sum_{N_1=0}^{P_1-1} \dot{X}(N_1, N_2, K_3) \times C(N_1, K_1).$$

At the *third stage*, the 1D transform of $\ddot{X}(K_1, :, K_3)$ is implemented for all (K_1, K_3) pairs, as the third block tensor-by-matrix multiplication:

$$\dddot{X}(K_1, K_2, K_3) = \sum_{N_2=0}^{P_2-1} \ddot{X}(K_1, N_2, K_3) \times C(N_2, K_2).$$

By slicing the cubical data, i.e. representing the three-way tensors as the set of matrices, it is possible to formulate the 3D transform as a conventional block *matrix-by-matrix multiplication* with its transpose/nontranspose versions. In this case, the initial data grid $X(N_1, N_2, N_3)$, is divided into 1D "slices" along one axis. Then, the 3D transform can also be computed in three data-dependent stages as chaining sets of block matrix-by-matrix products.

III. Algorithm Description

A. Multi-node Implementation

In the proposed approach it is assumed that each computer node CN(Q,R,S) has six bi-directional links labeled as $\pm Q$, $\pm R$ and $\pm S$. These nodes are toroidally interconnected. During processing, some blocks of tensor data are rolled, i.e. cyclically shifted, along (+) or opposite (-) axis (orbit). The first two stages implement the set of space-independent 2D forward transforms, in parallel, along the R-axis (orbit) slabs.

Note that, each stage of both forward and inverse transforms, with 3D data decomposition, has a common structure, i.e. steps of "compute-and-roll".

A three-stage orbital implementation of the 3D forward transform in a 3-dimensional network of toroidally interconnected nodes CN(Q,R,S) proceeds as follows.

Stage I.
$\dot{X}(N_1, N_2, K_3) = \sum_{0 \le N_3 < P_3} X(N_1, N_2, N_3) \times C(N_3, K_3)$:

- **for all** CN(Q, R, S) **do** P_3 times:
  1) **compute**: $\dot{X} \leftarrow X \times C + \dot{X}$
  2) **data roll**: $\xleftarrow{+S}$ X $\xleftarrow{-S}$

Stage II. $\ddot{X}(K_1, N_2, K_3) =$
$\sum_{0 \le N_1 < P_1} C(N_1, K_1)^T \times \dot{X}(N_1, N_2, K_3)$:

- **for all** CN(Q, R, S) **do** P_1 times:
  1) **compute**: $\ddot{X} \leftarrow C^T \times \dot{X} + \ddot{X}$
  2) **data roll**: $\xleftarrow{+Q}$ $\dot{X}$ $\xleftarrow{-Q}$

Stage III.
$\dddot{X}(K_1, K_2, K_3) = \sum_{0 \le N_2 < P_2} \ddot{X}(K_1, N_2, K_3) \times C(N_2, K_2)$:

- **for all** CN(Q, R, S) **do** P_2 times:
  1) **compute**: $\dddot{X} \leftarrow \ddot{X} \times C + \dddot{X}$
  2) **data roll**: $\xleftarrow{+R}$ $\ddot{X}$ $\xleftarrow{-R}$

For more details, see [5].

It should be noted that the implementation described here is a modification of the parallel algorithms proposed in [5]. The main differences between our implementation and the original algorithm are:

1) The implemented parallel algorithm works only for the 3D DCT and the 3D DFT;
2) The proposed implementation uses additional arrays to store elements of the coefficient matrix C. In the case of the DCT, we use one array with $4N$ elements; while for the DFT two arrays with N elements each. In this way, we avoid rolling the coefficient matrix. In other words, we simplify the communication, while paying the price of somewhat increasing (by $O(N)$ elements) the total memory utilization.

Since the tensor-by-matrix, or the matrix-by-tensor, multiplications can be expressed as the set of matrix-by-matrix multiplications, we can use an existing GEMM subroutines, from the BLAS library [2], to compute the 3D transform.

B. Multi-thread Implementation

There exists two possible ways to compute the tensor-by-matrix multiplication on computers with multi-core processors. The first one is to use the multi-threaded library, such as the Engineering and Scientific Subroutine Library (ESSL, see http://www-03.ibm.com/systems/software/essl/index.html) or the Intel Math Kernel Library (MKL, see http://software.intel.com/en-us/articles/intel-mkl/). Here, each slice of the tensor is computed by multiple threads. The other possible approach is to use OpenMP. In the current implementation, we have linked our code to the multi-threaded library for the parallelization on a single (multi-core) node of the computer system.

IV. Experimental Results

A portable parallel code was designed and implemented in C. The parallelization was based on the MPI standard [6], [7]. In the code, we used the BLAS subroutines SGEMM, DGEMM, CGEMM, and ZGEMM to perform matrix-by-matrix multiplication. In order to obtain a better mapping of the processors to the physical interconnect topology of computers actually used in experiments, functions MPI_Dims_create and MPI_Cart_create were used to create a logical 3D Cartesian grid of processors. Let us also note that we used one MPI process per computer node.

The parallel code has been tested on the following systems: (1) a cluster computer *Galera*, located in the Polish Informatics Center TASK, and (2) two IBM Blue Gene/P machines, one at the Bulgarian Supercomputing Center, and one at the HPC Center of the West University of Timisoara (UVT).

In our experiments, times have been collected using the MPI provided timer, and we report the best results from multiple runs. In the following tables, we report the elapsed (wall-clock) time T_p, in seconds, using p MPI processes, and the parallel speed-up $S_p = T_1/T_p$.

Tables I and II show the results collected on the Galera. It is a Linux cluster with 336 nodes, and two Intel Xeon quad core processors per node. Each processor runs at 2.33 GHz. Processors within each node share 8, 16, or 32 GB of memory. Nodes are interconnected with a high-speed InfiniBand network (see also http://www.task.gda.pl/kdm/sprzet/Galera). When running our code on Galera, we used the Intel C compiler, and compiled the code with the options "-O3 -openmp". To use the BLAS subroutines, we linked our code to the optimized multi-threaded Intel MKL library.

The symbol * in the tables denotes that, in the given case, the memory of p nodes was not large enough to compute the 3D transform for data of size $N \times N \times N$.

The reported execution time for $N = 100$ shows that the problem is "small" and can be executed on one node of the cluster (no need for parallelization). Here, there is no significant improvement from using two or more nodes. However, already for the problems of size $N = 600$ a significant performance gain can be observed (see, also, below). Considering the fact that some of the applications that need 3D transforms involve "real-time processing of data," it is worthy noting that, using the proposed method, similar time is required to find the solution on a single node for the problem of size $N = 600$ as finding solution using 256 nodes for the problem of size $2000 < N < 2400$.

Table III contains the speed-up obtained on the Galera. For the largest problem, which can be executed on a single node, the parallel efficiency is above 50% for the number of nodes up to 16 for the DCT and up to 32 for the DFT. We note that the main advantage of the parallel algorithm is that the code allows performing the 3D transform for very large data. Taking into account the largest cases reported in Tables I and II, we

600	2.44	4.74	8.73	16.29	28.59	47.11	79.60	110.08

can see that increasing the number of nodes from 128 to 256 results in efficiency of 60-69% for the DCT, and 40-60% for the DFT (depending if the transform forward or backward and if it runs in single or double precision).

Tables IV and V present times collected on the IBM Blue Gene/P supercomputers. For our experiments we used the BG/P machine located at the Bulgarian Supercomputing Center and a slightly different one located at the HPC Center of the West University of Timisoara (UVT). The supercomputer in Bulgaria has two BG/P racks, while the supercomputer in Romania has one BG/P rack. One BG/P rack consists of 1024 compute nodes with quad core PowerPC 450 processors (running at 850 MHz). Each node of the Bulgarian rack has 2 GB of RAM, while each node of the Romanian rack has 4 GB of RAM. For the point-to-point communications a 3.4 Gb 3D mesh network is used (for more details, see http://www.scc.acad.bg/ and http://hpc.uvt.ro/infrastructure/bluegenep/). In our experiments, to compile the code we have used the IBM XL C compiler and compiled the code with the following options: "-O5 -qstrict -qarch=450d -qtune=450 -qsmp=omp". To use the BLAS subroutines, we linked our code to the multi-threaded ESSL library.

Here, again the execution time for $N = 100$ shows that the code can be executed on one node and it is not necessary to use the parallel algorithm. Note that the memory of a single node of the IBM supercomputer is substantially smaller than that on the Galera cluster and is not sufficient for solving large problems. While both BG/P machines have the same processors, the one located in Romania has larger memory (with 4 GB memory per node). This is thus the machine used to run experiments with larger data sets. Due to the lack of space, and relative similarity of results, we do not report results obtained on both machines separately (when running problems of the same size). Note that individual processors on supercomputer are slower than these on the Galera cluster. For the double precision DFT the Blue Gene is approximately three times slower than the Galera.

Let us also observe that almost the same time was spent solving the problem of size $N = 600$ on a single node as it was spent when solving problem of size $N = 1600$ on 64 nodes. This indicates that the BG/P is more efficient in supporting parallel computing than the Galera cluster.

Table VI shows the speed-up obtained on the Blue Gene. Because of smaller memory per node we calculated the actual speed-up only for $N = 100, 200, 300, 400$. Furthermore, only for the single precision DCT the speed-up for $N = 600$ is reported. For $N = 400$ the parallel efficiency is more than 50% on up to 64 nodes for the DCT and on up to 512 nodes for the DFT.

An interesting observation comes from comparing results reported in Tables VI and VI, as well as those found in Tables II and V. For instance, in the most complex problem (where such

comparison was possible), for the backward double precision DFT, for $N = 400$ and 256 nodes, speedup obtained on Galera is 43, while on the BG/P it reaches 157. Furthermore, for the same problem (backward double precision DFT) the execution time on Galera on 256 nodes is 18 seconds, which is almost exactly the time needed to compute the same problem on 1024 nodes of the BG/P. Overall, this indicates that, in the case of the BG/P, somewhat slower nodes have been combined with superior network infrastructure, which is exactly the opposite than in the case of the Galera cluster (where more powerful processors are connected through a slower network).

Finally, in Figure 1, we represent execution time of the code, which performs one forward and one backward DFT. Results are presented for single and double precision, for problems of size $N = 400$ and $N = 600$. Here, it becomes even clearer that for both problems, using more than 64 nodes on the Galera cluster results in, so called, Amdahl's effect (where adding more resources does not result in a commensurate time reduction). This is not the case for the BG/P machines. Nevertheless, for up to 256 nodes, for $N = 600$, the cluster is faster in completing the task.

V. CONCLUDING REMARKS

The aim of this paper was to describe our attempt at implementing a slightly simplified version of a novel algorithm for 3D forward/inverse discrete transforms, and to report its performance on two different parallel computers. Obtained results show that the proposed approach allows solution of large 3D problems on a supercomputer as well as on a cluster. Furthermore, the initial estimates indicate quite good scalability of the proposed implementation. It should be noted

that the code was tested on the machines in case of which we deal with a discrepancy between the physical layout of the computing nodes and the layout assumed by the method. Nevertheless, we believe that the initial results are encouraging enough to continue work. Here, the first step will be to perform more involved testing of the performance to establish performance profile (especially for the largest problems). We also plan to investigate the performance on the cluster utilizing Intel Phi coprocessors.

ACKNOWLEDGMENTS

Computer time grants from the TASK computing center in Gdansk, Poland, the Bulgarian Supercomputing Center, and the HPC Center from West University of Timisoara are kindly acknowledged. This research was partially supported by grants DCVP 02/1 and I01/5 from the Bulgarian NSF. Work presented here is a part of the Poland-Bulgaria collaborative grant "Parallel and distributed computing practices." Work of Marcin Paprzycki was completed in part, while he was visiting University of Aizu.

***Abstract*—Let $E_n = \{x_k = 1,\ x_i + x_j = x_k,\ x_i \cdot x_j = x_k :\ i,j,k \in \{1,\ldots,n\}\}$. For a positive integer n, let $f(n)$ denote the smallest non-negative integer b such that for each system $S \subseteq E_n$ with a solution in non-negative integers $x_1,\ldots,x_n$ there exists a solution of S in non-negative integers not greater than b. We prove that if a function $\Gamma : \mathbb{N} \setminus \{0\} \to \mathbb{N}$ is computable, then f dominates Γ i.e. there exists a positive integer m such that $\Gamma(n) < f(n)$ for any $n \geq m$. For positive integers n, m, let $g(n,m)$ denote the smallest non-negative integer b such that for each system $S \subseteq E_n$ with a solution in $\{0,\ldots,m-1\}^n$ there exists a solution of S in $\{0,\ldots,b\}^n$. Then,**

$$g(n,m) \leq m-1, \tag{1}$$

$$0 = g(n,1) < 1 = g(n,2) \leq g(n,3) \leq g(n,4) \leq \ldots \tag{2}$$

and

$$g(n,f(n)) < f(n) = g(n,f(n)+1) =$$
$$g(n,f(n)+2) = g(n,f(n)+3) = \ldots \tag{3}$$

We present an infinite loop in *MuPAD* which takes as input a positive integer n and returns $g(n,m)$ on the m-th iteration.

***Index Terms*—Hilbert's Tenth Problem, infinite loop, limit-computable function, *MuPAD*, trial-and-error computable function.**

LIMIT-computable functions, also known as trial-and-error computable functions, have been thoroughly studied, see [6, pp. 233–235] for the main results. Our first goal is to present an infinite loop in *MuPAD* which finds the values of a limit-computable function $f : \mathbb{N} \setminus \{0\} \to \mathbb{N} \setminus \{0\}$ by an infinite computation, where f dominates all computable functions. There are many limit-computable functions $f : \mathbb{N} \setminus \{0\} \to \mathbb{N} \setminus \{0\}$ which cannot be bounded by any computable function. For example, this follows from [2, p. 38, item 4], see also [5, p. 268] where Janiczak's result is mentioned. Unfortunately, for all known such functions f, it is difficult to write a suitable computer program. The sophisticated choice of a function f will allow us to do so.

Let

$$E_n = \{x_k = 1,\ x_i + x_j = x_k,\ x_i \cdot x_j = x_k :\ i,j,k \in \{1,\ldots,n\}\}.$$

For a positive integer n, let $f(n)$ denote the smallest non-negative integer b such that for each system $S \subseteq E_n$ with a solution in non-negative integers $x_1,\ldots,x_n$ there exists a solution of S in non-negative integers not greater than b. This definition is correct because there are only finitely many subsets of E_n. For positive integers n, m, let $g(n,m)$ denote the smallest non-negative integer b such that for each system $S \subseteq E_n$ with a solution in $\{0,\ldots,m-1\}^n$ there exists a solution of S in $\{0,\ldots,b\}^n$. Then, conditions (1)-(3) stated in the abstract hold.

Obviously, $f(1) = 1$. The system

$$\begin{cases} x_1 = 1 \\ x_1 + x_1 = x_2 \\ x_2 \cdot x_2 = x_3 \\ x_3 \cdot x_3 = x_4 \\ \ldots \\ x_{n-1} \cdot x_{n-1} = x_n \end{cases}$$

has a unique integer solution, namely $\left(1,2,4,16,\ldots,2^{2^{n-3}},2^{2^{n-2}}\right)$. Therefore, $f(n) \geq 2^{2^{n-2}}$ for any $n \geq 2$.

The Davis-Putnam-Robinson-Matiyasevich theorem states that every recursively enumerable set $\mathcal{M} \subseteq \mathbb{N}^n$ has a Diophantine representation, that is

$$(a_1,\ldots,a_n) \in \mathcal{M} \iff$$
$$\exists x_1,\ldots,x_m \in \mathbb{N}\quad W(a_1,\ldots,a_n,x_1,\ldots,x_m) = 0 \qquad (\mathrm{R})$$

for some polynomial W with integer coefficients, see [3]. The polynomial W can be computed, if we know the Turing machine M such that, for all $(a_1,\ldots,a_n) \in \mathbb{N}^n$, M halts on $(a_1,\ldots,a_n)$ if and only if $(a_1,\ldots,a_n) \in \mathcal{M}$, see [3]. The representation (R) is said to be single-fold, if for any $a_1,\ldots,a_n \in \mathbb{N}$ the equation $W(a_1,\ldots,a_n,x_1,\ldots,x_m) = 0$ has at most one solution $(x_1,\ldots,x_m) \in \mathbb{N}^m$. Yu. Matiyasevich conjectures that each recursively enumerable set $\mathcal{M} \subseteq \mathbb{N}^n$ has a single-fold Diophantine representation, see [4].

Let $\mathcal{R}ng$ denote the class of all rings $\boldsymbol{K}$ that extend $\mathbb{Z}$.

Lemma ([8, p. 720]). *Let $D(x_1,\ldots,x_p) \in \mathbb{Z}[x_1,\ldots,x_p]$. Assume that $\deg(D,x_i) \geq 1$ for each $i \in \{1,\ldots,p\}$. We can compute a positive integer $n > p$ and a system $T \subseteq E_n$ which satisfies the following two conditions:*

978-83-60810-58-3/$25.00

`Condition 1.` *If* $\boldsymbol{K} \in \mathcal{R}ng \cup \{\mathbb{N},\ \mathbb{N} \setminus \{0\}\}$*, then*

$$\forall \tilde{x}_1, \ldots, \tilde{x}_p \in \boldsymbol{K} \left(D(\tilde{x}_1, \ldots, \tilde{x}_p) = 0 \Longleftrightarrow \right.$$

$$\left. \exists \tilde{x}_{p+1}, \ldots, \tilde{x}_n \in \boldsymbol{K}\ (\tilde{x}_1, \ldots, \tilde{x}_p, \tilde{x}_{p+1}, \ldots, \tilde{x}_n)\ \textit{solves}\ T \right)$$

`Condition 2.` *If* $\boldsymbol{K} \in \mathcal{R}ng \cup \{\mathbb{N},\ \mathbb{N} \setminus \{0\}\}$*, then for each* $\tilde{x}_1, \ldots, \tilde{x}_p \in \boldsymbol{K}$ *with* $D(\tilde{x}_1, \ldots, \tilde{x}_p) = 0$*, there exists a unique tuple* $(\tilde{x}_{p+1}, \ldots, \tilde{x}_n) \in \boldsymbol{K}^{n-p}$ *such that the tuple* $(\tilde{x}_1, \ldots, \tilde{x}_p, \tilde{x}_{p+1}, \ldots, \tilde{x}_n)$ *solves* T*.*

Conditions 1 and 2 imply that for each $\boldsymbol{K} \in \mathcal{R}ng \cup \{\mathbb{N},\ \mathbb{N} \setminus \{0\}\}$*, the equation* $D(x_1, \ldots, x_p) = 0$ *and the system* T *have the same number of solutions in* $\boldsymbol{K}$*.*

Theorem 1. *If a function* $\Gamma : \mathbb{N} \setminus \{0\} \to \mathbb{N}$ *is computable, then there exists a positive integer* m *such that* $\Gamma(n) < f(n)$ *for any* $n \geq m$*.*

Proof. The Davis-Putnam-Robinson-Matiyasevich theorem and the Lemma for $\boldsymbol{K} = \mathbb{N}$ imply that there exists an integer $s \geq 3$ such that for any non-negative integers x_1, x_2,

$$(x_1, x_2) \in \Gamma \Longleftrightarrow \exists x_3, \ldots, x_s \in \mathbb{N}\ \ \Phi(x_1, x_2, x_3, \ldots, x_s), \quad \texttt{(E)}$$

where the formula $\Phi(x_1, x_2, x_3, \ldots, x_s)$ is a conjunction of formulae of the forms $x_k = 1$, $x_i + x_j = x_k$, $x_i \cdot x_j = x_k$ $(i, j, k \in \{1, \ldots, s\})$. Let $[\cdot]$ denote the integer part function. For each integer $n \geq 6 + 2s$,

$$n - \left[\frac{n}{2}\right] - 3 - s \geq 6 + 2s - \left[\frac{6+2s}{2}\right] - 3 - s \geq 6 + 2s - \frac{6+2s}{2} - 3 - s = 0$$

For an integer $n \geq 6 + 2s$, let S_n denote the following system

$$\begin{cases} \text{all equations occurring in} \\ \qquad \Phi(x_1, x_2, x_3, \ldots, x_s) \\ n - \left[\frac{n}{2}\right] - 3 - s \text{ equations} \\ \qquad \text{of the form } z_i = 1 \\ \qquad\qquad t_1 = 1 \\ \qquad\qquad t_1 + t_1 = t_2 \\ \qquad\qquad t_2 + t_1 = t_3 \\ \qquad\qquad \ldots \\ \qquad\qquad t_{[\frac{n}{2}]-1} + t_1 = t_{[\frac{n}{2}]} \\ \qquad\qquad t_{[\frac{n}{2}]} + t_{[\frac{n}{2}]} = w \\ \qquad\qquad w + y = x_1 \\ \qquad\qquad y + y = y \text{ (if } n \text{ is even)} \\ \qquad\qquad y = 1 \text{ (if } n \text{ is odd)} \\ \qquad\qquad x_2 + t_1 = u \end{cases}$$

with n variables. By the equivalence `(E)`, S_n is satisfiable over $\mathbb{N}$. If a n-tuple $(x_1, x_2, x_3, \ldots, x_s, \ldots, w, y, u)$ of non-negative integers solves S_n, then by the equivalence `(E)`,

$$x_2 = \Gamma(x_1) = \Gamma(w + y) = \Gamma\left(2 \cdot \left[\frac{n}{2}\right] + y\right) = \Gamma(n)$$

Therefore, $u = x_2 + t_1 = \Gamma(n) + 1 > \Gamma(n)$. This shows that $\Gamma(n) < f(n)$ for any $n \geq 6 + 2s$. □

Theorem 2. *There exists a computable function* $\varphi : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ *which satisfies the following conditions:*

`1)` *For each non-negative integers* n *and* l*,*

$$\varphi(n, l) \leq l$$

`2)` *For each non-negative integer* n*,*

$$0 = \varphi(n, 0) < 1 = \varphi(n, 1) \leq \varphi(n, 2) \leq \varphi(n, 3) \leq \ldots$$

`3)` *For each non-negative integer* n*, the sequence* $\{\varphi(n, l)\}_{l \in \mathbb{N}}$ *is bounded from above.*

`4)` *The function*

$$\mathbb{N} \ni n \overset{\theta}{\longrightarrow} \theta(n) = \lim_{l \to \infty} \varphi(n, l) \in \mathbb{N} \setminus \{0\}$$

dominates all computable functions.

`5)` *For each non-negative integer* n*,*

$$\varphi(n, \theta(n) - 1) < \theta(n) = \varphi(n, \theta(n)) =$$

$$\varphi(n, \theta(n) + 1) = \varphi(n, \theta(n) + 2) = \ldots$$

Proof. Let us say that a tuple $y = (y_1, \ldots, y_n) \in \mathbb{N}^n$ is a *duplicate* of a tuple $x = (x_1, \ldots, x_n) \in \mathbb{N}^n$, if

$$(\forall k \in \{1, \ldots, n\}\ (x_k = 1 \Longrightarrow y_k = 1)) \wedge$$
$$(\forall i, j, k \in \{1, \ldots, n\}\ (x_i + x_j = x_k \Longrightarrow y_i + y_j = y_k)) \wedge$$
$$(\forall i, j, k \in \{1, \ldots, n\}\ (x_i \cdot x_j = x_k \Longrightarrow y_i \cdot y_j = y_k))$$

For non-negative integers n and l, we define $\varphi(n, l)$ as the smallest non-negative integer b such that for each $x \in \{0, \ldots, l\}^{n+1}$ there exists a duplicate of x in $\{0, \ldots, b\}^{n+1}$. Theorem 1 implies the claim of item `4)` whereas the following *MuPAD* code performs a Turing computation of $\varphi(n, l)$.

```
input("input the value of n",n):
input("input the value of l",l):
n:=n+1:
X:=[i $ i=0..l]:
Y:=combinat::cartesianProduct(X $i=1..n):
W:=combinat::cartesianProduct(X $i=1..n):
for s from 1 to nops(Y) do
for t from 1 to nops(Y) do
m:=0:
for i from 1 to n do
if Y[s][i]=1 and Y[t][i]<>1
then m:=1 end_if:
for j from i to n do
for k from 1 to n do
if Y[s][i]+Y[s][j]=Y[s][k] and
Y[t][i]+Y[t][j]<>Y[t][k]
then m:=1 end_if:

end_for:
end_for:
print(max(max(W[z][u] $u=1..n) $z=1..nops(W))):
```

Code 1
A Turing computation of $\varphi(n,l)$

□

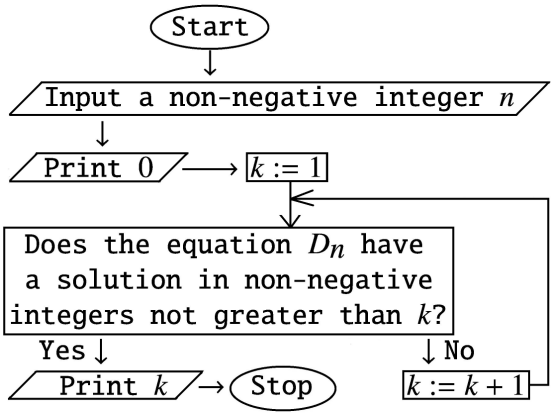
Code 1 is also stored in [10]. The following algorithm performs an infinite computation of $f(n)$, because it returns $g(n,m)$ on the m-th iteration, where m stands for any positive integer.

```
input("input the value of n",n):
i:=0:
while TRUE do
print(φ(n-1,i)):
i:=i+1:
end_while:
```

Algorithm 1
An infinite computation of $f(n)$

A slightly changed *MuPAD* code that implements Algorithm 1 is stored in [10, Code 4].

Let us fix a computable enumeration $D_0, D_1, D_2, \ldots$ of all Diophantine equations. The following flowchart illustrates an infinite computation of a limit-computable function that cannot be bounded by any computable function.



Algorithm 2
A loop whose execution does not always terminate, and that defines a partially computable function that cannot be bounded by any computable function from $\mathbb{N}$ to $\mathbb{N}$

For each non-negative integer n, the function has a non-zero value at n if and only if the equation D_n has a solution in non-negative integers. Unfortunately, the function does not have any easy implementation.

The following *MuPAD* code is stored in [10].

```
input("input the value of n",n):
print(0):
A:=op(ifactor(210*(n+1))):
B:=[A[2*i+1] $i=1..(nops(A)-1)/2]:
S:={}:
for i from 1 to floor(nops(B)/4) do
if B[4*i]=1 then
S:=S union {B[4*i-3]} end_if:
if B[4*i]=2 then S:=S union
{[B[4*i-3],B[4*i-2],B[4*i-1],"+"]}
end_if:
if B[4*i]>2 then S:=S union
{[B[4*i-3],B[4*i-2],B[4*i-1],"*"]}
end_if:
end_for:
m:=2:
repeat
C:=op(ifactor(m)):
W:=[C[2*i+1]-1 $i=1..(nops(C)-1)/2]:
T:={}:
for i from 1 to nops(W) do
for j from 1 to nops(W) do
for k from 1 to nops(W) do
if W[i]=1 then T:=T union {i} end_if:
if W[i]+W[j]=W[k] then
T:=T union {[i,j,k,"+"]} end_if:
if W[i]*W[j]=W[k] then
T:=T union {[i,j,k,"*"]} end_if:
end_for:
end_for:
end_for:
m:=m+1:
until S minus T={} end_repeat:
print(max(W[i] $i=1..nops(W))):
```

Code 2
A loop whose execution does not always terminate, and that defines a partially computable function that cannot be bounded by any computable function from $\mathbb{N}$ to $\mathbb{N}$

Theorem 3. *The above code implements a limit-computable function $\xi : \mathbb{N} \to \mathbb{N}$ that cannot be bounded by any computable function. The code takes as input a non-negative integer n, returns 0, and computes a system S of polynomial equations. If the loop terminates for S, then the next instruction returns $\xi(n)$. If the loop does not terminate, then $\xi(n) = 0$. The loop defines a partially computable function that cannot be bounded by any computable function from $\mathbb{N}$ to $\mathbb{N}$.*

Proof. Let $n \in \mathbb{N}$, and let ${p_1}^{t(1)} \cdot \ldots \cdot {p_s}^{t(s)}$ be a prime factorization of $210 \cdot (n+1)$, where $t(1), \ldots, t(s)$ denote positive integers. Obviously, $p_1 = 2$, $p_2 = 3$, $p_3 = 5$, and $p_4 = 7$.

For each positive integer i that satisfies $4i \leq s$ and $t(4i) = 1$, the code constructs the equation $x_{t(4i-3)} = 1$.

For each positive integer i that satisfies $4i \leq s$ and $t(4i) = 2$, the code constructs the equation $x_{t(4i-3)} + x_{t(4i-2)} = x_{t(4i-1)}$.

For each positive integer i that satisfies $4i \leq s$ and $t(4i) > 2$, the code constructs the equation $x_{t(4i-3)} \cdot x_{t(4i-2)} = x_{t(4i-1)}$.

The last three facts imply that the code assigns to n a finite and non-empty system S which consists of equations of the

forms: $x_k = 1$, $x_i + x_j = x_k$, and $x_i \cdot x_j = x_k$. Conversely, each such system S is assigned to some non-negative integer n.

Starting with the instruction $m := 2$, the code tries to find a solution of S in non-negative integers by performing a brute-force search. If a solution exists, then the search terminates and the code returns a non-negative integer $\xi(n)$ such that the system S has a solution in non-negative integers not greater than $\xi(n)$. In the opposite case, the execution of the code never terminates.

A negative solution to Hilbert's Tenth Problem ([3]) and the Lemma for $\boldsymbol{K} = \mathbb{N}$ imply that the code implements a limit-computable function $\xi : \mathbb{N} \to \mathbb{N}$ that cannot be bounded by any computable function. □

The execution of the last code does not terminate for $n = 7 \cdot 11 \cdot 13 \cdot 17 \cdot 19 - 1 = 323322$, when the code tries to find a solution of the system $\{x_1 + x_1 = x_1,\ x_1 = 1\}$. Execution terminates for any $n < 323322$, when the code returns 0 and next 1 or 0. The last claim holds only theoretically. In fact, for $n = 2^{18} - 1 = 262143$, the algorithm of the code returns 1 solving the equation $x_{19} = 1$ on the $\left(2 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 13 \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 37 \cdot 41 \cdot 43 \cdot 47 \cdot 53 \cdot 59 \cdot 61 \cdot 67^2 - 1\right)$-th iteration.

Let $\mathcal{P}$ denote a predicate calculus with equality and one binary relation symbol, and let Λ be a computable function that maps $\mathbb{N}$ onto the set of sentences of $\mathcal{P}$. The following pseudocode in *MuPAD* implements a limit-computable function $\sigma : \mathbb{N} \to \mathbb{N}$ that cannot be bounded by any computable function.

```
input("input the value of n",n):
print(0):
k:=1:
while Λ(n) holds in all models of size k do
k:=k+1:
end_while:
print(k):
```

Algorithm 3

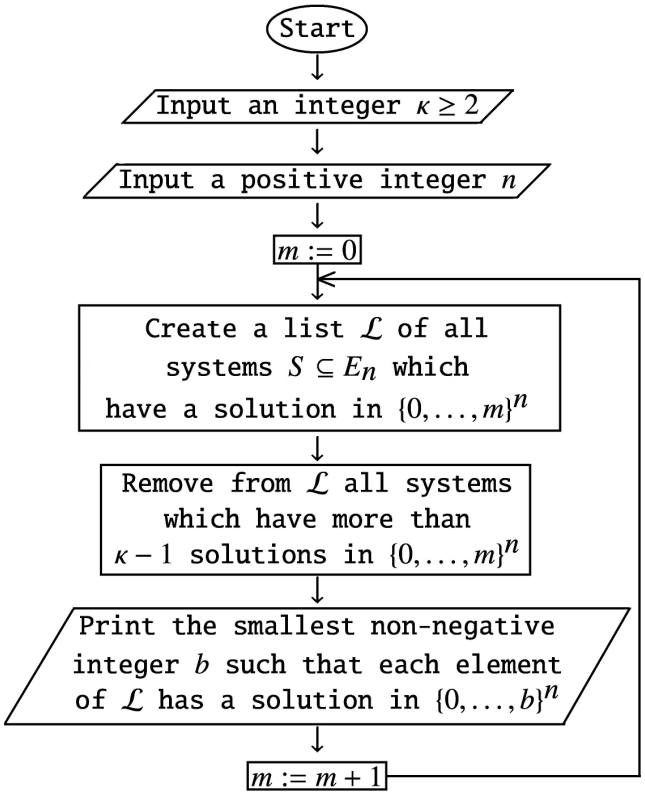
A loop whose execution does not always terminate, and that defines a partially computable function that cannot be bounded by any computable function from $\mathbb{N}$ to $\mathbb{N}$

The proof follows from the fact that the set of sentences of $\mathcal{P}$ that are true in all finite and non-empty models is not recursively enumerable, see [1, p. 129], where it is concluded from Trakhtenbrot's theorem. The author has no idea how to transform the pseudocode into a correct computer program.

The commercial version of *MuPAD* is no longer available as a stand-alone product, but only as the *Symbolic Math Toolbox* of *MATLAB*. Fortunately, the presented codes can be executed by *MuPAD Light*, which was and is free, see [11]. Similar codes in *MuPAD Light* are presented and discussed at http://arxiv.org/abs/1310.5363.

Limit-computable functions are related to the question of the decidability of Diophantine equations with a finite number of solutions in non-negative integers. Let $\kappa \in \{2, 3, 4, \ldots, \omega, \omega_1\}$. For a positive integer n, let $f_K(n)$ denote the smallest non-negative integer b such that for each system $S \subseteq E_n$ which has a solution in non-negative integers $x_1, \ldots, x_n$ and which has less than κ solutions in non-negative integers $x_1, \ldots, x_n$, there exists a solution of S in non-negative integers not greater than b. Since $f_{\omega_1} = f$, f_{ω_1} is limit-computable by Algorithm 1.

Obviously, $f_2(n)$ is the smallest non-negative integer b such that for each system $S \subseteq E_n$ with a unique solution in non-negative integers $x_1, \ldots, x_n$ this solution belongs to $[0, b]^n$. If $\kappa < \omega$, then the function f_K is limit-computable as the flowchart below describes an infinite computation of $f_K(n)$.



Algorithm 4

An infinite computation of $f_K(n)$

The following *MuPAD* code is stored in [10, Code 3] and performs an infinite computation of $f_2(n)$.

```
input("input the value of n",n):
X:=[0]:
while TRUE do
Y:=combinat::cartesianProduct(X $i=1..n):
W:=combinat::cartesianProduct(X $i=1..n):
for s from 1 to nops(Y) do
for t from 1 to nops(Y) do
m:=0:
for i from 1 to n do
if Y[s][i]=1 and Y[t][i]<>1 then m:=1 end_if:
for j from i to n do
for k from 1 to n do
```

```
if Y[s][i]+Y[s][j]=Y[s][k] and
Y[t][i]+Y[t][j]<>Y[t][k] then m:=1 end_if:
if Y[s][i]*Y[s][j]=Y[s][k] and
Y[t][i]*Y[t][j]<>Y[t][k] then m:=1 end_if:
end_for:
end_for:
end_for:
if m=0 and s<>t then
W:=listlib::setDifference(W,[Y[s]]) end_if:
end_for:
end_for:
print(max(max(W[z][u] $u=1..n) $z=1..nops(W))):
X:=append(X,nops(X)):
end_while:
```

Code 3
An infinite computation of $f_2(n)$

Theorem 5 implies that f_2 dominates any function $h : \mathbb{N} \setminus \{0\} \to \mathbb{N}$ with a single-fold Diophantine representation. Therefore, Matiyasevich's conjecture on single-fold Diophantine representations implies that f_2 dominates all computable functions from $\mathbb{N} \setminus \{0\}$ to $\mathbb{N}$.

Obviously, $f_K(1) = 1$ and $f_K(n) \geq 2^{2^{n-2}}$ for any $n \geq 2$. Theorem 1 implies that the equality

$$f_K = \{(1,1)\} \cup \left\{\left(n, 2^{2^{n-2}}\right) : n \in \{2,3,4,\ldots\}\right\}$$

is false for $\kappa = \omega_1$. The above equality is also false for any $\kappa \in \{2,3,4,\ldots,\omega\}$. The conjecture in [8] is false. The conjecture in [9] is false. The last three results were recently communicated to the author.

The representation (R) is said (here and further) to be κ-fold, if for any $a_1,\ldots,a_n \in \mathbb{N}$ the equation $W(a_1,\ldots,a_n,x_1,\ldots,x_m) = 0$ has less than κ solutions $(x_1,\ldots,x_m) \in \mathbb{N}^m$

Theorem 4. *([7, Theorem 2]) Let us consider the following three statements:*

(*a*) *There exists an algorithm $\mathcal{A}$ whose execution always terminates and which takes as input a Diophantine equation D and returns the answer* YES *or* NO *which indicates whether or not the equation D has a solution in non-negative integers, if the solution set $Sol(D)$ satisfies* $\mathrm{card}(Sol(D)) < \kappa$.

(*b*) *The function f_K is majorized by a computable function.*

(*c*) *If a set $\mathcal{M} \subseteq \mathbb{N}^n$ has a κ-fold Diophantine representation, then $\mathcal{M}$ is computable.*

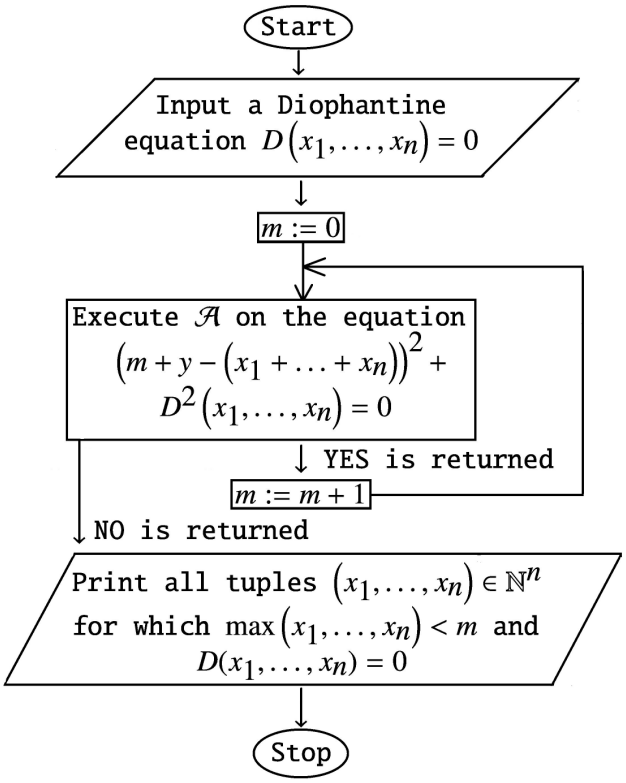
We claim that (*a*) *is equivalent to* (*b*) *and* (*a*) *implies* (*c*).

Proof. The implication $(a) \Rightarrow (c)$ is obvious. We prove the implication $(a) \Rightarrow (b)$. There is an algorithm Dioph which takes as input a positive integer m and a non-empty system $S \subseteq E_m$, and returns a Diophantine equation $\mathrm{Dioph}(m,S)$ which has the same solutions in non-negative integers $x_1,\ldots,x_m$. Item (*a*) implies that for each Diophantine equation D, if the algorithm $\mathcal{A}$ returns YES for D, then D has a solution in non-negative integers. Hence, if the algorithm $\mathcal{A}$ returns YES for $\mathrm{Dioph}(m,S)$, then we can compute the smallest non-negative integer $i(m,S)$ such that $\mathrm{Dioph}(m,S)$ has a solution in non-negative integers not greater than $i(m,S)$. If the algorithm $\mathcal{A}$ returns NO for $\mathrm{Dioph}(m,S)$, then we set $i(m,S) = 0$. The function

$$\mathbb{N} \setminus \{0\} \ni m \to \max\left\{i(m,S) : \emptyset \neq S \subseteq E_m\right\} \in \mathbb{N}$$

is computable and majorizes the function f_K. We prove the implication $(b) \Rightarrow (a)$. Let a function h majorizes f_K. By the Lemma for $\boldsymbol{K} = \mathbb{N}$, a Diophantine equation D is equivalent to a system $S \subseteq E_n$. The algorithm $\mathcal{A}$ checks whether or not S has a solution in non-negative integers $x_1,\ldots,x_n$ not greater than $h(n)$. □

The implication $(a) \Rightarrow (c)$ remains true with a weak formulation of item (*a*), where the execution of $\mathcal{A}$ may not terminate or $\mathcal{A}$ may return nothing or something irrelevant, if D has at least κ solutions in non-negative integers. The weakened item (*a*) implies that the following flowchart



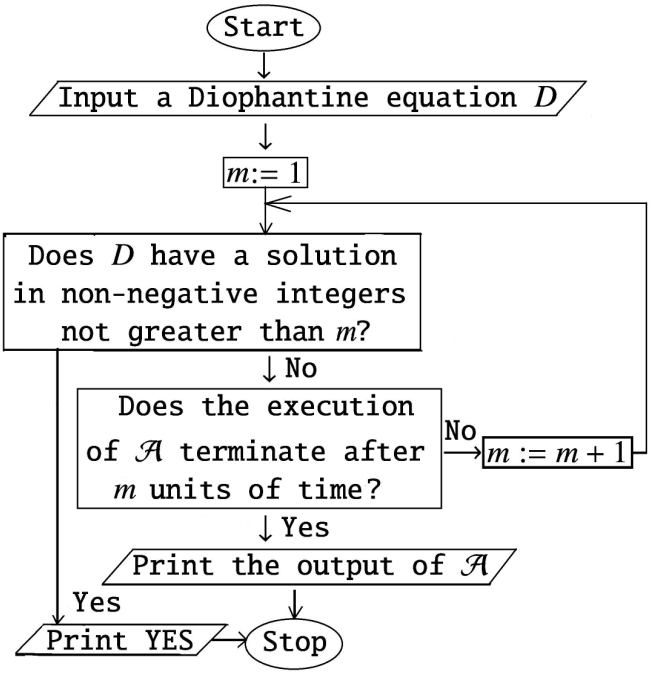
Algorithm 5
An algorithm that conditionally finds all solutions to a Diophantine equation which has less than κ solutions in non-negative integers

describes an algorithm whose execution terminates, if the set

$$Sol(D) := \{(x_1,\ldots,x_n) \in \mathbb{N}^n : \ D(x_1,\ldots,x_n) = 0\}$$

has less than κ elements. If this condition holds, then the weakened item (*a*) guarantees that the execution of the flowchart prints all elements of $Sol(D)$. However, the weakened item (*a*) is equivalent to the original one. Indeed, if the algorithm $\mathcal{A}$

satisfies the weakened item (*a*), then the flowchart below illustrates a new algorithm $\mathcal{A}$ that satisfies the original item (*a*).



Algorithm 6
The weakened item (*a*) implies the original one

The equality $f_{\omega_1} = f$ and Theorem 1 imply that item (*b*) is false for $\kappa = \omega_1$. By this and Theorem 4, we alternatively obtain a negative solution to Hilbert's Tenth Problem.

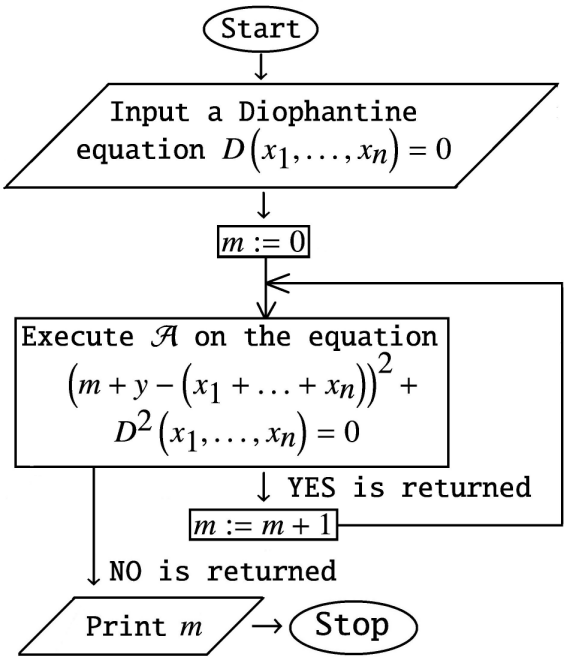
Theorem 5. *([7, Theorem 1]) If a function $h : \mathbb{N} \setminus \{0\} \to \mathbb{N}$ has a κ-fold Diophantine representation, then there exists a positive integer m such that $h(n) < f_K(n)$ for any $n \geq m$.*

By the Davis-Putnam-Robinson-Matiyasevich theorem, Theorem 1 is a special case of Theorem 5 when $\kappa = \omega_1$. Let us pose the following two questions:

Question 1. *Is there an algorithm $\mathcal{B}$ which takes as input a Diophantine equation D, returns an integer, and this integer is greater than the heights of non-negative integer solutions, if the solution set has less than κ elements? We allow a possibility that the execution of $\mathcal{B}$ does not terminate or $\mathcal{B}$ returns nothing or something irrelevant, if D has at least κ solutions in non-negative integers.*

Question 2. *Is there an algorithm C which takes as input a Diophantine equation D, returns an integer, and this integer is greater than the number of non-negative integer solutions, if the solution set is finite? We allow a possibility that the execution of C does not terminate or C returns nothing or something irrelevant, if D has infinitely many solutions in non-negative integers.*

Obviously, a positive answer to Question 1 implies the weakened item (*a*). Conversely, the weakened item (*a*) implies that the flowchart below describes an appropriate algorithm $\mathcal{B}$.



Algorithm 7
The weakened item (*a*) implies a positive answer to Question 1

Theorem 6. *A positive answer to Question 1 for $\kappa = \omega$ is equivalent to a positive answer to Question 2.*

Proof. Trivially, a positive answer to Question 1 for $\kappa = \omega$ implies a positive answer to Question 2. Conversely, if a Diophantine equation $D(x_1, \ldots, x_n) = 0$ has only finitely many solutions in non-negative integers, then the number of non-negative integer solutions to the equation

$$D^2(x_1, \ldots, x_n) + (x_1 + \ldots + x_n - y - z)^2 = 0$$

is finite and greater than $\max(a_1, \ldots, a_n)$, where $(a_1, \ldots, a_n) \in \mathbb{N}^n$ is any solution to $D(x_1, \ldots, x_n) = 0$. □

***Abstract*—The paper illustrates the concept of the map with logarithmically invertible decomposition. We introduce families of multivariate cryptosystems such that there security level is connected with discrete logarithm problem in Cremona group. The private key of such cryptosystem is a modification of graph based stream ciphers which use stable multivariate maps. Modified version corresponds to a stable map with single disturbance. If the disturbance (or initial condition) allows fast computation then modified version is almost as robust as original one. Methods of modification improve the resistance of such stream ciphers implemented on numerical level to straightforward linearisation attacks.**

I. Introduction

THE FORMAL concepts of multivariate map with logarithmically invertible decomposition is introduced by the author in Extended Abstracts Of Central European Conference on Cryptology, 2014. In this paper the examples of a cryptosystem based on this idea will be presented. The complexity estimates of an encryption and a decryption procedures are given. The construction uses walks on graphs $D(n,K)$ or $A(n,K)$ for purpose of Multivariate Cryptography. Such walks firstly used for the constructions of fast stream ciphers. The multivariate maps induced by such walks turn out to be fast cubical transformations of the plainspace (variety of vertices or variety of flags (see [1], [2]). It makes them useful for a design of stream ciphers and key exchange protocols. It was shown [3], [4] that the inverses of encryption maps are also cubical transformations. This fact restricts their use in public key cryptography. In [5] more general idea of multivariate map corresponding to *symbolic walk* on the graph has been introduced. Paper [6] suggests the deformation of such nonlinear map by two affine transformations and the use of deformated transformation in Multivariate Cryptography, but important questions of estimation of degrees, orders, densities are still under investigation.

Currently symbolic walks are used for the development of stream ciphers with high resistance to plaintext - ciphertext attacks of the adversary.

Current paper contains description of algorithms which allows a repetition of chosen walks on the graph $D(n,K)$ and $A(n,K)$. This rout makes the bridges towards discrete logarithm problem for cyclic subgroups of Cremona group.

Preliminaries on Multivariate Cryptography are collected in the section 2 which contains definitions of special multivariate maps. Section 3 is devoted to information on problems of Extremal Graph Theory which leads to discovery of graphs $D(n,F_q)$ and $A(n,q)$. The descriptions of graphs $D(n,K)$ and their connected components together with cryptographical applications are given in section 4. The graph based explicit construction of requested multivariate transformations is given in section 5. It comes together with the decryption of multivariate public key based on graphs $D(n,K)$.

The last section is the conclusion.

II. On multivariate cryptography and special multivariate transformations

Multivariate cryptography (see [7]) is one of the directions of Postquantum Cryptography, which concerns with algorithms resistant to hypothetic attacks conducted by Quantum Computer. The encryption tools of Multivariate Cryptography are nonlinear multivariate transformations of affine space K^n, where K is a finite commutative ring. Nowadays this modern direction of research requires new examples of algorithms with theoretical arguments on their resistance to attacks conducted by ordinary computer (Turing machine) and new tasks for cryptanalists.

Recall, that *Cremona group* $C(K^n)$ is a totality of invertible maps f of affine space K^n over a Commutative ring K into itself, such that the inverse map f^{-1} is also a polynomial one.

Let us refer to the sequence of maps $f(n)$ from $C(K^n)$, $n=1,2,\dots$ as *the family of bounded degree*, if the degree of each transformation is bounded by the finite parameter s.

Assume that a transformation $f=f(n)$ is written in the form: $x_i \to f_i(x_1,x_2,\dots,x_n)$, $i=1,2,\dots,n$, where each $f_i \in K^n$ is determined by the list of their monomial terms with respect to some chosen order.

A family of elements $f(n) \in C(K^n)$, $n>1$ is called stable if each nonidentity multiple iteration of $f(n)$ with itself has the same degree with $f(n)$. Let $|g|$ be the order of $g \in C(K^n)$.

978-83-60810-58-3/$25.00

We say, that $f(n)$ is a family of increasing order if $|f(n)|$ for n.

Let us consider the discrete logarithm problem for a stable family f^n of increasing order. We have to solve the equation $f(n)^y = b(n)$ with respect to an integer unknown y. Notice, that $\deg(f(n)) = \deg(b(n))$. It means, that studies of degrees $(f(n))^k$, $k = 1, 2, \dots$ do not bring us any new information for the task execution. If the order of an element $f(n)$ is growing fast with the growth of n, then discrete logarithm problem can be NP - hard.

We say that a family $f(n) \in C(K^n)$ has an invertible decomposition of speed d if $f(n)$ can be written as a composition of elements $f^1(n), f^2(n), \dots, f^{k(n)}(n)$ and this decomposition will allow us to compute the value of $y = f(x)$ and the re-image of given y in time $k(n)O(n^d)$ (see the authors extended abstract for Central European Conference on Cryptology 2014).

In the case $d = 1$ we say that invertible decomposition is of linear speed. The complexity of computation of the value of each $f^i(n)$ in a given point x is $O(n^d)$. We refer to the family of multivariate maps $h_{n+1} : K^{n+1} \to K^{n+1}$ as a family with logarithmically invertible decomposition of speed t with the initial function $f(x_1, x_2, \dots, x_n)$ if there exists decomposition $h_{n+1} = h_{n+1,1}h_{n+1,2} \dots h_{n+1,k(n)}$ such that the knowledge about it allows us to solve the equation

$h_{n+1}{}^{\alpha}(x_1, x_2, \dots, x_n, f(x_1, x_2, \dots, x_n)) = (b_1, b_2, \dots, b_{n+1})$ for unknowns $\alpha, x_1, x_2, \dots, x_n$ in time $k(n)O(n^t)$.

We say that function $u : Z^+ \to Z^+$ is computationally equivalent to n^s, $s \geq 0$ and write $u(n^s$ if $C_1 n^s \leq u(n) \leq C_2 n^s$ for some positive constants C_1 and C_2.

Examples of stable families $f(n) \in C(K^n)$ of bounded degree and increasing order defined in terms of algebraic graph theory are given in [4], [8], [9], [11]. An example of stable transformations of linear degree and increasing order is proposed in [12] (see also survey [10], [13] and 14] for extra examples).

III. Extremal algebraic graphs corresponding to special families of multivariate maps and their usage in symmetric cryptography

Recall, that the girth is the length of minimal cycle in the simple graph. Studies of maximal size $ex(C_3, C_4, \dots, C_{2m}, v)$ of the simple graph on v vertices without cycles of length $3, 4, \dots, 2m$, i. e. graphs of girth $> 2m$, form an important direction of Extremal Graph Theory (see [15]).

As it follows from famous the Even Circuit Theorem by P. Erdős we have inequality

$$ex(C_3, C_4, \dots, C_{2m}, v) \leq cv^{1+1/n},$$

where c is a certain constant. The bound is known to be sharp only for $n = 4, 6, 10$. The first general lower bounds of kind $ex(v, C_3, C_4, \dots C_n) = \Omega(v^{1+c/n})$, where c is some constant $< 1/2$ were obtained in the 50th by Erdős via studies of *families of graphs of large girth*, i.e. infinite families of simple regular graphs Γ_i of degree k_i and order v_i such that $g(\Gamma_i) \geq c\log_{k_i} v_i$, where c is the independent of i constant. Erdős proved the existence of such a family with arbitrary large but bounded degree $k_i = k$ with $c = 1/4$ by his famous probabilistic method.

First two explicit families of regular simple graphs of large girth with unbounded girth and arbitrarily large k appeared in 90th: the family $X(p, q)$ of Cayley graphs for $PSL_2(p)$, where p and q are primes, which has been defined by G. Margulis [10] and investigated by A. Lubotzky, Sarnak and Phillips [17] and the family of algebraic graphs $CD(n, q)$ [18]. Graphs $CD(n, q)$ appear as connected components of graphs $D(n, q)$ defined via a system of quadratic equations [19]. The best known lower bound for $d \neq 2, 3, 5$ has been deduced from the existence of above mentioned families of graphs $ex(v, C_3, C_4, \dots, C_{2d}) \geq cv^{1+2/(3d-3+e)}$ where $e = 0$ if d is odd, and $e = 1$ if d is even.

Recall, that family of regular graphs Γ_i of degree k_i and increasing order v_i is a *family of graphs of small world* if $\mathrm{diam}(\Gamma_i) \leq c\log_{\mathrm{k_i}}(v_i)$ for some independent constant c, $c > 0$, where $\mathrm{diam}(\Gamma_i)$ is a diameter of graph G_i. The graphs $X(p.q)$ form a unique known family of large girth which is a family of small world graphs at the same time. There is a conjecture known since 1995 that family of graphs $CD(n, q)$ for odd q is an other example of such kind. Currently, it is proved that the diameter of $CD(n, q)$ is bounded from above by polynomial function $d(n)$, which does not dependent from q. Expanding properties of $X(p, q)$ and $D(n, q)$ can be used in Coding Theory (magnifiers, superconcentrators, etc). The absence of short cycles and high girth property of both families can be used for the construction of LDPC codes [20]. This class of error correcting codes is an important tool of security for satellite communications. The usage of $CD(n, q)$ as Tanner graphs producing LDPC codes leads to better properties of corresponding codes in the comparison to the usage of Cayley - Ramanujan graphs (see [21]).

Both families $X(p, q)$ and $CD(n, q)$ consist of edge transitive graphs. Their expansion properties and the property to be graphs of large girth also hold for random graphs, which have no automorphisms at all. To make better deterministic approximation of random graph we can look at regular expanding graphs of large girth without edge transitive automorphism group.

Below We consider an optimization problem for simple graphs which is similar to the problem of finding maximal size for graph on v vertices with the girth $\geq d$.

Let us refer to the minimal length of a cycle, through the vertex of the given vertex of the simple graph Γ as a *cycle indicator of the vertex*. The *cycle indicator of the graph* $\mathrm{Cind}(\Gamma)$ will be defined as a maximal cycle indicator of its vertices. Regular graph will be called a *cycle irregular graph* if its indicator differs from the girth (the length of minimal cycle). The solution of the optimization problem of computation of maximal size $e = e(v, d)$ of the graph of an order v with the size greater than d, $d > 2$ has been found very recently.

It turns out that

$$e(v,d) \Leftrightarrow O(v^{1+[2/d]})$$

and this bound is always sharp (see [22] or [23] and further references).

We refer to the family of regular simple graphs Γ_i of degree k_i and order v_i as a *family of graphs of large cycle indicator*, if

$$\mathrm{Cind}(\Gamma_i) \geq c\log_{\mathrm{k_i}}(v_i)$$

for some independent constant c, $c > 0$. We refer to the maximal value of c satisfying the above inequality as *speed of growth* of the cycle indicator for a family of graphs Γ_i. As it follows from the written above evaluation of $e(v,d)$ the speed of growth of the cycle indicator for the family of graphs of constant but arbitrarily large degree is bounded above by 2.

We refer to such a family as a *family of cyclically irregular graphs of large cycle indicator* if almost all graphs from the family are cycle irregular graphs.

The following theorem was proved in [23]:

There is a family of almost Ramanujan cyclically irregular graphs of large cycle indicator with the speed of cycle indicator 2, which is a family of graphs of small word graphs.

The explicit construction of the family $A(n,q)$ like in previous statement is given in [22], [23]. Notice, that members of the family of cyclically irregular graphs are not edge transitive graphs. The LDPC codes related to new families are presented in [24], computer simulations demonstrate essential advantages of new codes in comparison to those related to $CD(n,q)$ and $D(n,q)$.

A. On the stream ciphers corresponding to special families of multivariate maps

Graphs $D(n,q)$, $A(n,q)$ and $CD(n,q)$ have been used in symmetric cryptography together with their natural analogs $D(n,K)$, $A(n,K)$ and $CD(n,K)$ over general finite commutative rings K since 1998 (see [1]). The theory of directed graphs and language of dynamical system have been very useful for studies of public key and private key algorithms based on graphs $D(n,K)$, $CD(n,K)$ and $A(n,K)$ (see [10], [25], and further references).

There are several implementations of symmetric algorithms for cases of fields (starting from [7]) and arithmetical rings ([19], in particular). Some comparison of public keys based on $D(n,K)$ and $A(n,K)$ are considered in [21].

The general scheme is the following one. We can use a family of elements $f(n)$ with invertible decomposition of speed d of increasing order for purposes of symmetric cryptography. We assume that the variety K^n is a plainspace of the encryption algorithm, the list of $(f(n,i)$, $i = 1,2,\ldots,k(n)$, is a password. Then the computation of the value c of encryption function $f(n,1)f(n,2)\ldots f(n,k(n))$ in the given plaintext $\mathrm{p} \in K^n$ and the reimage of the ciphertext c require time $O(n^d)$. Usually the parameter $k(n)$ can be chosen free. In fact, in practical cases $k(n)$ is either constant or linear function in variable n (see surveys [20]. [23], [25] on the use graph based multivariate functions as symmetric encryption functions). To hide the graph nature of $f(n)$ correspondents (Alice and Bob) can create a new encryption map $h(n)$ as a conjugation of $f(n)$ with special invertible affine transformation $\tau = \tau(n)$ (degree equals 1) of K^n. In case of private keys both correspondents know the invertible decompositions and family $\tau(n)$ of affine transformation as part of the key.

IV. On the explicit constructions

A. Description of graphs $A(n,K)$

The graph $A(n,K)$, where K is a finite commutative ring, is defined by the following way. This is a bipartite graph with the point set $P = \{x_1,x_2,\ldots,x_n)|x_i \in K\} = K^n$ and the line set $L = \{[y_1,y_2,\ldots,y_n]|y_i \in K|\} = K^n$ and such that a point $\mathrm{x} = (x_1,x_2,\ldots,x_n)$ is incident to a line $\mathrm{y} = [y_1,y_2,\ldots,y_n]$ if and only if equations $x_i - y_i = y_1x_1$ hold for even i and relations $x_j - y_j = x_1y_j$ hold for an odd j, $j \geq 3$. We identify such an incidence relation with the corresponding bipartite graph $I = A(n,K)$. We refer to the first coordinate $x_1 = \rho(\mathrm{x})$ of a point x and the first coordinate $y_1 = \rho(\mathrm{y})$ of a line y of the line as the colour of the vertex (point or line). The following property holds for the graph: there exists a unique neighbour $N_t(v)$ of a given vertex v of a given colour $t \in K$.

As it follows from the definition the projective limit of $A(n,K)$, $n \to \infty$ is well defined. The points $\mathrm{p} = (p_1,p_2,\ldots,p_n,\ldots)$ and lines $\mathrm{l} = [l_1,l_2,\ldots,l_n,\ldots]$ are tuples with finite number of nonzero coordinates. A point and a line are incident when infinite number of equations $p_2 - y_l = l_1p_1, p_3 - l_3 = p_1l_2,\ldots$ hold.

B. Description of graphs $D(n.K)$ and their connected components

We define the family of graphs $D(k,K)$, where $k > 2$ is positive integer and K is a commutative ring, such graphs have been considered in [15] for the case $K = F_q$.

Let P_D and L_D be two copies of Cartesian power K^N, where K is the commutative ring and N is the set of positive integer numbers. Elements of P_D will be called *points* and those of L_D *lines*.

To distinguish points from lines we use parentheses and brackets. If $x \in V$, then $(x) \in P_D$ and $[x] \in L_D$. It will be also advantageous to adopt the notation for co-ordinates of points and lines introduced in [30] for the case of general commutative ring K:

$$(p) = (p_{0,1},p_{1,1},p_{1,2},p_{2,1},p_{2,2},p'_{2,2},p_{2,3},\ldots,$$

$$p_{i,i},p'_{i,i},p_{i,i+1},p_{i+1,i},\ldots),$$

$$[l] = [l_{1,0},l_{1,1},l_{1,2},l_{2,1},l_{2,2},l'_{2,2},l_{2,3},\ldots,$$

$$l_{i,i},l'_{i,i},l_{i,i+1},l_{i+1,i},\ldots].$$

The elements of P and L can be thought as infinite ordered tuples of elements from K, such that only finite number of components are different from zero.

Now, we introduce a linguistic incidence structure (P_D, L_D, I_D) defined by infinite system of equations as follows. We say that the point (p) is incident with the line $[l]$, and we write $(p)I[l]$, if the following relations between their co-ordinates hold:

$$\begin{aligned} l_{i,i} - p_{i,i} &= l_{1,0}p_{i-1,i} \\ l'_{i,i} - p'_{i,i} &= l_{i,i-1}p_{0,1} \\ l_{i,i+1} - p_{i,i+1} &= l_{i,i}p_{0,1} \\ l_{i+1,i} - p_{i+1,i} &= l_{1,0}p'_{i,i} \end{aligned} \tag{6}$$

(These four relations are defined for $i \geq 1$, $p'_{1,1} = p_{1,1}$, $l'_{1,1} = l_{1,1}$). The incidence structure (P_D, L_D, I_D) we denote as $D(K)$. Now we speak of the *incidence graph* of (P_D, L_D, I_D), which has the vertex set $P_D \cup L_D$ and edge set consisting of all pairs $\{(p), [l]\}$ for which $(p)I[l]$.

For each positive integer $k \geq 2$ we obtain a symplectic quotient $(P_{D,k}, L_{D,k}, I_{D,k})$ as follows. Firstly, $P_{D,k}$ and $L_{D,k}$ are obtained from P_D and L_D, respectively, by simply projecting each vector into its k initial coordinates. The incidence $I_{D,k}$ is then defined by imposing the first $k-1$ incidence relations and ignoring all others. The incidence graph corresponding to the structure $(P_{D,k}, L_{D,k}, I_{D,k})$ is denoted by $D(k, K)$.

To facilitate notation in the future results on "connectivity invariants", it will be convenient for us to define $p_{-1,0} = l_{0,-1} = p_{1,0} = l_{0,1} = 0$, $p_{0,0} = l_{0,0} = -1$, $p'_{0,0} = l'_{0,0} = -1$, $p'_{1,1} = p_{1,1}, l'_{1,1} = l_{1,1}$) and to assume that our equations are defined for $i \geq 0$.

Notice, that for $i = 0$, the written above four conditions are satisfied by every point and line, and for $i = 1$ the first two equations coincide and give $l_{1,1} - p_{1,1} = l_{1,0}p_{0,1}$.

Let $k \geq 6$, $t = [(k+2)/4]$, and let $u = (u_\alpha, u_{11}, \cdots, u_{tt}, u'_{tt}, u_{t,t+1}, u_{t+1,t}, \cdots)$ be a vertex of $\mathrm{D}(k, K)$ ($\alpha \in \{(1,0),(0,1)\}$, it does not matter whether u is a point or a line). For every r, $2 \leq r \leq t$, let

$$a_r = a_r(u) = \sum_{i=0,r} (u_{ii}u'_{r-i,r-i} - u_{i,i+1}u_{r-i,r-i-1}),$$

and $a = a(u) = (a_2, a_3, \cdots, a_t)$. Similarly, we assume that $a = a(u) = (a_2, a_3, \cdots, a_t, \dots)$ for the vertex u of infinite graph $D(K)$.

Proposition 4.1: Let u and v be vertices from the same component of $D(k, K)$. Then $a(u) = a(v)$. Moreover, for any $t-1$ field elements $x_i \in F_q$, $2 \leq t \leq [(k+2)/4]$, there exists a vertex v of $D(k, K)$ for which
$a(v) = (x_2, \dots, x_t) = (x)$.

V. On flag systems of graphs $A(n, K)$ and $D(n.K)$, walks on them and multivariate maps

Graphs $D(n, K)$ and $A(n, K)$ have somme common properties. We refer to the first coordinate $x_{1,0} = \rho(\mathrm{x})$ ($x_1 = \rho(\mathrm{x})$ of a point x from graph $D(n, K)$ (graph $A(n, K)$, respectively) and the first coordinate $y_{1,0} = \rho(\mathrm{y})$ ($y_1 = \rho(\mathrm{y})$) of a line y as the colour of the vertex (point or line). The following property holds for the graph: there exists a unique neighbour $N_t(v)$ of a given vertex v of a given colour $t \in K$.

A flag of the incidence system $D(n, K)$ or $D(K)$ ($A(n, K)$ or $A(K)$) is an unordered pair $\{(\mathrm{x}), [\mathrm{y}]\}$ such that $(\mathrm{x})I[\mathrm{y}]$. Obviously, the totalities of flags $FD(n, K)$ or $(FA(n, K))$ of the bipartite flag $D(n, K)$ (or $A(n, K)$, respectively) are isomorphic to the variety K^{n+1}. So, flag $\{(\mathrm{x}), [\mathrm{y}]\}$ of $D(n, K)$ is defined by the tuple $(x_{10}, x_{11}, \dots, y_{01})$. Notice, that $N_{y_1}(\{\mathrm{x}\}) = [\mathrm{y}]$.

We consider an operator $NP_\alpha(\{(\mathrm{x}), [\mathrm{y}]\})$, $\alpha \in K$ mapping flag $\{(\mathrm{x}), [\mathrm{y}]\}$ of the incidence structure $G(n, K)$ (where G is D or A)) into its image $\{(\mathrm{x}'), [\mathrm{y}]\}$, where $\mathrm{x}') = N_\alpha([\mathrm{y}])$.

Similarly, an operator $NL_\alpha(\{(\mathrm{x}), [\mathrm{y}]\})$ maps $\{(\mathrm{x}), [\mathrm{y}]\}$ into $\{(\mathrm{x}), N_\alpha(\mathrm{x})\})$.

Let $\alpha_1, \alpha_2, \dots, \alpha_k$ and $\beta_1, \beta_2, \dots, \beta_k$ be chosen sequences of elements from the commutative ring K. The composition

$$E = NP_{\alpha_1}NL_{\beta_1}NP_{\alpha_2}NL_{\beta_2}\dots NP_{\alpha_k}NL_{\beta_k}$$

transforms flag $\{(\mathrm{x}), [\mathrm{y}]\}$ into the new flag $\{(\mathrm{x}'), [\mathrm{y}']\}$. The process of recurrent computations of $E(\{(\mathrm{x}), [\mathrm{y}]\} = \{(\mathrm{x}'), [\mathrm{y}']\}$ corresponds to the walk in a graph $G(n, K)$ with the original vertex (x) and the final point (x'). Notice, that $[\mathrm{y}'] = N_\alpha(\mathrm{x}')$.

Let us assume now that we have two finite families of polynomials of $K[z_1, z_2] : \phi_1(z_1, z_2), \phi_2(z_1, z_2), \dots, \phi_{k+1}(z_1, z_2)$ and $\psi_1(z_1, z_2), \psi_2(z_1, z_2), \dots, \psi_k(z_1, z_2)$. We assume that their density is restricted by independent constant d and their degree is bounded by the linear function $\alpha n + \beta$.

The transformation $\tilde{E}$ shifts a flag $\{(\mathrm{x}), [\mathrm{y}]\}$ into its image for the map

$$\begin{aligned} &NP_{\phi_1(x_1,y_1)}NL_{\psi_1(x_1,y_1)}NP_{\phi_2(x_1,y_1)}NL_{\psi_2(x_1,y_1)}\cdots \\ &\dots NP_{\phi_k(x_1,y_1)}NL_{\psi_k(x_1,y_1)}. \end{aligned}$$

Additionally, we assume that the system of equations $\phi_k(z_1, z_2) = a$, $\psi_k(z_1, z_2) = b$ has exactly one solution independently from the choice of a and b (boundary requirement). The written above condition insure that the reimage of $\{\mathrm{x}', [\mathrm{y}']$ for $\tilde{E}$ is uniquely determined. Really, parameters x_1 and y_1 are determined by the system of equations.

It allows us to compute each expression of kind $\phi_i(x_1, y_1)$ and $\psi_j(x_1, y_1)$ and to obtain the reverse walk in the graph with the origin x' and final point x. So, we get the original flag $(\mathrm{x}), [\mathrm{y}]$ with $[\mathrm{y}] = N_{y_1}(\mathrm{x})$. The code of our flag is $(x_1, x_2, \dots, x_n, y_1)$.

Let $f = f_n$ be the transformation of affine space K^{n+1} into itself which maps flag $(x_1, x_2, \dots, x_n, y_1)$ into the image for $\tilde{E}$ defined by the family of bivariate polynomials from $K[z_1, z_2]$. Assume that f_n is written in a standard form $x_i \to f_i(x_1, x_2, \dots, x_n, y_1)$, $i = 1, 2, \dots, n$, $y_1 = f_{n+1}(x_1, x_2, \dots, x_n, y_1)$.

Let ${g_n}^i : K^{n+1} \to K^{n+1}$ be the transformation moving $\mathrm{z} = (z_1, z_2, \dots, z_n, u_1)$ into $NP_{\phi_{i_{z_1,u_1}}}(\mathrm{z})$ and ${h_n}^j$ be the transformation moving z into $NL_{\psi_{j_{z_1,u_1}}}(\mathrm{z})$. Obviously, $f = {g_n}^1{h_n}^2{g_n}^2{h_n}^2\dots{g_n}^k{h_n}^k$ is the invertible decomposition of f of speed $O(n)$. Notice, that generally speaking it is not true that each ${g_n}^i$ or ${h_n}^i$ is invertible. The following statement is a

direct corollary of results [3] in the case $G(n,K)=D(n,K)$, and results of [4] in the case of $G(n,k)=A(n,K)$.

Theorem 5.1: The $G(n,K)$ graph based transformations $f_n : K^{n+1} \to K^{n+1}$ defined above for $\phi_j(z_1,z_2)=z_1+a_j$ and $\psi_j(z_1,z_2)=z_2+b_j$ where $a_j,b_j \in K$, $j=1,2,\dots,k$ are stable cubical maps.

It means that we always have $O(n^4)$ monomial terms for the map f_n. Notice that f_n is given by its invertible decomposition. The following statement is a direct corollary from the theorem.

Proposition 5.1: Let us consider the specialization $\tilde{f}_n$ of f_n given by relations $y_{0,1}=h(x_{1,0})$ ($y_1=h(x_1$ in case of graphs $A(n,K)$, respectively), where $h(x) \in K[x]$ is a polynomial expression of degree t, such that equation of kind $h(x_{1,0})=b$, $b \in K$ ($h(x_1)=b$) has no more than one solution. Then degree of $\tilde{f}_n$ is bounded by t^3.

Remark 5.1:

We can change variables $x_{1,0}$ and x_1 of the proposition for y_{01} and y_1, respectively.

Recall, that M is a multiplicative subset of commutative ring K if it is closed under multiplication and does not contain zero. Let us consider the following special choice of coefficients a_j and b_j. The following statement is proved in [23] (see also [13], [14]).

Theorem 5.2: Let $f_n : K^{n+1} \to K^{n+1}$ be $G(n,K)$ graph based transformation $f_n : K^{n+1} \to K^{n+1}$ defined for $\phi_j(z_1,z_2)=z_1+a_j$ and $\psi_j(z_1,z_2)=z_2+b_j$, where $a_j,b_j \in K$, $j=1,2,\dots,k$ in theorem 1.

Let M be a multiplicative set of K and $a_1,b_1 \in M$, $a_{i+1}-a_i \in M$, $b_{i+1}-b_i \in M$ for $i=1,2,\dots,k-1$. Then the order of a transformation f_n is going to infinity with the growth of n.

Remark 5.2: In the case of graph $D(n,K)$ we can change polynomial $h(x_{1,0}$ for the $h(x_{1,0},a_2(\mathrm{x}),a_3(\mathrm{x}),\dots,a_t(\mathrm{x}))$, where $h(z_1,z_2,\dots z_t) \in K[(z_1,z_2,\dots z_t]$, $t=[(n+2)/4]$.

We can look at f_n as function with invertible decomposition with initial relation $y_{0,1}=h(x_{1,0}$ (case of $D(n,K)$) or $y_1=h(x_1)$ (case of $A(n,K)$. Really, invertible decomposition of f_n allows to solve

$(f_n)^s(x_{1,0},h(x_{1,0},x_{1,1},\dots,)) = (c_{1,0},c_{0,1},c_{1,1},c_{2,1},\dots)$ or

$(f_n)^s(x_1,h(x_1,x_2,\dots,x_n)) = (c_1,c_1',c_2,\dots,c_n)$ can be solved fast in some special simple cases.

For simplicity of writing we assume that $G(n,K)=D(n,K)$. Let us consider the system of equation $(*)$: $x_{10}+\alpha_k s=c_{1,0}$, $h(x_{1,0})+\beta_k s=c_{0,1}$

We can eliminate parameter s: $\beta_k x_{1,0}+\alpha_k\beta_k s=\beta_k c_{1,0}$

$h(x_{1,0})\alpha_k+\alpha_k\beta_k s=c_{1,0}\alpha_k$.

So, we get an equation of kind $c_{0,1}\alpha_k-\beta_k c_{1,0}=h(x_{1,0})\alpha_k x_{1,0}\beta_k$ (*)

Let us assume that $h(x_{1,0})\alpha_k x_{1,0}\beta_k=c$ has not more than one solution for each $c \in K$.

Under this condition we can solve (*) for x_1. So, if α_k or β_k differs from 0 we can find parameter s.

Assume that characteristics of ring K is a large prime p. Let us consider the following two simple cases:

(a) $\alpha_k=0$ but β_k is a regular ring element. It is clear that in this case $x_{1,0}$ is known and we can find parameter s with arbitrarily chosen function $h(x)$.

(b) $\beta_k=0$ and equation $h(x_{1,0})=c$ has no more than one solution. In this case one can find $x_{1,0}$ and find parameter s from the first equation.

We say that multivariate map $g_n : K^{n+1}=K^{n+1}$ is symmetrical if $\deg(g_n)=\deg(g_n)^{-1}$. Obviously, each stable transformation is symmetrical. It is clear that in the case (a) we get a stable transformation of K^n into itself. In case of $\deg(g_n)\neq\deg(g_n)^{-1}$ we refer to g_n as assymetrical map.

The following cryptosystem can be used.

Alice chooses a function $h(x_{1,0},a_2(\mathrm{x}),a_3(\mathrm{x}),\dots,a_t(\mathrm{x}))$ of finite degree t and invertible affine transformation: $\tau_1 : K^n \to K^n$, which sends x onto xA+b. Assume that it will be extended till K^{n+1} via the rule $\tau_1 : z \to az+l(\tau_1(\mathrm{x}))=z'$, where l is some linear function from x. Let τ be an expanded linear transformation.

Alice takes the symbolic tuple $(x_{1,0},x_{1,1},\dots,z)$ applies τ and gets the vector $u_{1,0},u_{1,1},\dots,z'=\mathrm{u}$. She will treat this tuple as a flag from $FD(n,K)$.

She writes the equation $z'=h(x_1,x_2)$ and rewrites it in the form $z=h'(x_1,x_2)$.

Alice choses the pseudorandom strings $\alpha_1,\alpha_2,\dots\alpha_k$ and $\beta_1,\beta_2,\dots,\beta_k$ of ring elements.

She generates defined above transformation $f_n : K^{n+1} \to K^{n+1}$. Alice computes symbolically $f_n(\mathrm{u})=\mathrm{w}$ and applies τ^{-1} to w.

She forms a stable cubical transformations $E=g_n=\tau f_n\tau^{-1}$ and writes it in standard form

$$\begin{aligned} x_{10} &\to x'_{1,0}=g_{1,0}(x_{1,0},x_{1,1},\dots,z)\\ x_{11} &\to x'_{1,1}=g_{1,1}(x_{1,0},x_{1,1},\dots,z)\\ &\vdots\\ z &\to z'=g_{0,1}(x_{1,0},x_{1,1},\dots,z)\end{aligned}$$

In the case of the first n rules Alice uses the specialisation $z=h'(\mathrm{x})$ and writes $\tilde{g}'_{1,0}(\mathrm{x})=g_{1,0}(h'(\mathrm{x},x_{1,0},x_{1,1}\dots)$, $\tilde{g}'_{1,1}(\mathrm{x})=g_{1,1}(h'(\mathrm{x}),x_{1,0},x_{1,1},\dots)$, $\dots$, in a standard form. The specialisetion gives us a restriction E' of our encryption map on the point set isomorphic to K^n.

Bob gets these n rules from Alice together with initial condition $z=h'(x_{1,0},x_{1,1},\dots)$.

He takes his plaintext $(\mathrm{x})=(p_{1,0},p_{1,1},\dots)$ and applies the restricted map E' iteratively s times.

Thus, he gets consecutively $E'^i(\mathrm{p})$, $i=1,2,\dots,s$ and computes recursively

$$\begin{aligned} z_1 &= g_{0,1}(p_{1,0},p_{1,1},\dots,h'(\mathrm{p}),\\ z_2 &= g_{0,1}(E(\mathrm{p},z_1)),\\ &\vdots\\ z_s &= g_{0,1}(E^{s-1}\mathrm{p},z_{s-1}).\end{aligned}$$

He sends Alice his expanded ciphertext as a pair $\mathrm{c}=E'^s(\mathrm{p})$ and parameter z_s.

For the decryption Alice applies transformation τ to the c concateneted with z_s and gets c_1. She computes $E^{-1}(\mathrm{c}_1) = c_2$. Computation $\tau^{-1}(\mathrm{c}_2)$ gives her the plaintext p.

Let us consider some obvious properties of defined above cryptosystem in special cases (a) and (b).

(a) We can see that our encryption is of symmetrical degree. Let $\mathrm{deq}h = t$, then our map f_n has a degree bounded by t^3. If parameter t is a constant then the map E' is computable in polynomial time. Notice, that linearisation attacks are possible, they allow to compute E'^{-1}. This fact is not yet a breaking of the system, because E' is a stable map which order is growing with the growth of parameter n.

Thus, finding the solution for $E'^s = H(\mathrm{x})$ can be a difficult task. The discrete logarithm problem for cyclic subgroup of Cremona group of increasing order appears there. Notice, that only one value of $H(\mathrm{x})$ can be given for chosen by Bob parameter s. Algorithm can be used in dynamical mode: every session Alice changes encryption base and every time Bob changes parameter s.

Notice, that $s = s(n)$ can be a function from parameter n. Bob can encrypt for polynomia time $s(n)O(n^{t^3})$. Alice can decrypt because of the logarithmical invertibility of the map.

(b) Let us just consider a simple example

$$h(x_{1,0}, a_2(\mathrm{x}), \ldots, a_t(\mathrm{x})) = (d(a_2(\mathrm{x}), a_3(\mathrm{x}), \ldots, a_t(\mathrm{x}))x_{1,0} + \\ + b(a_2(\mathrm{x}), \ldots, a_t(\mathrm{x}))^r + c(a_2(\mathrm{x}), a_3(\mathrm{x}), \ldots, (a_t\mathrm{x})),$$

d, b, c are multivariate functions, r is odd and equation $x^r = \alpha$ in K has not more than one solution for each parameter α. If we skip degenerate cases, our encryption function E' will be assymetric. It means that even finding the inverse E' can be a hard task in this case.

We presnt here a well known case of the pair (r, K) which satisfies to written above property (see the description of Imai-Matsumoto method in [26]). Let $K = F_{q^n}$ be an extention of the field F_q of characteristic 2. We take r as a parameter of kind $q^\beta + 1$ for some parameter β, such that the greatest common divisor of $q^\beta + 1$ and $q^n - 1$ is 1. Then map $x \to x^r$ is one to one correspondence and equation $x^r = \alpha$ has a unique solution.

VI. Conclusions

Known methods of symmetric encryption according to chosen walks on flags of bipartite graphs $A(n, K)$ and $D(n, K)$ use special colouring of their points and lines. The increasing girth and good expansion properties of these graphs lead to good mixing properties of the stream cipher based on stable transformation. The weakness of such method is an option of cubical linearisation attacks based on the fact that decryption map is also cubical (complexity of the attack is $O(n^{10})$, so its costly, but possible. There were several implementations of such algorithms for practical use in academic networks and ORACLE based university management systems for various cases of fields and rings: [2], [27], [28] devoted to ciphers used in The University of South Pacific (Fiji), [30], [31], [35] discussed algorithms used at Sultan Qaboos University (Oman), [31], [32], [35] were used in University of Maria Curie - Sklodovska (Poland), algorithm of [29] and [34] were used in teaching process of Kiev Mohyla Academy (Ukraine) and University of British Columbia (Canada), respectively.

Private key algorithm, presented in this paper allows to modificate discussed above programs with essential increase of resistence to linearisation attack without damage of theoretical speed ($O(n)$ in the case of keys of constant length and $O(n^2)$ for passwords of length $O(n)$). We can create encryption maps of large symmetric degree or assymetrical maps with inverses of high degree.

In a public mode we introduce the multivariate cryptosystems such that their security is connected with discrete logarithm problem for large cyclic subgroups of Cremona group. We hope that a new class of multivariate cryptosystems can be an interesting objects for cryptanalitical studies.

7th International Symposium on Multimedia Applications and Processing

ORGANIZED BY

SOFTWARE Engineering Department, Faculty of Automation, Computers and Electronics, University of Craiova, Romania "Multimedia Applications Development" Research Centre

Background and Goals

Multimedia information has become ubiquitous on the web, creating new challenges for indexing, access, search and retrieval. Recent advances in pervasive computers, networks, telecommunications, and information technology, along with the proliferation of multimedia mobile devices - such as laptops, iPods, personal digital assistants (PDA), and cellular telephones - have stimulated the development of intelligent pervasive multimedia applications. These key technologies are creating a multimedia revolution that will have significant impact across a wide spectrum of consumer, business, healthcare, educational and governmental domains. Yet many challenges remain, especially when it comes to efficiently indexing, mining, querying, searching, retrieving, displaying and interacting with multimedia data.

The Multimedia - Processing and Applications 2014 (MMAP 2014) Symposium addresses several themes related to theory and practice within multimedia domain. The enormous interest in multimedia from many activity areas (medicine, entertainment, education) led researchers and industry to make a continuous effort to create new, innovative multimedia algorithms and applications.

As a result the conference goal is to bring together researchers, engineers, developers and practitioners in order to communicate their newest and original contributions. The key objective of the MMAP conference is to gather results from academia and industry partners working in all subfields of multimedia: content design, development, authoring and evaluation, systems/tools oriented research and development. We are also interested in looking at service architectures, protocols, and standards for multimedia communications - including middleware - along with the related security issues, such as secure multimedia information sharing. Finally, we encourage submissions describing work on novel applications that exploit the unique set of advantages offered by multimedia computing techniques, including home-networked entertainment and games. However, innovative contributions that don't exactly fit into these areas will also be considered because they might be of benefit to conference attendees.

Call for Papers

MMAP 2014 is a major forum for researchers and practitioners from academia, industry, and government to present, discuss, and exchange ideas that address real-world problems with real-world solutions.

The MMAP 2014 Symposium welcomes submissions of original papers concerning all aspects of multimedia domain ranging from concepts and theoretical developments to advanced technologies and innovative applications. MMAP 2014 invites original previously unpublished contributions that are not submitted concurrently to a journal or another conference.

Papers acceptance and publication will be judged based on their relevance to the symposium theme, clarity of presentation, originality and accuracy of results and proposed solutions.

Topics

Topics of interest are related to Multimedia Processing and Applications including, but are not limited to the following areas:

- Audio, Image and Video Processing
- Animation, Virtual Reality, 3D and Stereo Imaging
- Multimedia File Systems and Databases: Indexing, Recognition and Retrieval
- Machine Learning, Data Mining, Information Retrieval in Multimedia Applications
- Multimedia in Internet and Web Based Systems:
  - E-Learning, E-Commerce and E-Society Applications
- Human Computer Interaction and Interfaces in Multimedia Applications
- Multimedia in Medical Applications
- Entertainment and games
- Security in Multimedia Applications: Authentication and Watermarking
- Distributed Multimedia Systems
- Network and Operating System Support for Multimedia
- Mobile Network Architecture
- Intelligent Multimedia Network Applications

Gaussian-Based Approach to Subpixel Detection of Blurred and Unsharp Edges

Anna Fabijańska
Lodz University of Technology
Institute of Applied Computer Science
18/22 Stefanowskiego Str., 90-924 Lodz, Poland
Email: anna.fabijanska@p.lodz.pl

***Abstract*—In this paper the problem of edge detection with subpixel accuracy is considered. In particular, the precise detection of significantly blurred edges is regarded. A new method for subpixel edge detection is introduced. The method attempts to reconstruct image gradient function at the edge using the Gaussian function. The results of subpixel edge detection in the artificially created and the real images obtained by the introduced approach are presented and compared with the results of previously proposed methods. In particular, the moment based methods, the gravity center method and the parabola fitting method are considered in the comparison. The presented results prove the robustness of the introduced approach against the averaging and the Gaussian blur. Additionally, the comparison shows, that the introduced approach outperforms the existing state-of-art methods for subpixel edge detection.**

I. Introduction

EDGE detection is the problem of crucial importance in image processing. Edges define location and geometric features of objects present in the scene. Therefore, in a typical vision system, edge detection is performed during low level processing and provides information for operations performed in the following stages, such as quantitative analysis, target recognition or image coding etc.

Recently, the requirements for edge detection accuracy rapidly increase. Satellite remote sensing, telemetry, photogrammetry, medical image analysis, industrial inspection, geometrical measurement and other applications where accuracy is at premium require precision of tenths or even hundredths of pixel.

The traditional, well-established methods for edge detection such as gradient operators (Sobel, Prewitt, Roberts), Canny edge detector, operator LoG etc. all belong to pixel level. Therefore, they are mostly insufficient for practical applications of modern machine vision. Due to their low precision of edge location and extracted wider edges, these approaches more and more often have difficulties in meeting the actual accuracy requirements of vision systems. Therefore, the development of subpixel techniques for edge detection has become one of the hotspots of the current research in image processing. Some work has already been done on this problem. However, the major methods for subpixel edge detection are still to be developed. It should be also underlined that while there has been substantial work performed on the detection of clear and well defined edges at subpixel accuracy, a little has been done on the subpixel edge detection in low contrast images containing blurred, noisy and unsharp edges [1][2].

This paper presents a new method which is a step forward through introducing subpixel analysis into edge detection. In particular, it considers precise edge detection of significantly blurred edges. As the already proposed methods deal mostly with sharp, regular and well defined edges the introduced approach can be considered like a novelty.

This paper is organized as follows. Firstly, in Section 2 background on subpixel edge detection is given. Then, in Section 3 the proposed method for subpixel edge detection is introduced. Section 4 presents results of the new algorithm obtained for synthetic images. Resistance of the method to Gaussian blur and averaging is tested. Next, in Section 5 results of edge detection obtained for real images are shown. Finally, Section 6 concludes the paper.

II. Background on Subpixel Edge Detection

The main idea behind subpixel edge detection is to divide pixel into classes by determining edge location inside a pixel. Such approach is fundamentally different to the classical image processing where pixel is the basic and indivisible image component which is fully qualified to one class.

Subpixel edge detection is a challenging task. The discrete structure of a pixel grid causes irreversible loss in image intensities, influences shape of the objects present in the image and reduces edge information. Therefore, edge position inside a pixel can only be estimated with some probability.

The need of edge detection at subpixel level was firstly mentioned by the researchers in the late 70's [3]. Since then the issue of image processing with subpixel accuracy gained an interest of scientists and several approaches to this problem were proposed. Recently, methods for subpixel edge detection can be qualified into three main groups:

This work was not supported by any organization

1) curve fitting methods;
2) moment based methods;
3) reconstructive methods.

They are briefly characterized in the following subsections.

A. Curve fitting methods

Curve fitting methods determine subpixel edges by fitting various curves into edge points determined with a pixel accuracy. Firstly, for edge detection at pixel level the traditional edge detectors are used. Then, fitting is performed in an image plane in order to obtain continuous border.

This methodology was used by Yao and Ju [4] who fitted cubic splines into spatial data points provided by Canny operator or by Breder [5] who applied B-spline interpolation. Similar approach was also proposed by Kisiworo [6] who used deformable models to obtain subpixel edge position.

The accuracy of subpixel edge obtained using curve fitting methods is strongly limited by the accuracy of edge detection at pixel level. These methods are also sensitive to badly defined edge points which can deform the resulting shape of the object. Therefore, curve fitting methods yields reasonable results only in applications where shape of the object is known a priori and edge is accurately located at pixel.

B. Moment based methods

Moment based approaches determine edge position by relating image moments into parameters of subpixel edge. Methods which use image intensity moments (regarding only pixel intensities) and spatial moments (regarding both pixel intensities and spatial information about pixel neighborhood) have been proposed.

History of the moment based approaches dates back to 80's when Machuca and Gilbert [7] proposed the first method using image moments to determine edge position. The method integrates region containing the edge in order to determine its position using moments found within the integrated region. The moments are defined based on properties of vector from the given pixel to the gravity center of a pixel square neighborhood. Although Machuca and Gilbert's method has no ability to determine edge with subpixel accuracy it was an inspiration for the following approaches to the considered problem.

Tabatabai and Mitchell [8] proposed a method for subpixel edge detection which fits three intensity moments into the ideal step edge. In their approach the ideal edge is defined as sequence of one intensity followed by the sequence of the second intensity. The moments are defined as a sum of pixel intensity powers and do not consider any spatial information. The main drawback to this method is that it determines edges only in non-decreasing or non-increasing intensity sequences.

Geometric moment approach developed by Lyvers [9] fits moments into 2D model of an ideal edge. This model is described by four parameters which indicate subpixel edge position. The relation between the parameters of an ideal edge and image moments is established; then edge subpixel position is determined. This procedure requires evaluation of six moments by convolving an image with circular masks. As a result, the method is computationally complex. Additionally, geometrical moments proposed by Lyvers are not orthogonal, what makes the method lacks optimality in information redundancy. Approach proposed by Ghosal and Mehrotra [10] eliminates this weakness by fitting orthogonal Zernike moments into Lyvers' edge model. Additionally, the complexity of the method is decreased as only three masks are required. Zernike moments have difficulty in describing small objects, however they are most commonly applied for subpixel edge detection. Recently, Bin [11] put forward orthogonal Fourier-Mellin moments (OFMM) proposed by Sheng and Shen [12] into the Lyvers' edge model. However, determination of subpixel edge position using OFMMs requires application of seven circular masks what causes complexity of the method.

The main drawback to moment-based approaches is lack of clear criteria for classifying pixels as edge or non-edge. Moreover, they produce response (i.e. parameters of subpixel edge) for every set of pixels containing change in image intensity and work properly only in a close neighborhood of the edge pixel. Therefore in the current form they can mostly be used to refine position of the properly defined coarse edges.

C. Reconstructive methods

Reconstructive approaches to subpixel edge detection attempt to restore continuous information about an edge from the discrete intensity sample values. These sample values are provided by the traditional methods to edge detection such as Sobel, Canny or LoG. Next, different interpolation, approximation and extrapolation techniques are applied.

The continuous image information can be reconstructed independently in the vertical and the horizontal direction or simultaneously in both directions. In the first case one dimensional image intensity functions are retrieved in every direction and the final result is a superposition of results obtained in each direction. For reconstruction performed in all directions simultaneously two-dimensional function is found. In both cases the coordinates of the characteristic points of the reconstructed image function (i.e. local extremes, zero crossings, inflection points, etc.) indicate edge position with subpixel accuracy. In order to diminish the complexity of edge detection, image intensity function is often reconstructed in some neighborhood of a coarse border. Therefore, firstly, standard feature selection is applied in order to determine the coarse edge. Then this location is refined to subpixel level by adapting local feature pattern in the closest neighborhood.

The reconstructive approaches to subpixel edge detection can be divided into following groups:

1. ***methods reconstructing image intensity function*** [13] which determine subpixel edge position based on properties of function modeling image intensity at the edge; these methods however are in minority, due to lack of characteristic points of image intensity function at the edge;
2. ***methods reconstructing image first derivative function*** [14], [15] which retrieve image gradient function at the edge based on gradient sample values provided by operators like Sobel, Prewitt [14] or Canny [15] - most commonly second order polynomial is fitted into gradient sample values in a small (3 - 5 pixels) neighborhood; several approaches using wavelet transform instead of image first derivative have also been proposed [19], [20];
3. ***methods reconstructing image second derivative function*** [16]–[18] which reconstruct continuous image 2nd derivative function at the edge based on sample values provided by operator LoG; most commonly image derivative function is linearly interpolated in the neighborhood where the 2nd image derivative function changes its sign [16], [17] then coordinates of the zero-crossings of the reconstructed derivative function determine edge position with subpixel accuracy.

D. Other methods

There are also several subpixel edge detection methods which do not meet the classification presented in the previous subsections. One of them is approach used by Stanke [23] or Ji [24] where subpixel edge position is indicated by center of gravity of a gradient peak. Bie and Liu [25] applied quad-tree decomposition to divide pixels into subpixels while Kisworo [6] determined subpixel edge using image energy computed based on image intensities and their Hilbert transform. Some methods based on curvelets [21][22] have also been proposed.

Regarding the classification presented in the preceding subsections, the method introduced in this paper is a combination of reconstructive and curve fitting methods. More detailed description of the method is given in the following part of this paper.

III. THE PROPOSED METHOD

The proposed method attempts to retrieve continuous edge information at the edge from the discrete image data. Reconstruction is performed only in the neighborhood of the edge. Therefore, the method starts from defining the coarse edge location. Then edge position is refined to subpixel level. Finally, continuous edge is obtained via cubic spline interpolation. The detailed description of the above mentioned steps is given in the following subsections.

A. Coarse edge determination

For the coarse edge determination Sobel gradient masks are applied. Input image L is convolved with the horizontal h_x and the vertical h_y gradient masks in accordance with Equation (1).

$$\nabla L \approx \sqrt{\left(h_x \otimes L\right)^2 + \left(h_y \otimes L\right)^2} \tag{1}$$

where $\otimes$ denotes convolution. The gradient image ∇L is next thresholded with a global threshold T. The value of T is determined using ISODATA algorithm [26]. The applied threshold selection method is an iterative approach which starts from assigning an arbitrary initial threshold. Then mean intensities of pixels above the initial threshold and below the initial threshold are computed and the new threshold is obtained as their average. The procedure is repeated based upon a new threshold as long as the threshold value changes.

When value of T is determined thresholding is performed in accordance with Equation (2). The operation produces binary image corresponding with the region of the highest gradient.

$$\nabla L'(x) = \begin{cases} 1 & for \;\; \nabla L \geq T \\ 0 & for \;\; \nabla L < T \end{cases} \tag{2}$$

Finally, the coarse edge is obtained as a result of skeletisation performed on the binary image $\nabla L'(x)$ in accordance with Equation (3) [27].

$$\partial L = \bigcup_{n=0}^{N} \left[\left(\nabla L' \Theta nH'\right) - \left(\nabla L' \Theta nH'\right) \circ H \right] \tag{3}$$

where: H denotes structuring element (see Fig. 1), Θ and $\oplus$ denote erosion and dilation respectively, $\circ$ denotes morphological opening and:

$$N = \max\{n \,|\, \nabla L'(x) \Theta nH' \neq \emptyset\} \tag{4}$$

$$H' = \{-h \,|\, h \in H\} \tag{5}$$

$$nH = \begin{cases} \overbrace{\{\bar{0}\} \oplus H \oplus \ldots \oplus H}^{n} & for \;\; n = 1,2,\ldots \\ \{\bar{0}\} & for \;\; n = 0 \end{cases} \tag{6}$$

Equation (3) is iterated until the convergence with the structuring elements shown in Figure 1 and all their 90° rotations.

Fig. 1 Structuring elements used for skeletisation.

Successive steps of the coarse border determination in a sample image are presented in Figure 2. Particularly, Figure 2a presents input image. In Figure 2b gradient image is shown. The result of global ISODATA thresholding is presented in Figure 2c. Finally, Figure 2d presents the coarse border.

B. Refining edge to subpixel level

In this step of the algorithm, reconstruction of gradient profile at the edge is performed. Gaussian function given by Equation (7) is fitted along the normal direction of edges into a gradient sample values provided by Sobel operator.

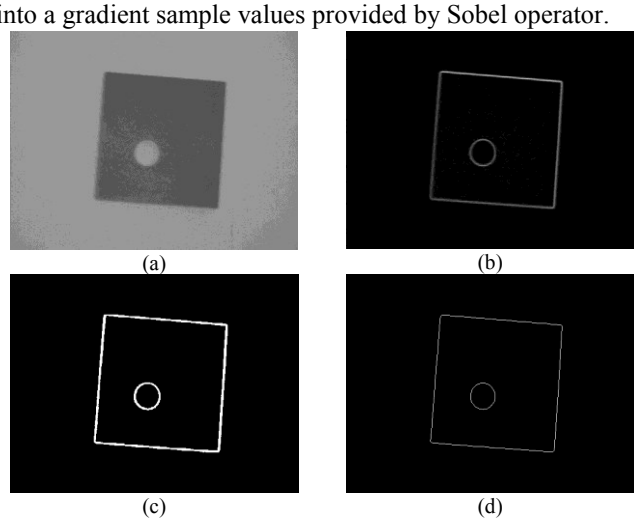

Fig. 2. Successive steps of coarse border determination; (a) input image; (b) gradient image; (c) image after ISODATA thresholding; (d) coarse edge.

$$f(x) = Ae^{\frac{-(x-\mu)^2}{2\sigma^2}} \tag{7}$$

where *f(x)* denotes gradient value at location *x*. The fitting is performed in a neighbourhood of every pixel from the coarse edge. It's linear neighbourhood in the gradient direction (the horizontal or the vertical) is considered. Several pixels on each side of the coarse edge are used.

The main idea of the proposed method is presented in Figure 3. In particular, in Figure 3a direction of a linear neighbourhoods used for gradient reconstruction are indicated. Figure 3b explains the idea of Gaussian function fitting along the normal direction of the edge. The figure presents 3D surface plot where gradient intensity is represented as a third dimension.

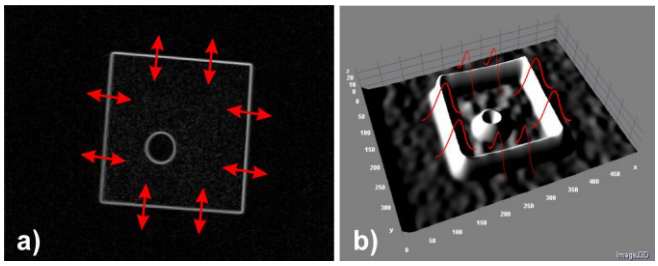

Fig. 3. The main idea of the proposed method; (a) direction of linear neighborhoods used for gradient reconstruction; (b) an idea of Gaussian function fitting along the normal direction of the edge presented in 3D surface plot.

Parameters of the Gaussian function fitted into a gradient sample values determine properties of the edge. Specifically:

– σ - describes a blur level of the edge;
– A - corresponds with gradient maximum value at the edge;
– μ - determines subpixel position of the edge pixel.

An example Gaussian function fitted into the discrete gradient sample values in a neighbourhood of pixel at location $x=27$ is presented in Figure 4. Empty circles correspond with gradient sample values shown under the graph. The coordinate μ of the maximum of the approximating Gaussian function indicates the edge location with subpixel accuracy.

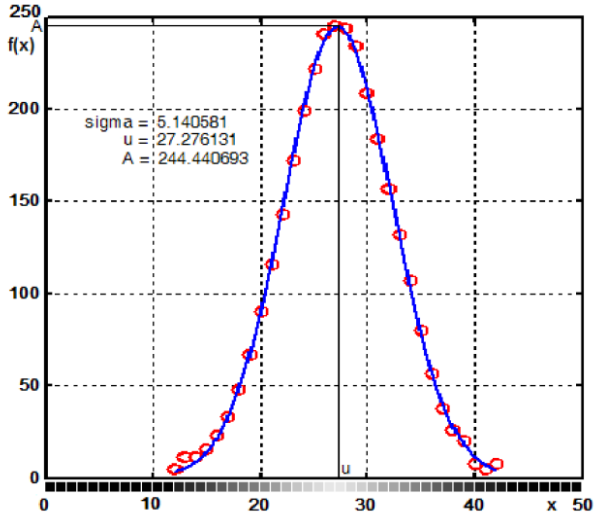

Fig. 4. Gaussian function fitted into gradient sample values.

Parameters of the Gaussian function are obtained via multidimensional unconstrained nonlinear minimization using Nelder-Mead algorithm [28]. This is an effective and computationally compact, simplex based method for finding a local minimum of a function of several variables. The algorithm works iteratively and uses only function values, without any derivative information. Each iteration of the simplex-based direct search begins with a simplex (i.e. a generalized triangle in n dimensions), specified by its n_s+1 vertices and the associated function values. One or more test points are computed, along with their function values, and the iteration terminates with bounded level sets.

The initial estimates for the fitting are as follows:

– for A – the maximum gradient value in the current neighbourhood;
– for μ – x coordinate of the central pixel in the regarded neighbourhood in case of the horizontal fitting and y coordinate of the central pixel in the regarded neighbourhood in case of the vertical fitting;
– for σ – size of a neighbourhood used for gradient function reconstruction.

C. Edge linking

In the last step of the algorithm edge linking is performed. It aims at obtaining continuous border from the subpixel positions of the coarse edge points determined in the previous step.

Firstly, the coarse edge is represented by means of chain code i.e. connected sequence of straight line segments of a specified length and direction; 8-connectivity segments are considered [29]. Despite the information about the succeeding pixel, each node of the chain contains information about the corresponding subpixel position.

Next, Cubic spline interpolation is performed over the subpixel positions corresponding with the consecutive pixels in the chain code in accordance with Equation (8).

$$F(x) = \sum F_i(x) \tag{8}$$

where: $x \in [x_i, x_{i+1}]$, $x_{p'0}=x_0<x_1<...<x_{n-1}<x_n=x_{p'k}$ and:

$$F_i(x) = a_i(x-x_i)^3 + b_i(x-x_i)^2 + c_i(x-x_i) + d_i \tag{9}$$

$$F_i(x_i) = y_i, F_i(x_{i+1}) = y_{i+1} \tag{10}$$

$$F'_{i-1}(x_i) = F'_i(x_i), F''_{i-1}(x_i) = F''_i(x_i) \tag{11}$$

$$F''_0(x_0) = 0, F''_{i-1}(x_n) = 0 \tag{12}$$

IV. Tests on Simulated Data

Firstly, the proposed method for subpixel edge detection was tested on the simulated data to verify if it works correctly. Specifically, the robustness of the method against the Gaussian blur and the averaging was investigated. In order to present robustness of Gaussian function in determining blurred edge position, the third step of the algorithm (i.e. edge linking) was not performed on the presented results.

Geometrically created 8-bit grayscale image of a circle was used to test the performance of the proposed approach. The circle of radius 50 pixels was centered at the position (75.0, 75.0). The intensity of the background was 52 while the intensity of the circle was 255.

The assessment of edge detection quality was made by means of:

- coordinates of the determined circle center;
- an average radius of the determined circle;
- standard deviation of the radius of the determined circle.

Coordinates of the circle center were defined as a center of gravity of the determined subpixel edge points and computed in accordance with the Equation (13).

$$\begin{cases} x_c = \dfrac{1}{k}\sum_{i=1}^{k} x_i \\ y_c = \dfrac{1}{k}\sum_{i=1}^{k} y_i \end{cases} \tag{13}$$

where k is number of subpixel edge points and x_i, y_i denote coordinates of i-th subpixel edge point. Radius was defined as an average distance of subpixel edge points from the real circle center (i.e. (75.0, 75.0)). This is expressed by Equation (14).

$$\bar{r} = \frac{1}{k}\sum_{i=1}^{k}\sqrt{(75-x_i)^2 + (75-y_i)^2} \tag{14}$$

The test image was distorted by:

- Gaussian filter of an increasing radius (from 1 to 10);
- an average filter of an increasing size (from 1 to 10).

Results provided by the proposed method (series: *gauss*) were compared with the previously proposed approaches to subpixel edge detection, such as:

- Tabatabai and Mitchell's method [8] (series: *tabatabai*);
- Zernike moments approach [10] (series: *zm*);
- parabola fitting approach [14][15] (series: *par*);

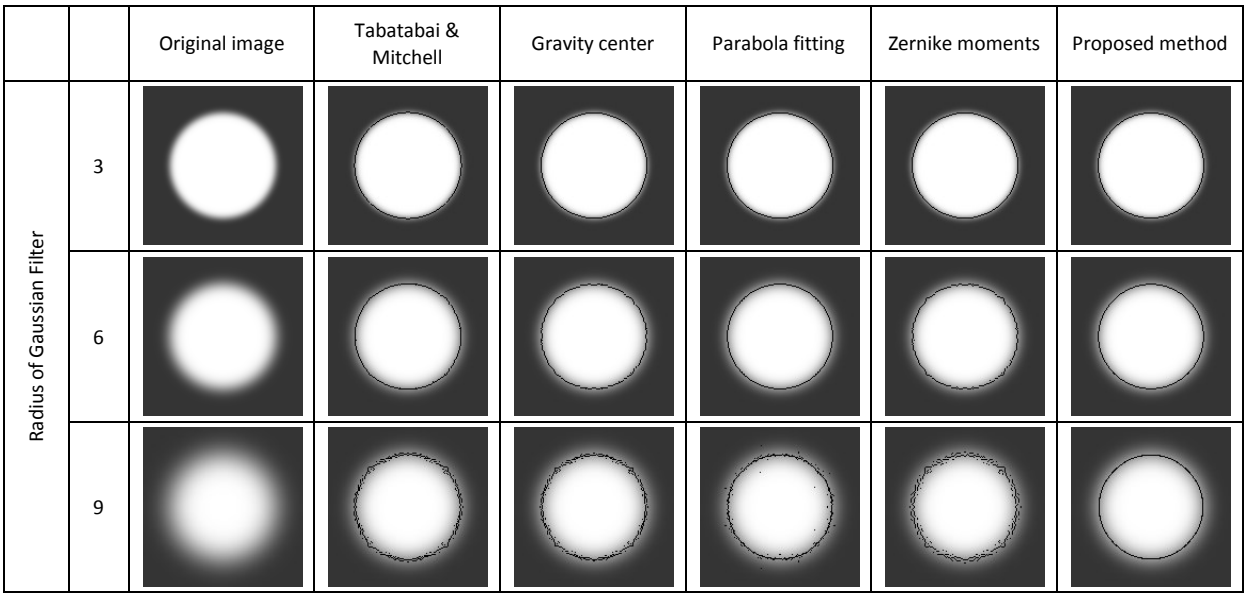

Fig. 5. Results of edge detection at sub-pixel level in images distorted by Gaussian blur.

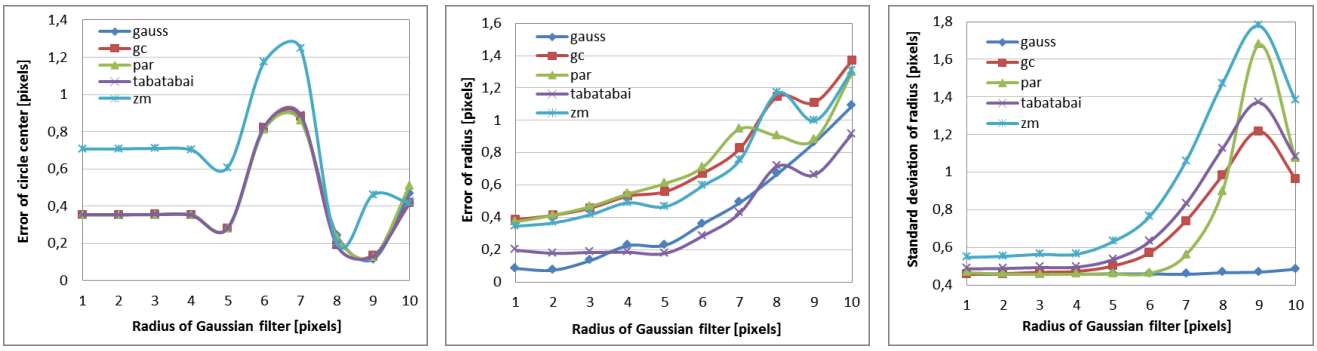

Fig. 6. Results of edge detection at sub-pixel level in images distorted by Gaussian filter.

– gravity center approach [23][24] (series: *gc*).

In all the cases the neighborhood equal to the diameter of the filter used to distort the image was regarded while determining edge position.

The results of edge detection in images distorted by the Gaussian blur are presented in Figures 5 and 6. Specifically, Figure 5 shows edges obtained with subpixel accuracy rounded to the closest pixel. Method used for edge detection is indicated above each column. Radius of the Gaussian filter used for blurring is given at the beginning of each row.

Figure 6 presents the comparison of edge detection results at subpixel level. Specifically, Figure 6a shows the error of circle center determination in function of radius of Gaussian filter used for blurring. The error is expressed by means of Euclidean distance between the real and the determined (in accordance with Eq. (13)) circle center. Figure 6b presents the error of circle radius determination in function of radius of Gaussian filter used for blurring. The error is expressed by means of the difference in length between the real and the determined (in accordance with Eq. (14)) radius. Finally, Figure 6c presents standard deviation of the circle radius in function of radius of Gaussian filter used for blurring.

Results of edge detection in images distorted by an average filter are presented in Figures 7 and 8. As previously, Figure 7 shows edges obtained with subpixel accuracy rounded to the closest pixel while Figure 8 presents comparison of edge detection results at subpixel level. The error of circle center (Fig. 8a), the error of radius (Fig. 8b) and the standard deviation of radius (Fig. 8c) are presented in function of size of an average filter used for blurring.

The results presented in Figures 5-9 prove the robustness of the proposed method against the Gaussian blur and the averaging.

Firstly, based on visual assessment (Fig. 5, Fig. 7), it should be underlined that only the proposed Gaussian fitting approach produces continuous and regular edges for a wide range of blur corruption. This is in the case of both: the Gaussian blur and the averaging for all regarded dimensions of filter used for image corruption. The other regarded approaches to subpixel edge detection produce continuous and regular edges only for low level of blur. With increasing blur, increases irregularity and discontinuity of the determined edge. This is also proved by graphs on Figures 6c and 8c showing standard deviations of the determined radius in function of radius of blurring filter.

Considering the comparison at subpixel level (Fig. 6,

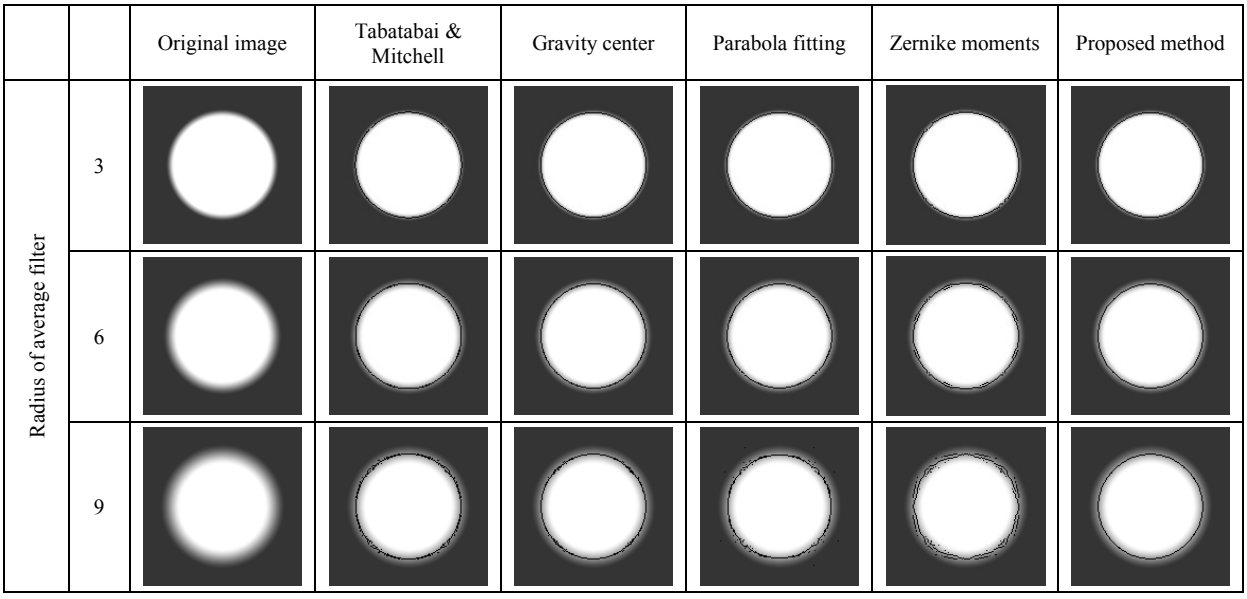

Fig. 7. Results of edge detection at sub-pixel level in images distorted by an average filter.

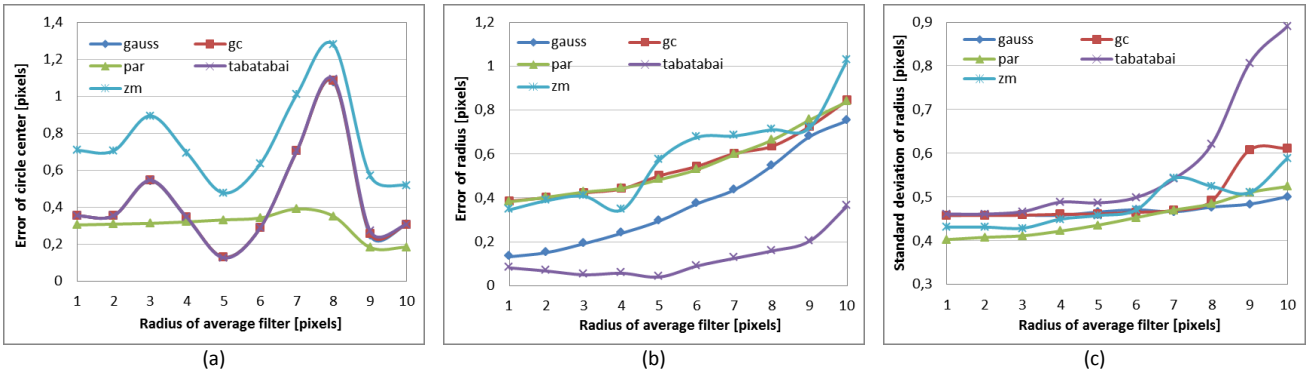

Fig. 8. Results of edge detection at sub-pixel level in images distorted by an average filter.

Fig. 8) it is clear that the best results are provided by the proposed method. In the case of Gaussian, blur the error of circle center determination is similar for all tested methods (see Fig. 8a). However, the smallest errors of an average radius provide the Gaussian fitting approach and Tabatabai and Mitchell's method (see Fig. 8b). Having in mind irregularity of edges provided by the second method, Gaussian fitting approach is superior in the case of Gaussian blur corruption. In the case of averaging, the error of an average radius provided by the proposed method is indeed higher than the error of Tabatabai and Mitchell's method, however, due to a very high standard deviation of radius of the latter method again Gaussian fitting approach can be regarded superior.

It should be also underlined, that Zernike moments approach fails when applied to blurred images (by both: Gaussian blur and averaging) - specifically for high level of blur the method produces the most irregular and discontinuous edges from all tested methods. Parabola fitting approach yields reasonable results for low and medium level of blur corruption, but for very blurry images the method has some problems with stability and produces edge points which significantly outstand from the border. Gravity center approach is always stable and for low level of blur produces continuous edges. However for increasing blur the method changes object shape. It can be observed that for large blur the determined edges become squarer.

Here, it should be concluded, that results obtained for the synthetic images prove correctness of the introduced method, its robustness against blurred edges and its superiority over other approaches to subpixel edge detection.

V. Tests on Real Data

In the next step, the tests on real images were performed in order to define the scope of applicability of the introduced method for subpixel edge detection. Specifically, images of heat-emitting specimens of metals and alloys obtained from the computerized system for high temperature measurements of surface properties [30][31] were considered. Due to the intense thermal radiation, usage of gas protective atmosphere and application of infrared filters the images are characterized by low contrast and blurred edges. Sample images obtained from the regarded system are shown in Figure 9. They present specimens of: copper at 853°C (Fig. 9a), steel at 797°C (Fig. 9b), copper at 1265°C (Fig. 9c) and steel at 1104°C (Fig. 9d).

Results of subpixel edge detection in sample images from Figure 9 are presented in Figure 10. Ten pixels at each side of the coarse edge pixel was regarded while refining edge position. Edges provided by the proposed approach are compared with results provided by other approaches. Specifically, the coarse edges are presented in the first row. The second row shows results of refining edge position using the proposed Gaussian fitting approach. The following rows presents edges provided by the gravity center approach, the parabola fitting approach, the Zernike moments approach and Tabatabai and Mitchell's method respectively. The results are rounded to the closest pixel. Interesting regions of specimen border are highlighted by red rectangles and magnified. In order to present robustness of the Gaussian function in determining blurred edge position, the third step of the algorithm (i.e. edge linking) was not performed on the presented results.

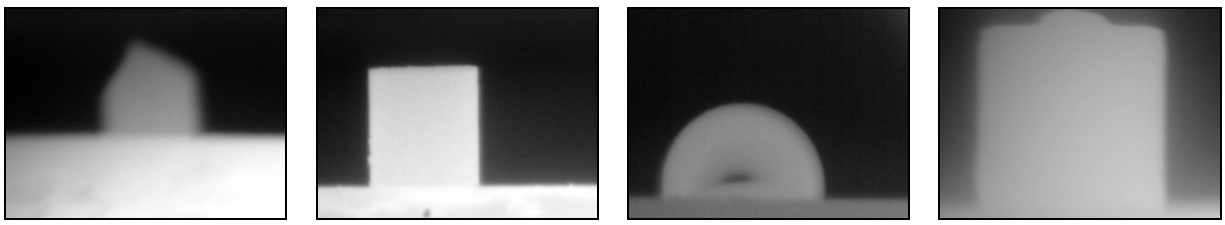

Fig. 9. Sample images of heat-emitting specimens of metals and alloys; (a) copper, 853°C; (b) steel, 797°C; (c) copper, 1265°C; (d) steel, 1104°C.

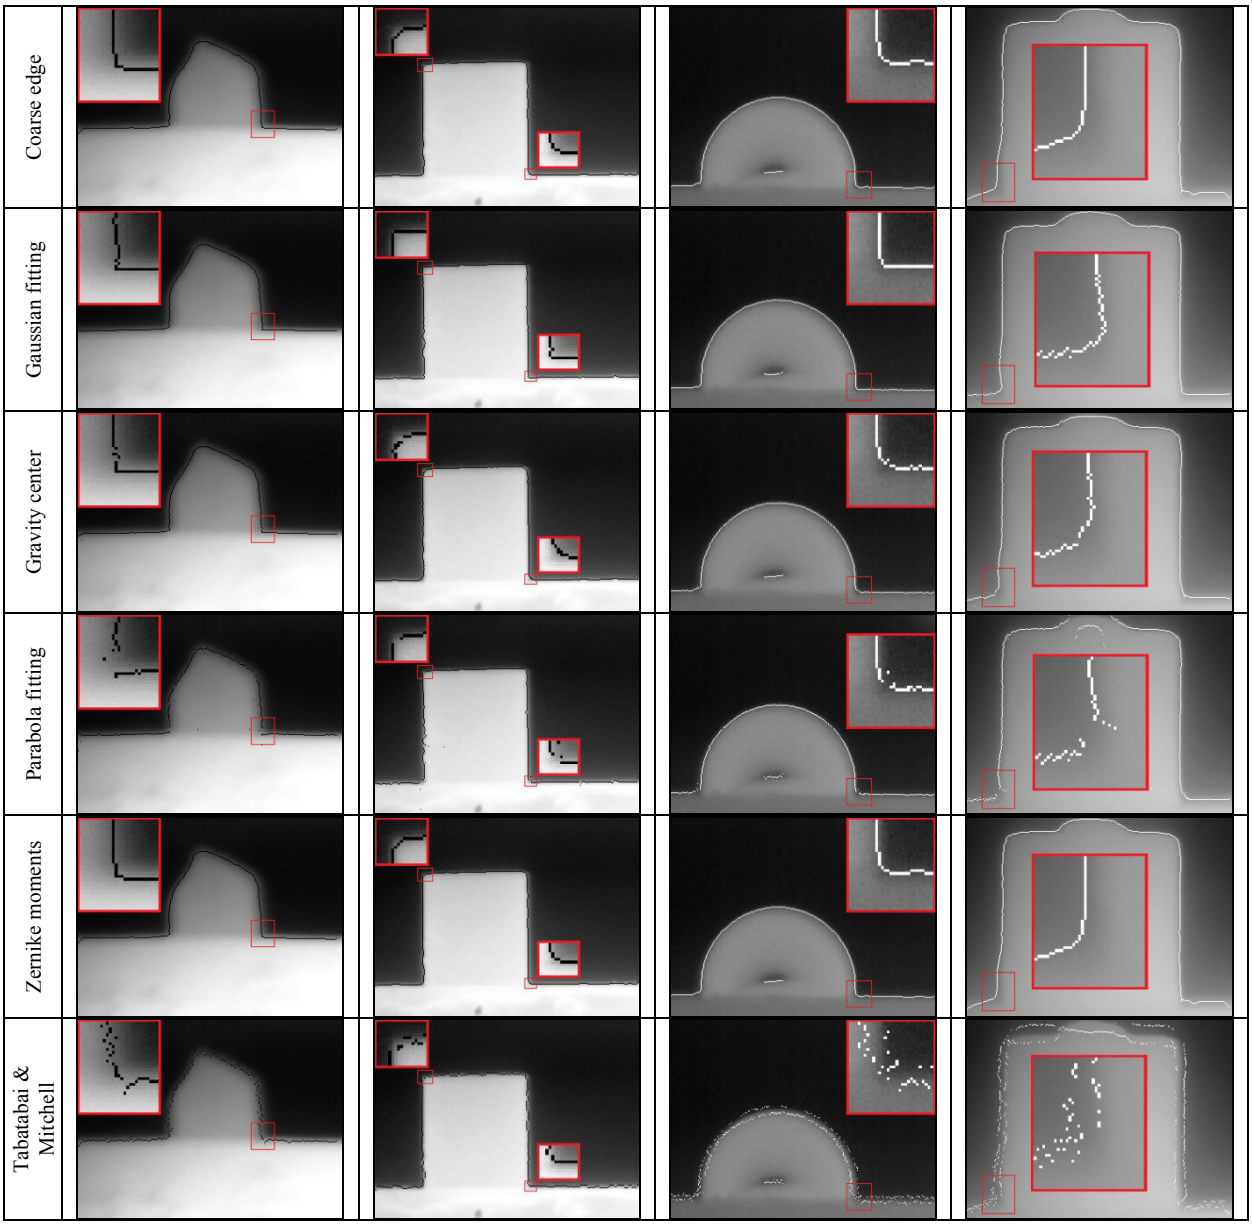

Fig. 10. Results of subpixel edge detection in images of heat-emitting specimens of metals and alloys. The original images are shown in Figure 9. Method used for edge detection is indicated at the beginning of each row.

Results shown in Figure 10 clearly show, that the proposed method significantly improves quality of edge detection in images of heat-emitting specimens of metals and alloys and outperforms other regarded approaches.

Firstly, it should be underlined that Zernike moments approach and Tabatabai and Mitchell's method fail when applied to the images of heat-emitting specimens. Subpixel edge provided by Zernike moments approach is at pixel level identical with the coarse edge. At subpixel level the differences between the coarse and the refined edge are negligible. In the case of the considered class of images Tabatabai and Mitchell's method becomes unstable and provides jagged, discontinuous, irregular and ambiguous edges what is unacceptable. Also parabola fitting approach has some problems with the continuity and the stability as it determines subpixel position of singular edge points visibly outstanding from the edge location. It is especially in the case when the supposed edge position is not in the center of the neighborhood of the coarse edge regarded while refining its position.

Both: the gravity center approach and the proposed Gaussian fitting approach are stable and provide continuous edges. However, the gravity center approach is sensitive to blur - it has problems in describing corners and rounds them off. In the examples shown in Figure 10 it is especially visible in contact of specimen, base and background or in case of image of steel at 797°C (Fig. 9b). Moreover, the gravity center approach tends to move border from the object when big neighborhood is used while refining the edge position.

The most significant increase in edge detection accuracy can be observed when the proposed Gaussian fitting

approach is used. Subpixel edges produced by the introduced method are regular. Moreover, they are continuous what diminishes number of edge information to be guessed during edge linking and makes the results more unequivocal. Additionally, improved edge fits closely specimen shape. Corners are sharp and well defined. This makes the method adequate for the considered class of images.

VI. CONCLUSIONS

In this paper problem of edge detection at subpixel level was considered. Specifically, precise edge detection in blurred images was regarded. The reconstructive method for subpixel edge detection was introduced. The method firstly determines the coarse edge using Sobel gradient masks, thresholding and skeletisation. Then it attempts to reconstruct continuous image gradient function at the coarse edge using Gaussian function. Position of the maximum of the reconstructing Gaussian function indicates edge position with subpixel accuracy.

The correctness and robustness of the method was proven by tests performed on geometrically created synthetic images under a wide range of blur corruption. Obtained results clearly show that the proposed method significantly improves quality of edge detection. The refined edges are continuous and much more regular than those provided by the previously proposed approaches to subpixel edge detection. The more blurred is the edge, the difference is more significant. The advantage of the Gaussian function based method can be seen both: in accuracy and the stability of the obtained subpixel edge position.

Tests performed on the real images obtained from the high temperature industrial vision system proved that the introduced method can be particularly useful in case of low contrast images with blurred and unsharp edges. In consequence it can be successfully applied in a wide spectrum of machine vision applications where accuracy is at premium.

***Abstract*—In this paper an image processing algorithm for automatic evaluation of scanned examination sheets is described. The discussed image contains selected function graphs sketched on a prepared sheets. This type of task is characteristic of final high school exams of natural sciences. Our challenge was to develop an evaluation algorithm, which works with a precision comparable to the teacher. If the image contains the correct solution, the algorithm should husk it from a set of random lines, deletions, amendments, drafts, bearing in mind, that lines were drawn by hand. In addition, the algorithm should calculate scores for partially correct solutions. An essential part of our proposal, which is image segmentation and identification, is based on least-squares fitting combined with 1-NN classification. The proposed solution is flexible and can be extended to other types of tasks such as drawing geometrical figures.**

I. Introduction

ELECTRONIC marking (e-marking), also known as Computer Assisted Assessment (CAA) or Computer Based Assessment (CBA) is relatively a new idea in the field of teaching. Its main advantage is facilitating the laborious process of design, delivery, collection, scoring and analysis of the assessments [10]. Other advantages of CAA are easier schedule and administration of assessments, the immediacy of results, their increased objectivity and security, the possibility of monitoring students and suitability for distance learning [6].

Students also seemed to consider CBA as being more promising, credible, objective, fair, interesting, fun, fast and less difficult or stressful, while they stated that they preferred computerized versus written assessment [7], [5]. In [11] it has been shown, that introduction of CAA allows to keep original accuracy of the exam and increase its reliability and even improve exam quality.

E-marking has been widespread in Great Britain and the USA. The experience gained by Examination Boards like AQA, OCR and EDEXCEL in Great Britain and ETS in the USA suggests that introducing e-marking improves the quality and reliability of the exams.

CAA and e-marking systems described in the literature have been designed for automatic evaluation of the exams carried out at the computer, which means, they use analytical or lexical form immediately.

The prevalence of this form of examination in the case of final examinations in primary and secondary schools can be difficult, due to the need to build IT infrastructure capable to handle a large number of people using the system at the same time.

We anticipate that still the dominant number of examinations will be carried out on the paper sheets and will be checked by humans.

Designing a system that will identify and evaluate the content of the answer sheets based on image processing and understanding algorithms can solve this problem, and in addition will be the value of research in the field of artificial intelligence.

Among the available literature and documentation we have not found any CAA systems that rely on image analysis and could be compared with ours, although there exist possible useful for our problem applications of:

- optical character recognition / intelligent character recognition (OCR/ICR) [18];
- lexicography analysis [13];
- image understanding techniques [14];
- neural networks to OCR/ICR and text identification algorithms [4], [12];
- Hough transform to object identification [9].

Our method of evaluation sketched function graphs relies on

- conversion the sketched shapes to its analytical form (coefficients an equation of a straight line or a parabola)
- merging of graph fragments basing on the evaluated coefficients
- comparison of the sketched graphs to model graphs by comparison of the evaluated coefficients to required values

In contrast to our previous approaches we do not use any reference image (possibly sketched by a teacher).

In practice each image should be segmented into individual primitives before the comparison. In our previous works [15],

978-83-60810-58-3/$25.00

[16], [17] we utilized cross-correlation [3] and Generalized Hough Transform (GHT) for this purpose. Unfortunately, the methods, we utilized, did not prove to be flexible and requires major redesign of the algorithm and for assessing new tasks. On the contrary, the least squares method can be used to identify most of the lines described analytically (through equation). The difficulty lies only in the transformation of the figure equation to the form of which the iterative process of fitting is convergent.

II. Description of the Task

The students have been asked to draw two graphs. First one is a function that has two points of discontinuity(eq. 1).

$$f(x) = \begin{cases} -4, & \text{for } x \leq -4 \\ -0.5x + 3, & \text{for } x \in (-4; 4) \\ -x + 9, & \text{for } x \geq 4 \end{cases} \quad (1)$$

Its graph (Fig. 1) consists of three line segments:

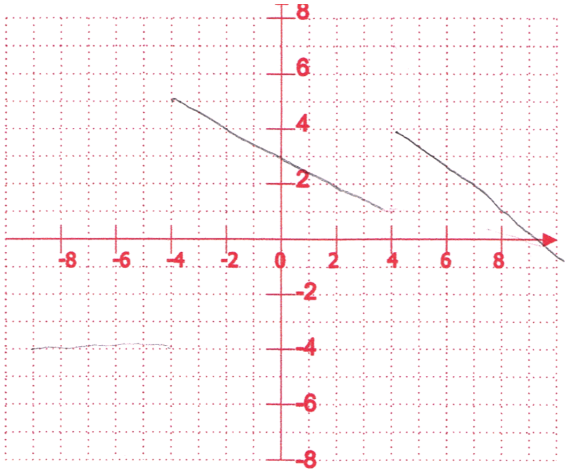

Fig. 1. An example of correctly sketched graph of the linear function

Second one is a parabola given by the formula (eq. 2):

$$f(x) = x^2 - 6 \cdot x + 5 \quad (2)$$

It has zeros in $x_1 = 1$ and $x_2 = 5$ and the minimum in the point $(3, -4)$ (see Fig. 2)

III. Fitting Shapes using Least-Squares

In the literature one can find a few examples of the use of fitting methods for finding the unknown parameters of geometric figures or function graphs. The publications are related to circles and ellipses [2], spheres, ellipses, hyperbolas, and parabolas [8]. Authors of these studies often adopt a two-phase method: first phase - algebraic fitting, second phase geometrical fitting.

Algebraic fit consists in solving the equation:

$$F(x, z) = \theta \quad (3)$$

where z is a vector of n parameters, x are points in l-dimensional (for example $l = 2$) space. To calculate the

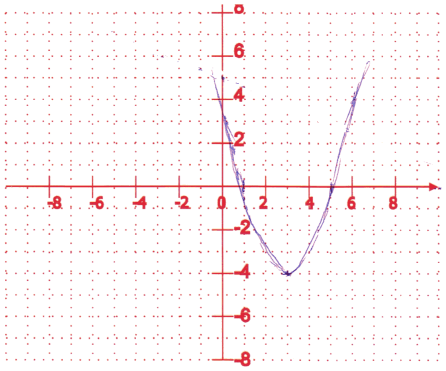

Fig. 2. An example of correctly sketched graph of the parabola

parameters for an analytical form of the function using fitting we must create the matrix B for which:

$$[B] = \theta B = \begin{bmatrix} f_1(x_1) & f_2(x_1) & \cdots & f_{k-1}(x_1) & 1 \\ f_1(x_2) & f_2(x_2) & \cdots & f_{k-1}(x_2) & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ f_1(x_m) & f_2(x_m) & \cdots & f_{k-1}(x_m) & 1 \end{bmatrix} \quad (4)$$

Then, for each point $x_p, p = 1 \ldots m$, we have

$$f_1(x_p) \cdot a_1 + f_2(x_p) \cdot a_2 + \ldots + f_{k-1}(x_p) \cdot a_{k-1} + a_k = 0 \quad (5)$$

The algebraic fit usually does lead to the exact solution as it consists in solution of the overdetermined system ($m \gg k$) and choice the approximate solution to minimize the mean square error. In our approach we have chosen Singular Value Decomposition.

The idea of decomposition of the matrix $[B], (m \times k)$ is creation of a column orthogonal matrix $[U], (m \times m)$, a diagonal matrix $[W](m \times k)$ with zero or non-zero elements and a square, orthogonal matrix $[V](k \times k)$. We obtain the following equation:

$$[B] = [U] \cdot [W] \cdot [V]^T \quad (6)$$

The condition of orthogonality is

$$[U]^T \cdot [U] = [V]^T \cdot [V] = 1 \quad (7)$$

Evaluated matrix V corresponding to smallest singular value of $[B]$ contains a vector of parameters z in its last column.

$$[V] = \begin{bmatrix} v_{11} & \cdots & z_1 \\ v_{21} & \cdots & z_2 \\ \vdots & \ddots & \vdots \\ v_{k1} & \cdots & z_k \end{bmatrix} \quad (8)$$

This solution is taken as the starting point for the iterative process of geometric fit method, which allows a more accurate

approximation of the sought parameters. We also control the convergence of the iteration process, and at each step we can estimate the error. This in turn give grounds for considering whether it is possible to fit the selected function to given set of points.

The objective of the geometric fit is to minimize the geometric square error.

$$\epsilon = \sum \|x - x_0\| \tag{9}$$

In this study the Gauss-Newton method is used.

IV. Proposed algorithms

The proposed method of sketched graphs assessment is based on the analysis of all connected components in the image, obtained in the process of preprocessing. In the phase of image preprocessing, all printed content of the examination sheet is erased - only sketched lines remain. However, the process of overprints removal as well as the way in which the student draws a graph causes some defects - the filtered lines may not remain connected, for example, the circle becomes a dozen of arcs. Next the lines are thinned to a single pixel.

Assuming that the exercise was to draw a graph of a linear function, which is a straight line, the algorithm will work as follows:

1) For each connected component, run fitting procedure that finds a, b, c parameters for the equation $a \cdot x + b \cdot y + c = 0$. If the process is not convergent – it means that the component is not a line segment and reject it.
2) Calculated vectors $z = (a, b, c)$ form a feature linear space. Using clustering, find the most similar vectors. This means that the corresponding sets of points belong to one line.
3) for the union of the components obtained in the previous step re-do the fitting to accurately determine the parameters of the line.

This method can be generalized to simultaneously search for several straight lines. Then, the obtained vectors (a, b, c) will be subjected to clustering to indicate several groups of similar vectors.

In case the student task is to draw a number of different geometric shapes, we will try to adjust the parameters of different functions to each of them, looking for the best fit.

A. Fitting a straight line

In the first phase, the algorithm will minimize the algebraic error. Assume that a simple algebraic representation a straight line in the plane is given by

$$\begin{aligned} &F(x) = A^T \cdot x + c = 0, \\ &A = (a, b) \in \mathbb{R}^2, \\ &x \in \mathbb{R}^2, \\ &c \in \mathbb{R} \end{aligned} \tag{10}$$

The aim is to find values of a, b, c for given points x. Substituting the coordinates of the points in the above equation we obtain the system of equations. $[B] \cdot z = 0$, for the parameters $z = (a, b, c)$, where B is in the form:

$$[B] = \begin{bmatrix} x_{11} & x_{12} & 1 \\ x_{21} & x_{22} & 1 \\ \vdots & \vdots & \vdots \\ x_{m1} & x_{m2} & 1 \end{bmatrix} \tag{11}$$

Assuming, that $m > 3$, B is a rectangular, the system is overdetermined and probably inconsistent. The solution is approximated with Singular Value Decomposition.

Denote the obtained solution by $z = (a_0, b_0, c_0)$.

In the case of good fit such a solution is sufficient. However, if there are points x lying far from the approximated line, the bias arises, and therefore a second phase of the algorithm – geometric fit – must be launched.

Since there are many combinations of (a_0, b_0, c_0) corresponding to one line, one of the co-ordinates should be eliminated. Choose $z_M = \max(|a_0|, |b_0|, |c_0|)$ and assume, that $z = (1, b_0/z_M, c_0/z_M)$ or $z = (a_0/z_M, 1, c_0/z_M)$ or $z = (a_0/z_M, b_0/z_M, 1)$

The Gauss-Newton method involves the iteration which consists of two operations:

- solution of the system $-[J] \cdot h = f$ with the unknown vector h;
- correction of the solution $z = z + h$.

In the above system f is the objective function. It is a vector of distances of each point to the fitted line. J is the Jacobian - contains derivatives of the coordinates of the vector z (sought parameters). Formally:

$$\begin{aligned} &f = (f_1, f_2, \ldots, f_m); \quad f_i = \tfrac{|ax_{1i} + bx_{2i} + c|}{\sqrt{a^2 + b^2}}; \\ &J = \begin{bmatrix} \frac{\partial f_1}{\partial a} & \frac{\partial f_1}{\partial b} & \frac{\partial f_1}{\partial c} \\ \frac{\partial f_2}{\partial a} & \frac{\partial f_2}{\partial b} & \frac{\partial f_2}{\partial c} \\ \vdots & \vdots & \vdots \\ \frac{\partial f_m}{\partial a} & \frac{\partial f_m}{\partial b} & \frac{\partial f_m}{\partial c} \end{bmatrix}; \\ &J_{i1} = \frac{\operatorname{sgn}(ax_{1i} + bx_{2i} + c) \cdot x_{2i} - |ax_{1i} + bx_{2i} + c| \cdot \frac{a}{\sqrt{a^2 + b^2}}}{a^2 + b^2} \\ &J_{i2} = \frac{\operatorname{sgn}(ax_{1i} + bx_{2i} + c) \cdot x_{2i} - |ax_{1i} + bx_{2i} + c| \cdot \frac{b}{\sqrt{a^2 + b^2}}}{a^2 + b^2} \\ &J_{i1} = \frac{\operatorname{sgn}(ax_{1i} + bx_{2i} + c)}{\sqrt{a^2 + b^2}} \end{aligned} \tag{12}$$

The condition of convergence is calculated by the relative difference between the current and the previous solution.

$$\Delta = \frac{\|h\|_\infty}{\|z\|_\infty} \tag{13}$$

B. Fitting a parabola

In our discussion we will consider only the parabola which symmetry axis is parallel to the y-axis in the coordinate system. Accordingly, the parabola is defined by the algebraic equation:

$$F(x) = a \cdot x_1^2 + b \cdot x_1 + c \cdot x_2 + d = 0 \tag{14}$$

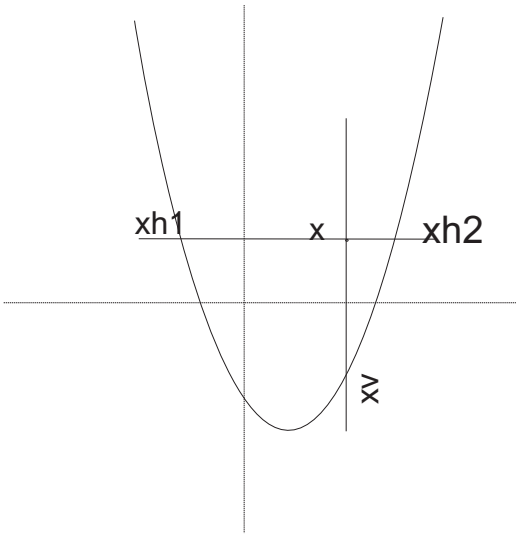

Fig. 3. Approximation of the distance of the point from the parabola

Denote the searched value $z = (a, b, c, d)$. To find the algebraic fitting for the equation denote:

$$[B] = \begin{bmatrix} x_{11}^2 & x_{11} & x_{12} & 1 \\ x_{21}^2 & x_{21} & x_{22} & 1 \\ \vdots & \vdots & \vdots & \vdots \\ x_{m1}^2 & x_{m1} & x_{m2} & 1 \end{bmatrix} \tag{15}$$

Just as in the case of a straight line, the system of equations is solved by SVD giving the value of $z_0 = (a_0, b_0, c_0, d_0)$. Then the geometric fit is carried out.

Similarly, as in the case of a straight line, in order to avoid ambiguity (and, consequently, the divergence of the process) we eliminate one of the parameters. Given the assumed position of the parabola it will be a parameter c.

$$F(x) = a/c_0 \cdot x_1^2 + b/c_0 \cdot x_1 + x_2 + d/c_0 = 0 \tag{16}$$

Iterative process will be conducted the same way as in the case of a straight line. However, due to a difficulty in determining the distance from the point to the parabola, some simplification will be used.

To calculate the distance of a point x to the parabola together with its partial derivatives, we derive a straight line from this point, parallel to the x-axis. It may cross the parabola at points X_{H1} and X_{H2}. We also derive a line from x, parallel to the y-axis, which always intersects the parabola (the point X_V). The points of intersection are calculated straight out of the equation of the parabola. Denote:

$$\begin{aligned} f_x &= \min(\rho(x, x_{h1}); \rho(x, x_{h2})) \\ f_y &= \rho(x, x_v) \end{aligned} \tag{17}$$

If x_{h1} and x_{h2} do not exist, assume that $f_x = f_y$.

Assuming that x_{H1} is a closer point, we calculate the partial derivatives of its distance.

$$\begin{aligned} \frac{\partial f_x}{\partial a} &= \text{sgn}(x_1 - x_{h1,1}) \cdot b \cdot (b + \sqrt{\Delta} + 2a(x_2 + c)/\sqrt{\Delta})/2a^2 \\ \frac{\partial f_x}{\partial b} &= \text{sgn}(x_1 - x_{h1,1}) \cdot (-1 - b/\sqrt{\Delta})/2a \\ \frac{\partial f_x}{\partial c} &= \text{sgn}(x_1 - x_{h1,1}) \cdot \sqrt{\Delta} \\ \frac{\partial f_y}{\partial a} &= \text{sgn}(x_2 - x_{v,2}) \cdot x_1^2 \\ \frac{\partial f_y}{\partial b} &= \text{sgn}(x_2 - x_{v,2}) \cdot x_1 \\ \frac{\partial f_y}{\partial c} &= \text{sgn}(x_2 - x_{v,2}) \end{aligned} \tag{18}$$

As an approximate distance of the point to the parabola we use the geometric average of calculated values f_x, f_y.

$$sf = f_x^2 + f_y^2 \qquad f = \frac{f_x \cdot f_y}{\sqrt{sf}} \tag{19}$$

Then, the Jacobian is defined by equations.

$$\begin{aligned} J_1 &= \left(\left(\frac{\partial f_x}{\partial a} f_y + \frac{\partial f_y}{\partial a} f_x \right) \sqrt{sf} - f \left(\frac{\partial f_x}{\partial a} f_x + \frac{\partial f_y}{\partial a} f_y \right) \right) / sf \\ J_2 &= \left(\left(\frac{\partial f_x}{\partial b} f_y + \frac{\partial f_y}{\partial b} f_x \right) \sqrt{sf} - f \left(\frac{\partial f_x}{\partial b} f_x + \frac{\partial f_y}{\partial b} f_y \right) \right) / sf \\ J_3 &= \left(\left(\frac{\partial f_x}{\partial c} f_y + \frac{\partial f_y}{\partial c} f_x \right) \sqrt{sf} - f \left(\frac{\partial f_x}{\partial c} f_x + \frac{\partial f_y}{\partial c} f_y \right) \right) / sf \end{aligned} \tag{20}$$

V. The main algorithm for image processing

Due to the fact that each image may have a different content and may include various types of function graph we decided to identify the graph using least-squares method for each line segment found in the image.

The preprocessing phase includes separation of the drawing from the rest of scanned examination sheet. Our method described in [16] has been replaced by more efficient color discrimination. For this purpose the coordinate system had to be printed red, while students use blue or black pen.

The color filtration condition is presented by the formula

for all pixel p IN I_l **do**
  if $|red(p) - green(p)| > 35 AND |red(p) - blue(p)| > 20$ **then**
    $p = (255, 255, 255)$
  end if
end for

Next steps of the preprocessing algorithm:

- image binarization using Otsu method [1];
- using morphological filters thin the lines, remove isolated points;

$$interval = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{21}$$

- using hit-miss transform detect and remove all crossings – trench the crossing lines;

$$interval = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{22}$$

- segment the image – label all connected components. We obtain I_l image containing $1 \ldots l$ components.

The following sections present our methods of analyzing and assess individually: discontinuous linear function and quadratic function.

A. Analyzing straight lines

The main part of the image processing is summarized in the following algorithms

Algorithm 1 Processing of connected components of I_l

$count \leftarrow 0$; $tolerance \leftarrow 1e-5$;
while $d > tolerance$ AND $count < 10$ **do**
  for all $line$ IN I_l **do**
    if $size(line) > 20$ **then**
      $(a_0, b_0, c_0) \leftarrow$ AlgebraicFitLine $(line)$
      $W_i \leftarrow (a, b, c, x_{\min}, x_{\max}, y_{\min}, y_{\max})_i \leftarrow$ GeometricFitLine $(line, a_0, b_0, c_0)$
    end if
  end for
  $d \leftarrow \max(res)$
  $count \leftarrow count + 1$
  $lines \leftarrow$Merge$(lines)$
end while

Here is the explanation of the Alg. 1. Repeat the operations until the error of fit is greater than expected: For each connected component, greater than 20 pixels do the operations: (if the number of iterations reaches 10, the procedure breaks regardless the obtained result)

1) algebraic fit (see sec. IV-A). A result is a vector (a_0, b_0, c_0)
2) geometric fit (see sec. IV-A). A result is a vector (a, b, c) and the convergence error res. The procedure of geometric fit is iterative and the iteration breaks if the expected convergence is reached ($tol < 1e-3$) or the number of iterations exceeds the established number ($maxiter > 10$).
3) find two nearest connected components and if the distance and merge them (assign the same label)

From the set of recognized lines we choose these, that lie nearest to the model lines. This is required, when the graph to be drawn consists of a few line segments (the function is not continuous). Model line parameters are obtained from the analytical form of the function. The comparison is carried out using 1-Nearest Neighbor statistical classifier, with the feature space identical to W_i vector in Alg. 1.

B. Obtaining a score

Each of line segments of the discontinuous function which is to be drawn is assessed independently, so if there are three segments of the graph, the maximum mark is 3. We take into account A, B, C coefficients of the linear function and the minimum and maximum x coordinate of the found line.

C. Analyzing a parabola

The initial phase of the algorithm is similar to Alg. 1 for processing straight lines

Algorithm 2 Processing of connected components of I_l

$count \leftarrow 0$; $tolerance \leftarrow 1e-1$;
while $d > tolerance$ AND $count < 10$ **do**
  for all $line$ IN I_l **do**
    if $size(line) > 20$ **then**
      $(a_0, b_0, c_0, d_0) \leftarrow$ AlgebraicFitParabola $(line)$
      $W_i \leftarrow (a, b, c, x_{\min}, x_{\max}, y_{\min}, y_{\max})_i \leftarrow$ GeometricFit $(line, a_0, b_0, c_0, d_0)$
    end if
  end for
  $d \leftarrow \max(res)$
  $count \leftarrow count + 1$
  $lines \leftarrow$Merge$(lines)$
end while

The main loop is repeated until we reach a required tolerance but no more than 10 times. As for straight lines, the algebraic fit followed by geometric fit are calculated. Again, as for straight lines, we merge the neighboring curves. The merge is done conditionally. For each pair the fitting is performed as for one set of points. If the convergence does not increase more than three times, the curves may be merged. After completion the process of fitting and merging the curves we obtain one or more curves that are possibly parabolas.

For the process of the assessment we take into account:

- (a, b, c) coefficients for the parabola equation $a \cdot x^2 + b \cdot x + c = 0$
- $(x_{\min}, x_{\max})$ - a position of the curve in the coordinate set.
- $(y_{\min}, y_{\max})$ - minimum or maximum value of the drawn function
- a count of pixels, that are not assigned as parabolas (these are possibly amendments)

If for the examined graph true are the statements:

1) values $(x_{\min}, x_{\max})$ and $(y_{\min}$ or $y_{\max})$ fall within a specified range
2) two of (a, b, c) parameters fall within a specified range
3) the count of amendment pixels is less than a specified threshold

the student receives 1 point. Moreover if all of (a, b, c) parameters fall within a specified range, the student receives a maximum score - 2 points.

If the count of amendment pixels exceeds a specified threshold, the graph is assigned as unrecognized.

VI. Teaching the algorithms

The algorithm for graphs classification runs in a supervised manner (with teaching). For each new type of the image (modified print-out, different task, different scanner) the step of teaching must be repeated. The teaching phase consists of evaluation acceptable ranges in the feature space. Some of them are calculated from the formula of the task:

- a, b, c parameters (both lines and parabola)
- x_{min} and x_{max} values

- y_{min} or x_{max} value (only for a parabola)

but their tolerances must be evaluated experimentally. Other parameters are:

- a threshold for detection of amendments
- a threshold for minimal length of a line (only for lines)

The teaching is carried out by comparing the proper scores (given by a teacher) for several test images containing graph sketches with the scores calculated by algorithms.

The aim of the tune-up is to minimize the overall error (number of different scores)

For the experiments 57 sheets with Task 1 and 72 sheets with task 2 have been used. All the sheets have been assessed by teachers for comparison. The examination sheets have been scanned in color mode with resolution 300 DPI. With this resolution each image containing extracted coordinate set with sketches has an area about 1 Megapixel.

Table I contains results of manual assessment of Task 1 for 11 exemplary works and the parameters obtained by an algorithm.

TABLE I
TASK 1: 11 EXEMPLARY SHEETS - ASSESSED BY A TEACHER

Sample	score for a segment 1	2	3	Total Score	Notes
1	1	1	1	3	
2	0	0	0	0	
3	0	0	0	0	
4	1	1	1	3	additional lines
5	1	1	1	3

Parameter $maxpix$	< 600

VII. THE RESULTS OF THE EXPERIMENT

In Table V the best results (for parameters presented in Tables II and IV) for training sets have been summarized.

TABLE V
THE OF RESULTS FOR TRAINING SETS COMPARED TO TEACHER SCORES

Item	Test 1	Test 2
Samples	36	36
Unrecognized	3	1
Underestimated score	1	0
Overestimated score	2	1
Compliant score	30	34
Recognized compliant ratio	83%	94%

In Figs 4 – 8 exemplary correct and incorrect results are presented.

Table V summarizes the results obtained for testing sets.

TABLE VI
THE OF RESULTS FOR TESTING SETS COMPARED TO TEACHER SCORES

Item	Test 1	Test 2
Samples	36	36
Unrecognized	6	0
Underestimated score	2	1
Overestimated score	1	5
Compliant score	27	30
Recognized compliant ratio	75%	83%

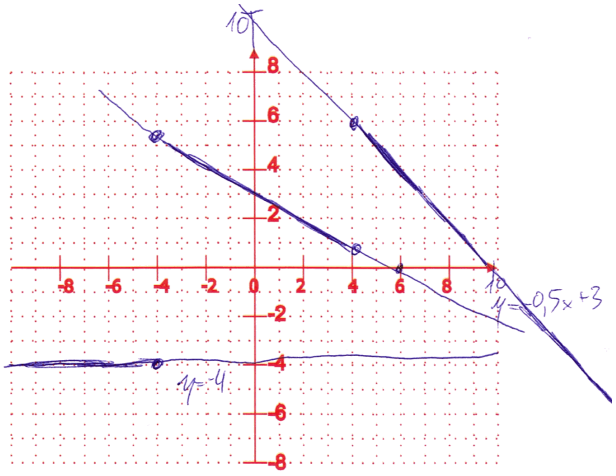

Fig. 4. Task 1, sample 4. A correct solution - but the algorithm did not recognize the sketches

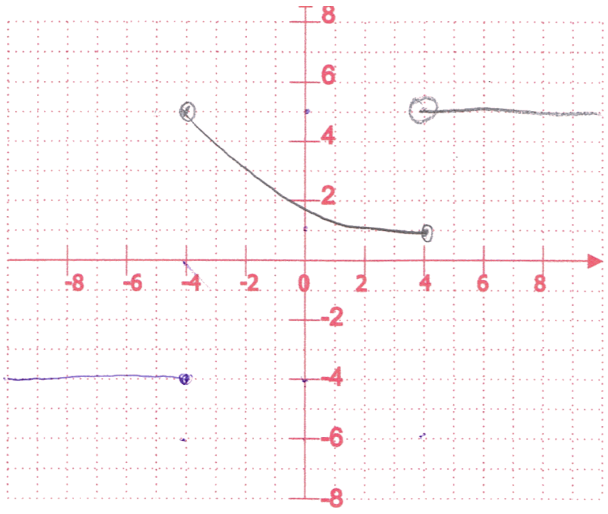

Fig. 6. Task 1, sample 32. An incorrect solution - the central line is not straight. The algorithm qualified this line as correct.

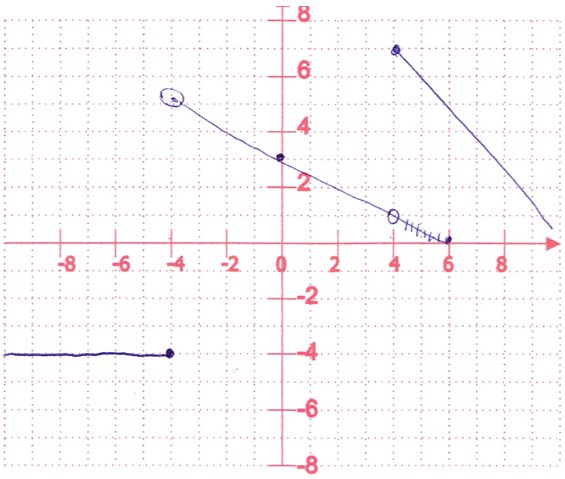

Fig. 5. Task 1, sample 29. A correct solution - underestimated by the algorithm. The central line has been disqualified.

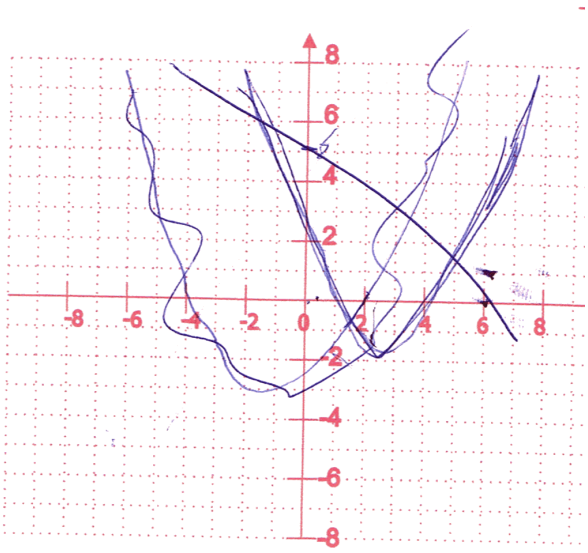

Fig. 7. Task 2, sample 18. Unrecognized sketches

VIII. Conclusions

According to this report (Table VI) the algorithm works properly for the case of the tested task. The errors occurred for the cases when the solutions contained amendments, strike-throughs. Tasks which were not recognized, contained additional objects or the drawings were done careless. Parameters of the algorithm were chosen so as to minimize the amount of erroneous assessments among the training set, even at the cost of increase of the number of unresolved tasks.

A general drawback of this approach is a necessity to train the algorithm before an assessment of a new task, but some of the parameters may be read from the analytical form of the function. Other parameters, which are tolerance, can be expressed as a percentage of the size of the unit.

Our future research will include the detection and assessment of graphs of trigonometric, exponential and rational functions. We'll try to extract multiple types of function graphs from one sketch (the task may include drawing a graphical solution of the set of inequalities)

Furthermore the algorithm of identification acceptable and redundant objects will be improved.

***Abstract* -- In this paper we extend our previous work for planar images by adding a new step in the volumetric segmentation algorithm that allows us to determine regions closer to it. There are huge of papers for planar images and segmentation methods and most of them are graph-based for planar images and very few papers for volumetric segmentation methods. However, even if image segmentation is a heavily researched field, extending the algorithms to spatial has been proven not to be an easy task. A true volumetric segmentation remains a difficult problem to tackle due to the complex nature of the topology of spatial objects, the huge amount of data to be processed and the complexity of the algorithms that scale with the new added dimension. The problem of partitioning images into homogenous regions or semantic entities is a basic problem for identifying relevant objects. Visual segmentation is related to some semantic concepts because certain parts of a scene are pre-attentively distinctive and have a greater significance than other parts. A number of approaches to segmentation are based on finding compact regions in some feature space. A recent technique using feature space regions first transforms the data by smoothing it in a way that preserves boundaries between regions. The key to the whole own algorithm of volumetric segmentation is the honeycomb cells. The pre-processing module is used mainly to blur the initial RGB spatial image in order to reduce the image store and to make algorithms to be efficient. Then the volumetric segmentation module creates virtual cells of prisms with tree-hexagonal structure defined on the set of the image voxels of the input spatial image and a volumetric grid graph having tree-hexagons as cells of vertices. Early graph-based methods use fixed thresholds and local measures in finding a volumetric segmentation.**

Index terms- Volumetric Segmentation; Graph-based segmentation; Color segmentation; Syntactic segmentation

I. Introduction and Related Works

THERE is a wide range of computational vision problems for planar images that could use of segmented images. The problem of partitioning images into homogenous regions or semantic entities is a basic problem for identifying relevant objects. Higher-level problems such as object recognition and image indexing can also make use of segmentation results in matching, to address problems such as figure-ground separation and recognition by parts. In both intermediate level and higher-level vision problems, contour detection of objects in real images is a fundamental problem. However the problems of planar image segmentation and grouping remain great challenges for computer vision. As a consequence we consider that a spatial segmentation method can detect visual objects from images if it can detect at least the most objects. We develop a visual feature-based method which uses a virtual spatial graph constructed on cells of prisms with tree-hexagonal structure containing half of the image voxels in order to determine a forest of spanning trees for connected component representing visual objects. Thus the spatial image segmentation is treated as a spatial graph partitioning problem. In addition our spatial segmentation algorithm produces good results from both from the perspective perceptual grouping and from the perspective of determining homogeneous in the input images. Early graph-based methods use fixed thresholds and local measures in finding a spatial segmentation.

In [1] one determined the normalized weight of an edge by using the smallest weight incident on the vertices touching that edge. Other methods for planar images [2], [3] use an adaptive criterion that depends on local properties rather than global ones. In contrast with the simple graph-based methods, cut-criterion methods capture the non-local cuts in a graph are designed to minimize the similarity between pixels that are being split [4] [5]. The normalized cut criterion [5] takes into consideration self similarity of regions. An alternative to the graph cut approach is to look for cycles in a graph embedded in the image plane. In [6] the quality of each cycle is normalized in a way that is closely related to the normalized cuts approach. Other approaches to planar image segmentation consist of splitting and merging regions according to how well each region fulfills some uniformity criterion. Such methods [7] use a measure of uniformity of a region. In contrast [2] and [3] use a pair-wise region comparison rather than applying a uniformity criterion to each individual region. Complex grouping phenomena can emerge from simple computation on these local cues [8]. A number of approaches to segmentation are based on finding compact regions in some feature space [9]. A recent technique using feature space regions [10] first transforms the data by smoothing it in a way that preserves boundaries between regions. Our previous works [11] and [12] are related to the works in [2] and [3] in the sense of pair-wise comparison of region similarity. In these papers we extend our previous work by adding a new step in the spatial segmentation algorithm that allows us to determine regions closer to it.

II. Constructing a Virtual Tree-Hexagonal Structure

The pre-processing module is used mainly to blur the initial RGB spatial image in order to reduce the image noise [13] and to apply the spatial segmentation algorithm. Then the segmentation module creates virtual cells of prisms with tree-hexagonal structure defined on the set of the image voxels of the input spatial image and a spatial triangular grid graph having tree-hexagons as cells of vertices. In order to allow a unitary processing for the multi-level system at this level we store, for each determined component C, the set of the tree-hexagons contained in the region associated to C and the set of tree-hexagons located at the boundary of the component. In addition for each component the dominant color of the region is extracted. This color will be further used in the post-processing

module if any. The contour extraction module determines for each segment of the image its boundary. The boundaries of the de determined visual objects are closed contours represented by a sequence of adjacent tree-hexagons. At this level a linked list of points representing the contour is added to each determined component. The post-processing module (if any) extracts representative information for the above determined visual objects and their contours in order to create an efficient index for a semantic image processing system.

A spatial image processing task contains mainly three important components: acquisition, processing and visualization. After the acquisition stage an image is sampled at each point on a three dimensional grid storing intensity or color information and implicit location information for each sample. The grid is the most dominant of any grid structure in image processing and conventional acquisition devices acquire square sampled images. An important advantage of using this grid is the fact that the visualization stage uses directly the voxels of the digitized image. We do not use a hexagonal lattice model because of the additional actions involving the double conversion between square and tree-hexagonal voxels. However we intent to use some of the advantages of the tree-hexagonal grid such as uniform connectivity. This implies that there will be less ambiguity in defining boundaries and regions [14]. As a consequence we construct a virtual tree-hexagonal structure over the grid voxels of an input image, as presented in Figure 1. This virtual tree-hexagonal grid is not a tree-hexagonal lattice because the constructed hexagons are not regular.

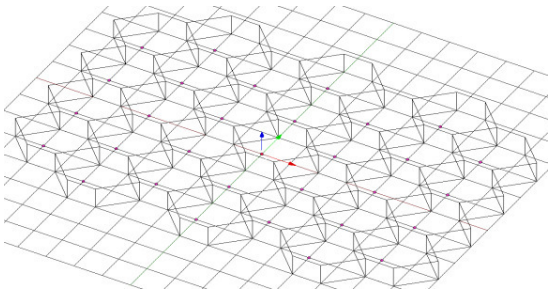

Fig. 1. Virtual Tree-Hexagonal structure constructed on the image voxels

Let I be a spatial initial image having the dimension h×w× z (e.g. a matrix having 'h' rows, 'w' columns and 'z' deep of matrix voxels). In order to construct a tree-hexagonal grid on these voxels we retain an eventually smaller image with

$$\begin{aligned} h' &= h-(h-1) \bmod 2, \\ w' &= w-w \bmod 4, \\ z' &= z- z \bmod 4. \end{aligned} \tag{1}$$

In the reduced image at most the last line of voxels and at most the last three columns and deep of matrix of voxels are lost, assuming that for the initial image h > 3 and w > 4 and z > 4, that is a convenient restriction for input spatial images.

Each tree-hexagon from the tree-hexagonal grid contains sixteen voxels: such twelve voxels from the frontier and four interior frontiers of voxels. Because tree-hexagons voxels from an image have integer values as coordinates we select always the left up voxel from the four interior voxels to represent with approximation the gravity center of the tree-hexagon, denoted by the pseudo-gravity center. We use a simple scheme of addressing for the tree-hexagons of the tree-hexagonal grid that encodes the spatial location of the pseudo-gravity centers of the tree-hexagons as presented in Figure 1.

Let h× w× z the three dimension of the initial spatial image verifying the previous restriction (e.g. h mod 2 = 1, w mod 4 = 0, z mod 4 = 0, h ⩾ 3 and w⩾4 and z⩾4). Given the coordinates (l,c,d) of a voxel p' from the input spatial image, we use the linearized function, $ip_{h,w,z}(l,c,d) = (l-1)w+c+d$, in order to determine an unique index for the voxel.

Let 'ps' be the sub-sequence of the voxels from the sequence of the voxels of the initial spatial image that correspond to the pseudo-gravity center of tree-hexagons, and' hs', 'ws' and 'zs' the sequence of tree-hexagons constructed over the voxels of the initial spatial image. For each voxel 'p' from the sequence ps having the coordinates (l,c,d), the index of the corresponding tree-hexagon from the sequence hs, ws and zs are given by the following relation:

$$f h_{h,w,z}(l,c,d) = [(l-2)w+c+d-2l]/4 +1 \tag{2}$$

In this case the following relation holds:

$$f h_{h,w,z}(l,c,d) = i. \quad . \tag{3}$$

Moreover it is easy to verify that the function 'f h' defined by the relation (2) is bijective. Its inverse function is given by:

$$f h^{-1} h, w, z (k) = (l,c,d) \tag{4}$$

where:

$$l = (2+ 4(k-1)/w \text{ if } h < w,$$

$$l = 2+ 4(k-1)/w +tw \text{ if } h \geqslant w, \text{ and } h = tw+h' , \tag{5}$$

$$c = 4(k-1)+2l-(l-2)w, \tag{6}$$

$$d = 4(k-1)+2l-(l-2)w. \tag{7}$$

Relations (4), (5), (6) and (7) allow us to uniquely determine the coordinates of the voxel representing the pseudo-gravity center of a tree-hexagon specified by its index (its address). In addition these relations allow us to determine the sequence of coordinates of all sixteen voxels contained into a tree-hexagon with an address 'k'.

The sub-sequence 'ps' of the voxels representing the pseudo-gravity center and the function 'fh' defined by the relation (2) allow to determine the sequence of the tree-hexagons 'Hs' that is used by the segmentation and contour detection algorithms. After the processing step the relations (4), (5), (6), (7) allow to up-date the voxels of the spatial initial spatial image for the visualization step.

Each tree-hexagon represents an elementary item and the entire virtual tree-hexagonal structure represents a triangular grid graph, G = (V,E), where each tree-hexagon 'H' in this structure has a corresponding vertex v ∈V. The set E of edges is constructed by connecting tree-hexagons that are neighbors in a 20-connected sense. The vertices of this graph correspond to the pseudo-gravity centers of the hexagons from the tree-hexagonal grid and the edges are straight lines connecting the pseudo-gravity centers of the neighboring hexagons, as presented in Figure 2.

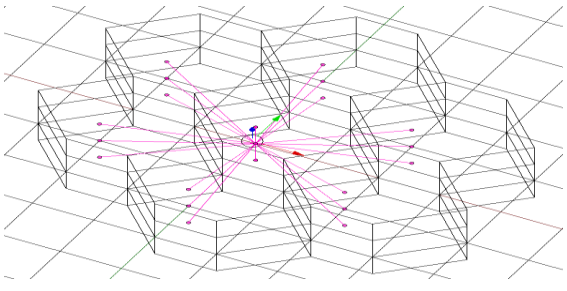

Fig.2. Triangular grid graph constructed on the pseudo-gravity centers of the tree-hexagonal grid

There are two main advantages when using tree-hexagons instead of all voxels as elementary piece of information:

• The amount of memory space associated to the graph vertices is reduced. Denoting by 'np' the number of voxels of the initial spatial image, the number of the resulted tree-hexagons is always less than np/4, and thus the cardinal of both sets V and E is significantly reduced;

• The algorithms for determining the visual objects and their contours are much faster and simpler in this case.

We associate to each tree-hexagon 'H' from V two important attributes representing its dominant color and the coordinates of its pseudo-gravity center, denoted by c(h) and g(h). The dominant color of a tree-hexagon is denoted by c(h) and it represents the color of the voxel of the tree-hexagon which has the minimum sum of color distance to the other twenty voxels. Each tree- hexagon 'H' in the tree-hexagonal grid is thus represented by a single point, g(h), having the color c(h). By using the values g(h) and c(h) for each tree-hexagon information related to all voxels from the initial image is taken into consideration by the spatial segmentation algorithm.

III. Volumetric Segmentation Algorithm

Let $V = \{h_1, \ldots, h_{|V|}\}$ be the set of virtual tree-hexagons constructed on the input spatial image voxels as presented in previous section and $G = (V,E)$ be the undirected spatial grid-graph, with E containing pairs of honey-beans cell (tree-hexagons) that are neighbors in a 20-connected sense. The weight of each edge $e = (h_i,h_j)$ is denoted by w(e), or similarly by w(hi,hj), and it represents the dissimilarity between neighboring elements 'hi' and 'hj' in a some feature space. Components of a spatial image represent compact regions containing voxels with similar properties. Thus the set V of vertices of the graph G is partitioned into disjoint sets, each subset representing a distinct visual object of the initial image.

As in other graph-based approaches [15] we use the notion of segmentation of the set V. A segmentation, S, of V is a partition of V such that each component $C \in S$ corresponds to a connected component in a spanning sub-graph

$GS = (V,ES)$ of G, with $ES \subseteq E$.

The set of edges $E - ES$ that are eliminated connect vertices from distinct components. The common boundary between two connected components $C', C'' \in S$ represents the set of edges connecting vertices from the two components:

$$cb(C',C'') = \{(hi,hj) \in E \mid hi \in C', hj \in C''\} \quad (8)$$

The set of edges $E-ES$ represents the boundary between all components in S. This set is denoted by *bound(S)* and it is defined as follows:

$$bound(S) = \cup_{C',C'' \in S} cb(C',C''). \quad (9)$$

In order to simplify notations throughout the paper we use Ci to denote the component of a segmentation S that contains the vertex $hi \in V$.

We use the notions of segmentation too fine and too coarse as defined in [2] that attempt to formalize the human perception of salient visual objects from an image. A segmentation S is too fine if there is some pair of components $C', C'' \in S$ for which there is no evidence for a boundary between them. S is too coarse when there exists a proper refinement of S that is not too fine. The key element in this definition is the evidence for a boundary between two components.

The goal of a spatial segmentation method is to determine a proper segmentation, which represent visual objects from an image.

Definition 1 Let $G = (V,E)$ be the undirected spatial graph constructed on the virtual tree-hexagonal structure of an image, with $V = \{h1, \ldots, h|V|\}$. A proper segmentation of V, is a partition S of V such that there exists a sequence $[Si, Si+1, \ldots, S\ f-1, S\ f]$ of segmentations of V for which:

• $S = S^f$ is the final segmentation and S_i is the initial segmentation,

• S_j is a proper refinement of S_{j+1} (i.e., $S_j \subset S_{j+1}$) for each $j = i, \ldots, f-1$,

• segmentation S_j is too fine, for each $j = i, \ldots, f-1$,

• any segmentation S_l such that $S_f \subset S_l$, is too coarse,

• segmentation S^f is neither too coarse nor too fine.

Let $C',C'' \in Sa$ be two components obtained by splitting a component $C \in Sb$. In this case C' and C'' have a common boundary, $cb(C',C'') \neq \emptyset$.

Our segmentation algorithm starts with the most refined segmentation, $S_0 = \{\{h_1\}, \ldots, \{h_{|V|}\}\}$ and it constructs a sequence of segmentations until a proper segmentation is achieved. Each segmentation S j is obtained from the segmentation S_{j-1} by merging two or more connected components for there is no evidence for a boundary between them. For each component of a segmentation a spanning tree is constructed and thus for each segmentation we use an associated spanning forest.

The evidence for a boundary between two components is determined taking into consideration some features in some model of the spatial input image. When starting, for a certain number of segmentations the only considered feature is the color of the regions associated to the components and in this case we use a color-based region model. When the components became complex and contain too much tree-hexagons, the color model is not sufficient and geometric features together with color information are considered. In this case we use a syntactic based with a color-based region model for regions. In addition syntactic features bring supplementary information for merging similar regions in order determine salient objects.

For the sake of simplicity we will denote this region model as syntactic-based region model.

As a consequence, we split the sequence of all segmentations,

$$S_i^f = [S_0,S_1, \ldots, S_{k-1},S_k], \quad (10)$$

in two different subsequences, each subsequence having a different region model,

$$S_i = [S_0,S_1, \ldots, S_{t-1},S_t],$$
$$S^f = [S_t, S_{t+1}, \ldots, S_{k-1},S_k], \quad (11)$$

where Si represents the color-based segmentation sequence, and Sf represents the syntactic-based segmentation sequence.

The final segmentation St in the color-based model is also the initial segmentation in the syntactic-based region model.

For each sequence of segmentations we develop a different algorithm. Moreover we use a different type of spanning tree in each case: a maximum spanning tree in the case of the color-based segmentation, and a minimum spanning tree in the case of the syntactic-based segmentation. More precisely our method determines two sequences of forests of spanning trees,

$$F_i = [F_0,F_1, \ldots, F_{t-1},F_t],$$
$$F^f = [F_{t'}, F_{t'+1}, \ldots, F_{k'-1},F_{k'}], \quad (12)$$

each sequence of forests being associated to a sequence of segmentations.

The first forest from Fi contains only the vertices of the initial graph, F0 = (V, Ø), and at each step some edges from E are added to the forest $F_l = (V,E_l)$ to obtain the next forest, $F_{l+1} = (V,E_{l+1})$. The forests from Fi contain maximum spanning trees and they are determined by using a modified version of Kruskal's algorithm, where at each step the heaviest edge (u,v) that leaves the tree associated to 'u' is added to the set of edges of the current forest.

The second subsequence of forests that correspond to the subsequence of segmentations Sf contains forests of minimum spanning trees and they are determined by using a modified form of Boruvka's algorithm. This sequence uses as input a new graph,

$G' = (V', E')$, which is extracted from the last forest, Ft , of the sequence Fi. Each vertex 'v' from the set V' corresponds to a component Cv from the segmentation St (i.e. to a region determined by the previous algorithm). At each step the set of new edges added to the current forest are determined by each tree T contained in the forest that locates the lightest edge leaving T. The first forest from F^f contains only the vertices of the graph G' , $Ft' = (V', \emptyset)$.

We focus on the definition of a logical predicate that allow us to determine if two neighboring regions represented by two components, Cl' and Cl'', from a segmentation Sl can be merged into a single component Cl+1 of the segmentation Sl+1. Two components, Cl' and Cl'' , represent neighboring (adjacent) regions if they have a common boundary:

$$ad\,j(Cl', Cl'') = true \quad if \quad cb(Cl', Cl'') \neq \emptyset,$$
$$ad\,j(Cl', Cl'') = false \quad if \quad cb(Cl', Cl'') = \emptyset \qquad (13)$$

We use a different predicate for each region model, color based and syntactic-based respectively.

$$PED(e,u) = [w_R(R_e - R_u)^2 + w_G(G_e - G_u)^2 + w_B(B_e - B_u)^2\,]^{1/2} \qquad (14)$$

where the weights for the different color channels, wR, wG, and wB verify the condition wR +wG +wB = 1. Based on the theoretical and experimental results on spectral and real world data sets, Gijsenij et al. [16] is concluded that the PED distance with weight-coefficients (wR =0.26, wG = 0.70, wB =0.04) correlates significantly higher than all other distance measures including the angular error and Euclidean distance.

In the color model regions are modeled by a vector in the RGB color space. This vector is the mean color value of the dominant color of tree-hexagons belonging to the regions.

The evidence for a boundary between two regions is based on the difference between the internal contrast of the regions and the external contrast between them [2] and [15]. Both notions of internal contrast and external contrast between two regions are based on the dissimilarity between two colors.

Let h_i and h_j representing two vertices in the graph G =(V,E), and let $w_{col}(h_i,h_j)$ representing the color dissimilarity between neighboring elements hi and hj, determined as follows:

$$w_{col}(h_i,h_j) = PED(c(h_i),c(h_j)) \quad if\ (h_i,h_j) \in E,$$
$$w_{col}(h_i,h_j) = \infty \quad otherwise, \qquad (15)$$

where PED(e,u) represents the perceptual Euclidean distance with weight-coefficients between colors 'e' and 'u', as defined by Equation (14), and c(h) represents the mean color vector associated with the tree-hexagon 'H'. In the color-based segmentation, the weight of an edge (hi,hj) represents the color dissimilarity,

$$w(h_i,h_j) = w_{col}(h_i,h_j).$$

Let Sl be a segmentation of the set V. We define the internal contrast or internal variation of a component $C \in S_l$ to be the maximum weight of the edges connecting vertices from C:

$$IntVar(C) = \max_{(h_i,h_j) \in C}(w(h_i,h_j)). \qquad (16)$$

The internal contrast of a component C containing only one tree-hexagon is zero:

$$IntVar(C) = 0, \quad if\ |C| = 1.$$

The external contrast or external variation between two components, $C', C'' \in S$ is the maximum weight of the edges connecting the two components:

$$ExtVar(C',C'') = \max_{(h_i,h_j) \in cb(C',C'')}(w(h_i,h_j)). \qquad (17)$$

We chosen the definition of the external contrast between two components to be the maximum weight edge connecting the two components and not to be the minimum weight, as in [2] because: (a) it is closer to the human perception (in the sense of the perception of the maximum color dissimilarity), and (b) the contrast is uniformly defined (as maximum color dissimilarity) in the two cases of internal and external contrast.

The maximum internal contrast between two components, $C', C'' \in S$ is defined as follows:

$$IntVar(C',C'') = \max(IntVar(C'), IntVar(C'')), \qquad (18)$$

The comparison predicate between two neighboring components C' and C'' (i.e., ad j(C',C'') = true) determines if there is an evidence for a boundary between C' and C'' and it is defined as follows:

$$diffcol(C',C'') = true, \ if$$
$$ExtVar(C',C'') > IntVar(C',C'') + th^{kg}(C',C''),$$

$$diffcol(C',C'') = false, \ if$$
$$ExtVar(C',C'') \leqslant IntVar(C',C'') + th^{kg}(C',C''), \qquad (19)$$

with the the adaptive threshold $th^{kg}(C',C'')$ given by

$$th^{kg}(C',C'') = th^{kg} / \min(|C'|, |C''|) \ , \qquad (20)$$

where |C| denotes the size of the component C (i.e. the number of the tree-hexagons contained in C) and the threshold 'th^{kg}' is a global adaptive value defined by using a statistical model.

The predicate 'diffcol' can be used to define the notion of segmentation too fine and too coarse in the color-based region model.

Definition 2 Let G = (V,E) be the undirected spatial graph constructed on the tree-hexagonal structure of a spatial input image and S a color-based segmentation of V. The segmentation S is too fine in the color-based region model if there is a pair of components $C', C'' \in S$ for which

$$ad\,j(C',C'') = true \wedge diffcol(C',C'') = false.$$

Definition 3 Let G = (V,E) be the undirected spatial graph constructed on the tree-hexagonal structure of a spatial input image and S a segmentation of V. The segmentation S is too coarse if there exists a proper refinement of S that is not too fine.

We decided to use the RGB color space because it is efficient and no conversion is required.

Let G= (V,E) be the initial graph constructed on the virtual tree-hexagonal structure of a spatial image. The proposed segmentation algorithm will produce a proper segmentation of V according to the Definition 1. The sequence of segmentations, Si f , as defined by Equation (10), and its associated sequence of forests of spanning trees, Fi f , as defined by Equation (12), will be iteratively generated as follows:

- The color-based sequence of segmentations, Si, as defined by Equation (11), and its associated sequence of forests, Fi, as defined by Equation (12), will be generated by using the color-based region model and a maximum spanning tree construction method based on a modified form of the Kruskal's algorithm [17].
- The syntactic-based sequence of segmentations, Sf, as defined by Equation (11), and its associated sequence of forests, F f, as defined by Equation (12), will be generated by using the syntactic-based model and a minimum spanning tree construction method based on a modified form of the Boruvka's algorithm.

The general form of the segmentation procedure is presented in Algorithm 1

Algorithm 1 Segmentation algorithm
1: procedure SEGMENTATION (l,c,d,P,H,Comp)
2: Input l, c, d, P
3: Output H, Comp
4: H ←CREATEHEXAGONALSTRUCTURE(l, c, d, P)
5: G←CREATEINITIALGRAPH(l, c, d, P,H)
6: CREATECOLORPARTITION (G,H,Bound)
7: G' ←EXTRACTGRAPH (G,Bound, th^{kg})
8: CREATESYNTACTICPARTITION(G,G', th^{kg})
9: Comp ←EXTRACTFINALCOMPONENTS(G')
10: end procedure

The input parameters represent the image resulted after the pre-processing operation: the array P of the spatial image voxels structured in 'l' lines, 'c' columns and 'd' depths. The output parameters of the segmentation procedure will be used by the contour extraction procedure: the tree-hexagonal grid stored in the array of tree-hexagons H, and the array Comp representing the set of determined components associated to the salient objects in the input spatial image. The global parameter th^{kg} is the thresholds.

The color-based segmentation and the syntactic-based segmentation are determined by the procedures CREATECOLORPARTITION and CREATESYNTACTICPARTITION respectively.

The color-based and syntactic-based segmentation algorithms use the tree-hexagonal structure H created by the function CREATEHEXAGONALSTRUCTURE over the voxels of the initial spatial image, and the initial triangular grid graph G created by the function CREATEINITIALGRAPH. Because the syntactic-based segmentation algorithm uses a graph contraction procedure, CREATESYNTACTICPARTITION uses a different graph, G', extracted by the procedure EXTRACTGRAPH after the color-based segmentation finishes.

Both algorithms for determining the color-based and syntactic based segmentation use and modify a global variable (denoted by CC) with two important roles:

• to store relevant information concerning the growing forest of spanning trees during the segmentation (maximum spanning trees in the case of the color-based segmentation, and minimum spanning trees in the case of syntactic based segmentation),

• to store relevant information associated to components in a segmentation in order to extract the final components because each tree in the forest represent in fact a component in each segmentation S in the segmentation sequence determined by the algorithm.

In addition, this variable is used to maintain a fast disjoint set-structure in order to reduce the running time of the color based segmentation algorithm. The variable CC is an array having the same dimension as the array of hexagons 'H', which contains as elements objects of the class Tree with the following associated fields:

(isRoot, parent, compIndex, frontier, surface, color)

The field 'isRoot' is a boolean value specifying if the corresponding tree-hexagon index is the root of a tree representing a component, and the field 'parent' represents the index of the tree-hexagon which is the parent of the current tree-hexagon. The rest of fields are used only if the field 'isRoot' is true. The field 'compIndex' is the index of the associated component.

The field 'surface' is a list of indices of the tree-hexagons belonging to the associated component, while the field 'frontier' is a list of indices of the tree-hexagons belonging to the frontier of the associated component. The field 'color' is the mean color of the tree- hexagon colors of the associated component.

The procedure EXTRACTFINALCOMPONENTS determines for each determined component C of Comp, the set sa(C) of tree-hexagons belonging to the component, the set sp(C) of tree-hexagons belonging to the frontier, and the dominant color c(C) of the component.

IV. Color-Based Region Algorithm

Let G = (V,E) be the undirected spatial graph constructed on the tree-hexagonal structure of a spatial image. The proposed color-based segmentation algorithm will produce a proper segmentation of V according to the Definition 1, where the notion of segmentation too fine is given by the Definition 2.

The sequence of segmentations, $(S_0,S_1, \ldots ,S_{t-1},S_t)$, and its associated sequence of growing forests, $(F_0,F_1, \ldots ,F_{t-1},F_t)$, will be iteratively generated, based on a maximum spanning tree construction method. We use a modified form of the Kruskal's algorithm [17] presented in Algorithm 2, where the trees generated at each step represent the connected components of spatial segmentation.

The input parameters of the color-based segmentation algorithm are the initial spatial graph 'G' and the array 'H' of the tree-hexagons from the tree-hexagonal grid. The output parameter is the list 'Bound' of edges representing the boundary of the final spatial segmentation. The global parameter threshold 'th^{kg}' is determinate by using Algorithm 1.

This value is used at the line 19 of Algorithm 2, where the expression th^{kg} (ti, t j) is given by the relation (20), t_i and t_j representing the components Ct_i and Ct_j respectively.

Because we use maximum spanning trees instead of minimum spanning trees the list of the edges E(G) is sorted in non-increasing edge weight. The forest of spanning trees is initialized in such a way each element of the forest contains exactly one tree-hexagon.

Algorithm 2 Color-based segmentation

1: **procedure CREATECOLORPARTITION(G,H, Bound)
2: Input G = (V,E), H = {h1, . . .,h|V|}
3: Output Bound
4: th^{kg} ←*DETERMINETHRESHOLD(G)
5: Bound ←hi ◅ Initialize Bound
6: for all i←1, |V| do
7: *MAKESET(hi) ◅ Initialize the disjoint set data structures
8: end for
9: ◅ At this point l ←0
10: ◅ and S0 ←{{h1}, . . . ,{h|V|}}
11: *SORT(E,$E\pi$)
12: ◅ $E\pi$ = ($e_{\pi 1}$, . . ., $e_{\pi|E|}$) is the sorting of E
13: ◅ in order of non-increasing weight
14: **for all** k←1, |E| **do**
15: ◅ Let $e_{\pi k}$ = (h_i ,h_j) be the current edge in $E\pi$
16: t_i ←*FINDSET(h_i)
17: t_j ←*FINDSET(h_j)
18: **if** $t_i \neq t_j$ **then**
19: if w(hi ,hj) ⩽ INTVAR(ti, t j)+ th^{kg} (ti, t j) then
20:* UNION(ti, t j,w(hi,hj))
21: ◅ l ←l+1
22: ◅ Sl ←Sl−1−{{Cti},{Ct j }} ∪ {Cti ∪Ct j }
23: else
24:* Add the edge (hi ,hj) the the list Bound
25: ◅ bound(Sl)←bound(Sl−1) ∪ {(hi,hj)}
26: end if
27: else
28: ◅ Do nothing, ti ∈ Ct j
29: end if
30: end for
31: end procedure

The expression th^{kg} (ti, t j) = th^{kg} /min(|Cti |,|Cj $_j$ |) at the line 19 of Algorithm 2 is very important at the beginning of the algorithm because initially the components considered contains only one tree-hexagon and in this case

IntVar(Cti ,Cj $_j$)=0, and th^{kg} /min(|Cti |,|Cj $_j$ |) = th^{kg}. In order to consider an edge (hi,hj) to belonging to the non-boundary class of edges and in consequence to merge the components Cti and Cj $_j$ corresponding to 'h_i' and 'h_j' respectively, it is necessary that $w(h_i,h_j) < th^{kg}$.

When the components grow and both components Ct_i and $C_{j\,j}$ contain more than one tree-hexagon, the external variation between Cti and $Cj_{\ j}$ decreases, and in this case the decision for merging or non-merging Cti and $Cj_{\ j}$ is affected more by their size than by the global threshold 'th^{kg}'.

For each segmentation Sl determined by Algorithm 2 and for each connected component C of the corresponding spanning graph Gl there is a unique maximum spanning tree, Fl(C), that maximize the sum of edge weights for this component.

The forest of all maximum spanning trees associated to the segmentation Sl is

$Fl = \cup C \in Sl\ \ Fl(C)$,

and algorithm makes greedy decisions about which edges to add to Fl . Every time when an edge is added to the maximum spanning tree a union of the two partial spanning trees containing the two vertices of the edge is made. In this way the sequence of the edges contained in the forest Fl of spanning trees is implicit determined at the line 14 of Algorithm 2.

Conversely for each spatial tree T from the forest Fl , the set of all vertices of the initial graph contained in the tree T is denoted by Set(T) and it represents the connected component of Sl associated to maximum spanning tree T:

$T = Fl(Set(T))$.

The functions MAKESET, FINDSET and UNION used by the segmentation algorithm implement the classical MAKESET, FIND-SET and UNION operations for disjoint set data structures with union by rank and path compression [17]. In addition the function call, UNION(ti, t j ,w(hi,hj)), performs the following operation, assuming that ti is the root of the new spanning tree resulted by combining the spanning trees represented by 'ti' and 't j' :

• determining CC[ti].surface as the concatenation of the lists CC[ti].surface and CC[tj].surface,

• determining CC[ti].frontier as a list of indices of tree-hexagons belonging to the frontier of the new component

$\{Cti \cup Ct\,j\}$,

• determining CC[ti].color as the value (ni*ci+nj*cj)/(ni+nj) , where ci = CC[ti].color, and 'ni' represents the number of elements in the tree CC[ti].

V. Syntactic-Based Region Algorithm

The syntactic-based region model uses some geometric properties of regions together with color information. We use a subset of syntactic features advocated [18] including homogeneity, compactness and regularity.

The region model contains the area of the region and the region boundary. As presented in the previous Subsection, for each region C the segmentation algorithm determines the set $sa(C)$ containing the tree-hexagons forming the region, and the set $sp(C)$ containing the tree-hexagons located at the boundary of the region. Because for each tree-hexagon 'H' we determine its dominant color $c(h)$ and its pseudo-gravity center $g(h)$, for each region C the following information can be further determined:

- the mean color of the region, $c(C)$, the area of the region, $a(C)$, and the length of the contour of the region, $p(C)$. In addition, for each pair of regions, Ci and Cj , the length $p(Ci,Cj)$ of the common boundary between these region can be determined.

In order to reduce the time complexity of the segmentation algorithm we estimate the area $a(C)$ and the perimeter $p(C)$ of a region C in function of the length of the sets $sa(C)$ and $sp(C)$ respectively. Assuming that the distance between two neighboring voxels situated on axis Ox, Oy or Oz has the value 1, the area of a tree-hexagon is 12 and thus the area of a region C is given by the following relation:

$$a(C) = 12\times|sa(C)|, \tag{21}$$

where $|sa(C)|$ represents the cardinal of the set $sa(C)$.

In order to determine a good final segmentation and to discover the salient objects from the input image, the syntactic based sequence of segmentations, Sf , as defined by Equation (11), can decomposed into several subsequences, each subsequence being determined by a modified form of the Boruvka's algorithm.

Let $i1 < i2 < \ldots < ix < ix+1$ be a sequence of indices, with $i1 = t$ and $ix+1 = k$, that allows a decomposition of the sequence Sf as follows:

$$\begin{aligned} Sf = (\ & Si1, Si1+1, \ldots, Si2-1, Si2, \\ & Si2+1, Si2+2, \ldots, Si3, \\ & \ldots \\ & Six+1, Six+2, \ldots, Six+1\ ). \end{aligned} \tag{22}$$

As presented in Algorithm 1 the procedure CREATESYNTACTICPARTITION implements the syntactic based segmentation, while the function GENERATEPARTITION is used to generate the subsequences of segmentations, $Sf1$, . . . ,Sfx , each subsequence of the form,

$$Sf\,j = (Si\,j, Si\,j+1, \ldots, Si\,j+1-1, Si\,j+1\ ), \tag{23}$$

being determined by the function GENERATEPARTITION at the j-th call. The last segmentation of the subsequence $Sf\,j$ generate by GENERATEPARTITION is also the input sequence of the $(\,j\,+1)$-th call of GENERATEPARTITION. The first input segmentation $Si1$ is the final segmentation St of the color based segmentation algorithm. The function DETERMINEWEIGHTS determines the set A of weights as defined by following relation.

The construction of A is realized as following:

1. Let SB = $[b_1,b_2,b_3,b_4]$ be the sequence contained the same elements as the set B in non-decreasing order. For this reasoning we choose another set of weight values, which is related to the initial set B;
2. Let 'r' be the lowest common divisor of the numbers (b2− b1), (b3−b2), and (b4−b3),
3. Let s = (b4−b1)/r ,
4. The set of weights that we use are:

$$A = \{a_0, a_1, \ldots, a_s\}, \tag{24}$$

where $a_0 = b_1$, $a_k = b_4$, $a_i = a_0$+i*r, for i = 1, . . . , s, and in addition $b_2, b_3 \in A$.

Algorithm 3 Syntactic-based Segmentation

1: ****procedure** CREATESYNTACTICPARTITION(G,G', th^kg)
2: **Input** G, G', th^kg
3: **Output** G'
4: A←*DETERMINEWEIGHTS(G')
5: $count$ ←0
6: **repeat**
7: G' ← *GENERATEPARTITION(G,G', th^kg,$newPart$)
8: **if** $newPart$ **then**
9: $count$ ←0
10: k←[$a0$ $a0$ $a0$ $a0$]^T
11: **end if**
12: th^kg ←*MODIFYWEIGHTS(G', k)
13: $count$ ←$count$ +1

14: *NEXTKVECTOR(k)
15: **until** $count = |A|^4$
16: **end procedure**

More formally, the j-th call of the function GENERATEPARTITION, for which the output parameter 'newPart' has the value 'true', is associated to the non-empty subsequence $Sf\ j$ of segmentations and it generates a sequence of graphs,

$$Gi\ j = (G^{i,j}i\ j\ ,G^{i,j}i\ j+1, \ldots ,G^{i,j}i\ j+1-1,G^{i,j}i\ j+1\ ), \quad (25)$$

and a sequence of associated forests of minimum spanning trees,

$$Fi\ j = (F^{i,j}i\ j\ ,F^{i,j}i\ j+1, \ldots ,F^{i,j}i\ j+1-1,F^{i,j}i\ j+1\ ), \quad (26)$$

such that the last forest is empty, $F^{i,j}i\ j+1 = \emptyset$. For each graph $G^{i,j}l$ from the sequence $Gi\ j$, $F^{i,j}l$ represents the forest of minimum spanning trees of $G^{i,j}l$, and $G^{i,j}l+1$ is the contraction of $G^{i,j}l$ over all the edges that appear in $F^{i,j}l$, as presented in Algorithm 4.
Because the last graph, $G^{i,j}i\ j+1$, of the sequence $Gi\ j$ cannot be further contracted the dissimilarity vectors of functions associated to the edge weights, $d(C(vi),C(vj))$, are not modified, and thus the edge weights, $w(vi,vj)$, as defined by the function GRAPH EXTRACTION are not modified. In order to restart the process for determining the new subsequence,

$$Sf\ j+1 = (Si\ j+1\ ,Si\ j+1+1, \ldots ,Si\ j+2\ ), \quad (27)$$

the first graph, $G^{i,j+1}i\ j+1$ of the sequence $Gi\ j+1$ differs from the last graph, $G^{i,j}i\ j+1$, of the sequence $Gi\ j$ by modifying only the weighted vector $\mathbf{k} \in \mathsf{K}$. The function MODIFYWEIGHTS of Algorithm 2 realizes this modification and recalculates the new global weighted threshold. In this case the values for the weighted vector $\mathbf{k}$ are sequential determined in the lexicographic order, generated by the procedure NEXTKVECTOR.

This constraint is necessary in order to realize a stopping criterion for the algorithm: the last graph cannot be modified and for all distinct values of the weighted vectors $\mathbf{k} \in \mathsf{K}$ and thus another partition cannot be determined. Each time when GENERATEPARTITION generates a non-empty sequence of segmentations, the output parameter 'newPart' became 'true' and the first vector of the set K is generated.

When GENERATEPARTITION generates an empty sequence of segmentations, 'newPart' is 'false' and the next vector in lexicographic order is generated by the procedure NEXTKVECTOR.

When sequentially for all distinct weighted vectors $\mathbf{k} \in \mathsf{K}$ (e.g. $|A|^4$ distinct vectors, with the set A specified by the relation (24)) generated in lexicographic order the function GENERATEPARTITION generates a empty sequence of segmentations, the procedure GCREATESYNTACTICPARTITION finishes.
Between the last graph, $G^{i,j}i\ j+1$, of the sequence $Gi\ j$ and the first graph, $G^{i,j+1}i\ j+1$ of the sequence $Gi\ j+1$, there is a sequence of graphs that differ only by the edge weights,

$$b\ Gi\ j = (\ b\ G^{i,j}1\ ,\ b\ G^{i,j}2\ , \ldots ,\ b\ G^{i,j}bni\ j\ ), \quad (28)$$

such that $b\ G^{i,j}1 = G^{i,j}i\ j$ and $b\ G^{i,j}bni\ j = G^{i,j+1}i\ j+1$. This sequence is obtained when the function GENERATEPARTITION generates an empty sequence of segmentations, with $bni\ j < |A|^4$.

As presented in Algorithm 4 the function GENERATEPARTITION generates at the j-th call the sequence of graphs $Gi\ j$ defined by Equation (25), and the sequence of forests of minimum spanning trees defined by Equation (26), where:

- the first graph of the sequence $Gi\ j$ is the input graph of the function (i.e. the parameter G'),
- the last graph of this sequence is the graph returned by the function.

The function GENERATEPARTITION is a generalized Greedy algorithm for constructing minimum spanning trees, as presented in [19]. At each iteration, 'l', of the function GENERATEPARTITION, the contraction of the tree $G^{i,j}l$ over all the edges that appear in the minimum spanning tree $F^{i,j}l$ is performed by the function CONTRACTGRAPH.

Algorithm 4 Generate a new sequence of partitions
1: ****function** GENERATEPARTITION(G,G', th^kg, *newPartition*)
2: **Input** G, G', th^kg, G' ◅ $G' = G^{i,j}i\ j$ is the input graph
3: **Output** *newPartition*

16: $e.inMST \leftarrow true$
17: **end if**
18: **end if**
19: **end for**
20: **if** $k > 0$ **then**
21: $G' \leftarrow$*CONTRACTGRAPH(G,G', th^kg)
22: ◅ Determination of the graph $G' = G^{i,j}i\ j+l+1$
23: ◅ $l \leftarrow l+1$
24: *newPartition*←*true*
25: **end if**
26: **until** $k = 0$
27: **return** G' ◅ $G' = G^{i,j}i\ j+1$ is the output graph
28: **end function**

The function DETERMINETHL returns the local weighted threshold th^{hl} associated to the components Cvi and Cvj , as presented in the following relations:

- the local weighted threshold associated with the weighted vector $\mathbf{k} \in \mathsf{K}$ and with the adjacent components C' and C'' of the segmentation Sl is denoted by $\mathbf{th}^{kl}(C',C'')$ and it is determined by considering the average of dissimilarity functions for anly adjacent components with C' and C'' from the segmentation Sl ,

$$\mathbf{th}^{kl}(C',C'') = b\mathbf{k}T\ \mathbf{l}(C',C''), \quad (29)$$

where the components of the vector $\mathbf{l}(C',C'')$ are determined, for

$i = 1,2,3,4$, as follows:

$$li(C',C'') = [\sum p(C',C'',Ca,Cb)edi(C',C'')]/[\sum p(C',C'',Ca,Cb)\ 1]\ , \quad (30)$$

where the predicate $p(C',C'',Ca,Cb)$ is defined as

$$p(C',C'',Ca,Cb) = ((Ca,Cb) \in Sl) \wedge (ad\,j(C',Ca) = true) \wedge (ad\,j(C'',Cb) = true). \quad (31)$$

The function implementing the contraction procedure, CONTRACTGRAPH, is similarly to the function EXTRACTGRAPH with the following differences:

- It detects the connected components specified by the edges marked as MST in the GENERATEPARTITION, and assigns to each vertex of the new generated graph the component it belongs to. The function DETERMINECOMPONENTS implements a *Depth-First-Search* traversal method on the input graph in order to enumerate the connected components.
- As in the color-based segmentation algorithm (see Algorithm 2), for each edge from the minimum spanning tree a union of the two partial spanning trees containing the two vertices of the edge is made by using the procedure UNION. In this way it is realized a reunion of the components associated to the vertices from each connected component of the input graph:

$$C(v) = \cup_{u \in Set(Tv)} C(u), \quad (32)$$

where '*Tv'* denotes the minimum spanning tree from the input graph associated to the connected component that represents the new created vertex in the output graph, and *Set*(*Tv*) represents the connected component associated to '*Tv'*.

- The weights of the new created edges and also the weighted threshold of the output graph use a weighted vector $\mathbf{k} \in K$ such that its components have a value random chosen from the set $A = \{a_0, a_1, \ldots, a_s\}$ by using the procedure ALEAKCHOOSE. This is an important aspect of the syntactic based segmentation algorithm and in this way the distribution of the weights of the four dissimilarity functions tends to became uniform.

The sequence $F\,f$ of forests of minimum spanning trees as defined by Equation (12) can be decomposed as the sequence Sf of segmentations as follows:

$$\begin{aligned} F\,f = (\ & Fi'1, Fi'1+1, \ldots, Fi'2-1, \\ & Fi'2, Fi'2+1, \ldots, Fi'3-1, \\ & \ldots \\ & Fi'x, Fi'x+1, \ldots, Fi'x+1-1\ ). \end{aligned} \quad (33)$$

Because the graph $G^{i\ j}i\ j+l$ and its corresponding minimum spanning tree $F^{ij}i\ j+l$, for $j = 1, \ldots, x$ and $l = 0, \ldots, i_{j+1} - i_j - 1$, share the same set of vertices, from algorithm of graph contraction one can see that each subsequence of forests determined at the jth call of the function GENERATEPARTITION,

$$F^{f}j = (Fi'j, Fi'j+1, \ldots, Fi'j+1-1, Fi'j+1\ ), \quad (34)$$

can determined for each $l = 0, \ldots, i_{j+1} - i^{j} - 1$ as follows:

$$E'i_{j}+l+1 = E'i_{j}+l \cup_{e \in F^{ij}i\,j+l} Orig(e), \quad (35)$$

where $E'u$ represents the set of the edges associated to the forest $F'u = (V',E'u\ )$, and $Orig(e)$ represents the edge from the initial graph G corresponding to the edge 'e' from the current graph $G^{ij}i\ j+l$.

The call of the procedure UNION at the line 22 of graph contraction allows the determination of the sequence of the segmentations $S\,f$ as defined by Boruvka's algorithm.

$$S^{i\,j+l+1} = \{Set(T) \mid T \in Fi\,j+l+1\} = \{C(v) \mid v \in G^{ij}i\,j+l+1\}, \quad (36)$$

for each $j = 1, \ldots, x$ and $l = 0, \ldots, i\,j+1-i\,j-1$. This relation specifies the fact that there is a bijective mapping between the components from the segmentations $Si\ j+l+1$ (or equivalently between the trees from the forests $Fi\,j+l+1$) and the vertices of the contracted graphs $G^{ij}i\,j+l+1$.

At *j-th* call of the function GENERATEPARTITION, each call of the function CONTRACTGRAPH generates a new segmentation, $S^{i\,j+l+1}$, with $l = 0, \ldots, i\,j+1 - i\,j - 1$, which tends to merge the components of the previous segmentation until regions closer to salient objects are detected.

VI. Segmentation Results and Quantitative Evaluation

These modalities produce high-resolution voxel based datasets which are in fact data points on a regularly spaced three dimensional grid.

Because sampling data points from the real world is performed slice by slice the existing spatial segmentation techniques are often planar in nature, applying existing planar algorithms to the volume data slice by slice. The results are inferior to native volumetric based solution because these algorithms ignore the interaction between adjacent slices [20], [21], [22], [23].

However, even if image segmentation is a heavily researched field, extending the algorithms to spatial has been proven not to be an easy task. A true volumetric segmentation remains a difficult problem to tackle due to the complex nature of the topology of volumetric objects, the huge amount of data to be processed and the complexity of the algorithms that scale with the new added dimension.

Martin thesis [24] states that human segmentation can be used as the ground-truth reference in benchmarking segmentations produced by different methods. On the other hand, one may argue that human segmentation is subjective and will produce different segmentations for the same image but in most cases they will differ only in certain regions of local refinement. This idea has been considered in [25], [26] as a method of avoiding penalizing segmentations that are coarser or more refined than others.

In pattern recognition and information retrieval, Precision-Recall method has received a world-wide acceptance and it's considered as a standard measure because it offers good results for relevance [26].

In the general case, precision (or confidence) is defined as the fraction of retrieved cases that are relevant, while recall (or sensitivity) is the fraction of relevant cases that are retrieved. In other words, in the context of classification, the precision for a class is equivalent with the true positives accuracy which is the number of true positives (i.e. the number of cases that are correctly labeled as belonging to that class) divided by the total number of cases labeled as belonging to that class (including false positives, which are cases that were incorrectly labeled as belonging to the class).

$$\text{Precision} = TP/(TP + FP) \quad (37)$$

Also in this context, recall is equivalent with the true positives rate which is defined as the number of true positives divided by the total number of cases that actually belong to the positive class (i.e. the sum of true positives and false negatives, which are cases that were not labeled as belonging to the positive class but should have been).

$$\text{Recall} = TP/(TP + FN) \quad (38)$$

The terms: true positives (TP), true negatives (TN), false positives (FP) and false negatives (FN) compare the classifier's prediction against apriority external information that is considered as the ground truth (observation). These are synthesized in the contingency table (or confusion matrix), expressed in Table I.

TABLE I. PRECISION-RECALL CONTINGENCY TABLE

	Observation	
Prediction	TP – Correct result	FP – Unexpected positive result
	TN - Correct absence of result	FN – Missing negative result

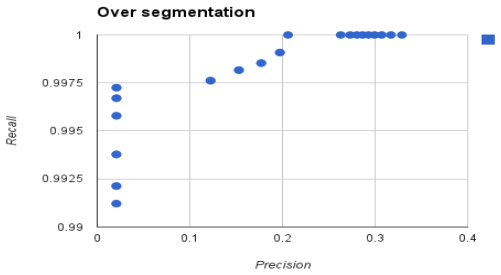

Fig. 3. Experiment Results

As said before, for image segmentation algorithms, Martin [24] proposes a method that outputs Precision-Recall curves as a mean to evaluate segmentation consistency. The curve offers a rich descriptor where both axes are sensitive and intuitive and the inherent trade-off between these two quantities can be easily analyzed.

Recall is defined as the proportion of boundary pixels/voxels in the ground truth that were successfully detected by the automatic segmentation, while precision is the proportion of boundary pixels/voxels in the automatic segmentation that correspond to the true boundary pixels. Precision is in fact a measure of the amount of noise in the classifier's result. The segmentation method used for the experimental results is based on simple hysteresis threshold. All voxels with the density within a specified threshold 'tk^{gh}' will be treated as boundary voxels while the others as empty space [27], [28], [29].

The results are as expected: the over-segmented volume has high recall and low precision (see figure 3), while the under-segmented image has low recall because it fails to find salient features for the volume, and also low precision (since because many boundary pixels remain unmatched).

VII. Conclusion

In this paper we present original and efficient volumetric segmentation methods. The major concept used in graph-based volumetric segmentation method is the concept of homogeneity of regions and thus the edge weights are based on color distance. Our previous works for planar images are related to other works in the sense of pair-wise comparison of region similarity. The key to the whole algorithm of volumetric segmentation is the honeycomb cells.

Here we presented only Color-based Segmentation, Syntactic-based Segmentation and Generate New Sequence of Partitions with Graph Contraction algorithms besides general algorithm of volumetric segmentation due to the entire space. Of course we have many procedures into general algorithm of volumetric segmentation methods. We have presented the original and efficient algorithm of volumetric segmentation methods and honeycomb cells used is the first run in volumetric segmentation algorithm. Then we can use the graph facilities and their related algorithms and computational complexity can be viewed as slow as the fundamental graph algorithms. Our original algorithms for Color-based Segmentation and Syntactic-based Segmentation are linear. Enhancement and generalization of this method is possible in several further directions. First, it could be modified to handle open curves for the purpose of medical diagnosis. Second, research direction is the using of composed shape indexing for both semantic and geometric image reasoning.

***Abstract*—This work describes the whole process of 3D model reconstruction. It begins with the representation of the method that is used to find the matching between photographs and the methodology to use the data to form the initial structure of the reconstructed model, represented by a point cloud. As a next stage, a refinement process is performed, using the bundle adjustment method. A set of stereovision methods is used later on to find a more detailed solution. Those algorithms use pairs of images, therefore as a prerequisite a set of routines that aggregates those results is studied. The paper is concluded with a description of how the point cloud is processed, including the surface reconstruction, to form the result. The described methodology is illustrated with reconstructions of three series of professional photographs from a public repository and one series of amateur photographs created especially for this work. The results were evaluated by the proposed area matching and contour matching measures.** ***Index Terms*—3D Reconstruction, Image Matching, Epipolar Geometry, Features Extraction, Models Evaluation**

I. Introduction

A RECONSTRUCTION of three dimensional (3D) models is one of the areas of the Computer Vision discipline that is quickly gaining momentum c.f. [1], [2], [3]. The development of information systems and the advancement in 3D graphics in general made it possible to create models that would depict real life objects. It has become even more important to be able to create models using two–dimensional photographs, taken using regular commodity digital cameras.

As one of the contributions of the following work, a computer tool has been developed that accomplishes the whole model reconstruction process. Out of a sequence of two–dimensional photographs, it can create a three dimensional full–colour model of the photographed object. The method is a mixture of algorithms based on features and solutions used in stereovision. The following project includes a description of this method. It also presents and comments on the results of applying the theory on a set of exemplary data series of digital photographs.

What follows is the main part of the work where the very process of 3D model reconstruction is explained. It begins with the representation of the method that is used to find the matching between photographs and the methodology to use the data to form the initial structure of the reconstructed model, represented by a point cloud. As a next stage, a refinement process is performed, using the bundle adjustment method. A set of stereovision methods is used later on to find a more detailed solution. Those algorithms use pairs of images, so as a prerequisite a set of routines that aggregates those results is studied. The description is concluded with information about the cloud processing, including the surface reconstruction, to form the result.

Each step of the process is illustrated with an exemplary image that show how the process progresses. This allows the reader to observe what the reconstruction process looks like. As an additional deliverable, a set of reconstructed models is presented. By comparing those images with the original models, the reader may decide on the quality of the process.

Several works present algorithms that result in high quality models. However, very often the reconstruction process bases on an expensive camera [2], specialist equipment such as a depth camera [3], or structured light [4].

The second important issue in the reconstruction based on computer vision algorithms (c.f. [5], [6], [7]) is lack of comparison methods. Very often, the result models are presented with evaluation of the quality different that visual comparison with the original object.

In this work, the proposed solution is based on low–cost algorithms and it is tested both on professional and amateur photographs. The snapshots from the four reconstructed model are presented in this work as well as the evaluation of their quality.

The paper is structured as follows. Section II presents basis of the epipolar geometry. The reconstruction process is briefly presented in Section III. The final models created from three series of photographs are described in Section IV and evaluated in Section V. Finally, the conclusions are presented in Section VI.

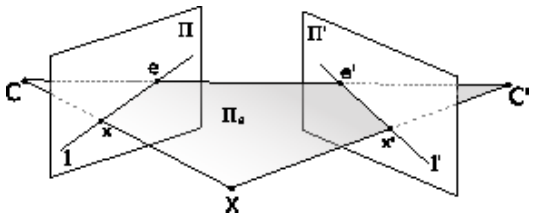

Fig. 2. Epipolar geometry defined by two cameras. $\mathbf{C}$ and $\mathbf{C}'$ – centres of cameras, Π and Π' – projection planes, $\mathbf{e}$ and $\mathbf{e}'$ – epipolar points, $\mathbf{x}$ and $\mathbf{x}'$ – projection of the point X on left and right view, $\mathbf{l}$ and $\mathbf{l}'$ – epipolar lines.

II. Preliminaries

The reconstruction bases on the epipolar geometry and essential information about its theoretical aspects are given in this section. The basis of the epipolar geometry is given in Figure 2. A 3D point X has projections $\mathbf{x}$ and $\mathbf{x}'$ on two views. The point X, both views $\mathbf{x}$ and $\mathbf{x}'$, and camera centres $\mathbf{C}$ and $\mathbf{C}'$ create the common plane. If the position of the point $\mathbf{x}$ is known it is also known that the projection $\mathbf{x}'$ lies on the line $\mathbf{l}'$. Therefore, the search for the point corresponding to $\mathbf{x}$ can be limited to the line $\mathbf{l}'$.

The algebraic representation of epipolar geometry is given by the fundamental matrix F. The matrix describes mapping between a point and its epipolar line. The special form of the fundamental matrix is the essential matrix E. The matrix E is a fundamental matrix corresponding to the pair of normalised cameras. A normalised camera describes the relation between image points expressed in normalised coordinates and 3D points. The relation is represented as the camera matrix P.

An important component of the matrix P is the calibration matrix K. The internal parameters K of the camera may be extracted from the matrix P by the decomposition. The inversion of calibration matrix creates normalised point on the basis of a point from a picture. This transformation is used to create an initial cloud of points in the presented process.

Detailed information on the epipolar geometry and relations between the matrices are given in [8].

Fig. 3. Photographs from tested series

III. Reconstruction

The reconstruction process described in this work consists of several stages. The schema of the process is given in Figure 1. The process starts with input photographs. Next, the matching between the photographs is detected. Two next steps create sparse clouds. Before the final reconstruction, a dense cloud is created. In the final stage, after a filtration, a surface is reconstructed. More information about the stages is given in the following sections.

A. Input data

The reconstruction procedure was tested on three examples from the public repository [9] and one created especially for this work. The data sets are series of photographs. Each professional series consists of photographs of objects placed on an automated turntable and photographed every 5 degrees. The photographs have a high 3 M–pixels resolution acquired by two Canon Powershot G1 digital cameras.

In our experiments, two series 'Teddy bear' and 'Horse' were represented by the full set of 72 photographs. In the second series 'Dinosaur', the number of photographs was reduced to 35. The resolution of photographs is 842×822 and 1600×1200 for the first and the second series respectively.

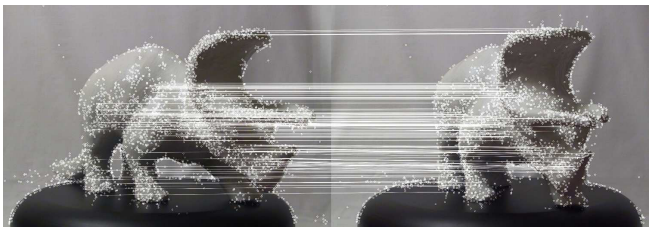

Fig. 4. Matching for two photographs with 20° rotation

The last series 'Troll' is a bit different from the others. The object was immobile and the photographer was moving. The photographs were taken without a stand with an irregular angle. The resolution of photographs is 1200×800. This series has only 33 photographs. The photographs were taken especially to test the reconstruction model presented in this work.

The three series present different approach to creation of data. The 'Teddy bear' and 'Horse' series are professional, detailed description of the objects. In the 'Dinosaur' series, photographs are still professional, but the number of images was reduced to decrease costs of documentation process. Both series were taken in a studio.

The 'Troll' series is an amateur documentation of the object created in an outdoor location.

Examples of photographs from all series are given in Figure 3.

B. Matching

In the first stage, relations between photographs are detected. The same points on multiple photographs are identified for that. In this work, the SURF method [10] was used to define characteristic points on the photographs. Other characteristic points that can be used in the matching are presented in [11].

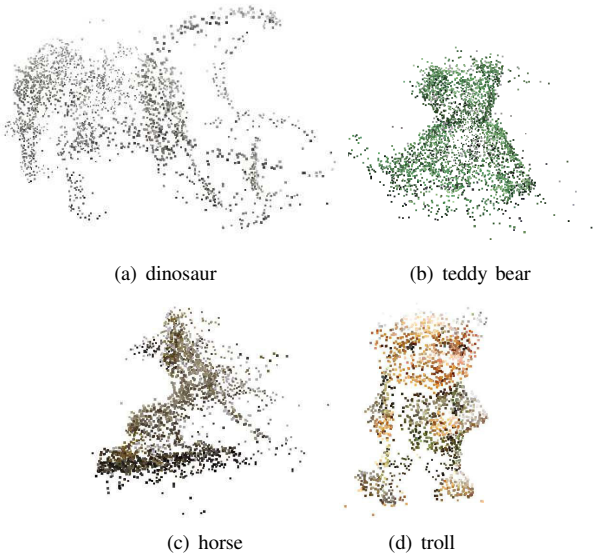
The SURF detector localises characteristic points on the basis of the maximum value of Hessian. For selected points, horizontal and vertical Haar wavelets are calculated to fix an orientation. After these operations, a description of the point is created. The description is invariant from a scale and a rotation.

The matching consists in finding the common description of two points from different images. However, to avoid a false match the following steps are added.

All matches from the background are removed. Such matches are easy to detect, because positions of characteristics points are nearly constant in all photographs in a sequence.

The second group of removed matched is established on the basis of points without a dominant match. Such points have two or more equivalents on the second photography. If any of them is not distinctly better than the rest then all matches that start from this point are eliminated.

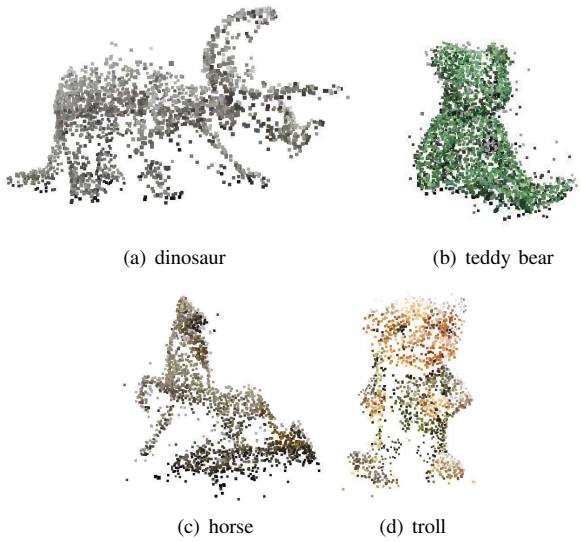
The next condition of the approval match is symmetry. The match between two points should be confirmed by two matching process. In the first process, the first photography is



(a) dinosaur (b) teddy bear

(c) horse (d) troll

Fig. 5. Sparse clouds created in the reconstruction stage



(a) dinosaur (b) teddy bear

(c) horse (d) troll

Fig. 6. Sparse clouds created in the bundle adjustment stage

taken as a source of characteristic points and the second one is area of searching for equivalents. In the second process, roles of photographs swap over.

All created matches should be confirmed by an epipolar model. The RANdom SAmple Consensus (RANSAC) approach [12] is used to detect the fundamental matrix. The matches that are inappropriate for the model are removed.

Finally, each match should be continued at least at three photographs. Each matched point from the second photograph should also be the beginning point for the subsequent math accepted in the matching process computing for the next pair of photographs.

The results of matching for a pair of photographs are presented in Figure 4. As can be seen, only a part of characteristic points have an approval match with a point from the second photograph.

C. Structure reconstruction

In the next stage, positions of detected points in 3D space are calculated as well as camera positions.

In practice, it is not enough to use the epipolar geometry to calculate positions of points separately for each pair of photographs. A calculation of the fundamental matrix is sensitive to noises and a detection of relations and translations between cameras results in errors cumulated in the final cloud.

To reduce the noises, the following solution is proposed.

A cloud of points is initiated by points localised on two first photographs. Each next photograph is used to add new points and calibrate the existing points from the cloud.

Before the calculation, coordinates of points from images are normalised. The normalised point is defined as $K^{-1}\mathbf{x}$, where $\mathbf{x}$ is the coordinate in image space and K is a calibration matrix.

The K matrix is estimated as

$$K = \begin{bmatrix} w+h & 0 & \frac{w}{2} \\ 0 & w+h & \frac{h}{2} \\ 0 & 0 & 1 \end{bmatrix}$$

where w and h are width and height of image respectively. The same estimation was used in [13].

Next, for a selected pair of photographs the eight–point algorithm is used to calculate a fundamental matrix [8]. Owning the fact that coordinates were normalised the essential matrix can be used to detect relations between cameras.

Information about sequential photographs is added iteratively. However, now 2D points from a photograph are compared with 3D points from the created cloud. If a point has an equivalent in the cloud then the 3D coordinates are recalculated on the basis of a new observation. Otherwise, a new point can be added but only if it is present on at least three following photographs.

An important aspect of the reconstruction process is that it uses neither the camera position nor the fact of using a turntable pedestal.

The stage results in a cloud. Examples for analysed objects are given in Figure 5.

D. Bundle adjustment

The created clouds show recognisable views of the modelling objects. However, the density of clouds is not good enough to reconstruct object surface. Moreover, errors from this stage may propagate on the final model. Therefore, an additional stage is necessary to improve a quality of the cloud.

Such method is the bundle adjustment [14]. The method minimises the total mean squared error between real positions of points in a photograph and a position calculated from a 3D projection and a camera position. The algorithm operates on

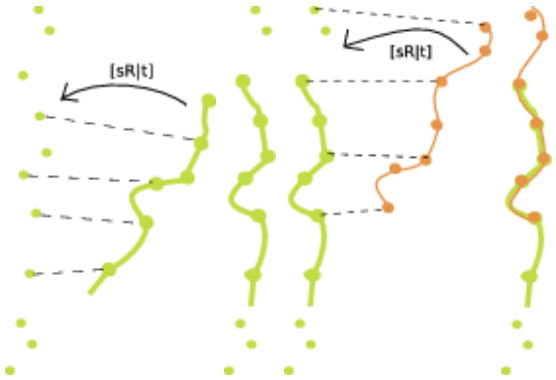


Fig. 7. Connection of the clouds:(a) the projection of the dense cloud on the sparse could, (b) the sparse cloud extended by the dense cloud, (c) the second dense cloud projected on the point of the sparse cloud matched to the first dense cloud, (d) the connected dense clouds.

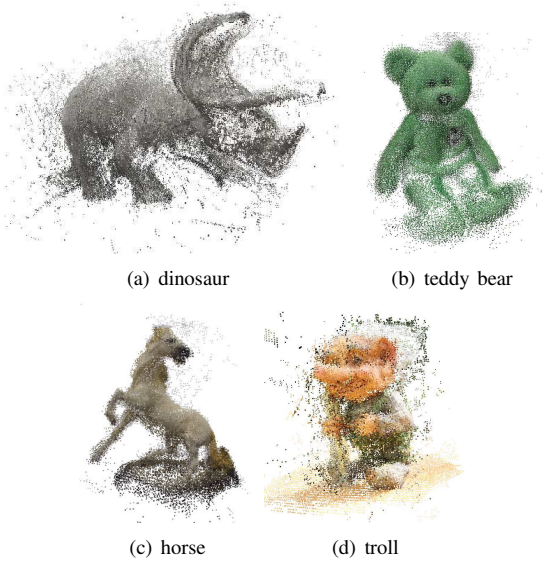

Fig. 8. Dense cloud created in the stage

the cloud calculated in the previous stage and camera parameters calculated using the Levenberg–Marquardt method [14].

The bundle adjustment is a general method. In this work, a specific implementation is used that calculates six parameters for each camera (three for a rotation and three for a translation) and three for each point from the cloud. Inner camera parameters are constant and common for all photographs.

This stage is optional, but definitely improves obtained results. In Figure 6, clouds after the bundle adjustment are presented. In the comparison with the previous clouds, objects are better visualised. However, clouds are still not dense enough to create a final reconstruction.

E. Dense cloud creation

The clouds created in the previous stages are too thin to reconstruct a high–quality surface. However, the clouds can be used to calculate a dense cloud, which will be a base for the final model.

The methodology used in this work bases on stereo block matching algorithms [15]. For a pair of photographs, equivalents of the same objects (pixels or small areas) should be localised on both photographs. A special transformation – rectification allows the algorithm to reduce a searching area to a line of even to a segment (under additional conditions) [16].

Collected data on the equivalents of points are stored as information about a distance between projections of points on a disparity map. With additional information about a camera localisation, the disparity map can be transformed into a depth map. The depth map codes information about the depth in the given point as an intensity.

In the 3D model reconstruction, many depth maps are connected and several problems arise in that process [17]. The maps are calculated for each pair of photographs. A relative small angle between the following photographs determines significant areas common for several maps.

The Iterative Closest Point technique [18] is commonly used to minimise the difference between two clouds of points. The algorithm uses the nearest neighbourhood criterion to find equivalents of an analysed point among clouds. Next, using a mean square cost function the transformation between clouds is solved. An iteration process is used to reduce the calculated cost.

When depth map are selected additional information is given and the connection process can be improved [19]. However, in this work, a new simple method that gives good results is proposed.

In the proposed method, clouds are connected together instead of disparity maps. Therefore, the filtration process plays major role in a quality of the final model. This solution is different that majority of solutions presented in other works, but a similar proposition can be found in [20].

Maps are transformed into dense clouds. Created cloud cannot be connected directly without creation of many noises. Therefore, the dense clouds are fitted in the sparse cloud created in the previous stage. Figure 7 presents the whole process.

The projection of the dense cloud to the sparse clouds is the minimalisation problem:

$$\sum_i ||b_i - \mathbf{s}\mathbf{R}a_i - \mathbf{t}||^2, \tag{1}$$

where a_i is a point from the sparse cloud, b_i an equivalent of the point in the dense cloud. The solution is the transformation that consists of the rotation R, the translation t, the scale s, and minimalises the formula (1).

The results of the stage are given in Figure 8. The created clouds are dense, but noisy. The noises will be removed in the next stage.

F. Surface reconstruction

In the first step of the final stage, the dense cloud is filtered. Several algorithms are used to improve a quality of the cloud:

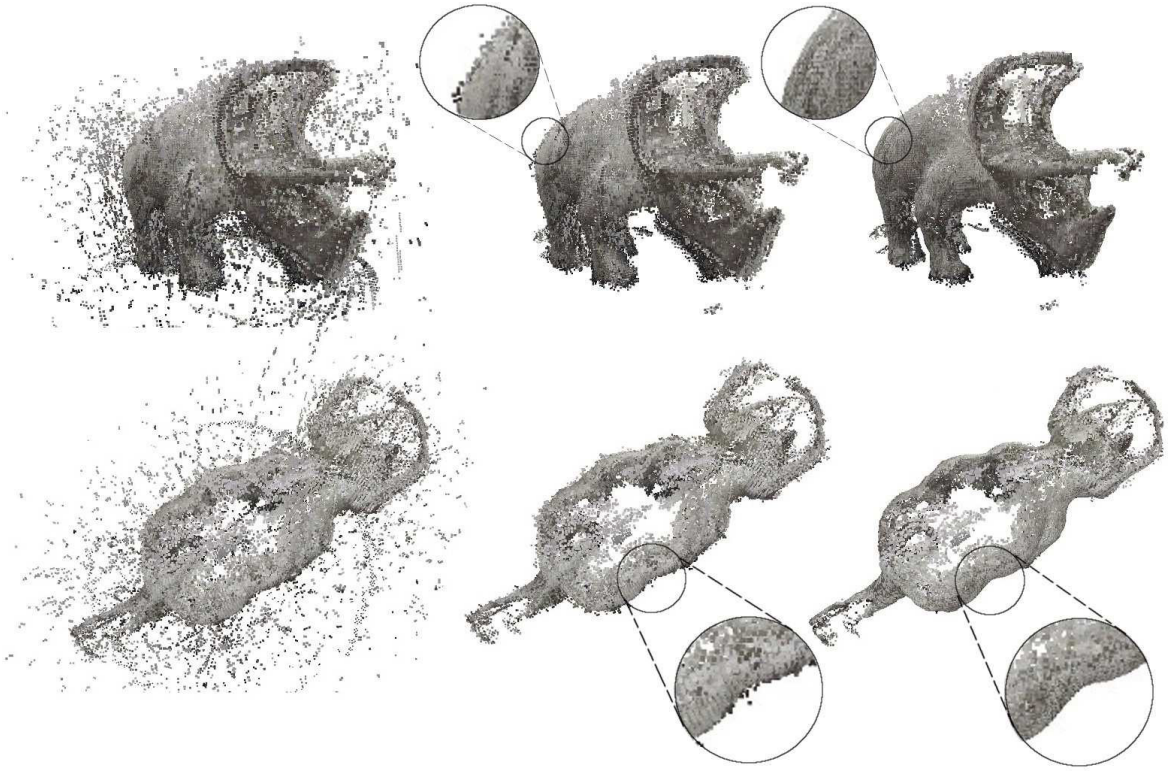

Fig. 9. Filtration. From the left: dense cloud, results of the SOR filter, and results of the MLS method.

the Statistical Outlier Removal filter, Voxel Grid filter, and the Moving Least Squares method.

The disparity maps have wide common areas. Therefore, points from an appropriate surface are located very dense. Otherwise, wrongly reconstructed points are located on random positions usually with small local density. Such points can be removed by the Statistical Outlier Removal filter [21]. For each point in the cloud, the filter calculates distances to k nearest neighbourhoods. On this base, a rejection threshold is calculated. When the average distance to the nearest points exceeds the threshold, a point is removed from the cloud.

The Voxel Grid filter reduces the number of points in the cloud. In a small neighbourhood, all points are reduced to a single point, which is the centroid.

Next, the cloud is smoothed. Noises near an appropriate surface could not be removed by the SOR filter. Therefore, the Moving Least Squares method [22] is used to remove the noises. In the method, a local surface is approximated and points are projected on the surface.

Effects of filtration are presented in Figure 9.

The last step is a surface reconstruction. The step is done by the Poisson method [23]. Before the reconstruction, normals for points should be calculated. The standard method that calculates normals [24] can be used. In the method, the Riemann graph is created with vertices defined by points and edges between nearest points. The graph forms the basis for a propagation of normals orientations.

The Poisson method creates a surface on the basis of the cloud of points with oriented normals. The method solves for an approximate indicator function of the inferred solid, whose gradient best matches the normals. The output scalar function is then iso–contoured using adaptive marching cubes.

IV. Results

The reconstruction time for a single model was about 6 minutes. The reconstructions were done on AMD Athlon 64 3000+ 2 GHz with Ubuntu system version 10.04.

The obtained results are presented in Figure 10. Reconstructed objects have good quality. Colours of triangles are interpolated from colours of corners. The colouring method is simple but brings satisfactory results. However, results show that a quality of the photography documentation influences the quality of the models.

The teddy bear (described by the full, professional documentation) is very well reconstructed including original depressions on its belly and back, while the horse model lost some details. In the dinosaur model (described by the professional, but reduced documentation), not all wrongly reconstructed points were removed. The model has a projection on its back. The troll model (described by the amateur documentation) has a distortion on the back. Moreover, a part of the stand was recognised as a part of the statue. Probably, this interpretation was caused by a shadow registered on the photographs. In a studio, this problem is eliminated.

Fig. 10. Reconstructed objects: Dinosaur, teddy bear, horse, and troll

V. Evaluation

The main issue of the evaluation of created model is a lack of digital patterns to compare with the reconstruction. Therefore, we propose the following schema of models evaluation on the base of the series of photographs.

The projection of model was projected back on the cameras. As a result, the initial two dimensions projection was reconstructed. The reconstructed projection was compared with the isolated object from the origin photograph. Figure 11 presents all elements.

Both reconstructed object and isolated object from the origin photograph was used to create masks. The areas are compared and the model is evaluated using

$$q = \frac{b + c}{s}, \tag{2}$$

where b is the number of reconstructed pixels that are not a part of the origin object, c is the number of pixels from the origin object that are not reconstructed, and s is the number of matching pixels. Figure 12 presents all elements of the area matching.

The second proposed evaluation method is a contour matching. The contour matching analyses a reconstruction of details. For the created masks, the contour is calculated as the morphological gradient with the colour structuring element and with the 11 pixels diameter. Next, two evaluation measures were calculated:

$$q' = \frac{s}{m}, \tag{3}$$

where s is the number of matching pixels for both contours and m is the number of pixels in the model contour;

$$q'' = \frac{s}{o}, \tag{4}$$

where s is the number of matching pixels for both contours and o is the number of pixels in the object contour;

The measure q' (3) defines the percent of coverage of the object contour by the model contour, and the measure q'' (4) defines the percent of coverage of the model contour by the object contour.

Figure 13 presents all elements of the contour matching.

Table I presents evaluation of the models. We calculated averages of the evaluating coefficients for whole series of photographs. For the area matching coefficient q smaller values are better, for the contour matching coefficients higher values are better.

Studios objects have the similar area matching coefficients. The contour matching coefficients show that solid objects (the horse, the dinosaur) have better reconstructed contours than fluffy (teddy bear). The worst results were obtained for the troll model. It was caused by recognising the base of the model as a part of the model. When we edited model manually, we obtained better results.

TABLE I
Evaluation of the models: q - area matching coefficient, q', q'', contour matching coefficients

model	**avg** q	**avg** q'	**avg** q''
dinosaur	0.10	0.68	0.65
horse	0.15	0.72	0.72
teddy bear	0.11	0.57	0.57
troll	0.91	0.33	0.31
edited troll	0.35	0.51	0.47

VI. Conclusions

In this work, the 3D models creating from photographs was presented. The method describes all stages of the reconstruction process from the features detection and the matching, through the creation of a sparse 3D cloud and a dense cloud, until the filtration and the surface reconstruction. All stages were illustrated with examples of their products.

The whole solution was implemented on the basis of open source libraries: OpenCV, Point Cloud Library and Sparse Bundle Adjustment. However, in several points original solutions were used. Especially original approach was used to connect the dense points clouds into one cloud using the sparse cloud.

Although some noises can be observed after a close inspection on the dinosaur model and the troll has some distortions, the obtained coloured reconstructions are good–looking and results are rewarding.

The presented process, together with the created application allows user to create complex 3D models without any expensive staff and advanced software.

***Abstract*—A real-time human head detection and tracking method for a fall detection system is presented. It utilizes RGBD images to obtain a head position in the three-dimensional space. The proposed method is designed to be insensitive to a body orientation and requires no initial calibration for the tracked person. The evaluation was performed on the basis of annotated videos with realistic non-studio indoor everyday activities and falls. The proposed method outperforms head tracking from the Microsoft Kinect SDK skeleton tracking.**

I. Introduction

TRACKING of a human head is an important aspect of any system striving to monitor human behavior or health condition. Many conclusions can be made based on the information about a head position and orientation. A certain application that can benefit from a reliable information about a human head position is a fall detection for an elderly people monitoring system. Existing solutions focus mostly on detecting or tracking a human face instead of a head in general. Most of them also takes an assumption about constant vertical orientation of a human body. In a vast majority of situations such an approach is sufficient but in the context of a fall detection system there is no suitable existing solution.

The aim of our research was to develop a robust head detection and tracking method that is capable of tracking a human head regardless of its orientation and independently of a tracked person. The method uses joined color, motion and depth data to effectively perform this task. The introduced method maintain its performance in situations when the head position and orientation change rapidly such as during a fall.

The content of this paper is organized as follows. In section II related works in the field of head tracking are introduced. In section III we formulate the research problem, which our method is designed to solve. In section IV we describe the presented solution. Section V is dedicated to the evaluation of our method and contains the description of the experiment and the dataset followed by test results compared to the Kinect SDK head tracking [1]. In section VI we conclude our work and propose future work directions.

II. Related works

The head tracking problem has been widely studied over the past few years. In the literature, definitions of this problem describe different tasks. The majority of papers identifies the problem of head tracking with face tracking. They only tackle situations when the face is clearly visible on a video image and take the assumption that it is located near the camera, as in [2], [3], [4], [5], [6], [7]. Two most common applications of such defined head tracking are to obtain certain facial features [6], [2], [3], [4], and to approximate a spatial head orientation [5], [8]. In this paper the problem of head tracking refers to determining the position of a head regardless of its rotation around the vertical axis.

Since the information about a human head position and orientation can be utilized in a vast number of applications, there are many different approaches to solve this problem. In this paper we focus on vision systems as most versatile ones. The highest performance can be achieved using a thermal camera [9] as a data source. It is a consequence of a human head being easily distinguishable on thermal images. This solution, however, cannot be widely applied due to the high cost of thermal cameras. A common approach to this problem is using a video camera as a data source. The video camera was utilized in the methods described in [2], [3], [4], [10], [11], [6]. Recent appearance of affordable sensors containing both video and depth camera has exposed new possibilities in the field of image processing. A widely used device, integrating a depth sensor and a color camera is Microsoft Kinect. It is used for the head tracking task in [5] and [8]. Additionally Microsoft Company released SDK for Kinect [1], providing a skeleton tracking functionality. Thanks to this solution, if a skeleton is recognized properly by the Kinect sensor, information about a head position can be easily obtained, however, as shown in this paper, it lacks robustness.

Among vision systems utilizing different data sources, there are various methods solving the head detection problem. A method presented in [12] uses background subtraction to detect a moving silhouette and treats its highest point as a head. In [11] the background subtraction is also used to find interest points. Then, a classifier is applied. In [10] each tracked head must be initially introduced to the tracking system from four directions. In [3] and [7] only a face is detected using a generic Haar cascade face detector [13]. In this case, a face needs to be visible in satisfactory resolution.

After the head is detected, the tracking process can be initiated. Most methods assume an invariant orientation of a head during tracking. Therefore, a template is captured

978-83-60810-58-3/$25.00

once and subsequently SURF [7] or a Template Matching algorithm is used to track the template. Other methods use CAMSHIFT [2] algorithm or intensity gradient and color histograms analysis [10] to perform tracking.

Existing methods fail, when the head is seen from different perspectives or a human body is not arranged vertically, for example during a fall. They also focus only on using a single data source, while composition of color and depth information allows greater versatility of a tracking system.

III. Research problem

The method described in this paper is designed to solve the head detection and tracking problem with an assumption to apply it to an elderly people monitoring system. The detection task is defined as locating a single human head on an image regardless of its rotation around the vertical axis. The tracking task is interpreted as providing consecutive information about the location of the initially detected head in each frame. Given a streaming sequence of color and depth images obtained from a RGBD sensor, the method returns a spatial position of a tracked head or information that there is no head detected.

The returned position is defined in the 3-dimensional coordinate system described in section IV. The detection and tracking is performed in the real time, thus providing the position of a head in the last processed frame. The input stream is analyzed with the speed of fifteen frames per second. The following assumptions are made. The method tracks a single person in an indoor environment. Neither person-specific nor room-specific calibration needs to be performed. The method is sensor-independent, however, for a head to be detected, it should be located within the sensor depth range, which is from 0.8m to 4m for the Kinect. In order to perform tracking successfully, the initially detected head needs to be visible on a color image. It is not required to stay in the depth range. The method should be robust to rapid changes in a position and orientation of a head in situations such as a fall.

IV. Method description

Our method uses image processing techniques and simple decision rules. It utilizes a combined information, extracted from color and depth images, obtained from a RGBD sensor. The method consists of four modules. The interaction between them for the *n*-th frame is presented in the Fig. 1.

The first module is capable of creating a motion image, based on three consecutive color frames. The second module, referred to as Detector, detects a head based on current color, motion and depth frames. The Tracker module also uses current color, motion and depth frames to track the head, detected in the previous frame. In the fourth module, referred to as Integrator, the information about the head position provided by Detector and Tracker is integrated and the spatial position of the head is returned.

An interest point for the head detection is the top of every vertical silhouette, segmented from the depth image. The interest region is marked as a *head* if it is recognized as a face or a movement in this area is detected on the color image.

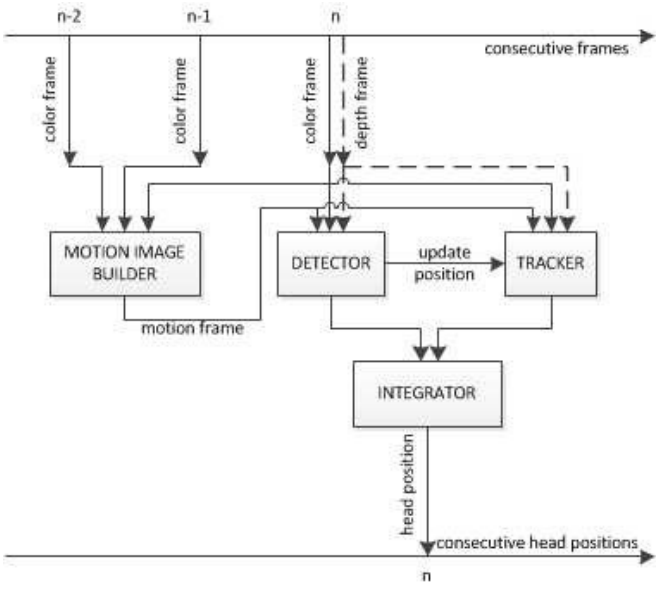

Fig. 1. The interaction between method modules for the *n*-th frame

TABLE I
Sensor-specific parameters

Symbol	Description	Kinect value
c_w, c_h	color image width and height [pixels]	640, 480
d_w, d_h	depth image width and height [pixels]	640, 480
sf	scaling factor	1.06
hd	horizontal displacement of the depth image on scaled color image [pixels]	6
hda	horizontal view angle of the depth camera [degrees]	58.5
vda	vertical view angle of the depth camera [degrees]	45.6
hca	horizontal view angle of the color camera [degrees]	62.0
vca	vertical view angle of the color camera [degrees]	48.6

The tracking is performed independently on the color image and on an image created as an absolute difference between consecutive color frames. This image will be referred to as a motion image. To increase the robustness of the tracking algorithm, both images are multiplied by the depth mask which cuts out the regions where the depth value differs significantly from the last known depth of the tracked head. The results returned by tracking on color and motion images are integrated as a weighted average based on the certainty of each of them.

A. Sensor-specific parameters

Due to a variety of RGBD sensors with different characteristics such as focal parameters, resolution and displacement of color and depth cameras, the presented method is parameterized to make it sensor-independent. Although the method was implemented and tested with the Kinect sensor, no additional Kinect SDK functionalities, such as skeleton tracking, were used to assure portability to other sensors. Defined parameters and their values for the Kinect sensor, described in the Kinect specification, are listed in the Tab. I

Color and depth image resolutions were selected from several options available for the Kinect sensor. The scaling factor was calculated with respect to the ratio of view angles of depth and color camera. The horizontal displacement is the consequence of displacement of cameras in the sensor. View angles are characteristics of the camera specified by a manufacturer.

To enable locating various points on the image in a real-world coordinate system, the information about the view angle of the depth camera and the depth value of the given point are used. The world coordinates are expressed in the right-handed coordinate system consistent with the one specified by Kinect SDK [1]. The origin is located at the center of the sensor, the Z-axis is pointing toward the direction of view and Y-axis points upwards. Whereas the image coordinate system has its origin in the top left corner of the image with the X-axis pointing to the right and the Y-axis pointing downwards. Image coordinate values are expressed in pixels. The real-world spatial coordinate (s_x, s_y, s_z) of a point (x, y) on the image, located at the distance d, measured in meters, is given by equations (1)

$$\begin{aligned} s_x &= 2d(\frac{x}{d_h} - 0.5)tg(\frac{hda}{2}), \\ s_y &= 2d(0.5 - \frac{y}{d_w})tg(\frac{vda}{2}), \\ s_z &= d, \end{aligned} \tag{1}$$

where d_w, d_h, hda, and vda are defined in the Tab. I.

The calculation allows a fast and accurate conversion from the depth image space to real-world coordinates. The choice of such coordinate system is justified by the possibility of comparing the method output with the Kinect skeleton tracking.

B. Preprocessing

The main problem, which needs to be solved in order to allow combining the depth and the color images is mapping between pixels of both images. The displacement of cameras and their different focal characteristics cause the difference between areas visible on both images. Kinect SDK provides an accurate conversion from the depth to color space. This conversion, however, only works in one direction and is only applicable to Kinect sensor. Additionally, it can only map a single depth pixel to color pixel which is computationally ineffective. A method similar to the Kinect solution was proposed in [14]. It is also unidirectional but in a contrast to the previous approach, it does not need Kinect sensor to be plugged in during its usage which allows wider application of this solution. It is only unidirectional since the precise inverse operation is not possible. It would require the analysis of depth pixels to find the one that matches best to the given color pixel. Such a solution would be very computationally complex. Since the existing methods do not use any fast bidirectional space mapping between color and depth images, a fast method of solving this problem is proposed. The color image is scaled and shifted to match the depth image. Given the resolution of the depth image d_w, d_h, the new size of the color image c_w', c_h' is calculated as in formula (2)

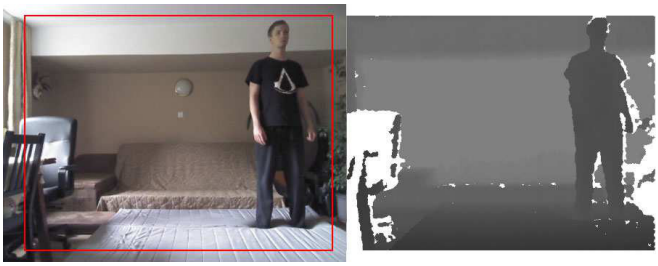

Fig. 2. Color image cropp rectangle

$$\begin{aligned} c'_w &= d_w sf, \\ c'_h &= d_h sf, \end{aligned} \tag{2}$$

where sf is the scaling factor defined in the Tab. I.

Subsequently, the color image is cropped to match the size of the depth image by extracting a sub-image of the size d_w, d_h, which top left corner is located in the point p_x, p_y calculated as in formula (3)

$$\begin{aligned} p_x &= \frac{c'_w - d_w}{2} + hd, \\ p_y &= \frac{c'_h - d_h}{2}, \end{aligned} \tag{3}$$

where d_w, d_h, and hd are defined in the Tab. I. The cropped subimage is presented in the Fig. 2.

Once the transformation is completed, both images are aligned and no further calculations are necessary. The transformation is designed to give the best projection between images. While the method is not as accurate as the one in [14] or Kinect SDK mapping, it is bidirectional and much faster. The error of this method is greater for pixels located near the camera but it is tolerable at the range where the full body is visible.

The motion image is created based on the absolute difference between three consecutive color frames. It is a simplified version of a Motion History Image, described in [21]. A value of the pixel (x, y) is given by the equation (4)

$$\begin{aligned} M_n(x,y) = \ & |2(K_n(x,y) - K_{n-1}(x,y))| \\ & + |(K_{n-1}(x,y) - K_{n-2}(x,y))|, \end{aligned} \tag{4}$$

where $M_n(x, y)$ is the value of pixel (x, y) on the motion image, $K_{n-2}(x, y)$, $K_{n-1}(x, y)$ and $K_n(x, y)$ are values of corresponding pixels on three consecutive color frames. This approach is used to accurately highlight the area where the silhouette is currently located.

C. Head detection

The Detector module utilizes a current color, depth and motion frame and returns lists of *heads* and *uncertain heads* detected as a result for an input frame.

Algorithm 1 Head detection - finding regions of interest

```
image ← Dilatate(image);
image ← Canny(image);
contourList ← Group(image);
for all contour in contourList do
  d ← AvgDepth(contour);
  h ← Height(contour);
  if h ≥ hTreshold then
    rect ← CropV(contour, hHeight);
    median ← Median(rect, contour);
    if minHBreadth ≤ median ≤ maxHBreadth
    then
      regionOfInterest ← CropH(rect, median);
      interestRegions.Add(regionOfInterest);
    end if
  end if
end for
return interestRegions;
```

The head detection is performed in two steps. In the first one, regions of interest are found. An interest region is a sub-image that may contain a head. In the second step, each interest region is labeled either as a *head* or as an *uncertain head*.

Since our methods measures detected objects to rule out those, that cannot be human silhouettes, we define size constraints that need to be satisfied. Corresponding to the anthropometric studies of a human body [15], [16], the average breadth of a human head is 13.9 cm for men and 13.3 cm for women, while its length is 18.0 cm for men and 17.2 cm for women and its height is 21.2 cm for men and 19.8 cm for women. Additionally, according to [17], the height of a human body exceeds 1m after being four years old. Based on the introduced measurements and taking into account various transformations applied to the processed image, we define the following parameters:

- *hHeight* - the height of a head (26.4 cm),
- *minHBreadth* - the minimum width of a head (12 cm),
- *maxHBreadth* - the maximum width of a head (24 cm),
- *hTreshold* - the minimum height of a silhouette (1 m).

The proposed values exceed the top and bottom limit of a size of an adult human in order to avoid an omission of any real head detection.

During the first stage of the head detection, the depth image is analyzed. We use it to detect regions of interest. The aim of its analysis is to find silhouettes of a human-like shape. The process of finding interest regions is presented in the Algorithm 1.

Firstly, the image is repeatedly dilated to rule out the noise and erroneous pixels, which are white pixels, indicating no depth data. It is then binarized by Canny edge detector. Edge points are grouped into contours using a method described in [18]. As a consequence of the dilatation, the average size of a head on the image is increased by approximately 20%. This information is vital since in our method, boundaries for various measurements of a human body are defined in the real-world coordinate system. For each silhouette, its average depth is calculated to determine its distance from the camera. Having the distance, the height of the human silhouette is calculated using formulas (1). Only silhouettes that are at least the height of *hTreshold* are considered as possible human silhouettes, others are instantly eliminated. Subsequently, the bounding box of each silhouette is cropped leaving only its top *hHeight*. The median of the width of the silhouette's part located within a cropped rectangle is calculated. The rectangle is rejected if the calculated median is outside of the range from *minHBreadth* to *maxHBreadth*. Otherwise, the rectangle is cropped horizontally to obtain the interest region of a width equal to the introduced median.

Algorithm 2 Head detection - head classification

```
for all region in interestRegions do
  if FaceDetected(region) then
    heads.Add(region);
  else
    if MovementDetected(region) then
      heads.Add(region);
    else
      uncertainHeads.Add(region);
    end if
  end if
end for
```

After finding regions of interest, each of them is labeled as a *head* or an *uncertain head*. The classification process is shown in the Algorithm 2.

A simple decision sequence is used for this labeling task. Initially a Haar cascade is used to detect a face in the given region. We use the cascade model for frontal face recognition provided by OpenCV [19]. If the face is detected, the region is labeled as a *head*. Otherwise, the occurrence of the movement is checked in the interest region. If the movement is detected, the region is labeled as a *head*. Otherwise it is labeled as an *uncertain head*. To perform the movement detection, the motion image is thresholded to filter out the noise and the erosion is performed to clear the stronger noise. Subsequently the image is transformed by a multiple dilatation to highlight the movement region. The process is illustrated in the Fig. 3. If the region being an *uncertain head* contains at least 20% of white pixels we treat it as a *head*.

This approach has the following justification. The situation when there is a vertical silhouette detected, which contains an object of a size matching a human head in its top part, is not sufficient to classify this object as a head. However, because a human is not able to stand still without any movement, the movement is a reasonable indicator of a human presence.

D. Head tracking

The Tracker module takes a current color, depth and motion frame as an argument and, using the information about the previously detected head, performs tracking and returns up to

Fig. 3. Color image (left), motion image (center), and post-processed motion image (right)

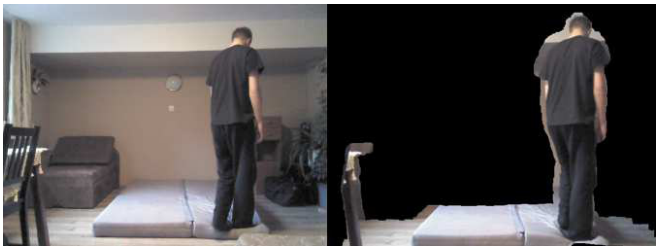

Fig. 4. Color image (left) and masked color image (right)

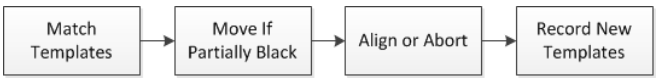

Fig. 5. Single tracking step for one image

4 possible head positions together with their *certainty factors*.

Tracking is initiated when an area labeled as a *head* is detected. It is performed independently on the color image and on the motion image introduced in section IV. Both images are multiplied by a binary mask cutting off areas where the depth value is significantly different from the depth value of the head. Such a mask is referred to as a depth mask.

In order to obtain the depth mask for each frame, auxiliary tracking is performed on the depth image. When the head is detected, a sub-image containing the head is recorded as a template. In the subsequent frame, an attempt is made to match the recorded template on the image. The search is performed in the region of interest, specified as the area containing the head in the previous frame, extended in each direction by a certain margin. The margin is designed to cover the distance that a head can traverse during the time of one frame. It is expressed in meters and transformed into pixels using the distance from the head to the sensor. The width of the margin is a parameter of the method and should be adjusted to match needs of the application. In our case, the video's frame rate is equal to 15 frames per second, thus the time span between consecutive frames is 66ms. For the fall detection system, where the speed of the head can be high, the reasonable margin value is 0.5m.

The template matching within the region of interest is performed using the Normalized Cross Correlation method (NCC), described in [20]. Once the best match is found, the template is updated with the newly found region, keeping its original size. The method returns a certainty measure to describe the quality of the match. This value is recorded together with a template position and will be referred to as a *certainty factor*. In the next step, the depth of the head is calculated and the depth mask is created as a binary image. The image has a black background and contains white pixels only in the regions, where the difference of the depth value and the depth of the head is not greater than the margin value.

Subsequently, the color and the motion images are multiplied by the depth mask. As a result of the multiplication, the areas where the depth value differs from the depth of the head are black, and those with a similar depth value are left unchanged. The example of a depth masking is shown in the Fig. 4.

Once masking is done, tracking on color and motion images is performed. For both images the same technique is used. The single step of tracking on one image is presented in Fig. 5. For each image, two templates are recorded. One having the size of the detected head and the other, located centrally within the first one and having a half of its size. It has been noticed that different sizes of the template perform better under different conditions, therefore tracking is executed independently for two templates. NCC is used to find the best template match. Next, the correction of the determined template location is done. In case a part of the template contains a large number of black pixels, its location is moved in the opposite direction.

If the best match of the template is located entirely in the black area, its position is aligned to the second tracked template. If this situation occurs to both templates simultaneously, tracking on the image is terminated.

Tracking is executed in parallel to the head detection process for each frame. If the *head* is detected within the range of the margin value of any of tracked templates, the size and position of each tracked template, including the auxiliary depth template, is updated with the area of the newly detected head. If no *head* is detected but there is an *uncertain head* in the rectangle overlapping one of the tracked templates, it is considered a *head* and all templates are updated as stated above.

After tracking is ceased, the positions of the tracked templates are returned together with their *certainty factors*.

E. Result integration

The Integrator module is capable of integrating the results returned by the Detector and the Tracker. The output of this module is a 3-dimensional position of a single head or information, that there was no head detected.

If any *head* was detected by the Detector, the results of the Tracker are ignored and the detected head is treated as a final result. Otherwise, the results of tracking are integrated in the following manner. In each frame there are two templates tracked on the color image and additional two on the motion image, therefore tracking results need to be integrated in order to provide a single location of the head. The location of the head is determined as a weighted average of all template positions. A *certainty factor* is used as a weight. This approach

Fig. 6. The example of a color frame (left) and a depth frame (right) from the dataset

causes inaccurate matches having less impact on the final outcome. Only templates matched on the color and the motion images are used in the integration process, because tracking on the depth image tends to be less accurate.

In order to obtain the spatial location of the tracked head, the formula (1) is used with the head position on the image and its depth value. It is then returned as a result of this module and the whole method.

V. Evaluation

The evaluation of the method was performed to assess its effectiveness and to compare it to the existing solution, implemented in the Kinect SDK. Since there is no RGBD benchmark dataset for the head tracking problem, the proper dataset was prepared. The dataset is described in details in the next subsection. Subsequently, the evaluation procedure, including experimental method and description of used measures, is presented. Finally, the results for our method and the Kinect SDK are shown and commented.

A. Dataset description

The dataset consists of 480 short films, recorded at 15 fps and containing video and depth images for each frame. All scenes are recorded in the indoor scenery and last from 6s to 24s, averagely 13s. Each scene shows one of two actors: a man or a woman. Each film presents either a daily action or a fall. The following actions were recorded: walking, standing, sitting on a chair, sitting on the ground, bending down, lying on a bed, lying on the ground, standing on a chair, cleaning, falling forward, falling backward and falling sideward.

Each action was recorded 20 times per actor and, excluding lying on a bed, contains records, where the actor was viewed from the front, back, left and right. Each film begins showing the empty room and captures the moment, when the person enters the frame and, except falls, finishes after the person leaves the frame. Films showing falls end when a person is lying on the ground. The example frame is shown in Fig. 6.

The dataset was annotated with a current head position to enable the evaluation of a head detection method, however, due to laboriousness of the frame annotation process, for each film, only 3 frames were annotated. They were located at 1/4, 1/2 and 3/4 of the film duration. The first and the last frame was not taken into account, because a vast majority of them was showing only the empty room. The annotation was performed

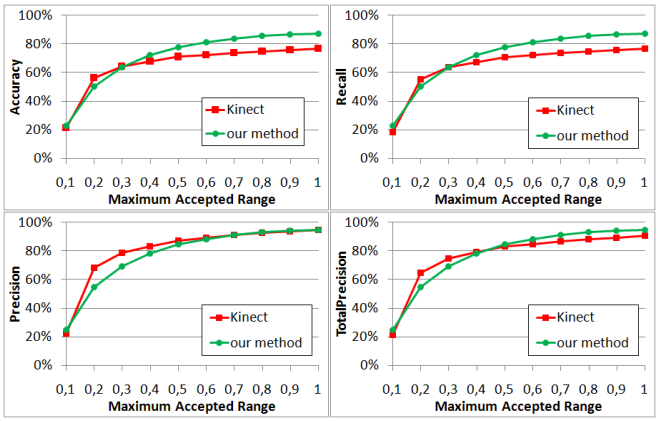

Fig. 7. Accuracy, Recall, Precision and TotalPrecision as a function of accepted range

by one person and validated by another one. On each annotated frame, the head position is specified or the frame was labeled as containing no head. The head position was labeled as a single point on the color image, located in the center of a head and transformed, using the depth information, into the real-world coordinate system. Together the 1440 frames are annotated in 480 films. In 1350 of them, there was a head visible in the frame, and in 90 of them, there was no head visible.

To compare our method to the method from the Kinect SDK, the skeleton information obtained from the Kinect sensor is also recorded for each frame.

B. Test method

Both methods were evaluated using various measures to provide a more comprehensive analysis of their performance. They were then compared to recognize differences in their functioning.

In the first step of the evaluation process, each film was replayed and analyzed by our method to detect and track the head in the real time. In each film, 3 frames, that are annotated with the head position, were evaluated. The number of heads annotated, tracked by our method and tracked by the Kinect SDK was stored for each frame. Additionally, if both numbers of annotated and tracked heads were greater or equal to 1, the following distances were calculated:

- the 3-dimensional Euclidean distance between tracked and annotated head, measured in meters, presented in formula (5),
- the distance between vertical components of positions of both heads, measured in meters, calculated as in (6).

$$d = \sqrt{(t_x - a_x)^2 + (t_y - a_y)^2 + (t_z - a_z)^2}, \quad (5)$$

$$d_v = \sqrt{(t_y - a_y)^2}, \quad (6)$$

where d is the 3-dimensional distance, (t_x, t_y, t_z) is the position of a tracked head in the real-world coordinate system, (a_x, a_y, a_z) is the position of an annotated head in the real-world coordinate system and d_v is a distance between vertical components of those points.

In order to consider different precision requirements, various measures were calculated as functions of the maximal distance between the annotated and the tracked head to treat it as detected correctly. The maximal distance is referred to as a range and extends from 10 cm to 1 m with 10 cm intervals.

The measures presented in the formula (7) were calculated for both our method and the Kinect SDK method

$$\begin{aligned} Accuracy(r) &= \frac{TP_r + TN}{AF}, \\ Recall(r) &= \frac{TP_r}{AH}, \\ Precision(r) &= \frac{TP_r}{DH}, \\ TotalPrecision(r) &= \frac{ATP_r}{ADH}, \end{aligned} \tag{7}$$

where: r is the range, the measure is calculated for, TP_r is a number of frames, in which the head was detected within a range r, TN is the number of frames, correctly classified as containing no head, AF is the number of annotated frames (1440), AH is the number of frames, annotated as containing a head (1350), DH is thenumber of frames, in which at least one head was detected, ATP_r is the number of heads, detected within a range r, including multiple heads detected in one frame, and ADH is the number of all detected heads, including multiple heads detected in one frame.

Due to the fact, that our method is designed to track one head for each frame and Kinect SDK can track higher number of heads, to calculate *Accuracy*, *Recall* and *Precision* we choose one head tracked by the Kinect, closest to the head annotated in this frame, and compare it to the result of our method. Only while calculating the *TotalPrecision*, we take into account all the heads tracked by the Kinect independently, even if there were more than one head in a given frame.

C. Experimental results

In this subsection, results of the experiment described previously are presented and commented. Fig. 7. shows the comparison of *Accuracy*, *Recall*, *Precision* and *TotalPrecision* calculated for our method and for the Kinect SDK in the function of the range.

As it can be seen, the *Accuracy* and *Recall* of our method is mostly higher than of Kinect, except for the range of 20 cm while the *Precision* of Kinect is greater than ours considering the range from 20 cm to 60 cm. For the rest of ranges, *Precision* of both methods is comparable. However, the *TotalPrecision* calculated for all heads detected by the Kinect is only greater in the range of 20 cm to 40 cm, while in the range wider than 50 cm, our method outperforms the Kinect. It is also notable, that considering the range lower than 10 cm, every measure is slightly higher for our method. This can be caused by the fact, that Kinect tends to detect the head on the chin level or even on the neck, while the dataset was annotated with points located in the center of the head, approximately on the line of ears and eyes. The significant difference between the *Precision* and *TotalPrecision* of Kinect indicates the high number of heads detected wrong while there was another head detected correctly. It is important to highlight that in situations where the Kinect detected more than one head, only the best one was used to calculate *Accuracy*, *Precision* and *Recall* while the rest was ignored. The higher *Accuracy* and *Recall* of our method indicate that Kinect detects less heads but when it does, it tends to be more precise.

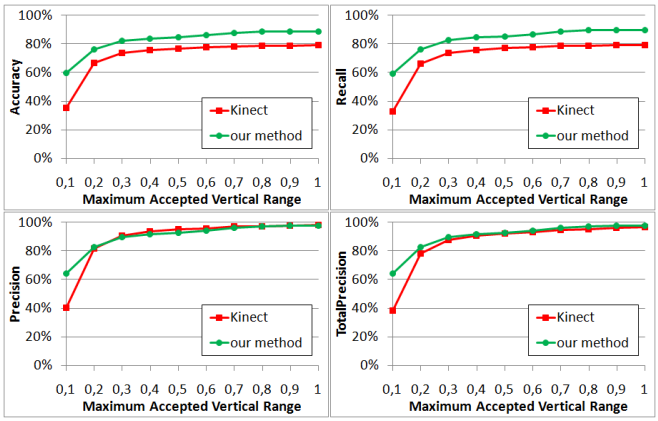

Fig. 8. Accuracy, Recall, Precision and TotalPrecision as a function of accepted vertical range

Regarding the fact, that our method is designed to match needs of a fall detection system, the correct vertical coordinate of a detected head is the one crucial for the proper functioning of such system. To asses both methods in terms of application in a fall detection system, the measures described by formulas (7) were calculated considering only the vertical component of the distance between the annotated and the tracked head. Results are presented in Fig. 8.

When only the distance between Y-coordinates is taken into account, *Accuracy* and *Recall* of our method is significantly greater than *Accuracy* and *Recall* of the Kinect. The *Precision* and *TotalPrecision* are also much greater considering the range of 10 cm and comparable for the rest of ranges.

VI. Conclusions

The above results lead to the conclusion that our method is more suitable for the application in a fall detection system than the method from the Kinect SDK. Among other possible applications, our method can be recommended for those, where the *Accuracy* and *Recall* are more important than the high *Precision*.

A. Summary

The method of human head detection and tracking on RGBD images was presented. As the evaluation shows, it outperforms the Kinect SDK skeleton tracking. Furthermore the method is independent of a used sensor and therefore its usage is not limited to the Microsoft Kinect. Promising

evaluation results indicate that it is a valuable head tracking method that can be successfully applied to tracking a single person in the indoor conditions. Our solution is particularly useful when there is no annotated dataset that could be used for any other machine learning approach since it requires no initial training and can be used to track any person without the necessity of previous calibration. Furthermore it is suitable for the fall detection task as it maintains its effectiveness during a fall. Therefore it can be used either as a primary data source for a newly developed fall detection system or as an auxiliary tracking method to boost the robustness of an existing fall detection system.

B. Future works

During the development and evaluation of our method, we identified various improvements that could potentially increase its effectiveness. During the classification of interest regions recognized as *uncertain heads*, a machine learning approach can be used to decide if the region should be classified as a *head*. Such a solution would require annotated objects, which are not heads, as negative examples and use them together with positively annotated heads to train a classifier. For that approach to be effective, the size of the dataset should be greater than the one used during the development of our method. The necessity to train a classifier would decrease the assumed versatility of our method but could improve its effectiveness in a specific target scenario. Potentially useful features for the classification task would be shape descriptors and color histogram components.

Another promising improvement is the dynamic adjustment of the margin value used during the tracking process to define the area where the search for a tracked head is performed. At present, the size of the margin is fixed to a reasonable value of 0.5m, which is suitable for the fall detection task. This value however could be adjusted based on the current speed of the tracked head.

Our method was designed to solve the head detection and tracking problem for a single person in the room, however it can easily be extended to track any number of heads. Such a modification would require developing a method of matching tracked and detected heads to allow integrating positions of corresponding heads.

Even though the presented configuration of our method has proven to be effective, its further improvements are still a subject of research. Since the method is flexible and divided into modules, each module can be used, modified and adjusted to fit special requirements independently.

***Abstract*—Today, mobile devices like smartphones and tablets are becoming more powerful and exhibit enhanced 3D graphics performance. However, the overall computing power of these devices is still limited regarding usage scenarios like photo-realistic gaming, enabling an immersive virtual reality experience or real-time processing and visualization of big data. To overcome these limitations application streaming solutions are constantly gaining focus. The idea is to transfer the graphics output of an application running on a server or even a cluster to a mobile device, conveying the impression that the application is running locally. User inputs on the mobile client side are processed and sent back to the server. The main criteria for successful application streaming are low latency, since users want to interact with the scene in near real-time, as well as high image quality. Here, we present a novel application framework suitable for streaming applications from high-end machines to mobile devices. Using real-time ETC1 compression in combination with a distributed rendering architecture we fully leverage recent progress in wireless computer networking standards (IEEE 802.11ac) for mobile devices, achieving much higher image quality at half the latency compared to other in-home streaming solutions.**

I. Introduction

THE ADVENT of powerful handheld devices like smartphones and tablets offers the ability for users to access and consume media content almost everywhere without the need for wired connections. Video and audio streaming technologies have dramatically evolved and have become common technologies. However, in scenarios where users need to be able to interact with the displayed content and where high image quality is desired, video streaming derived technologies are typically not suitable since they introduce latency and image artifacts due to high video compression. Remote desktop applications fail when it comes to using 3D graphics applications like computer games or real-time visualization of big data in scientific HPC applications. Enabling these applications over Internet connections suffers significantly due to restrictions induced by the limits of today's Internet bandwidth and latency. Streaming those in local networks, commonly referred to as in-home streaming, still remains a very challenging task in particular when targeted at small devices like tablets or smartphones that rely on Wi-Fi connections.

In this paper, we present a novel lightweight framework for in-home streaming of interactive applications to small devices, utilizing the latest developments in wireless computer networking standards (IEEE 802.11ac [1]) for mobile devices. Further, we use a distributed rendering architecture [2] in combination with a high-quality, hardware-accelerated decompression scheme utilizing the capabilities of modern handheld devices, resulting in much higher image quality and half the latency compared to other streaming solutions.

The setup is shown in Figure 1. The main application is running on a server or even a group of servers. Via network connection, the graphical output of the server application is streamed to a client application running on a mobile device. In addition, a back channel connection is present that collects user input events on the client and sends it back to the server. The server reacts to this input and produces an updated image, which is then transferred back and displayed at the client. The Quality of Experience is determined mainly by two factors: firstly, the delay between a user input issued on the client and the server-provided graphics refresh displayed at the client should be as low as possible. Secondly, the graphics quality of the streamed application on the client side should be as high as possible, even during scenarios with high motion.

II. Related Work

In this section we give an overview of known streaming technologies and applications, which we separate into three classes.

Classical desktop sharing and terminal applications: Examples are Microsoft's Remote Desktop Connection [3] or VNC (Virtual Network Computing) [4]. These are optimized for typical 2D applications like text processing or spreadsheet

978-83-60810-58-3/$25.00

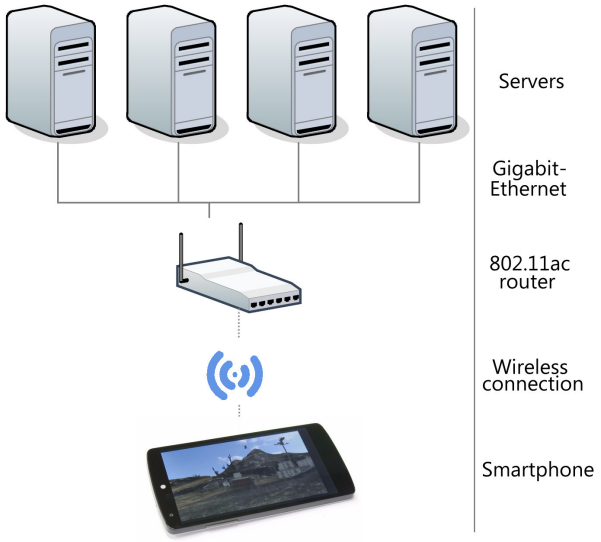

Fig. 1. *Distributed rendering, in-home streaming setup targeted at mobile devices. The four servers are rendering an image. Over Gigabit-Ethernet they transport it to a router with support for IEEE 802.11ac. The router sends the image data wirelessly to the client device (smartphone) which displays it.*

calculations. 3D support is typically very limited and, if supported, not capable to cope with the demands of real-time 3D games and visualizations.

Cloud gaming: The second class of streaming technologies has emerged from the field of computer gaming. Popular commercial solutions like Gaikai [5] or OnLive [6] aim at streaming applications, mainly games, via Internet connection from a cloud gaming server to a user's desktop. There are also open source approaches like Gaming Anywhere [7]. All of these are specifically optimized for usage with Internet connections and typically rely on the H.264/MPEG-4 AVC [8] video codec for streaming graphics. Gaikai and OnLive require a 3-5 Mbps internet connection at minimum and end-to-end latency values are at best 150 ms under optimal conditions (c.f. [7]). OnLive uses a proprietary hardware compression chip in dedicated gaming servers hosted by OnLive. Gaikai's approach has meanwhile been integrated into the PlayStation 4 console [9] after Sony aquired the company and has been renamed to "PlayStation Now" [10]. The service is limited on both the client and server side to dedicated hardware. In general, cloud gaming approaches are not optimized for in-home streaming, sacrificing image quality for lowering network traffic and reducing processing latency.

Dedicated in-home streaming: The third category are approaches designed for delivering applications to other devices in a local network using wired or wireless connections. Recently, Valve's game distribution platform Steam [11] introduced in-home streaming support in a beta version. Nvidia released a portable game console named Shield [12] in 2013, based on current mobile device hardware running an Android operating system. From a PC a game can be streamed to the console. Both approaches rely again on the H.264 codec and are exclusively capable of streaming games. In addition, Nvidia Shield is bound to Nvidia graphics cards and mobile platform architectures. A further streaming approach, which also handles in-home usage is Splashtop [13]. It can stream any application, game or the complete desktop from a single machine using H.264 compression.

We are not considering solutions like Miracast [14], Intel's WiDi [15] or Display as a Service [16] as these are aimed at replicating pixels to another display, not at streaming interactive applications. Further we exclude approaches like Games@Large [17] that stream hardware-specific 3D function calls that are usually not compatible with mobile devices.

III. System

In the following, we will propose a new framework for streaming applications from one or many high-end machines to a mobile device. Using a hardware-enabled decompression scheme in combination with a distributed rendering approach, we fully utilize the potential of recent progress in wireless computer networking standards on mobile devices. With this setup we achieve higher image quality and significantly lower latency than other established in-home streaming approaches. We first give an overview of the hardware setup used in our approach. Then we explain our decision on the compression scheme we used and after that we talk about the details of our software framework and application setup.

Our general system setup is depicted in Figure 1. The graphical output of a server application is streamed to a mobile device, in this case a smartphone, running the client mobile app. The server side consists of four machines in a distributed rendering setup. All devices operate in the same LAN. The server machines are connected by wire to a router which additionally spans a Wi-Fi cell to which the smartphone is connected.

A. Hardware Setup

Here, we describe the hardware specifics of our servers, the client and the network devices.

Our distributed rendering setup consists of four dual-socket workstations using the Intel Xeon X5690 CPUs (6 cores, 12 threads, 3.46 GHz) and the Intel 82575EB Gigabit Ethernet NIC. The client is a LG Nexus 5 smartphone which uses the Snapdragon 800 CPU (4 cores, 2.3 GHz) and the Broadcom BCM4339 802.11ac wireless chip. The devices are connected together through a Netgear R6300 WLAN Gigabit Router. The servers use wired Gigabit Ethernet to connect to the four Ethernet ports of the router. The smartphone connects wirelessly over 802.11ac (1-antenna setup).

B. Compression Setup

In this section we explain why we have chosen the Ericsson Texture Compression format (ETC1) [18] over other commonly used methods.

First we have a look at how displaying of streamed content is usually handled on the client side. Using the popular video library FFmpeg [19] and the H.264 codec an arriving stream at the client needs to be decoded. Using a CPU-based pipeline the decoding result is an image in the YUV420 [20] color space. As this format is usually not natively supported for displaying, the data is converted into the RGB or RGBA format. From there, the uncompressed image data will be uploaded to the graphics chip to be displayed.

If a hardware H.264 decoder is available then the arriving stream needs to be converted into packets, suited for that hardware unit and uploaded to it. The decoding process is started over a proprietary API and usually acts as a black box. Some decoders only handle parts of the decompression procedure; others do the full work and offer an option for either directly displaying the content or sending it back into CPU memory. Hardware H.264 decoders are usually optimized to enable good video playback, but not specifically for low-latency.

Next we have a look at our approach on displaying streamed content. An important feature of modern mobile device GPUs (supporting OpenGL ES 1.0 or higher) is that they have native support for displaying ETC1 textures. Therefore once an ETC1 compressed image arrives at the client we can directly upload it to the graphics chip where decoding to RGB values happens. Given the fixed compression ratio of ETC1 of 1:6 for RGB data the required transfer to the graphics chip is lower compared to uploading uncompressed RGB or RGBA data as described in the CPU-based pipeline for H.264.

ETC1 does an image by image (intra-frame) compression instead of using information across multiple frames (inter-frame). Therefore even if there is a lot of motion between frames a robust image quality is guaranteed. The video codec MJPEG [21] also has this characteristic, but as it lacks hardware decompression support on mobile devices it is not suited as it still requires non-accelerated decompression and the more bandwidth-intensive upload of uncompressed RGB/RGBA pixels to the GPU. Nevertheless, when comparing the image quality of an intra-frame with an inter-frame approach (like H.264) at the same bit rate, the latter will usually be of higher quality. However, codecs with inter-frame compression usually have higher latency.

C. Software Setup

Here, we describe the software setup and the communication between the client and server to enable streamed, distributed rendering.

The Microsoft Windows 7, 64-bit servers are running our custom written HPC ray tracing software, partly accelerated by Intel Embree [22] and multi-threaded through Intel Cilk Plus [23]. The ray tracer can be given the task to only render certain regions of the complete image. The ray tracer hands over the image section to the streaming module of our framework. This module can compress image data into the ETC1 format by using the etcpak library [24] which we multi-threaded using Intel Cilk Plus. Compressed data can be sent to the client using TCP/IP, supported by libSDL_net 2.0 [25]. Further, the server listens on a socket for updates that the client sends.

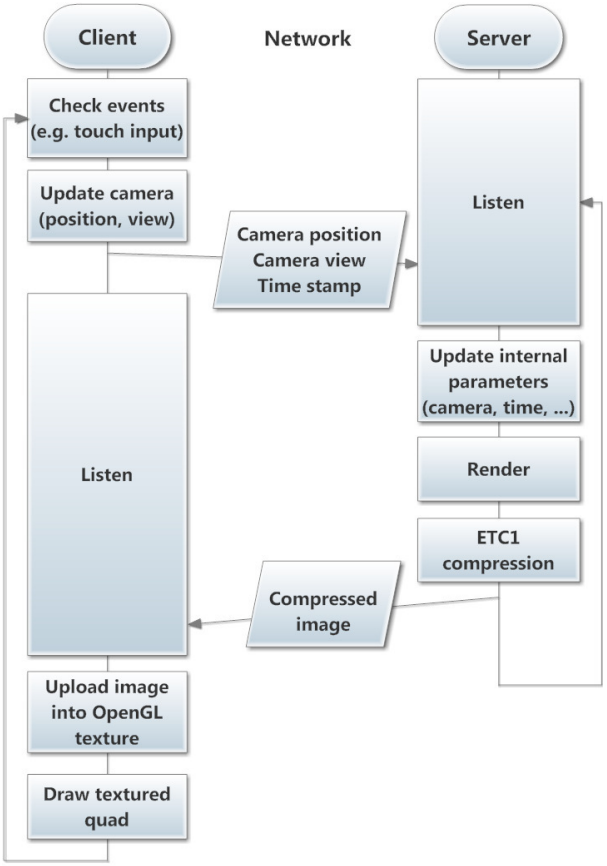

Fig. 2. *Tasks of the client and server architecture.*

The client runs Android 4.4.2 and executes an app that we wrote using libSDL 2.0 [25], libSDL_net 2.0 and OpenGL ES 2.0. All relevant logic has been implemented using the Android Native SDK (NDK r9b).

In the initialization phase the client informs the servers about the rendering resolution and which parts the render server should handle, parameters for loading content, and initial camera settings for rendering. Then the client will receive an image (or part of it) from the server. After the initialization steps the following procedure as described in Figure 2 will be processed every frame. The client checks for user input (like touch) and interprets this into changes in the camera setup (this step can also be done on the server side to stay application-independent). Those new settings, an unique time stamp and other application relevant data (total of 192 bytes) are then sent to the server. The server receives this

over the network and updates its internal states. An image (or part of it) is rendered, then compressed to ETC1 and sent to the client. There, the compressed image data is uploaded as an OpenGL ES texture. Next, a quad is drawn on the screen using that texture at the representing areas that have been assigned earlier to the rendering server.

Our used rendering algorithm, ray tracing, is known as an "embarrassingly parallel" problem [26] with very high scalability across the number of cores, CPUs and servers, because rendering the image can be split into smaller, independent tasks without extra effort. Therefore for the multi-server setup we naïvely split the image into four parts (one for each server), dividing the horizontal resolution by 4 and keeping the full vertical resolution. In order to achieve good scaling for a high number of servers we recommend instead using smaller tiles and to smartly schedule them over e.g. task stealing [27]. In addition to Figure 2 the client will now send one packet (192 bytes) to each server regarding the updates. The client will await the first part of the image from the first server, then upload it as OpenGL ES texture, then receive the second part of the image and so on.

As exemplary rendering content the "island" map from the game *Enemy Territory: Quake Wars*[1] is used.

It is our goal to make a very smooth experience by fully utilizing the display refresh rate of the smartphone (60 Hz). Given the properties of our hardware setup we choose to render at 1280×720 pixels instead of the full physical display resolution of the Nexus 5 (1920×1080 pixels) as it was in the current set-up not possible to transit higher resolutions with 60 Hz due to limitations of the data rate of a 1-antenna 802.11ac setup in current smartphones.

IV. Evaluation

Here, we evaluate our and other in-home streaming approaches in terms of data rate, latency, image quality and power consumption. We compare our implementation with Nvidia Shield[2] and Splashtop[3]. Steam's in-home streaming is currently still in beta and we encountered a high amount of frame drops during our tests, so we will not further compare it here.

A. Data Rate

We discuss the available data rate and the implications of it. The wireless networking standard 802.11ac allows a maximum data rate of 433 Mbit/s (for a 1-antenna setup). Hardware tests show an effective throughput of 310 Mbit/s (38.75 MB/s) for our router [28]. As our rendering resolution is 1280×720 pixels and has 8 bit per color channel this makes about 2.64 MB per image for uncompressed RGB data. Using ETC1 with the fixed compression ratio of 1:6 leads to 0.44 MB per image. Assuming the effective throughput this results in a maximum of about 88 frames per second (fps).

[1] id Software and Splash Damage

[2] Android 4.3, System Update 68

[3] Splashtop Personal 2.4.5.8 and Splashtop Streamer 2.5.0.1 on the Nexus 5

B. Latency

We have a detailed look at the latency of our and other streaming approaches.

The total latency from an user input to an update on the screen (motion-to-photons time) can have various causes of lag in an interactive streaming setup. The user input takes time to get recognized by the operating system of the client. Next, the client application needs to react on it. However, especially in a single-threaded application, the program might be busy doing other tasks like receiving image data. Afterwards, it takes time to transfer that input (or its interpretation) to the rendering server over network. There, the server can process the new data and start calculating the new image. Then compression takes place and the data is sent to the client, which might be delayed if the client is still busy drawing the previous frame. Once the image data is received, it will be uploaded to the GPU for displaying. Fixed refresh rates through VSync might add another delay before the frame can be shown. Some displays have input lag, which describes the time difference between sending the signal to the screen and seeing the actual content there. Additional delay happens when the client or server use multiple buffers for graphics. 3D application use double buffering, sometimes even triple buffering, to smooth the average frame rate. In our setup we are keeping the number of buffers as low as possible.

For the following measurements of our implementation we took the setup with four servers. As the distributed rendering approach does not work with the solutions we are comparing to, we modified the setup to use only one server and a very simple scene that achieves the same frame rate on a single machine as our four servers in the more complex rendering scenario. That way we have a fair comparison of the latency across the approaches. To get accurate motion-to-photons time we captured videos of user input and waiting for the update on the screen. Those videos are sampled at 480 frames per second using the Casio Exilim EX-ZR100 camera. In a video editing tool we analyzed the sequence of frames to calculate the total latency. Using our approach led to a motion-to-photons latency of 60 to 80 ms. On Nvidia Shield, which uses H.264 video streaming, we measured 120 to 140 ms. The Splashtop streaming solution, also relying on H.264, shows 330 to 360 ms of lag.

C. Image Quality

In this section we compare the image quality of our method with Splashtop, Nvidia Shield and with creating our own H.264 stream with different bit rate settings.

To analyze the difference in image quality we chose one image of a sequence in which a lot of camera movement is happening as shown in Figure 3. We quantify the image quality using the metrics of Peak Signal-to-Noise Ratio (PSNR) [29]

Fig. 3. *Left: Previous frame. Right: Frame for analysis with marked red area.*

and Structural Similarity (SSIM) [30] index, which takes human visual perception into account. For Nvidia Shield and Splashtop we were not able to test the distributed rendering setup, so we precalculated the ray traced frames offline and played them back from a single machine at the same speed that they would have been generated using four servers. That way a fair comparison of the image quality happens across all approaches. In Table I one can see that our approach has better image quality compared to Nvidia Shield, Splashtop and H.264 encoding at 5 Mbit/s. As expected, higher bit rate inter-frame encoding offers even higher image quality: going to 50 MBit/s using H.264 succeeds the quality delivered by ETC1. Using an even higher bit rate than 50 MBit/s during H.264 encoding does practically result in the same image quality for our setup.

D. Performance

Here, we report the rendering performance of our approach, the effective throughput and which tasks consume how much time.

We are able to achieve 60 frames per second at 1280×720 pixels. Given the ETC1 compression ratio of 1:6, this corresponds to an effective throughput of 210.93 Mbit/s (26.36 MB/s). The relevant components on the server side are rendering of the image region ($\sim$7 ms), network transfer ($\sim$3 ms) and ETC1 compression ($\sim$2 ms). On the client side network transfer ($\sim$12 ms) and OpenGL ES commands including swapping the display buffer and waiting on VSync ($\sim$4 ms) are the most time consuming tasks.

E. Battery Drain

Here we compare the battery drain of our approach, Splashtop and a locally rendered 3D application on the same smartphone and Nvidia Shield.

For the Nexus 5 we use the "CurrentWidget" app [31]. In our approach we observed an average battery usage of 850 mA, 605 mA for Splashtop and 874 mA for the locally rendered 3D game "Dead Trigger 2" [32] . The higher battery usage of our approach compared to Splashtop can be explained by the fact that we are handling much more data. The Nvidia Shield console uses different hardware; therefore the architectural difference has impact on the result and cannot be compared directly. Nevertheless, we report the number for completeness. The "CurrentWidget" app does not work on Nvidia Shield, so we measured the drop in percentage of the available battery power for an hour and by knowing the total battery capacity we got a value of 880 mA.

V. Enhanced Applications

In this section we have a look on various application scenarios that are enhanced by our high-quality, low latency in-home streaming solution. These can vary widely as the content of the displayed image is independent of the internals of the used compression, transportation and displaying method.

High-quality Gaming As there are already products evolving for in-home streaming for games, like Nvidia Shield and Steam's in-home streaming, this could potentially be an area of growth. The benefits are e.g. to play on the couch instead of sitting in front of a monitor or to play in another room where an older device is located that would not be able to render the game in the desired high quality. In fast-paced action games like first person shooters it is important to be able to react as fast as possible, therefore our reduced latency setup enriches the gaming experience. The commercially available solutions for in-home streaming of games are typically limited to using the rendering power of only one machine. Through the distributed rendering approach we potentially enable closer to photo-realism games by combining the rendering power of multiple machines.

Virtual Reality for Smartphones For virtual reality there are projects like FOV2GO [33] and Durovis Dive [34] (see Figure 4) that developed cases for smartphones with wide-angle lenses attached to it. Once this is strapped on the head of a user, mobile virtual reality can be experienced. For a good Quality of Experience high-quality stereo images need to be rendered that have pre-warped optical distortion compensation to cancel out spatial and chromatic distortions of the lenses. While this works good on desktop PCs [35], the performance

	Original	H.264 211 Mbit/s	H.264 50 Mbit/s	ETC1	H.264 5 Mbit/s	Splashtop	Nvidia Shield
PSNR	-	47.0	46.9	37.3	32.9	31.0	29.8
SSIM	1.0	0.997	0.997	0.978	0.877	0.861	0.779

TABLE I

PSNR and SSIM values for different codecs and platforms, exemplified by respective image sections as marked in Figure 3. Higher values are better. While with a high bit rate the image quality of H.264 surpasses ETC1, the later approach has significantly lower latency, which we show in section IV-B.

and quality that smartphones can achieve today is not very compelling for virtual reality. To achieve higher image quality, these applications have to switch from a local to a server-based rendering approach. As latency is an even more important issue in virtual reality, our latency-optimized approach is in particular suitable for this scenario. Solutions with a latency of 120 to 140 ms (Nvidia Shield) would lead to much more motion sickness compared to a latency of 60 to 80 ms. Nevertheless, optimizing virtual reality streaming applications for even lower latency might become more relevant in the future.

Fig. 4. *A mobile virtual reality platform that can be strapped on the head. In front of the case a smartphone is plugged in. Lenses bring the image into focus for the viewer. To compensate for optical distortions a high-quality, pre-warped stereoscopic image is used and streamed with low latency using our framework.*

Wearables: One of the emerging trends in the space of wearables are smartwatches. E.g. the Neptune Pine [36] is a fully independent Android device, equipped with its own CPU and GPU, 802.11n Wi-Fi and a 320x240 resolution display. Size, battery life and cost are limiting factors, so these devices are usually equipped with less capable processing units compared to other mobile devices. There is a chance that ETC1 streaming could unlock the full power of smartwatches - independent of their weak internal components. Further one could consider having the more powerful smartphone or tablet acting as a rendering server to feed the low-resolution smartwatch.

HPC and Big Data: A scenario where our streaming solution is also well suited for is real-time visualization of data-intensive computations like in the big data and HPC domain. Here, specialized applications either run analyses on huge amounts of data or computationally intensive calculations, typically relying on powerful back ends with a high amount of system memory. Typical application domains are health sciences, simulations in engineering, geographic information systems or marketing and business research. Being able to control, monitor and visualize these computations running on big server farms from small handheld devices is a very convenient benefit. Our solution, in comparison to other in-home streaming approaches, enhances graphics streaming for HPC applications as it supports a distributed scheme for rendering natively at high-quality and low latency. A testbed where we are currently integrating our streaming solution into is the molecular modeling and visualization toolkit BALL/BALLView [37], [38], see Figure 5. In BALLView,

running computationally demanding molecular dynamics simulations in combination with real-time ray tracing visualization on complex molecular data sets [39] requires a powerful compute server. Operating these experiments from a handheld device like a tablet is considered highly preferable.

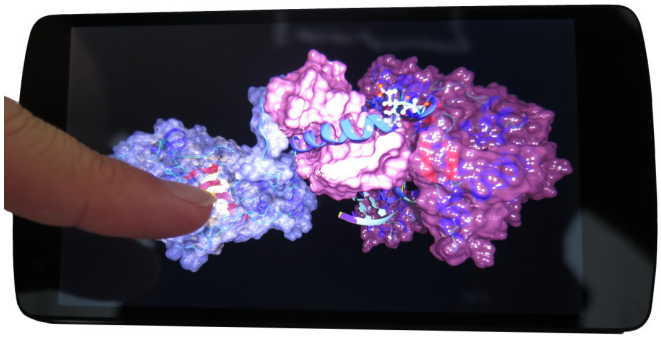

Fig. 5. *Molecular visualization from BALLView displayed on a mobile device.*

VI. Conclusion and Outlook

We conclude what we have demonstrated in this paper and give an outlook on future work.

We have shown a new approach to in-home streaming that fully leverages the latest development in wireless network standards and utilizes a hardware-accelerated intra-frame decompression scheme supported by modern mobile devices. The approach is well suited for streaming of interactive real-time applications and offers significantly higher image quality and half the latency in comparison to other recent solutions targeting this space.

Further optimizations like hardware encoders for ETC, switching to ETC2 [40] compression and using a 2×2 antenna network connection setup, as supported by IEEE 802.11ac, will lead to even higher image quality, faster performance and will enable 1080p at 60 fps.

***Abstract*—This paper introduces an optimized version of the standard K-Means algorithm. The optimization refers to the running time and it comes from the observation that after a certain number of iterations, only a small part of the data elements change their cluster, so there is no need to re-distribute all data elements. Therefore the implementation proposed in this paper puts an edge between those data elements which won't change their cluster during the next iteration and those who might change it, reducing significantly the workload in case of very big data sets. The prototype implementation showed up to 70% reduction of the running time.**

I. Introduction

THE MORE data volumes continue to grow in complexity and diversity, the harder it is to structure and manipulate them. Finding data with similar characteristics and labeling it accordingly has become one of the greatest challenges in nowadays data analyzing applications. Grouping data based on common characteristics is what we call clustering. Clustering algorithms fall into the unsupervised classification techniques category. They classify a set of objects into a subset of clusters based on similarities between them. Differences between clusters have to be obvious and clearly expressed.

Clustering can be applied to a wide range of domains like: marketing [1] (market analysis and recommendations, methodological weaknesses), medicine [2] (medical image segmentation), e-business [3] (comments analysis on news portal) or e-learning [4][5] (prediction of students' academic performance).

There is no secret recipe for choosing the best clustering algorithm. The choice should be based on experimental studies and data description possibly mixed with some human intuition unless there is no obvious mathematical model.

Some of the problems raised by clustering algorithms which worth investing research efforts are: scalability, handling heterogeneous data, execution time complexity when dealing with very large data sets, multi-dimensional data, etc.

The standard K-Means algorithm represents one of the most popular unsupervised exclusive clustering algorithms. It has been successfully applied to medical image segmentation as shown in [6] where the authors propose an algorithm for the segmentation of three-dimensional (3-D) image data based on a combination of adaptive K-Means clustering and knowledgebased morphological operations.

K-Means is based on the minimization of the average squared Euclidean distance between the data items and the cluster's center (called centroid). The results of the algorithm are influenced by the initial centroids. Different initial configurations might lead to different final clusters. The cluster's center is defined as the mean of the items in a cluster.

This paper focuses on the execution of the K-Means algorithm, namely it tries to improve the running time when dealing with high volumes of data. The standard implementation of K-Means consists of successive iterations. Each iteration requires visiting the entire data set in order to assign data objects to their corresponding cluster. At the end of each iteration, new centroids are being computed so that the next iteration will employ the new centroids. After a certain number of such iterations, the centroids will keep the same and the algorithm stops.

The optimization proposed by this paper relies on the observation that after performing a number of iterations, just a small part of the data set might change the cluster it belongs to. Our implementation traces a border between that part of the data set which could possibly switch to another cluster and the data that will hold the cluster it belongs to, during the next iteration. As K-Means algorithm's execution advances, the centroids come closer to their final position. The more iterations are performed, the less the centroids deviate from their current position, resulting in less data objects to be checked against. Similar to the classical implementation, the final clusters are sensitive to the initial configuration (initial centroids).

The rest of the paper is structured as follows: section II presents previous results in speeding up the K-Means algorithm, section III describes the proposed optimization for the K-Means algorithm, section IV experimentally evaluates the potential of the proposed optimization, while section V concludes the paper and presents our future research intentions.

978-83-60810-58-3/$25.00

Algorithm 1 Standard K-Means algorithm

1. Choose k data objects representing the cluster centroids;
2. Assign each data object of the entire data set to the cluster having the closest centroid
3. Compute new centroid for each cluster, by averaging the data objects belonging to the cluster
4. If at least one of the centroids has changed, go to step 2, otherwise go to step 5
5. Output the clusters.

II. Related Work

Researches have shown special interest for speeding up the K-Means algorithm, by either reducing the computation complexity or by adopting K-Means implementations for parallel and distributed platforms.

In [7] the authors propose an efficient implementation of the Lloyd's (K-Means) algorithm called the filtering algorithm which employs kd-trees for storing the data elements.

In [8], the authors propose an algorithm which reduces the computations for determining the closest centroid of a data element, by making use of the observation that if a data element gets closer to the centroid defined at the previous iteration, it won't switch the cluster it belongs to.

Other strategies [9][10][11][12][13] focused on parallelizing the K-Means algorithm and take advantage of powerful parallel and distributed environments, addressing issues specific to those environments, like data availability, synchronization, etc. and adapting the K-Means algorithm to different distributed architectures (client-server, peer-to-peer, etc). The results were satisfactory for very big data sets.

The highly-parallel GPUs haven't been ignored either. Papers [14][15] propose parallel implementations of K-Means to be run on GPUs.

III. Optimized K-Means Method

Before proceeding with our optimized K-Means, let us examine first the standard K-Means algorithm. It consists of repetitive steps, as presented in algorithm 1.

Let us have a look at the algorithm and try to identify what step causes the most computations. Obviously in case of very large data sets, step number 2 would require the biggest time frame in the algorithm's execution. The bigger the data set, the wider the time frame of step 2's execution as it visits each data object and performs some computations on it. The question that arises here is: do we need to visit the entire data space? Figure 1 illustrates the centroids' evolution in a standard K-Means execution.

The data objects are represented by 2D points. The algorithm starts with centroids A1, B1 and C1, which change their position with each iteration, successively to A_i, B_i and C_i, where i=1..6 until they no longer change. If we take a closer look, we can easily see that as the execution progresses, the centroids get very close to their final position. Actually, it happens very often that after only few iterations, the centroids undergo their trip to the very close neighborhood of their final position. This observation leads us to the conclusion that most of the data objects belonging to a cluster whose centroid slightly moves, should not be affected by the move; they will remain part of the same cluster during the next iteration. The less the centroid moves, the less points get affected by the move.

Being able to determine which of the data objects could be affected by a move, could lead us to a very important improvement on step number 2 as we no longer need to visit the entire data set, but just a small list of data objects (let us call that the 'border' list). Before deciding which data objects should be placed into the 'border' list we need to establish the criteria that need to be fulfilled by a data element so that it can be considered a 'border' element. Let us consider Figure 2 which assumes the iteration i is to be computed.

Let point P be part of cluster C. All other points have been omitted on purpose for the ease of presentation. Point P is part of cluster C as the distance from P to C (d_{PC})is less than the distance to A (d_{PA}) and less than the distance to B (d_{PB}). We want to know, how far away is point P from jumping to another cluster. That would obviously be:

$$e_P = min(d_{PA}\text{-}d_{PC},\ d_{PB} - d_{PC}) \quad (1)$$

We've labeled as e_P the distance from P to the closest edge. We can say that point P is e_P-away from switching the cluster.

At the end of iteration i, centroids need to be updated based on the new clusters' configuration. Let us assume that centroid A moved to A', centroid B moved to B' and centroid C moved to C'.

In the context shown in figure 2, the worst case scenario for point$P$ would be: point C got farther away from P by $|CC'|$ while point A got closer by $|AA'|$ and point B got closer by $|BB'|$. What would be the condition for P to stay in cluster C? Obviously that would be

$$e_P > |CC'| + |AA'| \quad (2)$$

and

$$e_P > |CC'| + |BB'| \quad (3).$$

To simplify a little the algorithm and reduce the computations, we can blend conditions (2) and (3):

$$e_P > 2 * max(|AA'|, |BB'|, |CC'|). \quad (4)$$

That being said, we've just found a way of determining whether a point is part of the 'border' list or not.

But, we're still not ok because checking the inequality for each of our data elements at each iteration gets us back to where we started. To avoid such computations, we can map all of our data elements into wider intervals for the value of e, as shown in algorithm 2:

The algorithm 2 groups points with close values of e so that instead of visiting each data element and checking against their close-to-the-edge distance, we can do that that for the entire group. This compromise is the key of the entire optimization. The *WIDTH* constant has a big influence on the optimization. If the value of *WIDTH* is to small, then the

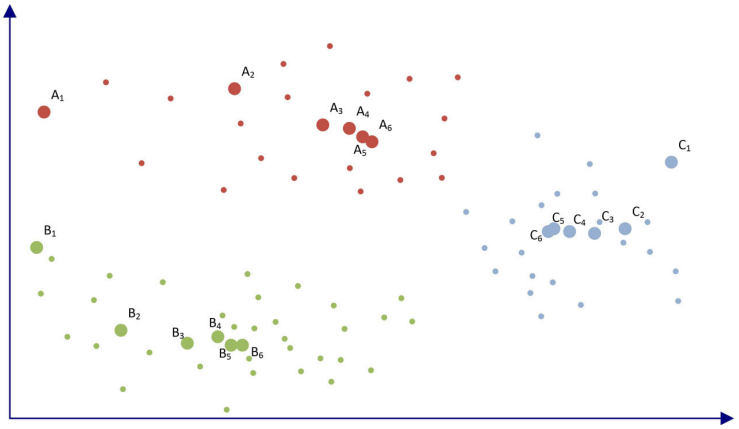

Fig. 1. Example of centroids evolution

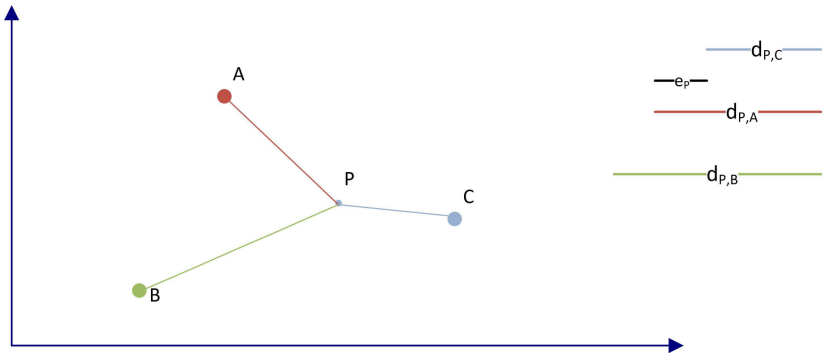

Fig. 2. Edge condition for data elements

Algorithm 2 Optimized K-Means algorithm

1. Define constant *WIDTH*
2. Define intervals I_i = *[i * WIDTH, (i+1) * WIDTH)* and tag them with value *i * WIDTH*
3. Mark the entire data set to be visited
4. For each point to be visited
5. Compute $e = min(d_{PC_l} - d_{PC_w})$ where C_w is the center of the winner (closest) cluster and C_l, $l=1..k$, $l \neq w$ stands for all other centroids
6. Map all points with $i * WIDTH < e < (i+1) * WIDTH$ to interval $i * WIDTH$ where i is a positive integer
7. Compute new centroids C_j, where $j=1..k$ and their maximum deviation $D = max(|C_jC_j'|)$
8. Update I_i's tag by subtracting $2 * D$ (points owned by this interval got closer to the edge by $2 * D$)
9. Pick up all points inside intervals whose tag is less or equal to 0, and go to *4* to revisit them

number of intervals will increase and the workload involved by checking and updating the intervals at each iteration can increase significantly. If the value of *WIDTH* is to big, then the number of points for each interval increases, and even though the number of intervals is reduced, the performance loss is obvious when a big interval is marked for re-visiting.

One can easily observe that the quality of the final clusters is not affected by the proposed optimization. At each iteration, the composition of clusters is exactly the same as if we would have run the standard K-Means.

IV. Prototype Evaluation

To validate the potential of our K-Means optimization, we've implemented a prototype that runs on data sets composed of 2D points having their coordinates greater than 0 and less than 1. There have been randomly generated data sets of different sizes ranging from 100,000 points to 5,000,000 points. The random numbers generator used for generating the points coordinates, made use of an uniform distribution. The data sets were split into 4, 8 or 12 clusters. The points belonging to each cluster have been grouped into 0.1 wide intervals (*WIDTH = 0.1*). The running time of the optimized algorithm was compared to the running time of the standard K-Means processing of the same data sets in exactly the same conditions (same centroids, same execution environment). Experiments were conducted on a machine consisting of an Intel i7-4700MQ CPU, 8 GB RAM memory. Many runs were carried out for each use case, and the running times were averaged. Let us have a look at the results.

Table I presents the running time for both optimized and standard versions of the K-Means algorithm where the data

TABLE I
OPTIMIZED K-MEANS VS. STANDARD K-MEANS RUNNING TIMES - 4 CLUSTERS

Data set size	Running Time Standard K-Means (ms)	Running Time Optimized K-Means (ms)	Improved by(%)
100,000	6300	1967	68.77
250,000	14382	4528	68.51
500,000	40321	11402	71.72
750,000	55088	15943	71.05
1,000,000	73957	21436	71.01
2,000,000	140339	42962	69.38
5,000,000	420516	116630	72.26

TABLE II
OPTIMIZED K-MEANS VS. STANDARD K-MEANS RUNNING TIMES - 8 CLUSTERS

Data set size	Running Time Standard K-Means (ms)	Running Time Optimized K-Means (ms)	Improved by(%)
100,000	75664	28418	62.44
250,000	148472	57485	61.28
500,000	629777	224277	64.38
750,000	1004100	359230	64.22
1,000,000	1096291	396923	63.79
2,000,000	2798319	1006918	64.01
5,000,000	9685205	3355996	65.34

sets were divided into 4 clusters.

The running time has been reduced by up to 72.26%

Table II, presents the running time for both optimized and standard versions of the K-Means algorithm where the data sets were divided into 8 clusters. The running time has been reduced by up to 64.48%, which is less than the improvement shown in case of only 4 clusters. That can be explained by the fact that the more clusters we use, the higher the chances are for a bigger maximum centroid deviation ($\max(|C_iC_i)$, where $i = 1..K$), which decrease the chances of fulfilling inequality (4) causing more points to become part of the 'border' area.

Table III, presents the running time for both optimized and standard versions of the K-Means algorithm where the data sets were divided into 12 clusters. The best improvement we have got here rises up to 53.42% which again, is less than the improvement we have got for 4 and 8 clusters. These results confirm that a higher number of clusters results in wider 'border' areas, reducing the computational gain.

V. CONCLUSIONS AND FUTURE WORK

The paper introduces an optimized version of the K-Means algorithm. The optimization refers to the running time. Optimization comes from the considerable reduction of the data space that is re-visited at each loop.

The algorithm defines a 'border' area made of those points that are close enough to the edge of their cluster so that the next centroids move could cause them to switch clusters.

A prototype implementation of a domain specific data set has been evaluated. The implementation assumes the data set is made of 2D points with their coordinates between 0 and 1. The data set has been generated using a uniform distribution generator.

TABLE III
OPTIMIZED K-MEANS VS. STANDARD K-MEANS RUNNING TIMES - 12 CLUSTERS

Data set size	Running Time Standard K-Means (ms)	Running Time Optimized K-Means (ms)	Improved by(%)
100,000	53879	27388	49.16
250,000	186923	90140	51.77
500,000	323584	158888	50.89
750,000	681331	317328	53.42
1,000,000	809675	377522	53.37
2,000,000	1650657	776873	52.93
5,000,000	4835146	2324173	51.93

Running times for 4, 8 and 12 centroids have been compared to the running times of the standard K-Means algorithm, showing a reduction ranging from 49.16% to 72.26 %. At this stage we can not confirm that the improvement shown by the prototype will be held in all real-world use cases, but the results are certainly encouraging.

Our future research will focus on the domain-independent implementation and evaluation of the algorithm. The algorithm's scalability as well as data sensitivity (form and distribution) are to be analyzed with the purpose of concluding upon what would be the best and the worst environments (data and configuration) for the algorithm.

A natural question would be if the algorithm can be improved. One can easily note that the grouping intervals' width might be a point of vulnerability for the performance gain. The lower the width, the more intervals are to be checked; the higher the width, the more points are to be checked when their interval's distance to the edge goes bellow 0. A tradeoff has to be made here, therefore we will also focus on designing an auto-calibration algorithm for the interval width.

Implementations for parallel and distributed environments, as well as integration with existing frameworks (Hadoop, Mahout) are also on our goals list as they could lead our way towards big data sets.

***Abstract*—Handwritten Signature Verification (HSV) systems have been introduced to automatically verify the authenticity of a user signature. In offline systems, the handwritten signature (represented as an image) is taken from a scanned document, while in online systems, pen tablets are used to register signature dynamics (e.g., its position, pressure and velocity). In online HSV systems, signatures (including the signature dynamics) may be embedded into digital documents. Unfortunately, during their lifetime documents may be repeatedly printed and scanned (or faxed), and digital to paper conversions may result in loosing the signature dynamics. The main contribution of this work is a new HSV system for document signing and authentication. First, we illustrate how to verify handwritten signatures so that signature dynamics can be processed during verification of every type of document (both paper and digital documents). Secondly, we show how to embed features extracted from handwritten signatures within the documents themselves (by means of 2D barcodes), so that no remote signature database is needed. Thirdly, we propose a method for the verification of signature dynamics which is compatible to a wide range of mobile devices (in terms of computational overhead and verification accuracy) so that no special hardware is needed. We address the trade-off between discrimination capabilities of the system and the storage size of the signature model. Towards this end, we report the results of an experimental evaluation of our system on different handwritten signature datasets.**

I. Introduction

BIOMETRIC recognition refers to the automatic identification of a person based on his/her anatomical (e.g., fingerprint, iris) or behavioral (e.g., signature) characteristics or traits. This method of authentication offers several advantages over traditional methods involving authentication tokens (including ID cards) or passwords: it ensures that the person is physically present at the point-of-identification; it makes unnecessary to remember a password or to carry a token. The most popular biometric traits used for authentication are face, voice, fingerprint, iris and handwritten signature.

In this paper, we focus on handwritten signature verification (HSV). Since people are used to signing documents in their everyday life, HSV is a natural and trusted method for user identity verification. HSV can be classified into two main categories, depending on the hardware used and on the method used to acquire data related to the signature: online and offline signature verification. Offline systems take handwritten signatures (represented as an image) from scanned documents. This means that offline HSV systems only process the 2D spatial representation (i.e., the shape) of the signature. On the contrary, online systems use specific hardware (e.g., pen tablets) to register pen movements during the act of signing. As a result, online HSV systems are able to process dynamic features, such as the time series of the pen's position, pressure, velocity, acceleration, azimuth and elevation. Online signature verification has been shown to achieve higher verification rate than offline signature verification [1], [2], [3], but unfortunately it suffers from several limitations.

First, the online approach works only for digital documents and it is currently unavailable for paper documents. In particular, during a document's life cycle, when a document is being printed, scanned or faxed, the signature dynamics are unavoidably lost. To overcome this limitation, there is an emerging need of designing new methods capable of embedding the signature dynamics within paper documents, along with the signature shape (the 2D spatial representation) which is the only feature usually preserved after printing. This will enable one to verify the authenticity of a document, regardless of its current (paper or digital) format, which is particularly important when the same document is repeatedly printed and scanned (or faxed) in a typical workflow.

Secondly, current online approaches raise privacy and security concerns since they store the genuine signatures of each user on a remote database server. Indeed, both commercial [4], [5], [6] and HSV systems proposed in the scientific literature [1], [7], [8] store genuine signatures of the users in a central database: during verification, specific signature data is retrieved from the database and compared to the actual signature. From the security viewpoint, an intruder who gains unauthorized access to the database containing dynamics of users' signatures can use this information to produce accurate forgeries. From the viewpoint of privacy, the recent news about the NSA surveillance program (see e.g., [9]) have definitely reduced our trust in providing sensitive data (such as signature features) to third parties. In order to address these privacy and security concerns, we need to design novel HSV

978-83-60810-58-3/$25.00

systems capable of supporting the online approach without using signature databases.

Thirdly, the online approach is often feasible only if special purpose hardware is available. Indeed, handwritten signatures are usually acquired by means of digitizing tablets connected to a computer, because smartphones and mobile tablets (that have worse sensitivity) may be not able to support the verification algorithms. As a result, the range of possible usages of the verification process is strongly limited by the hardware needed. To overcome this limitation, one needs techniques capable of verifying signatures acquired by smartphones and tablets in mobile scenarios.

To the best of our knowledge, there is no existing solution which is able to address all of those critical points simultaneously. The approach described in [1] addresses only the first point: by performing offline verification using online handwriting registration, the online approach is (partially) applicable for verifying signatures taken from paper documents, but this framework is not supported by mobile devices and requires an online signature database. Offline HSV solutions (such as [2], [10], [11]) address only the second point: they do not use remote signature databases, but unfortunately they are not able to take into account signature dynamics. Online HSV systems (such as [4], [5], [6], [7], [8]) address only the third point: they are supported by mobile devices, but cannot verify signatures taken from paper documents and are inherently based on remote database servers.

The goal of this paper is to address all of the above challenges by considering new mobile scenarios in which HSV can play a significant role. The novelties of our approach lie mainly in the following three aspects.

First, we present a new system to sign and verify documents so that the online approach is applicable for all kind of documents (including paper documents). It performs verification in a way that the signature dynamics can be used also when the signed documents are printed and scanned, thus allowing the online approach to operate in those cases where only the offline approach was available.

Secondly, we show how to embed features extracted from handwritten signatures within the documents themselves, so that no remote signature database is needed. To accomplish the embedding task, we make use of 2D barcodes. The main challenge here is to be able to store the signature dynamics (into documents), within the limited capacity of barcodes: on the one hand, we need to use a signature model whose size is small, while, on the other hand, we need to increase the capacity of state-of-art-barcodes. For this reason, we designed a color barcode denoted as High Capacity Colored 2-Dimensional (HCC2D) code [12], [13], which is well-suited for this framework because of its high data capacity (if compared with state of art barcodes). Specifically, it is capable of encoding about $4KB/inch^2$ (effective data density) with a success rate of 90% (reliability) [14], [15]. We designed a new barcode decoding algorithm based on graph drawing methods [16], which is able to run in few seconds even on mobile devices and to achieve nonetheless high accuracy in the recognition phase. The main idea of our algorithm is to perform color classification using force-directed graph drawing methods: barcode elements which are very close in color will attract each other, while elements that are very far will repulse each other. Figure 1 illustrates samples of HCC2D codes with 4 and 8 colors.

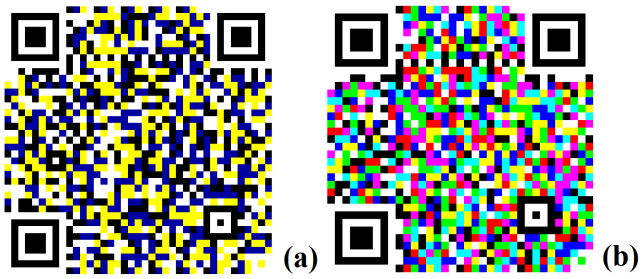

Fig. 1. Samples of the High Capacity Colored 2-Dimensional (HCC2D) code: (a) 4 colors and (b) 8 colors. Figure taken from [12]. (Viewed better in color).

Thirdly, we propose a method for the extraction and verification of signature dynamics which is compatible to a wide range of mobile devices (in terms of computational overhead and verification accuracy) so that no special hardware is needed. The main challenge here is to achieve a high verification performance, despite constrains due to the limited computational resources and pressure accuracy of mobile phones. For this reason, we designed a verification algorithm that can be run on mobile phones in fractions of a second and that weights the signature features based on the accuracy of the given device.

In order to assess the precision and recall of our HSV system, we conduct an experimental study whose results are reported for different data sets of signatures.

II. A Logical View of the HSV System

Our HSV system consists of three main modules, corresponding to three main phases. We next describe (from a logical point of view) the registration phase, the document signing phase and the document verification phase with our system.

A. The Registration Phase

The objective of the registration phase is to compute a compact representation of the signature dynamics of a given person. The process starts with the user writing his/her signature on the device's screen and ends with the generation of a biometric template representative of the user signatures. Figure 2 shows a high level, logical view of the registration procedure.

The registration phase consists of the following tasks. First, in order to take into account the variability among signatures produced by the same user, signature dynamics for at least three signatures are captured. Then, the features extracted from the various signatures are combined to form a template

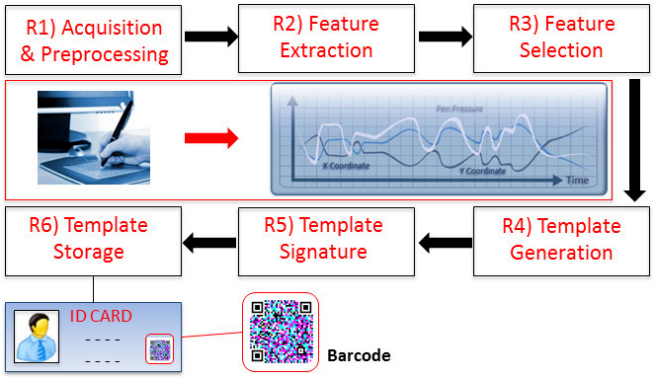

Fig. 2. Registration procedure for the proposed HSV system. (Viewed better in color).

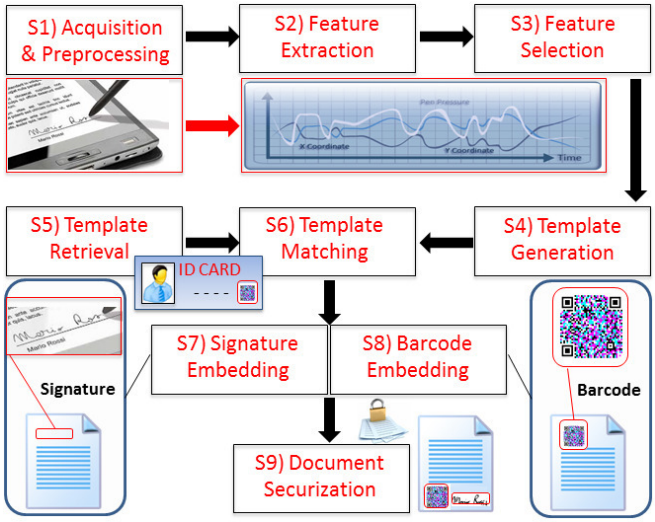

Fig. 3. Document signing procedure for our HSV system. (Viewed better in color).

representative of the given user. Finally, the template is digitally signed and securely stored in a barcode. The barcode is embedded within a card which is released only to the user to whom the template belongs, in order to address any privacy concern. We remark that in order to make this scenario possible, it is necessary that the barcode is capable of storing the whole template and the digital signature associated with it. We will describe in detail how to perform identity registration in Section III.

B. The Document Signing Phase

The objective of this phase is to sign documents on mobile devices so that: the signature dynamics are embedded within the documents themselves, (along with the spatial representation of the signature); the signature dynamics survive the document's life cycle, when a document is being printed, scanned or faxed.

Figure 3 shows a logical view of the document signing phase, which consists of the following steps.

1) Template Generation of the User to Be Verified (S1-S4): We need to generate a compact feature synthesis of the person to verify. In order to accomplish this task, we proceed through steps S1 to S4, which are equivalent to steps R1-R4 of the Registration phase, except for the fact that there is no need to capture three or more writings of the handwritten signature to be verified.

2) Retrieval of the Secure Template (S5): We retrieve the secure template (generated at the end of the registration phase) of the user corresponding to the claimed identity of the user to be verified.

3) Template Matching (S6): We compare the signature dynamics related to the identity to verify with the secure template retrieved at the previous step. This is a crucial step, because we do not allow unrecognized signatures to be embedded within documents. Note that in order to enhance security, we use strong authentication based on something the user has (i.e., a card storing the registered template) with something the user is (features of his/her handwritten signature captured at the moment).

4) Signature Embedding (S7): If the matching is successfully, we embed the spatial representation of the signature within the document.

5) Barcode Embedding (S8): If the matching is successfully, we embed the signature dynamics of the signature within the document by means of a high capacity barcode such as the HCC2D code.

The elements that need to be embedded by means of barcodes include the following:

- The template representing the signature dynamics.
- The timestamp of the signature.
- Information about the document the user is going to sign.
- The digital signature of all the above data.

The last three elements ensure that the barcode storing the signature dynamics cannot be copied and pasted on a new document for producing a forgery.

6) Document Securization (S9): The secure document is generated (with the signature image and the barcode). Because of the binding [signature features, document], no other document can be signed with features that are used for the given document.

C. The Document Verification Phase

The aim of the verification phase is to verify the authenticity of a handwritten signature. This phase ends with the authenticity of the document signature being accepted or rejected. Figure 4 shows a high level view of the document verification procedure, consisting of the following tasks.

1) Barcode Reading (V1): The objective of this step is to decode the HCC2D code which has been encoded in the document signing phase. This allows us to retrieve the secure template which has been stored within the barcode, along with the document metadata, the timestamp and the digital signature.

2) Template Retrieval (V2): The signature features used to sign the given document are retrieved from the barcode.

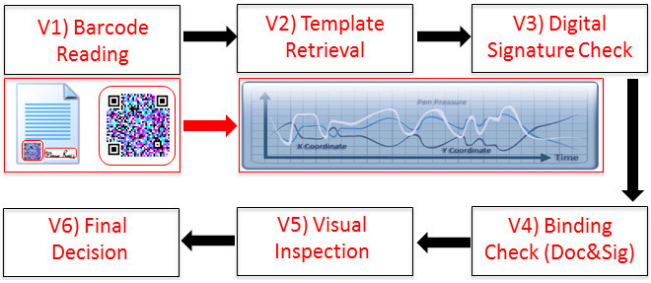

Fig. 4. Document verification procedure for our HSV system. (Viewed better in color).

3) Digital Signature Check (V3): The digital signature is checked before the retrieved data are processed, in order to ensure that they are not tampered with.

4) Binding Check (V4): The binding [signature features, document] is retrieved and showed to the user, in order to verify that those features were previously associated with the given document.

5) Visual Inspection and Final Decision (V5-V6): The signature matching is graphically showed to the user so that he/she is able to sense the similarity and the likelihood of a forgery. This is a crucial step because it ensures that the final decision is taken by the user.

In this stage, the shape of the signature is reconstructed from the signature dynamics stored in the barcode. We cannot completely trust the signature shape that is pasted on the document because it may be a forgery, but we can trust the reconstructed shape because data stored in the barcode are digitally signed.

III. The Signature Verification Algorithm

In this Section, we describe (from a technical point of view) our signature registration and verification methods.

A. Signature Registration Phase

The registration phase with our system starts with the user writing his/her signature on the device screen and ends with the generation of his/her biometric template (representative of his/her signature dynamics), which is embedded within a document (issued to the user) by means of a high capacity barcode. The procedure is as follows:

- First, the user is requested to make genuine signature 3 times.
- Once signatures are acquired, the system performs an analysis of the intra-person variability of the signature features. This allows the system to determine whether to accept or reject the 3 signatures upon which the user model has to be built: if variability is too high, the user is requested to repeat the acquisition step.
- If the intra-person variability is acceptable, for each signature, for each sampled point, the following elements (signature dynamics) are captured:
  - *Event Type*. The event which led to the generation of a sample can be of three different types: Pen-down, i.e., a pressed gesture has started (the motion contains the initial starting location); Pen-up, i.e., a pressed gesture has finished (the motion contains the final release location as well as any intermediate points since the last down or move event); Pen-Move, i.e., a change has happened during a press gesture (between a Pen-down and a Pen-up).
  - *Time*. The instant in which the pressed gesture has occurred (expressed as milliseconds since the first gesture event of the signature).
  - *X-Y coordinates*. The X and Y coordinates of the sampled point (expressed in pixels).
  - *Pressure*. The pressure with which the screen is pressed (expressed with a value ranging from 0, i.e., no pressure, to 1, i.e., maximum pressure).
- The signature dynamics of the three signatures are stored in a high capacity barcode which is embedded within a document.

Note that derivatives such as velocity or higher-order derivatives such as acceleration are not stored in this stage, as they can be computed at run-time during the verification phase. This is because we aim at minimizing the storage size of the signature model to be embedded by means of barcodes.

B. Signature Verification Phase

The verification phase determines the acceptance or the refusal of the claimed identity based on the similarity between the registered signature and the signature to verify. Our system can compute the similarity score in different ways depending on whether signatures are segmented or not (see below) before applying the verification algorithm, where signature segmentation refers to the process of partitioning the signatures into multiple strokes (i.e., segments). In our case, strokes are separated by discontinuities represented by pen-up events.

In the reminder of this section, we first describe the modes in which the system operates; then, we illustrate the verification algorithm. The same algorithm is used by the two modes: the main change is the way in which the algorithm is applied. We distinguish a segmented and an unsegmented mode.

- *Segmented Mode*. The matching is done by comparing each segment (or sub-sequence) of the signature to verify with the corresponding segment of the registered signature. This means that the verification algorithm is applied several times (for each pair of segments) and the final decision (acceptance or refusal) is taken according to the result of each segment pairing.
- *Unsegmented Mode*. The matching is done by comparing the whole sequence representing the signature to be verified with the corresponding registered signature. The verification algorithm is applied just once and the output is the final decision.

Now we turn to describe our verification algorithm, which is a scheme based on the Dynamic Time Warping (DTW)

algorithm. DTW is a popular and robust technique for comparing time series, capable of handling time shifting and scaling, which has been successfully used in literature for HSV (prevalently for online approaches like the methods proposed in [17], [18], but also for offline approaches such as the method described in [19]). We describe our verification stage for the segmented mode only, being the unsegmented mode a sub-case of the segmented mode in which the number of segments is exactly one.

The algorithm is as follows. First, for each feature f (such as X-Y coordinates, Pressure, X-Y Velocity, X-Y Acceleration) the following n-dimensional vector is computed, where n is the number of segments in which each of the three signatures is divided. S_j^i represents the i^{th} segment (related to feature f) of the j^{th} signature as a 1D time series, while $DTW(S_j^i, S_k^i)$ denotes the 1D Dynamic Time Warping method applied to the i^{th} segments of the j^{th} and k^{th} signatures.

$$\left\| \begin{matrix} f^1 \\ f^2 \\ ... \\ f^n \end{matrix} \right\| = \left\| \begin{matrix} \frac{DTW(S_1^1,S_2^1)+DTW(S_1^1,S_3^1)+DTW(S_2^1,S_3^1)}{3} \\ \frac{DTW(S_1^2,S_2^2)+DTW(S_1^2,S_3^2)+DTW(S_2^2,S_3^2)}{3} \\ ... \\ \frac{DTW(S_1^n,S_2^n)+DTW(S_1^n,S_3^n)+DTW(S_2^n,S_3^n)}{3} \end{matrix} \right\|$$

Then, once the $\|f\|$ vector is computed for each feature of interest, we get a $\|X\|$ and a $\|Y\|$ vector (x and y coordinates), a $\|P\|$ vector (pressure), a $\|V_x\|$ and a $\|V_y\|$ vector (velocity on x and y directions), a $\|A_x\|$ and a $\|A_y\|$ vector (acceleration on x and y directions).

Finally, we combine the metrics with the following weighted sums, by giving a weight to each of the kinds of signature features.

$$\left\| \begin{matrix} d^1 \\ d^2 \\ ... \\ d^n \end{matrix} \right\| = \left\| \begin{matrix} w_x \cdot X^1 + w_y \cdot Y^1 + w_p \cdot P^1 + ... + w_{a_y} \cdot A_y^1 \\ w_x \cdot X^2 + w_y \cdot Y^2 + w_p \cdot P^2 + ... + w_{a_y} \cdot A_y^2 \\ ... \\ w_x \cdot X^n + w_y \cdot Y^n + w_p \cdot P^n + ... + w_{a_y} \cdot A_y^n \end{matrix} \right\|$$

The weights w_x, w_y, w_p, ... , w_{a_y} must be experimentally determined as they are dependent on the device. For instance, even if the pressure change is generally a very discriminating feature (often leading to a high w_p coefficient), the influence of the capability of sensing pressure change (which is specific for each device) is significant and the weight should be lowered accordingly on low end devices.

The output distance vector $\|d\|$ represents the "distance" among the three signatures. The whole process is repeated twice; the first time using genuine registered signatures ($\|d_g\|$ as output), the second time using signatures to be verified ($\|d_v\|$ as output).

Finally, we compare the two distance vectors with each other. The similarity function is defined as follows.

$$Similarity\left(\left\| \begin{matrix} d_v^1 \\ ... \\ d_v^n \end{matrix} \right\|, \left\| \begin{matrix} d_g^1 \\ ... \\ d_g^n \end{matrix} \right\|\right) = \left(\sum_{i=1}^{n} F(d_v^i, d_g^i)/n\right)$$

where n is the number of segments and the $F()$ function is defined as follows (c is a tolerance coefficient).

$$f(d_v^i, d_g^i) = \begin{cases} 1 & \text{if } d_v^i \leq c \cdot d_g^i \\ 0 & \text{otherwise} \end{cases}$$

The higher the value of the similarity function, the more likely the claimed identity is correct. The final decision (accept or reject the claimed identity) depends on whether the similarity score is above or below of a given threshold.

Note that all the computation happens at verification time (including the tasks which process genuine signatures). We cannot move any computation at registration time, because the priority is to minimize the storage size of the output of the registration phase (to be embedded by means of barcodes).

IV. Experimentation

In this section we present experimental results concerning identity verification with our system. The accuracy of a recognition algorithm is generally measured in terms of two potential types of errors: false negatives (*fn*) and false positives (*fp*). False positives are cases where a claimed identity is accepted, but should not be, while false negatives are cases where a claimed identity is not accepted, while it should be. Two metrics building on true/false positives/negatives (*tp,fp,tn,fn*) are widely adopted: precision and recall. Recall ($tp/(tp+fn)$) is the probability that a valid identity is accepted by the system (i.e., true positive rate) while precision ($tp/(tp+fp)$) is the probability that a claimed identity which is accepted by the system is valid. F-measure (which is the harmonic mean of precision and recall) combines both metrics into a global measure ($f\text{-}measure = (2 \times prec \times recall)/(prec + recall)$). A more general f-measure is generally defined as function of a β parameter, which is used to weight f-measure in favor of precision ($\beta < 1$) or recall ($\beta > 1$).

A threshold on the similarity score must be identified for determining whether two signatures are similar (accept the identity) or significantly different (reject the identity). The higher the threshold, the higher the precision (i.e., the lower the risk of accepting invalid identities). However, a high threshold also decreases the recall of the system (i.e., the higher the risk to reject valid identities).

The performance of the proposed scheme has been assessed in terms of false positives, false negatives, precision, recall and f-measure on two kinds of dataset: first, on a standard dataset (i.e., the SVC database [20]), involving WACOM digitizing tablets, 100 sets of signature data, with 20 genuine signatures and 20 skilled forgeries for each set; secondly, on a custom dataset, built for this purpose using different smartphones (mainly from the Google Nexus family), involving 250 signatures partitioned into 5 sets of signature data, with 10 genuine signatures and 40 skilled forgeries for each set.

We start by describing the experimental set-up:

- For each user, 3 genuine signatures out of 20 (first dataset) or out of 10 (second dataset) were selected in rotation to form the template of the user.
- Every time a user template (building on 3 signatures) is selected, the remainder 7 genuine signatures were matched to the template itself in order to compute the false rejection rate (i.e., the false negatives rate) by means of the matching error. This process is repeated for every user.
- Given a user, the skilled forgeries (provided by users other than the one named) were matched to his/her template in order to compute the false acceptance rate (i.e., the false positives rate). This process is repeated for every user involved in the experiment.
- As for the first dataset, the SVC 2004 competition [20] consisted of two separate signature verification tasks, each of which was based on a different signature database. Each database of the SVC 2004 has 100 sets of signature data. Each set contains 20 genuine signatures from one signature contributor and 20 skilled forgeries from five other contributors. Contributors were asked to write on a digitizing tablet (specifically, a WACOM Intuos tablet).
- As for the second dataset, we used a custom dataset, built on data acquired by smartphones (i.e., no special purpose devices). We collected 250 handwritten signatures. Each user was requested to make genuine signature 10 times and to provide 10 (skilled) forgeries of any other user. The signatures were partitioned into 5 sets of signature data, where each set contains 10 genuine signatures of a specific user and 40 skilled forgeries of the signature of that user, produced by the other users involved in the experiment.

The experimental results in terms of precision, recall and f-measure (that vary according to the chosen thresholds) have been used for tuning the thresholds in order to get better performance (see Section IV-A). Then, once we fixed the threshold on the similarity score, we evaluated how subsampling the sequences (forming each signature) affected the overall precision and recall. This allowed us to identify the best trade-off between discrimination capabilities of the system and the storage size of the handwritten signature model, in order to ensure that the signature model fit into 2D barcodes (see Section IV-B).

The remainder of this section illustrates our results, which are in line with other work in the area, despite storage constrains due to barcode capacity and limitations in sensing and processing related to common devices such as smartphones and tablets.

A. Tuning the Thresholds to Enhance Precision and Recall

In this section we tune system thresholds by analyzing the curves of precision, recall and f-measure in order to get better performance (thresholds determine whether to accept or reject the claimed identity).

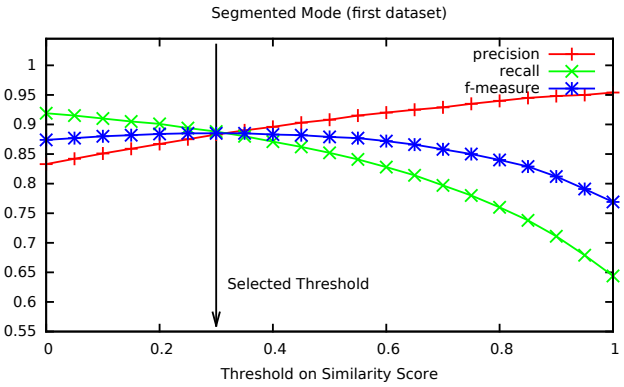

Fig. 5. 1^{st} dataset (SVC); segmented mode. Precision, recall and f-measure as functions of threshold on similarity score. (Viewed better in color).

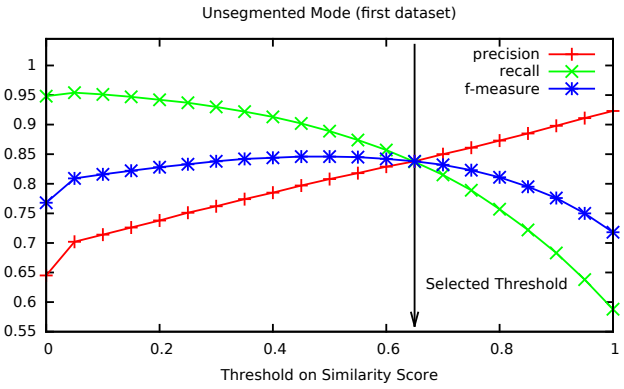

Fig. 6. 1^{st} dataset (SVC); unsegmented mode. Precision, recall and f-measure as functions of threshold on similarity score. (Viewed better in color).

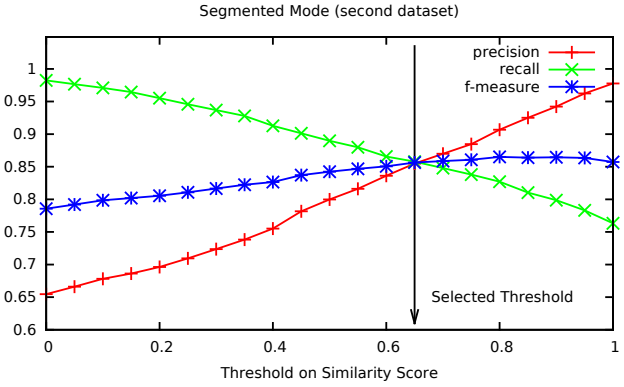

Fig. 7. 2^{nd} dataset; segmented mode. Precision, recall and f-measure as functions of threshold on similarity score. (Viewed better in color).

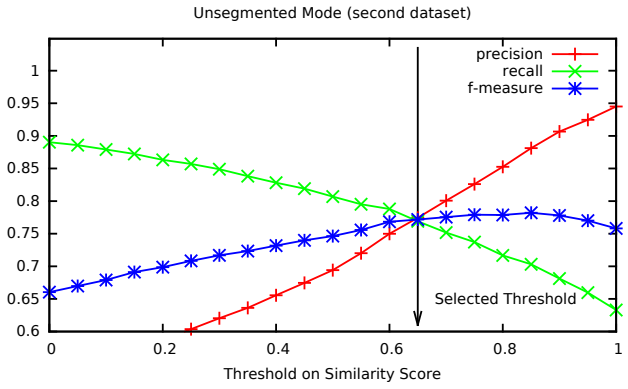

Fig. 8. 2^{nd} dataset; unsegmented mode. Precision, recall and f-measure as functions of threshold on similarity score. (Viewed better in color).

The four graphs of Figures 5, 6, 7 and 8 show the curves of precision, recall and f-measure as functions of threshold on the similarity score for each of the two working modes and for each of the two datasets. Claimed identities are accepted whenever the score is above the threshold, rejected otherwise. The higher the threshold, the higher the precision, but the lower the recall. The threshold which maximizes the f-measure is identified for each working mode and highlighted with an arrow in each graph. The best results (plotted in Figures 5 and 7) were achieved using the segmented mode. This is in agreement with the intuition that working at low granularity (i.e., comparing the subsequences segmented by pen-up events of a first signature with the corresponding subsequences of a second signature) leads to a more accurate comparison than just making a single comparison of the two signatures (considered in their entirety).

Precision and recall jointly reach a maximum of 89.50% in the graph of Figure 5 (SVC dataset). For this reason, at this operating point, where the curves of precision and recall cross each other, the false positive rate (also called the false acceptance rate - FAR) and the false negative rates (also called the false rejection rate - FRR) are both 10.50% as complementary values. This value is denoted as the equal error rate (EER), that is, the point where FAR equals FFR. We got good results, considering the EERs reported at the SVC competition: for instance, the EERs related to the SVC training set (with skilled, not random forgeries) range from a low of 5.50% to a high of 31.32% in the first verification task [21] and from 6.90% to 21.89% in the second verification task [22].

B. Trade-off between Precision/Recall and the Model Size

In this section we address the trade-off between precision and recall of the system and the space used for storing models of signatures. This allow us to show how to embed features extracted from handwritten signatures within the documents themselves by means of barcodes.

Consider that the size of a model depends on the number of samples with which we represent each handwritten signature. We expect that the more the space available for storing models of signatures, the more the precision and recall of the system are; at least, until a specific threshold value is reached, after which precision and recall remain almost constant. This is consistent with the intuition that getting more samples than needed (the limit is due to the precision of the acquiring devices) does not improve the overall performance.

Signatures data were subsampled as follows: 1:1 (all the samples captured by the device are kept), subsampled 2:1 (1 sample out of 2 is filtered out), subsampled 3:1 (2 samples out of 3 are filtered out), ..., subsampled 20:1 (19 samples out of 20 are discarded). For instance, from a signature which is 600 samples length we produce subsampled signatures whose length is 300 (subsampled 2:1), 200 (subsampled 3:1), ..., 30 (subsampled 20:1) samples. However, the actual signature length (expressed as number of samples) depends not only on the sampling rate of the device but also on the path length of the handwritten signature (expressed as length unit such as the millimeter).

In order to isolate the impact of the path lengths so that results do not depend on the length of the words forming the signature, we introduce the concept of samples density as the number of samples per unit length. In order to compute the samples density, the number of samples of a given signature is divided by the total path length of the signature itself. This is computed in pixels and is then converted from pixels to millimeters by referring to the number of points per inch (ppi) characterizing the device screen and to the (inches to millimeters) conversion factor. As a result, samples density is expressed here as number of samples per millimeter, which is a measure free from the signature word lengths and from device-dependent features such as the screen size.

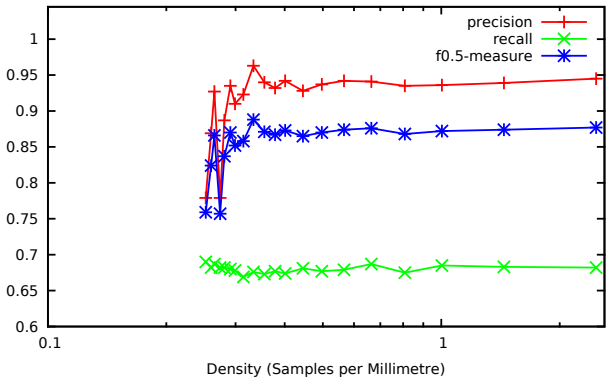

Fig. 9. Precision, recall and f-measure as functions of density (expressed as samples per millimeter) shown in log scale (Viewed better in color).

Figure 9 shows the precision, recall and f-measure of our system as functions of samples density. We used the f0.5-measure (with β equal to 0.5), which weights precision higher than recall. For our framework, increases in precision (that decrease the number of false positives) may be considered more important than increases in recall (that reduce the number of false negatives), since if a false instance is misclassified as

true (i.e., a false positive), a forgery is accepted as genuine, while, if a true instance is misclassified as false (i.e., a false negative), the user has only to re-enter the signature. The X-axis is on a log scale for visual clarity. On the far right side of the curves data are not subsampled (all the samples are kept), while the further we go towards the left side of the curves the more the data are subsampled (up to a maximum of 20:1). In absolute terms, the average path length of the signatures of our dataset was around 232 millimeters and the average number of samples (captured by the device for a single signature) was 581. Samples density ranges from around 2.5 to 0.125 samples per millimeter. This plot shows an interesting trend of decreasing precision and recall with decreasing samples density. The curves are almost constant initially (until a subsampling rate of 10:1 and a density of around 0.25), while at lower densities (or higher subsampling rates) the curves decrease sharply. This means that we are able to reduce the size of models of signatures by a factor of 10 (with respect to the sequence of samples acquired by the mobile device) without significant impacts on the overall precision and recall of the system. This, in turn, allows us to store models of signatures by means of barcodes, making our framework applicable to practical scenarios.

V. Conclusions

Our work presented a new HSV system for document signing and authentication, whose novelties lie mainly in the following aspects. First, we showed how to verify handwritten signatures so that signature dynamics can be processed during verification of every type of document (including paper documents). Secondly, we illustrated how to embed features extracted from handwritten signatures within the documents themselves, so that no remote signature database is needed. Thirdly, we proposed a method which is supported by a wide range of mobile devices so that no special hardware is needed. Finally, we showed how to reduce the size of models of signatures without significant impacts on the overall precision and recall of the system. In our experiments, Precision and recall cross at 89.50 (first dataset) and at 85.15% (second dataset). This is an interesting result, if noting that we used mobile devices (that is, no special-purpose hardware) to capture the signature dynamics needed by our experiments.

***Abstract*— The paper presents a solution to the problem of movement tracking in images acquired from video cameras monitoring outside terrain. The solution is resistant to such adverse factors as: leaves fluttering, grass waving, smoke or fog, movement of clouds etc. The presented solution is based on well known image processing methods, nevertheless the key was the use of an appropriate conduct procedure. In order to obtain a real-time system the CUDA technology was involved.**

I. Introduction

THE problem of movement detection in images [4] appeared relatively early [6]. The astronomy world struggled with objects detection in images [8] of the night sky acquired by telescopes long before the era of modern computers. In first systems images were alternately displayed in front of an operator who was able to perform detection of a motion celestial body. In such systems a natural subconscious human ability of movement detection was involved [9], [10].

Excluding cheap and simple movement detectors or sensors (passive infrared, ultrasonic, or microwave) the task of motion detection with the use of video cameras [11] is based on digital image processing [5]. Many present-day computer systems begin the work from the stage of a differential image of two images [14], which next undergoes a series of processes [16]. The detection of a movement [3] is not the only result – in modern systems a trajectory of a motion body can be determined [1] or even identification of the detected object may be performed [2], [22].

In this paper we consider the problem of object movement tracking [7] in images acquired from video cameras [12] monitoring outside terrain [13]. The assumption was to elaborate a solution resistant to such adverse factors as: leaves fluttering, grass waving, smoke or fog, movement of clouds etc. A set of well known image processing methods [19] is adopted, and the key was the use of an appropriate conduct procedure. In order to obtain a real-time system the CUDA technology was involved.

The CUDA (*Compute Unified Device Architecture*) technology appeared quite unexpectedly in 2007 as a result of new Nvidia's GPUs branded GeForce 8. CUDA gave the software developers direct access to the virtual instruction set and memory of the parallel computational elements in GPUs.

CUDA is a parallel computing platform and programming model [24] that makes using a GPU for general purpose computing simple and elegant. At present, there are two main CUDA architectures available: Fermi (see Fig. 1) and Kepler. The Maxwell architecture (20 nm technology node) is just about to be launched onto the market. From the programmer's point of view [25] the new architecture brings a set of features, both hardware and software, that is known as the compute capability of a device.

The idea of combining image processing methods or computer vision techniques with CUDA technology started relatively early [15] and going on, being very popular.

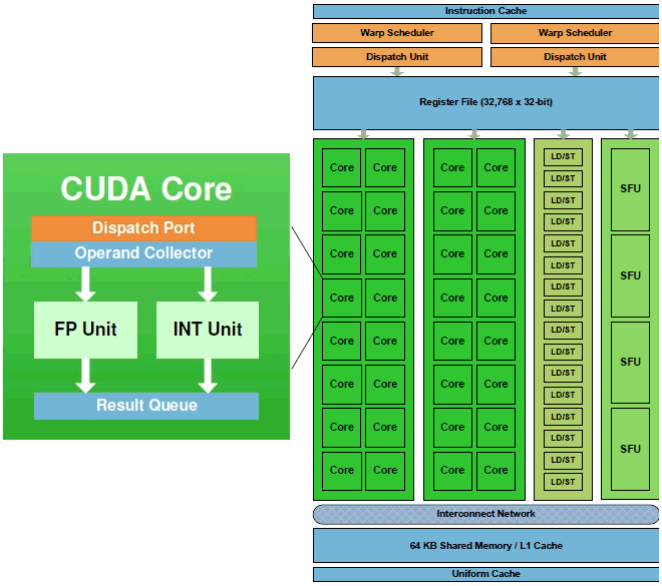

Fig. 1. CUDA core and Fermi SM (Streaming Multiprocessor) structure

978-83-60810-58-3/$25.00

This paper presents an announced earlier solution to movement detection and tracking, first elaborated using the Matlab environment, and finally independently implemented as the x86 and CUDA application.

The method was originally prepared for monitoring an airport's terrain, but for obvious reasons only neutral shots will be presented.

II. A Brief Presentation of the System

The used computer vision system consists of a PC equipped with a CUDA device (GTX 650 Ti, based on the Nvidia's Kepler architecture with compute capability 3.0), and an IP camera. It is supported by the Microsoft Visual Studio 2012 and CUDA 5.5 framework (the most important of it is the CUDA Toolkit component). Fig. 2 shows a visual scheme of the used computer vision system.

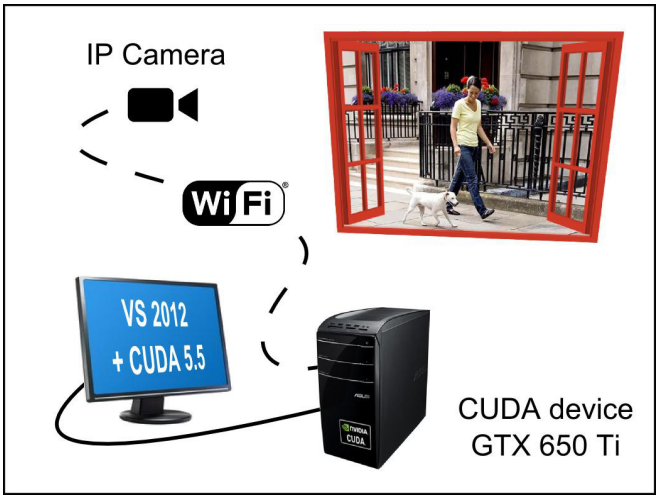

Fig. 2. Scheme of the used system

III. Matlab Implementation

The Matlab environment gives a possibility to elaborate the required procedure relatively fast. The amount of engineering tools included in the Matlab is impressive, nevertheless to obtain required speed the final implementation must be done with the CUDA technology.

A. Example source scenes

Source scenes have been acquired under various terrain and weather conditions. In this section two examples are presented (see Fig. 3). The first scene includes an object that is well visible, but also includes waving grass and clouds. The second scene is much more difficult, the object is comparatively small and there is a big tree with fluttering leaves. In both scenes a slight tilt effect is present between shots captured over a distance of a few seconds.

Fig. 3. The input source scenes

B. Compensation of the tilt effect

The initial obstacle is the tilt effect between shots, which may occur as a result of small vibration under the influence of wind or some mechanical reasons. To compensate the tilt one image is narrowed about a "frame" and matched with the second image in order to find a location with the smallest difference. Finally images of the scene are "framed" to guarantee the smallest difference between them. The source code in Fig. 4 gives details of the procedure. Fig. 5 shows (only) the cropping effect in the case of the second considered scene. The result will be visible in the case of difference images (the next section).

```

Fig. 5. The cropping effect of the tilt compensation – frames are visible

C. Getting a difference image

The difference image generation [16] is the first processing stage for a scene. This approach is extremely popular in astronomy [17] and is commonly referred to as difference image analysis (DIA). Results (presented in negative) obtained for the considered scenes (after the tilt compensation) are visible in Fig. 6 and Fig. 7.

Fig. 6. The difference image for the first scene in Fig. 3

Fig. 7. The difference image for the second scene in Fig. 3

D. Removing unwanted artifacts

The received differenced images include moving objects as well as include some unwanted artifacts. In the case of the first scene (Fig. 6) a remnant of the tilt effect is still visible (e.g. contour of a building), and in the second scene (Fig. 7) a tree is well exposed. Some of the artifacts are heavy, what is shown in Fig. 8, which is a 3D visualization of the content of Fig. 7.

At the first glance the task of removing unwanted artifacts seems to be difficult. To solve the problem it is necessary to notice that tracked objects generate comparatively low frequencies and the unwanted artifacts rather high frequencies (see Fig. 8). As an outcome of many trials it turned out that erosion, a fundamental operation of morphological image processing [18], gives the best results.

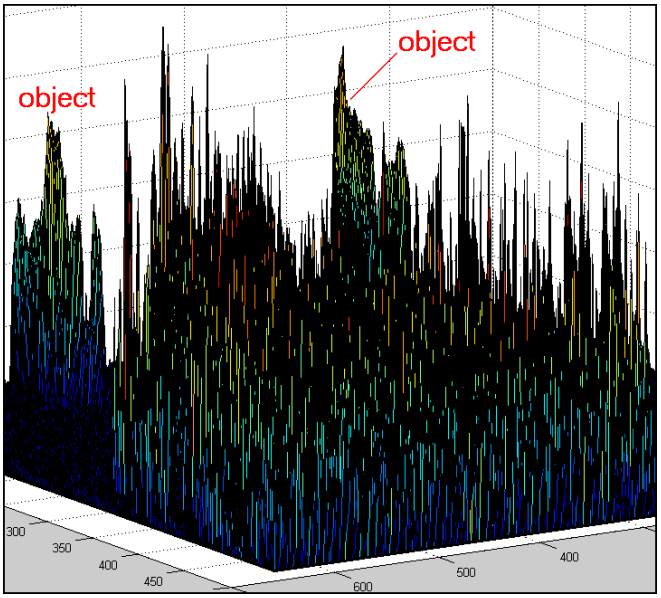

Fig. 8. A 3D visualization of the difference image from Fig. 7

The erosion operation is already available in Matlab as ready to use function (erode, imerode). Nevertheless, it was implemented "step by step" for gray-level images with the prospective x86 and CUDA implementations in mind. The source code in Fig. 9 shows details of the erosion implementation with a disk as the structuring element.

```
64    %erosion filter - "step by step"
65 -  SE=[  0     0     1     0     0;
66          0     1     1     1     0;
67          1     1     1     1     1;
68          0     1     1     1     0;
69          0     0     1     0     0]
70 -  [row col]=size(I_out1(:,:,1));
71 -  V=256*ones(5,5);
72 -  for i=1+2:row-3
73 -      for j=1+2:col-3
74 -          for k=-2:2
75 -              for l=-2:2
76 -                  if SE(k+3,l+3)==1
77 -                      V(k+3,l+3)=I_out1(i+k,j+l,1);
78 -                  end;
79 -              end;
80 -          end;
81 -          I_out2(i,j,1)=min(min(V));
82 -      end;
83 -  end;
84 -  I_out2(:,:,2)=I_out2(:,:,1);
85 -  I_out2(:,:,3)=I_out2(:,:,1);
```

Fig. 9. Matlab implementation of the erosion for gray-level images

The results obtained with the erosion are shown in Fig. 10 and Fig. 11. The objects are still well visible and the artifacts are predominantly filtered.

Fig. 10. The result after erosion for the first scene (compare Fig. 6)

Fig. 11. The result after erosion for the second scene (compare Fig. 7)

E. Exposing objects

The use of erosion filtering was beneficial to objects detection. It turned out that objects can be further exposed with the use of low-pass filtering. There are two possibilities: simple spatial filtering (neighborhood averaging) with a large mask 7x7 or just the standard transform FFT2. The second tool is faster and already available in majority of programming environments (including CUDA). In the case of Matlab we have two-dimensional convolution `conv2` and set of tools for two-dimensional discrete Fourier transform: `fft2`, `ifft2`, `fftshift`.

The process of FFT2 filtering is shown in Fig. 12, and a 3D result for the first scene is visible in Fig. 13, and for the second scene is presented in Fig. 14.

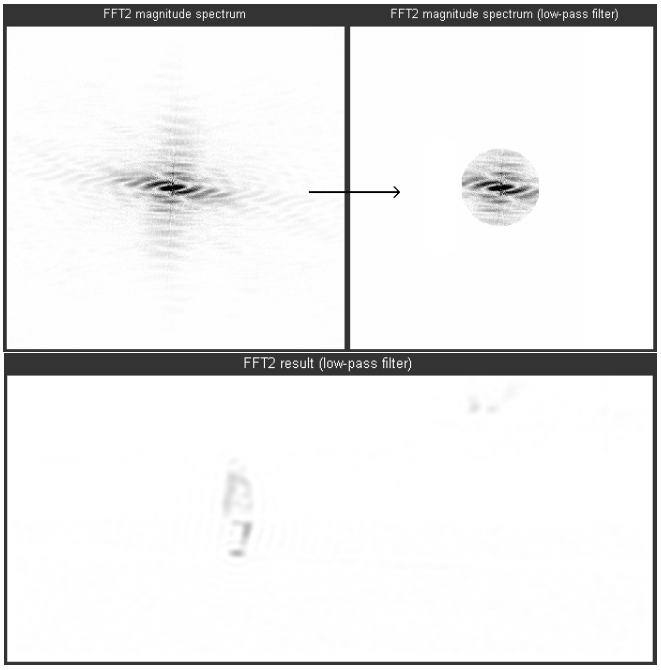

Fig. 12. The use of the FFT2 for the first scene (compare Fig. 10)

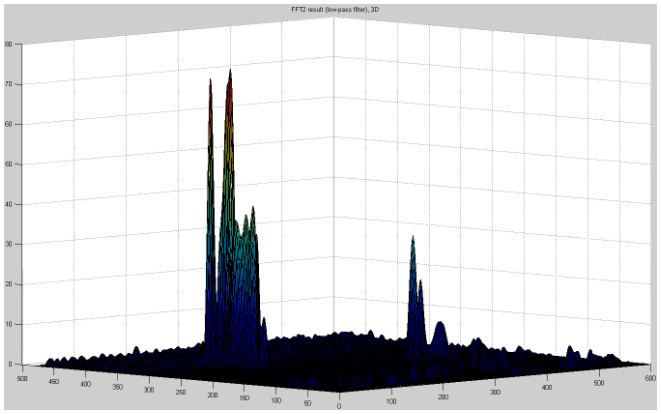

Fig. 13. The result of FFT2 for the first scene (see Fig. 12)

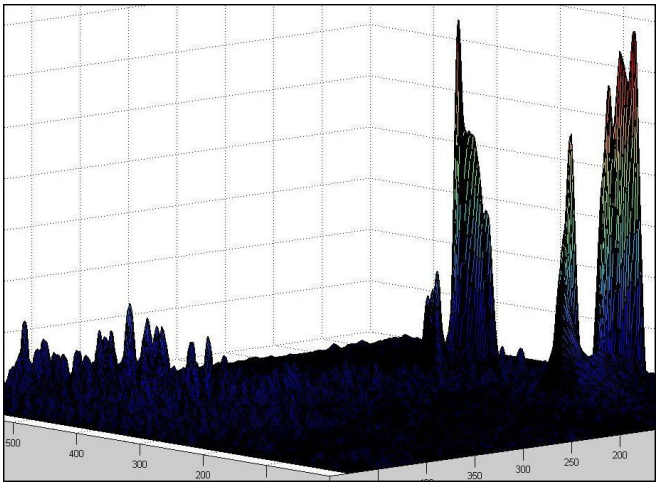

Fig. 14. The result of the FFT2 for the second scene (see Fig. 11)

F. Binarization and the decision

The results visible in Fig. 13 and 14 are rather satisfying. The last stage before the final decision about movement detection is binarization. The best results of binarization were received for threshold from the range of **20-50** of gray levels. The results of binarization are presented in Fig. 15.

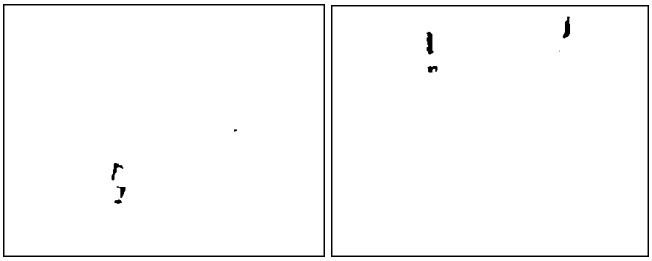

Fig. 15. The result of binarization for the considered scenes

The final decision about the movement detection is based on percentage size of objects in frames. In the case of Fig. 15 the percentage sizes of objects are respectively: 0,15% and 0,32%. The established threshold for the elaborated method is **0,1%**.

IV. x86 Implementation

The x86 implementation of the elaborated method has been made in C++ with the use of Visual Studio 2012. To speed up the implementation process the well known and free library called OpenCV was used. The library contains a set of ready to use computer vision algorithms (e.g.: linear filtering, cosine transform) as well as basic image processing functions (read/write images, conversion). Custom implementation has been made only for elements that are not included in the OpenCV or those which are poor optimized for the considered application.

C++ language has been chosen for both: x86 and CUDA implementation. Thanks to that it was possible to use exactly the same template project and therefore the execution is not overwhelmed by any language runtime.

A. Example source scenes

Source scenes were captured from an IP camera, flipped horizontally and then converted to 8 bits gray-scale images.

B. Compensation of the tilt effect

The tilt reduction function has been implemented independently in accordance with proposed algorithm and shown in following listing (Fig. 16). This function requires two images which we call “previous” and “current” frame. The previous frame is the frame captured first.

The only parameter required is *nop*. The *nop* stands for number of pixels. In our implementation we used constant value 5 which means that the previous frame is cropped by 5 pixels from all sides and the current frame is centered this way that the tilt effect (the images deference) to the previous frame is the smallest.

```
void Movement::tilt_reduction()
{
    int iw = this->iw - 2*nop,
        ih = this->ih - 2*nop,
        is = iw * ih;

    // crop the previous frame
    Mat roi_im1 = im1(Rect(nop, nop, iw, ih));

    int by = 0, bx = 0;
    int min = is*256;
    Npp8u *px;

    // find the best position in the current frame
    // where tilt is the lowest
    for (int y = 0; y < nop*2+1; y++)
        for (int x = 0; x < nop*2+1; x++)
        {
            Mat a = abs(roi_im1 - im2(Rect(x, y, iw, ih)));
            Scalar ssum = sum(a);
            int sum = ssum[0];
            if (sum < min)
            {
                by = y;
                bx = x;
                min = sum;
            }
        }

    Mat tmp_im = Mat::ones(this->ih, this->iw, CV_8U);
    Mat tmp_roi = tmp_im(Rect(nop, nop, iw, ih));

    // set "the previous frame"
    roi_im1.copyTo(tmp_roi);
    tmp_im.copyTo(im1);

    // set "the current frame"
    Mat roi_im2 = im2(Rect(bx, by, iw, ih));
    roi_im2.copyTo(tmp_roi);
    tmp_im.copyTo(im2);
};
```

Fig. 16. Compensation of the tilt effect in C++

C. Getting a difference image

The pixels from previous frame are subtracted from current frame then provided as an argument of *abs* function. The difference image is getting very easy using a ready function *abs* from OpenCV library and is coded as one line in movement detection function (see Fig. 17).

```
int Movement::detection(Mat &frame, Mat &result)
{
    frame.copyTo(im2);

    tilt_reduction();
    diff = abs(im1 - im2);
    erosion();
    low_pass_filter();
    binarization();

    im2.copyTo(im1);
    diff.copyTo(result);
    return 0;
}
```

Fig. 17. Movement detection in C++

D. Removing unwanted artifacts

To remove unwanted artifacts that might still persist in the processed image the erosion operator is applied. This has been made using our own implementation because we found it much faster than the option provided by OpenCV. The structuring element used in our implementation is disk inscribed in 5x5 matrix (see Fig. 18).

```
void Movement::erosion()
{
    unsigned disk[5][5] = {
        { 0, 0, 1, 0, 0 },
        { 0, 1, 1, 1, 0 },
        { 1, 1, 1, 1, 1 },
        { 0, 1, 1, 1, 0 },
        { 0, 0, 1, 0, 0 }
    };

    Mat out = Mat::zeros(ih, iw, CV_8U);
    Npp8u *data = (Npp8u *) diff.data,
        *out_d = (Npp8u *) out.data;

    for (int iy = 0; iy < ih-4; iy++)
        for (int ix = 0; ix < iw-5; ix++)
        {
            int min = 255, val;
            for (int dy = 0; dy < 5; dy++)
                for (int dx = 0; dx < 5; dx++)
                {
                    if (disk[dy][dx] == 1)
                    {
                        val = *(data + ((iy + dy) * iw + ix + dx));
                        if (val < min)
                        {
                            min = val;
                        }
                    }
                }
            *(out_d + (iy + 2) * iw + ix + 2) = min;
        }

    out.copyTo(diff);
};
```

Fig. 18. Erosion function in C++

E. Exposing objects

The last operation applied to the image before movement detection is convolution with 7x7 kernel of all ones.

```
void Movement::low_pass_filter()
{
  Mat kernel = Mat::ones(lowPassFilter, lowPassFilter, CV_64F), tmp1, tmp2;
  double mean = double(lowPassFilter * lowPassFilter);
  diff.convertTo(tmp1, CV_64F, 1./255);
  filter2D(tmp1, tmp2, -1, kernel);
  tmp2 = tmp2 / mean;
  tmp2.convertTo(tmp2, CV_8U, 255);
  tmp2.copyTo(diff);
}
```

Fig. 19. Low-pass filtering in C++

F. Binarization and the decision

```
void Movement::binarization()
{
    Mat to_compare = Mat::ones(ih, iw, CV_8U) * threshold;
    Mat out;
    compare(diff, to_compare, out, CMP_GT);
    out.convertTo(out, CV_8U);
    out.copyTo(diff);
}
```

Fig. 20. Binarization in C++

The result of all previous steps is still an grayscale image. Applying the threshold we got the final binarized image ready for the final step. This has been also achieved using one line ready to use function (see Fig. 20).

V. CUDA Implementation

Most of operations in proposed algorithm are available in Nvidia Performance Primitives [26]. The NPP is a collection of GPU-accelerated functions for image, video and signal processing. The library is freely available as a part of the CUDA Toolkit.

A. Use of the CUDA device structure

The only function that needed to be implemented independently was the tilt reduction. We couldn't match any function from NPP that would help us to achieve desired results therefore an own kernel has been implemented.

Although CUDA device allows to organize threads in 3D structure, 2D structure was enough. The X and Y axes responds to the position of pixels in the image. Block Index address pixels from “the previous” frame. Pixels from “the current” frame are further offset by the Grid Index. That makes two regions of interest (ROI) for each kernel iteration as shown in Fig. 21.

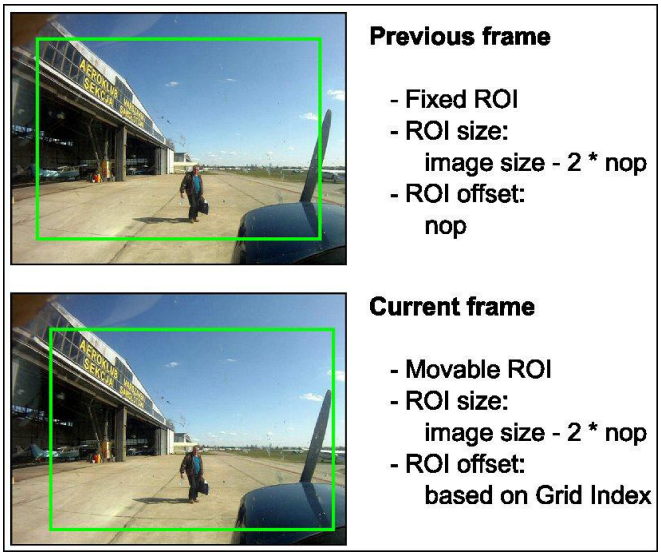

Fig. 21. Tilt reduction with regions of interest (ROI) in CUDA

Grid Size corresponds to *nop* parameter from the x86 implementation. Block Size is a parameter chosen empirically and have to be power of 2 for further reduction process. The source code of the CUDA kernel is presented in Fig. 22.

```
__global__ void tilt_reduction_kernel(Npp8u *im1, Npp8u *im2,
                                      int iw, int ih, int nop, int *ret)
{
    int iww = iw - 2*nop,
        ihh = ih - 2*nop;

    int thread = threadIdx.y * blockDim.x + threadIdx.x;

    __shared__ int sums[256];
    sums[thread] = 0;

    int offset1, offset2;
    int sum = 0;

    int iy = threadIdx.y,
        ix = threadIdx.x;

    while (ix < iww && iy < ihh)
    {
        // Offset in "the previous" frame
        offset1 = (iy + nop) * iw + ix + nop;
        // Offset in "the current" frame
        offset2 = (iy + blockIdx.y) * iw + ix + blockIdx.x;

        // Check the pixels difference
        int value = abs(*(im1 + offset1) - *(im2 + offset2));
        // Sum all differences for given ROI
        sum += value;

        ix += blockDim.x;
        if (ix >= iww)
        {
            ix = threadIdx.x;
            iy += blockDim.y;
        }
    }
    sums[thread] = sum;
    __syncthreads();

    // Reduction
    for (int i = blockDim.x * blockDim.y/2; i > 0; i /= 2)
    {
        if (thread < i)
        {
            sums[thread] += sums[thread + i];
        }
        __syncthreads();
    }

    // Save the result for given ROI
    if (thread == 0)
    {
        int return_offset = blockIdx.y * gridDim.x + blockIdx.x;
        *(ret + return_offset) = sums[0];
    }
}
```

Fig. 22. The source code for the CUDA kernel

B. CUDA implementation supported by the NPP library

The use of NPP library is relatively simply. The major difficulty is a preparation of the image data accordingly to NPP requirements. The NPP supports variety of data. Pixels may be provided as 8, 16 or 32 bits signed or unsigned integers or 32 bits floating point numbers. Unfortunately some functions don't support all data types. The choose should be made base on a function availability that need to be used.

What one need to remember is that the NPP is mainly C library. It is a reason that some features like function overloading are not available. One need to use functions that exactly match parameters types. To help to recognize functions a special function name convention has been introduced. Each NPP function begins with nppi. The data type that the function is dedicated for might be distinguish by its suffix. For example suffix R indicates the primitive operates only on a rectangular. Suffix I indicates that the primitive works "in-place". This is well described in the NPP documentation [26].

The image that is passed to the NPP is always described by three parameters: pointer to the image, image size (as ROI), and line step. Pointer to the image has to be the CUDA device pointer. Line step is the number of bytes between successive rows in the image. Fig. 23 shows the use of the NPP library.

```
void Movement::erosion()
{
    NppiSize oMaskSize = { 5, 5 };
    NppiPoint oAnchor = { 3, 3 };
    nppiErode_8u_C1R(pdDiff, iw, pdTmp, iw, oSizeROI,
        pdErodeMask, oMaskSize, oAnchor);
    swap(&pdTmp, &pdDiff);
};

void Movement::low_pass_filter()
{
    NppiSize oKernelSize = { lowPassFilter, lowPassFilter };
    NppiPoint oAnchor = { lowPassFilter, lowPassFilter };
    NppiSize oDstSizeROI = { iw + lowPassFilter, ih + lowPassFilter };
    int nDstStep = oDstSizeROI.width;
    int offset = lowPassFilter - lowPassFilter / 2;

    nppiCopyReplicateBorder_8u_C1R(pdDiff, iw, oSizeROI, pdTmp,
        nDstStep, oDstSizeROI, offset, offset);
    nppiFilter_8u_C1R(pdTmp, nDstStep, pdDiff, iw, oSizeROI,
        pdLPKernel, oKernelSize, oAnchor, lowPassFilter * lowPassFilter);
}

void Movement::binarization()
{
    nppiCompareC_8u_C1R(pdDiff, iw, (Npp8u) threshold, pdTmp,
        iw, oSizeROI, NPP_CMP_GREATER);
    swap(&pdTmp, &pdDiff);
}

void Movement::swap(Npp8u **a, Npp8u **b)
{
    Npp8u * tmp = *a;
    *a = *b;
    *b = tmp;
}
```

Fig. 23. CUDA implementation using the NPP library

VI. Movement Tracking

A basic extension to the issue of movement detection is the problem of object tracking. The simplest way of tracking can be performed by drawing a trajectory (a path) for the detected object as shown in Fig. 24-26.

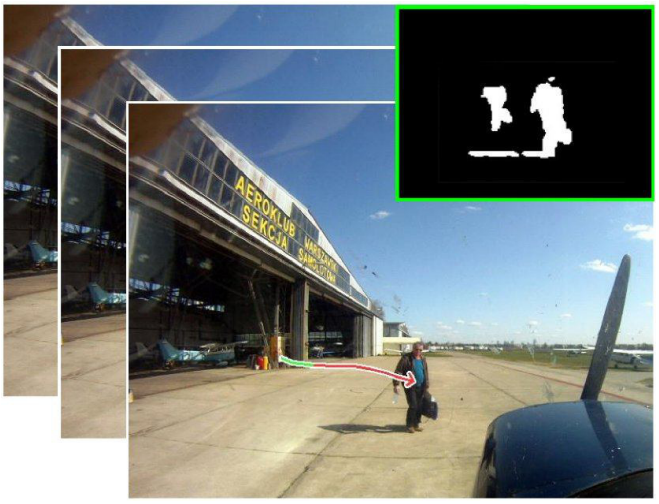

Fig. 24. An example of movement tracking in terrain conditions

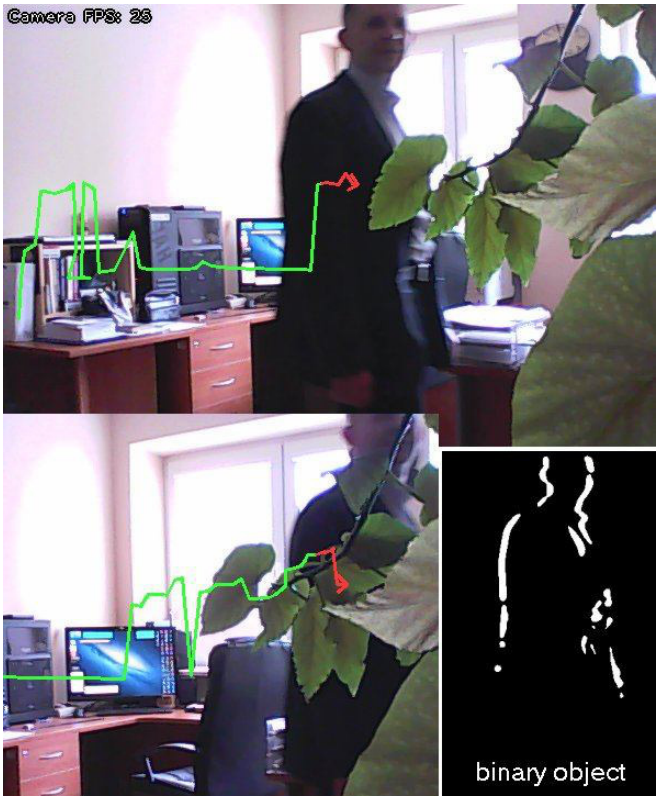

Fig. 25. An example of movement tracking inside a room

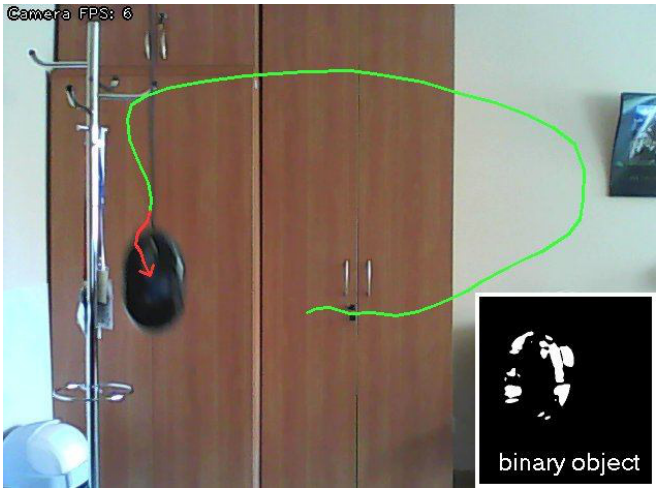

Fig. 26. An example of movement tracking of a small object (a mouse)

The suggested method allows to track only one object that is being detected. The object to be detected must occupy more than **0.1%** space of the binarized image. If that happens the object is surrounded by a rectangle and then center of its mass is calculated. If movement is detected in following frames then the track is plotted by joining calculated centers.

Aside of common template project, both implementations use the same algorithm for the considered stage, i.e. movement tracking. This is because of the algorithm simplicity which cause the CUDA implementation unnecessary. Thus, the function is common for x86 and CUDA implementation (see Fig. 27).

```
21  void process_result(Mat &result, t_detected_object &obj)
22  {
23      int iw = result.cols, ih = result.rows, is = iw * ih;
24      Npp8u * im = (Npp8u *) result.data;
25
26      obj.pt1.x = iw;
27      obj.pt1.y = ih;
28      obj.pt2.x = -1;
29      obj.pt2.y = -1;
30
31      int cnt = 0;
32      for (int y=0; y<ih; y++)
33          for (int x=0; x<iw; x++)
34          {
35              int offset = y * iw + x;
36              if (*(im + offset))
37              {
38                  cnt++;
39                  if (obj.pt1.x > x) obj.pt1.x = x;
40                  if (obj.pt1.y > y) obj.pt1.y = y;
41                  if (obj.pt2.x < x) obj.pt2.x = x;
42                  if (obj.pt2.y < y) obj.pt2.y = y;
43              }
44          }
45
46      if ((double) cnt / is > 0.001)
47      {
48          obj.detected = cnt;
49          obj.center.x = obj.pt1.x + (obj.pt2.x - obj.pt1.x) / 2;
50          obj.center.y = obj.pt1.y + (obj.pt2.y - obj.pt1.y) / 2;
51      }
52      else
53      {
54          obj.detected = 0;
55      }
56  }
```

Fig. 27. Movement tracking in C++

VII. Conclusion

There are two gains of the performed work that are fully concordant to the title of this paper: the elaboration of the method of movement tracking and its implementation in CUDA. The elaborated method can be described as a sequence of actions, what is shown in Fig. 28.

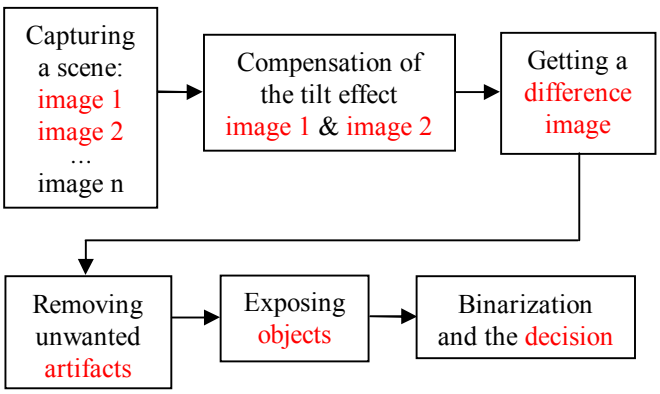

Fig. 28. A block diagram of processes for the elaborated method

CUDA and x86 implementations of the method were examined in details and optimized to receive the best performance. Performed benchmarks concerned only on selected portion of the source code directly responsible for

movement detection and tracking. Functions common for both implementations has been omitted in benchmarking.

The presented solution shows a significant performance difference between the implementation for x86 and the massively parallel implementation in CUDA. Both implementations give the same final result – confirmation that solution is correct. Performed benchmarks demonstrated substantial acceleration thanks to CUDA implementation which is suitable for a **real-time system**. It was possible to reach the speed of **25+ fps** for resolution **640x480**, at least **10 times faster** then in the case of x86 implementation. The upper limit velocity of tracked objects for the elaborated method is **4 m/s**. It is the outcome of the distance between adjacent frames. The lower limit velocity of tracked objects can be widely adjusted by the distance between analyzed frames.

In order to enrich the method an extension about identification of the detected object may be added using a method similar to one described in [23]. Another challenge is the problem of tracking multiple independent objects [20], [21].

***Abstract*—Humans can interact remotely with each other through computers. Systems supporting this include teleconferencing, games and virtual environments. There are delays from when a human does an action until it is reflected remotely. When delays are too large, they will result in inconsistencies in what the state of the interaction is as seen by each participant. The delays can be reduced, but they cannot be removed. When delays become too large the effects they create on the human-to-human remote interaction can be partially masked to achieve an illusion of insignificant delays. The MultiStage system is a human-to-human interaction system meant to be used by actors at remote stages creating a common virtual stage. Each actor is remotely represented by a remote presence created based on a stream of data continuously recorded about the actor and being sent to all stages. We in particular report on the subsystem of MultiStage masking the effects of delays. The most advanced masking approach is done by having each stage continuously look for late data, and when masking is determined to be needed, the system switches from using a live stream to a pre-recorded video of an actor. The system can also use a computable model of an actor creating a remote presence substituting for the live stream. The present prototype uses a simple human skeleton model.**

***Index Terms*—Effects of Latency; Mask the effects of delays; Temporal Casual Synchrony; Remote Interaction.**

I. Introduction

IN DISTRIBUTED acting, actors at different stages, physically separated by distance, interact to create a coherent play. The interaction can be lazy, allowing for large delays without breaking the illusion of being at the same stage. This is, for example, the situation when actors do a relaxed handshake, or don't interact directly at all. The interaction can also be eager, where even small delays break the illusion. This is, for example, the case when actors do fast action/reaction with causally related movements between each other, or move in synchrony as done in dancing.

Fig. 1 depicts distributed acting. Three stages, in Tromsø, Porto, and Florence, have a total of four actors doing eager interaction, dancing together. In Tromsø, there are two actors physically present, while there is one actor in Porto and one in Florence. At each stage, each actor is represented by a remote presence in the form of an independent streaming video.

Distributed acting is complicated by each stage having a different clock, and by communication delays and jitter. The clock at each stage can easily be sufficiently synchronized with a reference clock, but delays and jitter are unavoidable and are the result of the finite speed of light, and of the technologies and systems applied to create a distributed stage gluing together the individual stages.

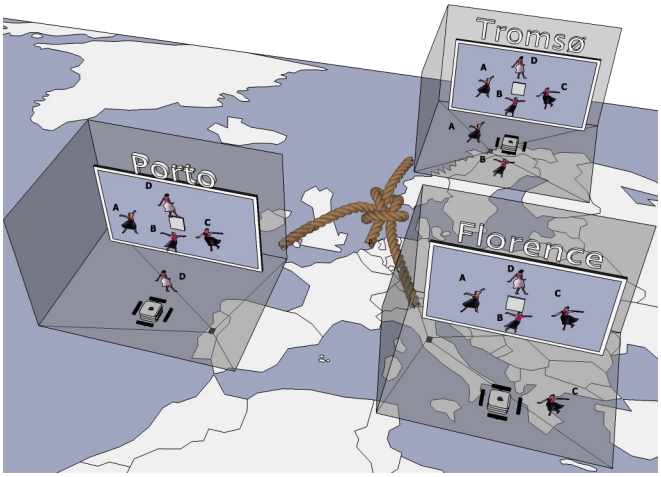

Fig. 1. Four dancers at different stages dance together. Each stage is equipped with sensors to detect actors and a display to visualize the remote presence of all the performers.

The speed of light defines the lower bound of a non-zero delay from an event happens until it can be observed. Table I shows the time needed for light to travel distances that may be typical in distributed acting. It takes about 3 microseconds between buildings, 30 milliseconds between cities and about 134 milliseconds around Earth's equator. The time it takes for light to travel from an actor to another and back is twice this amount of time. However, the actual delays experienced by actors interacting through a computer-based system are even higher.

TABLE I
Travel time at the speed of light

1 km	3.3 μs	Between buildings
1000 km	33 ms	Between cities
4000 km	134 ms	Around equator
2.4 x 10^{19} km	2.5M years	To Andromeda Galaxy

Figure 2 describes the total delay when observing a remote event. Delays are created by the sensors tracking actors, transfer of data from sensors to computers, processing of the sensor input, network transmission, on-route processing,

978-83-60810-58-3/$25.00

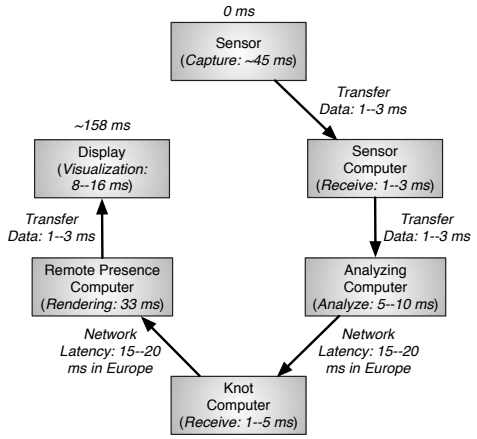

Fig. 2. Every Phase will add delay

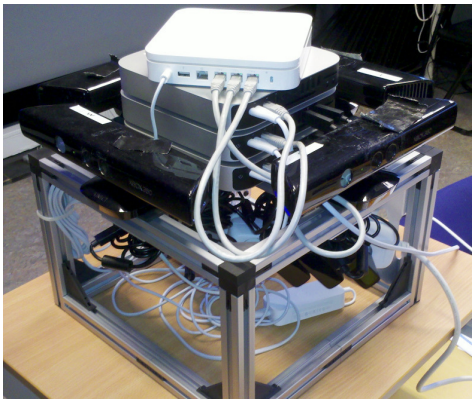

Fig. 3. The 360 degrees actor detection sensor rig comprising four 3D Kinect cameras, two Mac Mini computers, and wireless access point. One per stage is used.

receiving and processing the received data, and preparing and visualizing the data locally. The delays can be significantly larger than what is indicated in the figure if more processing is applied. These delays can be reduced and partially masked, but they can never be removed.

Delays are important when people interact. It has been documented [1], [2], [3], [4] that people accept delays below 200ms as insignificant when interacting tightly. When the delays grow beyond 200ms they become harder and harder to ignore, and actors can be expected to have problems interacting as if they were on the same physical stage.

The goal of the MultiStage system [5] is to aid actors at stages around the world in interacting with each other as if they were on the same stage. Each stage has a set of sensors, shown in figure 3, detecting and tracking the movements of the actors on the stage. The actors at the other stages are each represented by a remote presence. A remote presence is based upon having data about an actor available such that the actor's movements can be recreated remotely. A simple case is to have data representing a streaming video of the actor, and show it on a large display to visualize the actor in full scale. A more advanced case is when an actor's movements are used as input into a computation creating a remote presence of the actor. The remote presence can be visualized on a display or control a robot.

Several experiments were conducted to determine the objective and subjective performance of the system. Objective metrics include the delays in different parts of the prototype system, and processing and network resource usage. Subjective metrics include how much delay an actor will notice and tolerate when interacting, and when an actor experience that the switching of the masking in and out is smooth.

II. Masking Approaches

In [5], we define **loose temporal causal synchrony** to be when actions by actors happen causally in the correct order, but with no special demands on delays. **Interactive temporal causal synchrony** is when actions by an actor is seen in causal order and with delays as actors are used to when being on the same stage face to face. To achieve this even with delays and jitter being unavoidable, the idea is to mask the effects of delays as seen by the actors.

In the **Act-By-Actor**-approach, the actors react to the remote presences as if they were the actual actors. How the interaction looks and how it feels to actors and audiences depends on how large the delays are, by how much they vary, and by how good the actors are at compensating.

In the **Act-By-Director**-approach, a director keeps time and tells actors when to do actions according to a shared script or to a script for each actor. Even if the actors act on command it will seem to an audience as if they interact freely with each other.

A variant is to select a stage to be the **live** stage. The others are secondary stages. The start time for a performance at a secondary stage is the start time for the live stage minus the delay between them. Consequently, performances at secondary stages are started a little earlier than at the live stage such that when the live stage starts, the input from the secondary stages arrive. At the live stage the actors and an audience will experience a performance where local actors are in synchrony with the remote presences representing the remote actors. However, actors at a secondary stage will be out of sync with the remote presences. By switching which stage is the live stage at suitable points in the performance, each stage can be the live stage for a time.

A second variant of this approach is to **delay each local remote presence** at a stage. A local remote presence is the remote presence of an actor shown and heard at the stage where the physical actor also is. The effect is that an actor and an audience will experience a local and a remote event at the same time because they have both been delayed equally much. To make this approach practical, the delay cannot be so high as to make the actors and audience noticing it too much. Because delays between stages in practice tend to be different, this approach is most practical for just two stages with about equal delay between them.

A third variant is to **delay all remote presences** at a stage until data for the slowest remote presence arrives. With varying delays between the stages, they will soon be out of synchronization with each other. However, the local and remote presences at a stage will be in synchronization with each other. The delay waiting for the slowest can be long enough to be noticeable for actors and an audience. Consequently, the actors at a stage can be out of synchronization with the remote presences.

In the **Act-By-Wire**-approach, remote presences are manipulated to hide the effects of delays when delays reach predefined threshold values. Manipulations include just-in-time blending in of prerecorded videos of remote presences of actors, and just-in-time blending in of on-demand computed remote presences. A prerecorded and an on-demand computed remote presence will to a varying degree succeed in creating the illusion of low insignificant delays. If there is a script of what an actor should do at a given time, then a prerecorded remote presence can be created and played back at the correct time when delays go too high. When instead of using a static pre-recorded video a computation is run to create the remote presence, a wide range of possibilities are in principle available. These include blurring the movements of an actor such that delays are not so obvious, and predicting what an actor was going to do. We have not explored these possibilities yet.

III. Related Literature

Several systems try to enable interaction between local and remote users. The Distributed Immersive Performance (DIP) [6] and [7], is a multi-site interaction and collaboration system for interactive musical performances. In experiments, they artificially delayed the local stage and found out that (i) the tolerable latency for slow paced music is much higher than for fast paced music; (ii) to help performers pick up aural cues it is better having a low audio latency than synchronizing video and audio; and (iii) a roundtrip video delay of more than 230ms makes synchronization hard for the users. In [8], a series of experiments on the DIP system is described with focus on the audio delay, and how the delay affects musician's cooperation. An artificial delay of 50ms to the remote room's audio stream was tolerable. With the same latency added at both rooms it became possible to play easily together with a delay of up to 65ms. While they report on the effects of delays on audios, we report on the effects of delays on videos, and how they can be masked.

Other distributed collaboration systems include [9], [10], and [11]. These do not consider the effects of delays and how to mask them when users interact across distance.

Several techniques [12], [13], [14], [15] and [16], exist to reduce or hide network latency in network games and in distributed systems. The Dead-Reckoning (DR) technique is used in distributed simulations and to hide latency mostly in network games. Computers that own an entity will send unique information about the entity to other computers on the network. The information includes the position, velocity, and acceleration of the entity or more. Each computer simulates the movement of the entity. The computer which owns the entity will also simulate the entity as well as check the real state of the entity. When the simulated value and real value differs more than a threshold, the computer will send update information to the other computers. The dead-reckoning technique is a general way to decrease the amount of messages communicated among the participants.

IDMaps [17] measures the distance information on the Internet. This is used to predict latencies. King [18] uses recursive DNS queries to predict latency between arbitrary end hosts. In [19] a structural approach to latency prediction technique based on Internet's routing topology is proposed. In [20] the network latency is reduced based on estimates of the network path quality between end points. These approaches can be useful even if we don't mask latencies themselves, but the effects of delays. Predicting the very near future latency can be useful because we can start the masking right before large delays happen. The Local-Lag (LL) technique [21], provides for better fairness between local and remote players by making all see approximately the same delays. A local operation is delayed for a short time. During this short time period the operation is transmitted to remote computers participating in the game, and all computers can then execute the operation closer in time to each other. However, with more than two participants seeing significantly different latencies, the fairness cannot be maintained for all computers. In [22] and [23], the LL is integrated with DR to synchronize participants and keep better consistency among all computers.

In [14] and [22], some of the drawbacks of the above mentioned DR and LL techniques are identified. While the LL technique ensures fairness for two players, or for multiple with the same latencies between them, the fairness is not preserved when the latencies become too different. The same is the case for the DR approach because when a computer does an update, the time it takes to have data about this delivered at the other computers will vary depending on the latencies between the local computer and each of the other computers. This can result in a situation where a local player and some of the remote players can do actions earlier than other remote players.

Even if it is worthwhile to reduce network latencies and other delays, and do overlapping between communications and processing, delays cannot be removed. In this paper, we present several techniques to mask the effects of delays, and we also measure the cost of applying each technique.

There are several projects which have studied the effect of latency when remote users interact, including [24], [25], [2], [26], [4], [3], and [27]. When the latency from a user does an action until it is reflected in, say, a game, is more than 200ms, the user will notice the delay and his actions and scores are impacted by it. In a first person shooter game there is a 35% drop in shooting accuracy at 100ms of latency, and the accuracy drops sharply when the latency increases further. More than 200ms of latency should be avoided. For some sports and role-playing games a latency of 500ms can

be acceptable. Consequently, latency reduction and hiding techniques should aim at achieving end-to-end latencies less or equal to these numbers. When this cannot be achieved, then masking the effects of the various delays becomes interesting to apply as well.

In [28], a comparison is made between the end-to-end latency of an immersive virtual environment and a video conferencing system. The tolerable latency for verbal communication was found to be 150 ms. This was achieved by the teleconferencing system, but not the virtual environment system. A video was done capturing a person repeatedly moving an arm up and down. A video was also done of the same person as represented by the system. Synchronized cameras were used to be able to synchronize the two videos. The latency from the person moved an arm until it was reflected through the system was measured to be 100-120ms for the teleconferencing system, and 220-260ms for the virtual environment when the avatar for the user had been preloaded.

In [29] several techniques were used to reduce the latency for the head tracking system of an immersive simulation system. The techniques included disabling buffering and having a more direct path to the tracker hardware. This results in an almost 50% reduction in latency, from around 90ms to around 50ms.

Packet jitter [30] is the variation in the packet delay. Variations in packet size, buffer delay, and routing create packet jitter. The influence of the jitter in games is measured in [26], [31], [32], and [33]. They conclude that jitter had only a minor impact on the win probability, the scores and the user experience. However, when jitter increases, the tracking accuracy of a target, the users ability to keep a small and consistent distance between the center of the target and the cursor, declines.

In [34] they consider unfairness created by the cumulated errors between players. The system improves fairness by equalizing for all players, the errors of where an object of the game is placed and what it is doing. This resulted in a significant improvement in consistency between what players observed even for 100ms of delay between players at different computers.

IV. System Overview

Figure 4 shows the MultiStage system. The design and implementation is described in detail in [5].

The system is divided into a local and a global side. The local side of MultiStage primarily focuses on what is happening locally on a single stage. The global side is the glue binding stages together, taking care of distribution of data between stages, and doing analytics needing data from multiple stages.

The local stage monitoring (LSM) system detects local state at the stage, including actors and their movements, and streams it to the local stage analysis (LSA) system. The LSA analyzes the data to detect gestures (not expanded on in this paper), and forwards the data and data about detected gestures to the global side.

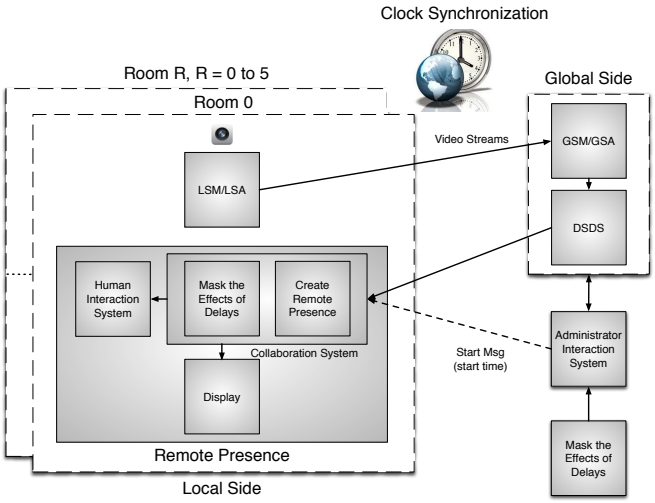

Fig. 4. The MultiStage system.

The LSM system produces an individual stream for each actor. This allows for great flexibility in treating each actor individually when looking for gestures, and where each actor's remote presence is manifested and located in relation to the others on the stages. In the present prototype, an individual stream for each actor is achieved by using a Kinect camera per actor. The system assumes that just a single actor is within the 3D field of view of the camera. All objects outside of this 3D space are ignored. The advantage of having a one-to-one relationship between actors and cameras is that it takes very little processing to create individual streams for the actors. This helps in reducing the delay from an actor moves until it is manifested in the remote presence at remote stages. The disadvantage is that when the number of actors increases, so must the number of cameras. Presently the prototype supports four actors per stage using four Kinect cameras arranged back to back. The back to back configuration avoids having the infrared dot cloud used by the cameras (to achieve depth information) to interfere with each other. While more Kinect cameras can be used, care must be taken to avoid interference. A more advanced sensor suite will help avoid this problem.

The remote presence system at each stage subscribes to streams from the global side. The data is used to locally create remote presences. In the prototype, remote presences are visualized on a big display. The visualization of a remote presence can take three forms. It can be 2D streaming videos based on color images captured by four Kinect cameras at each stage. Alternatively, 3D point streaming cloud videos can be used. These are created using color and depth images captured by the Kinect cameras. Finally, a remote presence can be visualized as an animated human skeleton created locally at each stage.

The LSM uses the Kinect cameras to sense actor movements. In principle, if the LSA identifies actor body movements, the data about this makes its way to the remote pres-

ence, and the computed human skeleton moves accordingly. In the present prototype, a script defining what each actor should do is used. When delays become to high, the human skeleton remote presence computation for an actor receives commands taken from the script. These commands are typically of the type "raise left arm" and "lower right arm". Computing a model of a human skeleton locally, and letting it react to just streaming movement commands, saves network bandwidth vs. distributing streaming videos.

The remote presence system includes the masking system. It looks for incoming data about remote actors being too delayed to do remote presences without the local actors noticing the delay. If the delays are too large, the masking system applies several techniques to mask the effects of the delays as seen by the actors. A limited form of masking is also done outside of the remote presence system. In this case the masking system provides information to the administrator interaction system (see below) such that it can tell the human interaction system at each stage what to do, like individual delayed start-up times of a performance for each stage.

The human interaction system at each stage informs actors what to do, and provides them a countdown for when they should start doing it. In the prototype, a display per stage is used to visualize this for the actors.

The global side monitoring (GSM) receives data streams from the local stages. It forwards the data to the global side analysis (GSA) system. The GSA system does analytics on the data streaming in from the stages looking for global state. An interesting global state is a collective gesture. It is comprised of several gestures done by several actors possibly at different stages. The idea is that when a given number of actors have done a certain gestures, this should result in actions taken at the stages, like, say, turning on a light or doing some modifications to the remote presences.

The GSA system forwards all data and information about global gestures to the distributed state distribution system (DSDS). The DSDS manages subscriptions from the remote presence system at each stage, and deliver streams to the subscribers.

The administrator interaction system lets a director manage the system, including setting and distributing to all stages the start time of a performance. Each computer in the system has a performance monitor measuring several metrics including latency between the computers and bandwidth. These measurements are made available to the administrator interaction system.

The sub-systems implementing the local side executes on computers local to a stage. This is done to achieve low local latencies, and reduce network bandwidth. It also distributes the global workload, and isolates the stages such that if one stage fails, the other stages have a higher probability of not being affected. The sub-systems implementing the global side executes on computers that are located relative to the stages to achieve high bandwidth and low latencies. The administrator interaction system is located on a computer which is convenient to use by an director.

Multistage is a distributed system, and the computers can have different clock values. The system assumes that all computers have the same time, and the clocks are therefore synchronized.

Experiments measuring the performance of the prototype have been done both with all stages locally on the same local area network, as well as kept more than 1500 km apart (Tromsø to Oslo and back). The system currently scales across the Internet with good performance to three stages, and comprises in total 15 computers, 12 cameras, and at least 12 outgoing and 36 incoming data streams.

The system was primarily implemented in Python. The OpenKinect Libfreenect library is used to fetch RGB and depth images from the cameras. The LSA motion detection using Python OpenCV is taken from Robin David on GitHub [35]. The human skeleton model is implemented in Python, using Pygame. Pygame is used to display the actor script. Python Tkinter module is used to display the Administrator Interaction System. The system runs on Linux and Mac OS X.

V. Design and Implementation of Masking the Effects of Delays

To do masking, several functionalities must be realized at each stage. A **shared clock** is assumed by the system. This is achieved with sufficient accuracy by using Network Time Protocol (NTP) [36] to set the local clocks. A **performance monitor** measures and computes the communication delays between all computers. To do so, every packet sent is time stamped. It also measures the clock differences between the computers at a stage and the DSDS distribution computer to determine if clock synchronization is needed to maintain the shared clock. The performance monitor is present at every computer of the system.

A **shared and individual performance start-times** are distributed by using the administrator interaction system to send a message with the performance start time to each stage. We assume that when needed there are predefined **actor scripts** available telling each actor what and when to do an action. In the prototype a display at each stage shows a count down until the next action is to be done, and visualizes with a simple drawing what the action is.

The following masking approaches are shown in figure 5. For all approaches we assume that the stages have already initiated subscriptions to data streams from each other, and that the streaming is in effect.

Live Stage: The administrator interaction system uses the performance monitor to measure the latency from the detection computer at each secondary stage to the distribution server. It also measures the latency from the distribution server to the remote presence computer at the live stage. The effective latency from a secondary stage to the live stage is the sum of these two latencies. A secondary stage's performance start time is the start time at the live stage minus the latency between the live and the secondary stage.

The administrator interaction system now sends a message to each stage with the start time of the performance and

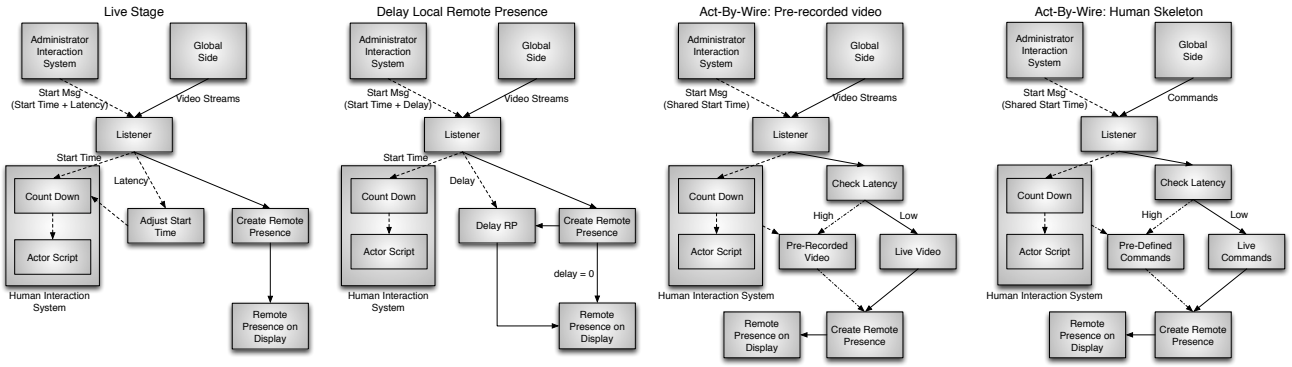

Fig. 5. Design and Implementation of the techniques to mask the effects of delays

the latency that should be decreased to the start time for that particular stage. The human interaction system at each secondary stage will now do a countdown with the start time of the live stage modified by the latency to the live stage. When the countdown ends, a visualization of what each actor should do is displayed. The human interaction system now acts as a director, counting-down to the next action of each actor, and then visualizing the action.

Delay Local Remote Presences: The administrator interaction system uses the performance monitor to measure the delay from the detection computer at each stage to the distribution server. It also measures the delay from the distribution server to the remote presence computer at the stage. If the delays are close an average delay is computed, and this approach to masking can be applied. The administrator interaction system sends a message to each stage with the start time of the performance and the average delay between the stages. The human interaction system starts a countdown at the given start-time. At a stage, each remote presence representing a local actor at the stage is locally delayed by the average delay. The remote presences from other stages are not delayed by the receiving stages.

Delay Locally the remote presences until data for the most delayed remote presence arrives: As for the Live Stage masking approach, the administrator interaction system uses the performance monitor to measure the delay from the detection computer at each stage to the distribution server. It also measures the delay from the distribution server to the remote presence computer at the stage. The effective delay from detection side of a stage to the display side of a stage is the sum of these two delays.

The administrative interaction system sends a message to each stage with the same start time, and the delay from every stage to the stage receiving the message. Each stage calculates by how much remote presences from each stage should be delayed to play back close in time to the remote presences coming from the stage with the longest delay. The human interaction system starts a countdown, and tells the actors what to do and when to do it. The create remote presence system creates remote presences as fast as it can, but remote presences from each stage are individually delayed by the calculated amount for each stage.

Act-By-Wire, blend in prerecorded video or compute a remote presence: The administrator interaction system sends the same start-time to the human interaction system at each stage. It starts a countdown and tells the actors what to do and when to do an action. For every image (or video frame) arriving to be used to create a remote presence, we check if the delta between the send timestamp of the image and the receive time is large enough to warrant masking. If more than a certain percentage of images are late, we start masking. If the percent goes down, we stop the masking. The threshold values used are based on subjectively trying the system on humans with different delay values, and determining when humans notice the delays in several settings, see later for more. We typically use a delay of about 280ms as the threshold for starting to do masking.

To mask short-term delays, the system check for delays over the last few seconds. The exact number of seconds used is tunable, depending upon how sensitive humans in a particular setting are to delayed remote presences.

The video used to mask the effects of delays is pre-recorded. The human interaction system does a countdown, and tells an actor what to do and when to do it, and a video is recorded. When later the same script is used during a performance, and the delays go above the threshold, the pre-recorded video blends in and takes over for the streaming video coming from a remote stage.

The masking system keeps ready the pre-recorded video in memory, and when masking is determined to be needed after checking the latency, it streams the pre-recorded video to the create the remote presence instead of the live streaming video.

Alternatively, instead of using a pre-recorded video, a model of an actor can be used. Instead of streaming a pre-recorded video to create a remote presence, the masking system streams the output from an implementation of the model. The model can receive input about detected body movements from the LSA (through the distribution server) of the remote stage. It can also use the script from the human interaction system to determine what an actor is meant to do. Presently, just a simple

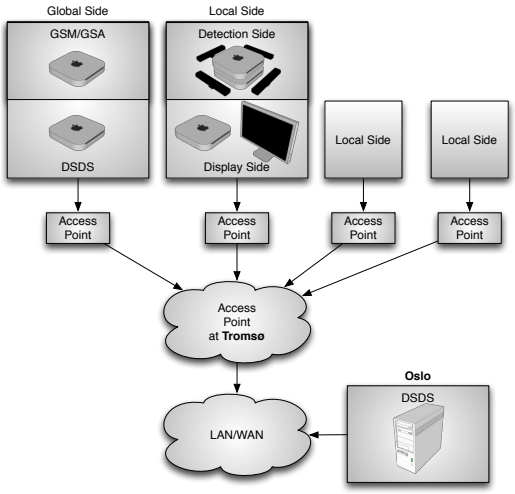

Fig. 6. The configuration of the experiments.

human skeleton model is used with arm movements taken from a script defining what an actor should do. It is future work to explore models and predicting actor behavior more fully.

VI. Evaluation

Several experiments were conducted to identify some of the effects of latency on the actors, and to document the measurable performance of the masking system. For the experiments the system was configured as given in figure 6. Computers used were Mac Minis at 2.7GHz and with 8GB 1333 MHz DDR3 memory. For all experiments all local side stages were on the same 1Gbit/s switched Ethernet LAN inside the Department of Computer Science at the University of Tromsø. The global side DSDS computer was either on the same LAN as the stages, or located on a Planetlab [37] computer at the University of Oslo, 1500km away.

System end-to-end one-way latency: The time it takes for a physical event happening on a stage to be picked up by the cameras and until a visualization of the actor is actually displayed on the same stage. We used a video camera with a high frame rate to record several videos of a user and the remote presence done on a display behind the user. We then counted frames to see how many frames it took from the user moved to the visualization caught up. On a LAN the end-to-end latency was between 90-125ms. With the DSDS at the computer in Oslo, the end-to-end latency was between 100-158ms. The variation in measured latency is because of several factors, including the distributed architecture of the prototype and the frame rate of the projector, video camera (240 fps) and the Kinects (30 fps), and other traffic on the LANs and WAN.

Global-to-Local round-trip latency: The latency going from the DSDS computer to a stage computer and back. We measured this by recording the time when we send a message from DSDS to a stage, and recording when a reply message comes back to DSDS. When all stages and the global side were on the same LAN, the round-trip latencies were between 1-2ms. When the DSDS system was on a computer in Oslo the round-trip latencies were around 32ms. This matches well with measurements reported by PingER [38] for Europe.

Actor-to-actor round-trip latency: The delay that actors will experience from when they do an action until they see the remote presence of another actor reacting. The typical latency between actors is two times the system end-to-end latency. Using the measured results from the system end-to-end one-way latency, the actor-to-actor round trip latency is from 180 to 316ms depending on where the DSDS computer is located.

Human response latency: The time it takes for a human actor to react to another actor's action. We used a high frame rate camera to record two actors' actions, and counted frames from when one actor initiated an action until the other actor responded to the action. The actions used were rapid and slow moving arm movements. The human response latency is about 345ms. We did not find that the latency varied significantly with the speed of an action.

Human noticeable latency: This is the latency at which a human actor will notice that an action is delayed. We simultaneously observed an actor and the corresponding remote presence. When the actor moves an arm, the remote presence moves an arm. In software we artificially added a delay to the remote presence until we noticed that the remote presence lagged behind the actor. When the added latency is more than 100ms, we did notice a difference of the movement between the actor and the remote presence.

Human tolerable latency: This is the latency an actor can tolerate before the illusion of being on the same stage with other actors breaks. We observed an actor shaking hands with another actor on the same stage. We then moved one of the actors to a remote stage, and repeated the shaking of hands. We now observed an actor shaking hands with a remote presence of the other actor. The delay between two actors were artificially increased until we subjectively decided that the handshake was not happening as fast as it did when the actors were physically on the same stage. We tried both rapid hand movement and slow hand movement. We subjectively decided that for a rapid hand movement, it is not tolerable when 150-200ms latency was added. The total actor-to-actor round-trip latency is in this case about 350-400ms. For slow hand movement, it is not tolerable when 600ms latency was added. The actor-to-actor roundtrip latency is about 800ms.

For handshake type of interaction, longer delays bordered on creating a feeling that the remote actor was being obnoxious by delaying just a bit too long before responding to a hand shake. However, this was not experienced unless we artificially added delays. This indicates that the prototype is able to maintain the illusion of being on the same stage for handshake type of interactions. However, we observe that the typical actor-to-actor round-trip latency in Europe is around 300ms or more. Consequently, when actors do fast and rapid interaction, the system can expect to have to mask the effects of the delays.

When to start masking: We simultaneously observed an actor moving an arm, and the corresponding remote presence.

In software we artificially added a random delay to every image used to create the remote presence. We tried different combinations of delays and for how many of the images were delayed. We found that when more than 50% of the received images during a period of three seconds were delayed 280ms or more there is a subjectively clearly visible lag in the remote presence vs. the actor. We therefore determine that when 50% of the images arrive 280ms late during the last three seconds, this is the threshold for when to start masking. This is a threshold that can be changed to customize for different usage scenarios.

When to stop masking: When masking is active, we need to establish a threshold for when to stop masking. We artificially create a situation where more than 50% of the images used to create a remote presence arrive too late. Consequently masking is done by the system. For the experiment we used the Act-By-Wire pre-recorded masking approach. We gradually decreased the percentage by 5% from 50% to 30%. We observe the switching back and forth between the live streaming of the remote presence and the pre-recorded stream. When 35-40% of the images arrive late the switch from the pre-recorded to the live streaming results in a transition without the observer noticing obvious effects of the delay. A higher percentage leads to a sooner switch, but the transition can be too fast and resulting in a blending in of the live streaming video with noticeable delays. A lower percentage results in keeping the pre-recorded video playing too long, and this can become noticeable by itself. The goal is to find a balance between when to start masking and when to stop. This can be different for different user activities and needs.

Above, we checked for late images during the last three seconds. A shorter period will lead to less delay in starting masking when needed, and a longer period is slower in starting masking. For shorter periods, a higher threshold for stopping the masking will reduce the likelihood of switching back and forth. For longer periods, a lower threshold for stopping the masking will increase the likelihood of switching back to the live streaming.

Cost of Masking: The CPU utilization at a remote presence computer without and with the masking technique active was measured. Two cameras were used sending images for two remote presences to a single remote presence computer. The CPU utilization without masking was about 22%. When masking was done for both remote presences using two pre-recorded videos the CPU utilization was basically the same, 22%. When masking was done using two human skeletons, the CPU utilization at the remote presence computer went down to 9%.

We explain this by observing that a significant part of the CPU load was consumed to display videos, making the masking itself insignificant. The very simple human skeleton approach is clearly less CPU demanding. We explain this by the simplicity of the model and that they use the display much less than the videos do.

The overhead of checking if masking is needed and to actually get the masking takes effect is about 40ms in average.

Table II shows the maximum system-end-to-end one-way latency at which each masking approach is in principle at least partially successful at masking the effects of delays.

VII. Discussion

Some of the masking techniques we applied need a synchronization of the clocks at every computer in, and consequently at, every stage of the system. The Network Time Protocol (NTP) provides time accuracy in the range of 1-30ms. The exact accuracy is highly dependent on the location of the computers vs. the NTP servers. If computers are on the same local area network, this will bring them close, around 1ms, to each other. If they are separated by the Internet, the clocks can be synchronized within tens of milliseconds to each other. However, network congestion and routing can cause the clock value used by each computer to be off hundreds of milliseconds. Therefore we do frequent NTP based clock settings and check explicitly for the clock difference between the computers to see if the clocks are more than 10ms off. If they are, we repeat using NTP to try to get all clocks within 10ms of each other. To further ensure that clocks are close enough, before the performance start time is sent to each stage, we again check the clock difference between the computer distributing data to all stages and the remote presence computers at every stage. The clock difference relevant for a stage is included in the message sent to each stage. A stage can then correct its performance start time accordingly if needed.

The experiments measured the objective metrics. No user studies were performed. The determination of thresholds was done naively based on the opinion of a few persons observing actors and remote presences.

The experiments used simple movements by an actor, primarily hand and arm movements. The results can be expected to be different for other actions done by actors, like body rotation, jumping, and dancing.

Different approaches to masking the effects of delays should be expected and to be needed based on what actors are doing. When actors do slow movements and the delays are low, the Act-By-Actor approach can be sufficient. However, it cannot mask the effects of larger delays. The Act-By-Director approach tells actors what to do and when to do an action. All actors are as such seen by an audience at a stage to be synchronized. This approach can mask the effects of large delays. The live stage approach will make just a single stage look synchronized. The other will typically be out of synchronization with the live stage and each other. The approach delaying the local remote presences by the amount of the delay to remote stages will make all stages synchronized if the artificial added delay is smaller than 65ms for audio and 300-400ms for video.

The approach of letting each stage do local delays of every remote presence waiting for the most delayed will make each stage to be in synchrony, but the stages will not be inter-stage synchronized. The Act-By-Wire approach can synchronize actors and remote presence of actors at all stages. However, it makes use of pre-recorded and creates on-the-fly remote

TABLE II
APPROACHES TO MASKING THE EFFECTS OF DELAYS. THE DELAY VALUES ARE THE MAXIMUM SYSTEM-END-TO-END ONE-WAY LATENCIES FOR WHEN AN APPROACH WILL BE AT LEAST PARTIALLY SUCCESSFUL AT MASKING THE EFFECTS OF DELAYS.

Approaches to masking the effects of delays	**Satisfactory synchrony between all remote presences at every stage**	**Satisfactory synchrony between all actors at every stage**	**Satisfactory synchrony between all actors and all remote presences at every stage**
Act-By-Actor	< 190-325ms	< 190-325ms	< 190-325ms
Act-By-Director	< 390-525ms	Any	< 390-525ms
Live Stage	Any (only at live stage)	< 390-525ms	Any (only at live stage)
Delay Local Remote Presence	Any	Any	< 390-525ms
Delay Locally All Remote Presences Waiting for the Slowest	Any	Any	< 390-525ms
Act-By-Wire (blend in pre-recorded remote presence)	Any	Any	Any
Act-By-Wire (blend in on the fly created remote presence)	Any	Any	Any

presences. These can be quite different from, say, a video of the actual actors.

All the masking approaches were tried in the prototype system. However, they are primarily documented as principles. To evaluate where they fit best in an actual interaction, they should be used, and the results should be studied.

The most advanced masking approach, Act-By-Wire using a model of the human to create the remote presence, can be applied with much more complex models than a human skeleton. This is future research. However, when a computable model of an actor is used, its execution should ideally produce results fast enough to not create further delays. If the model demands too long running time to create the needed output, a simpler model may have to be used. Alternatively, predictive techniques may be needed to have output ready when it is needed. The predictions can be based on pre-written scripts defining what a human is meant to be doing at any given time, or it can be based on analyzing the humans' actions in the near past. Predicting the behavior of an actor in the MultiStage system is future research.

VIII. CONCLUSION

In computer supported human-to-human interaction across distance, delays cannot be avoided. Consequently, while reducing the delays are well worth doing, sometimes they still become too large to ignore for humans. When this is the case, some of the effects of delays can be masked to create an illusion for the humans interacting, and for observers, that they are in the same room or on the same stage. However, the illusion created by masking has several limitations depending on which masking approach is used. There are two principally different types of masking. One type coordinates the interaction at suitable times to create a better illusion. The other frequently monitors the delays, and substitutes delayed data with data already available at each stage. Depending on the type of interaction, a suitable masking approach should be selected. The most complex approach, Act-By-Wire, will in all situations in principle create an illusion where interacting humans are fooled to believe that there are no significant delays perturbing the interaction. However, this approach can also create unexpected representations of remote humans, and when this happens it becomes clear that what is shown is only an approximation of the remote reality. The masking approaches we developed and did performance measurements on, demanded insignificantly more resources than not using them, and can even in the most complicated case when using Act-By-Wire, be switched in and out with insignificant delays.

Based on informal use of the system, we found that even 800ms of delay while interacting using slow movements in some cases were tolerable. However, the general case seems to be that delays above 200ms is noticeable when having remote presences based on vision and visualizations. We found that an actor-to-actor round-trip delay of above 200ms is frequently the case, and masking is consequently frequently needed.

ACKNOWLEDGMENT

***Abstract*—This paper presents the creation of the Pong game on an FPGA using a computer display. The game is optimized to work on both LCD and CRT displays too. The game is implemented from scratch, it has the two pads drawn, the ball is also drawn and the background is painted in white. Everything is implemented in hardware on FPGA, so this way at the end we are able to create the ASIC with the game. The goal is to create the Pong game on a single chip.**

I. Introduction

THE creation of games was always in the mind of the engineers. From the start of engineering scientists always thought about how to create something to entertain themselves, not only the required research work.

The beginning of the electronics gave big opportunities to the engineers to create games. The first games were also blinking lights and LEDs, but the real games could be made after the introduction of the displays.

One of the first games created was the predecessor of the Pong game, which origi-nal name is Tennis For Two, developed on oscilloscope and created by William Higinbotham in 1958.

On oscilloscope there were created two paddles and a ball, which could be hit by the paddles, if the ball was missed, the other player got a point.

We wanted to reproduce the history, but on FPGA and after on a standalone chip.

We wanted to recreate the Pong game from scratch, by drawing the paddles and the ball, panting the background and displaying it on a computer display.

We chose this game, because it one of the big classic games and it needs not so much drawing, but it's really much fun to play.

II. Problem Formulation

Our task was clear and simple; we needed to refresh the history by recreating one of the pioneers of the computer gaming history, the Pong game.

To make it a little more difficult and interesting, we set the task to create the game on FPGA, because in the future we plan to create the stand alone ASIC, the chip with the Pong game.

The hardware what we had was the NEXYS 2 development board (Fig. 1) with Spartan-3E FPGA (Fig. 3). With this we had also other hardware that we could use like a CRT or LCD computer display to be able to have the whole computer game system. A block diagram of the experimental setup can be seen on Fig. 2, we can see that all the Pong game is on the FPGA board which is connected via VGA port to a PC monitor. The game could be controlled with mouse, keyboard or as in our implementation with the 4 push buttons from the FPGA board.

III. Problem Solving

A. Theoretical Background

We needed to study the whole structure of the development board in order to be able to create the game and to be able to build the correct driver for the VGA monitor, even the Spartan-3E pins.

On Fig. 4 we can see the Spartan-3E other pins which can be connected to the switches, to the push buttons, to the LEDs or to the 7 segment display from the development board. In our Pong game we used the 4 push buttons, 2 for one paddle and 2 for the other paddle for moving them up and down.

The VGA port on the NEXYS 2 development board is interesting. On Fig. 5 we can see the structure of the VGA port which can be found on the NEXYS 2 development board.

Nexys2 board uses 10 FPGA lines to create a port with 8-bit color VGA and two standard lines of synchronization (HS - horizontal sync, VS - vertical sync). Color signals use a resistive divider circuit which together with the 75 Ω termination VGA display, create eight levels of signals, red and green lines, and four signal levels on the blue line.

The VGA timing needs to be set correctly. A VGA controller circuit must generate vertical sync signals – VS and horizontal sync signals – HS and a coordinate delivery of video data on a pixel clock. The pixel clock defines the time available to display one pixel of information. VS signal defines the frequency of the refresh of the screen and is common to all the information on the screen when is redrawn. The minimum refresh frequency is a function of

the intensity of the phosphor screen and electronic spot. Basically refresh frequency is in the range of 50-120 Hz. For a screen of 480 lines with 640 pixels per line, using a 25 MHz pixel clock and a refresh of 60 + /- 1Hz, signal timings are shown in Fig. 6. Synchronization time pulse width for intervals of “front” and “back porch” (these intervals are times pre-and post-synchronization, during when information cannot be displayed) are based on observations taken from actual VGA monitors.

A VGA controller circuit (Fig. 7) decodes the output horizontal sync counter, which is driven by the pixel clock, to generate horizontal sync HS times. This counter can be used to locate any pixel on a given line. Similarly, the output vertical sync counter that increments with each HS pulse can be used to generate VS vertical syn-chronization times and this number can be used to locate any given line. These two counters (continuously operating) can be used to address a memory.

B. Implementation of the Pong Game

The Circuit of the Game is not very simple. The chip of the Pong game can be seen on Fig. 8.

The inside structure of the Pong game can be seen on Fig. 9. As we can see that the inside structure is quite simple for our circuit. We have only 3 chips inside, one for the VGA sync and one for the graph part for drawing the balls and paddles. We made even the ball to be round by loading the binary values from ROM memory. The last chip is a D-latch for creating a delay for timing.

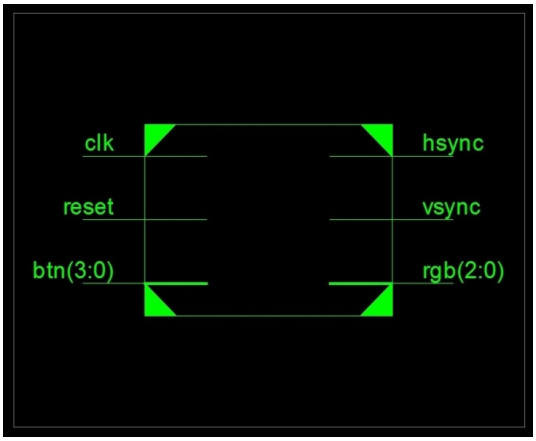

Fig. 8 The Pong game chip

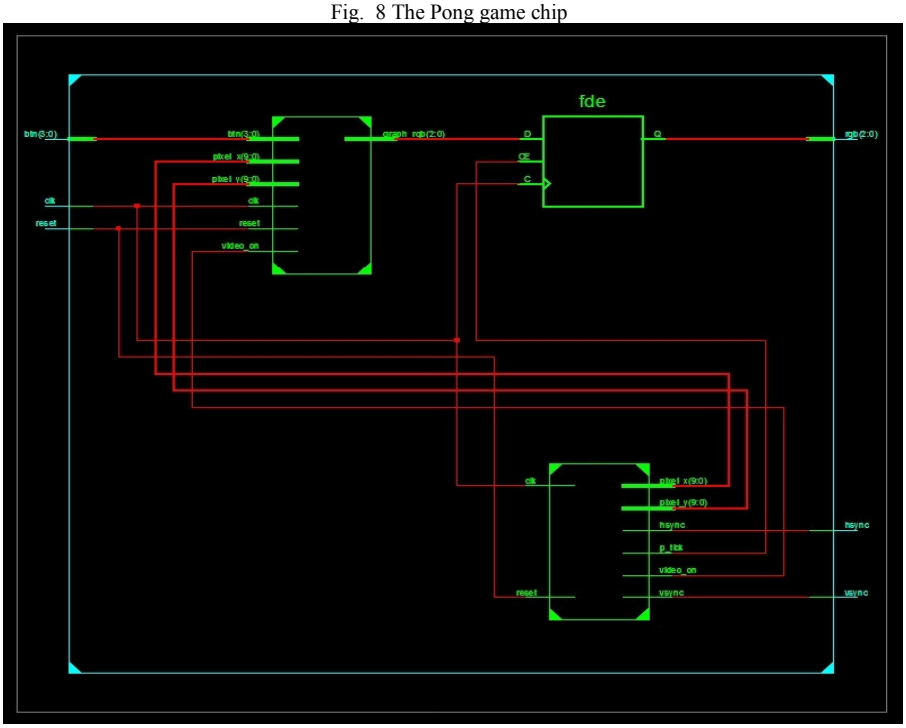

Fig. 9 The inside structure of the Pong game chip

Explanation of the game rules will be presented next. On Fig. 10 we can see the result of the Pong game on a CRT monitor with VGA input. The paddles are controlled with the push buttons from the NEXYS 2 development board.

The game consists of two blades and a ball. Background color of the paddles and the ball is configurable in software. The background is white, the paddles are red and blue, and the ball is green.

Two players can play the game with the 4 push buttons on the board. If the board is oriented in normal position, with the 4 push buttons right below, the first player, with blue paddle, will have the first 2 push buttons (BTN0 movement up, BTN1 movement down) and the second player, with red paddle, will have the last 2 push buttons (BTN2 movement up, BTN3 movement down).

The ball moves automatically hitting the top and bottom edge of the screen and the paddles when the ball it's hit by a player. If a player misses the ball, than he gets a goal, so the ball goes off the screen to the right or left side. For example, if a player misses the ball on the right, then left player gave a goal to the right player. After this it will be a new ball on the left, so the left player serves. The ball will move straight from left to right as long as the right player manages to hit the ball. If the right player scores a goal, then the ball starts its automatic movement from the right. The game is repeated until it it's stopped. The player, who manages to give the most goals, wins.

Fig. 10 The result of the Pong game on a CRT monitor

IV. Conclusion

As we could see we created a Pong game on FPGA. Our goal was to reproduce one of the most entertaining games of the computer game history. The Pong game was one of the first electronic games and maybe made the bases of the computer games history.

It was a good choice to create it on FPGA, because we had a suitable development board which has VGA port for interfacing a computer monitor and push buttons for controls. Making it on FPGA was a good idea also, because this way we had an embedded system, this way we don't have other dependencies not even operating sys-tem dependency. We also chose this platform, because this way we could create an ASIC, a standalone chip, by converting the VHDL code to Verilog with Mentor Graphic tools and we could create the layout of the chip for the final product. This way we had a game implemented on a chip, on hardware; this means that we have a standalone device with no speed issues, like if it would be made in software on a microcontroller.

In future we plan to extend the controls from push buttons to mouse and keyboard on PS/2 interface. We plan also to port the project to other platform too, like the ATLYS board, and create the video drivers on DVI or HDMI interfaces, for newer monitor types and create the keyboard and mouse drivers on USB interface or even add joystick drivers on USB interface.

***Abstract*—This paper presents an image hashing algorithm using robust features from jointed frequency domains. Extracted features are enciphered using a secure chaotic system. The proposed hashing scheme is robust to JPEG compression with low quality factors. This scheme also withstands several image processing attacks such us filtering, noise addition and some geometric transforms. All attacks were conducted using Checkmark benchmark. A detailed analysis was conducted on a set of 3000 color and gray images from three different image databases. The security of the method is assured by the robustness of the chaotic PRNG and the secrecy of the cryptographic key.**

I. Introduction

THE INCREASING popularity of mobile devices (smartphones, tablets and other gadgets) with high quality cameras and the development of high resolution digital cameras raised the number of digital images published over the Internet. An important contribution to this evolution was due to fast development of social networks and services dedicated to media sharing. All these services increased the number of images released in the online environment. This evolution raised the need of addressing some important issues such as: ownership protection, content authentication, fast image indexing and retrieval.

Digital watermarking was proposed as a first solution for these issues. Watermarking techniques are used to embed binary signatures (watermarks) modifying directly the content of the image. Watermarked images are identified detecting the presence of the watermark inside the image. However, many watermarking methods do not solve the problem of content identification. Most of the embedded watermarks are independent of the image content. An alternative of these problems was provided by the concept of image hashing.

Perceptual image hashing was used in the last years to solve ownership disputes, authentication and image retrieval problems. An image hashing scheme usually provides a sequence of values defining the visual characteristics of the image. The result is an image fingerprint usually protected with cryptographic techniques. Compared with conventional hash functions from cryptography, perceptual hash functions designed for images tolerate those modifications which do not affect the content of the image (i.e. compression, filtering, noise addition etc.). Thus, images with different representations, but with the same visual content, provide the same or very close hash values.

In the current work we propose a new algorithm which includes a perceptual hashing scheme for digital images secured with chaotic sequences. The interest was to find a suitable image representation space providing robust features to create an image hash for serving authentication of digital images, copyright protection and easy image database management. Our idea was to combine efficiently existent spaces in frequency domain for feature extraction.

This paper is organized as follows: Section II describes the design principles and properties of image hashing regarding some state of the art principles, Section III presents the construction of the image hashing scheme, Section IV illustrates the simulation results, Section V points some practical applications of the proposed algorithm and Section VI concludes the work.

II. Image Hashing – Design Principles and Properties

A. Design Principles

It is widely accepted that the basic components of perceptual image hashing are image pre-processing, feature extraction, feature post-processing and randomization.

By image pre-processing a new scaled version of the digital image is obtained. This is usually achieved reducing the representation space of the original image without losing the significant features of the content. The result is usually a scaled version of the input image, facilitating operations with low computational cost.

Feature extraction is the next phase in the construction of the image hash. This is an important stage because the feature space influences directly the robustness of the hash function. Depending on the application type of the image hashing scheme, a certain domain for feature extraction could be imposed. Robust algorithms are usually relied on frequency transforms for feature extraction. A scheme resilient to JPEG compression may use Discrete Cosine Transform (*DCT*) for the feature extraction stage. In [3], the authors proposed a scheme based on the statistical modeling

978-83-60810-58-3/$25.00

of DCT coefficients as a Gaussian distribution. The authors assert that invariance of DCT coefficients achieves robustness against attacks such as JPEG compression, filtering, scaling, brightness adjustment, histogram equalization and even small angle rotations. In [6], Fridrich and Gojan illustrate the advantage of considering low frequencies in DCT domain for feature extraction. Their reasoning is based on the properties of low frequency DCT coefficients which preserve the significant information of the image. Any modification in these frequencies is noticeable on the host image. Other transforms are also used in achieving perceptual image hashing. Guo and Dimitros propose the extraction of a robust feature set by using Discrete Wavelet Transform (DWT) followed by Radon transform [9]. The hash value is generated using a probabilistic quantization. This hash value is resilient to image compression, filtering, scaling and rotations. The authors assert good results even for image tampering. When high robustness against geometric attacks is required, the feature set may be extracted using transforms such as Discrete Fourier Transform or Mellin Fourier Transform. Swaminathan et al. [7] propose in their work an image hashing algorithm based on Mellin Fourier Transform. They claim to obtain good results against rotation operations up to 10^o and 20% cropping. This class of methods usually performs well against this type of attacks. However, they may be less robust against other common attacks such as noise addition.

The feature extraction process could be also realized in other transform domains such as Singular Value Decomposition (SVD) [5] or Fast Johnson-Lindenstrauss Transform (FJLT) [10].

The feature set extracted from a transform domain is generally built to assure the goals of the image hashing scheme.

Post-processing stage is usually a compression of the previously extracted features. A feature reduction technique is usually applied in this purpose in order to obtain a final binary feature set. This step is commonly realized using one of the following techniques: random projection of the feature set in another space, direct compression of the feature set, feature set quantization, clustering or by computing a cryptographic hash of the feature set.

Randomization is the last step in achieving the final perceptual hash value of the image. This step is mandatory and assures the unpredictability of the hash value obtained for each digital image, using a secret key.

B. Properties of Image Hashing

The final hash algorithm should provide the following features: one-way i.e. hard to recover the input from the hash value, collision resistant i.e. perceptually different images provide totally different hash values and key-dependence i.e. the hash value is highly dependent on the secret key.

The use of the hash value in verifying an image with a pair is resumed to the direct comparison of the two binary hashes. Few or zero differences between the hash values validate the authenticity of one image with respect to the other one.

The goal of this paper is to propose a robust hash function which respects both design principles and general features of image hashing algorithms. The proposed algorithm is potentially capable of solving copyright disputes, authenticating similar images and retrieving the image content from large image databases.

III. Proposed Image Hashing Scheme

As most of the image hashing algorithms, our scheme computes a global set of features from a digital image. A feature set is used to compute a perceptual hash value. The feature set is enciphered using a chaotic system. The novelty of the proposed algorithm is given by the feature set construction and the use of a proven secure chaotic system for the feature set encryption. A description of the proposed image hashing scheme is illustrated in the following subsections.

A. Image Pre-Processing

A color digital image is converted to grayscale and resized to a default size $m \times m$. The resizing procedure allows fast operations on the grayscale image. Comparing to the original input image, the content of the new image is not changed.

B. Feature Extraction

For the feature extraction step, the grayscale image is converted in frequency domain. This is the most significant stage in computing a robust feature set. A feature set built in frequency domain provides good robustness to certain classes of attacks.

Discrete Wavelet Transform (DWT) and Discrete Cosine Transform (DCT) are jointly used for extracting the global feature set. The first level DWT decomposition assures the separation of the information from the grayscale image in frequency sub-bands LL_1 (low-low), HL_1 (high-low), LH_1 (low-high) and HH_1 (high-high). The LL_1 sub-band carries most of the information from the grayscale image. For this reason, we consider the LL_1 sub-band in the feature generation process. A n –level decomposition is performed, considering LL_{n-1} sub-band ($n \geq 2$) at each iteration. At the n-level decomposition, the LL_n sub-band is obtained. This sub-band provides a matrix preserving most of the correlations from the original grayscale image. The DCT transform is applied for this sub-band on blocks of size $k \times k$. The Wavelet distribution from the LL_n sub-band is changed at the block level, and the new distribution follows the properties of DCT transform. Most significant frequencies are positioned in the top-left corner of the block, and the less significant frequencies are grouped in the bottom-right,

according to the DCT distribution. The first term of each DCT block, i.e. the (0,0) frequency, integrates the most important part of information from the block. This frequency, also called DC term, is extracted from each DCT block.

C. Feature Post-Processing

A feature vector containing the DC's of all DCT blocks computed from the LL_n sub-band is obtained at the previous step. At the current step, we apply a binarization technique for the feature vector. This is achieved by comparing each component of the feature set with the global mean of the feature set. Binary 0 is used to represent DC values under the mean and binary 1 is used to represent DC values above the mean. Thus, we obtain a binary fingerprint of the digital image.

D. Feature Randomization

This step is mandatory in order to assure the confidence of the binary feature set. The security of the feature set is obtained by direct enciphering with a recently proposed chaotic system. The chaotic generator proposed by Vlad et al. [8] is used as a stream cipher. This generator is based on tent-map and the running-key principle. The tent-map has the following formula:

$$x_{n+1} = f(x_n) = \begin{cases} \frac{x_n}{a}, & 0 \le x_n \le a \\ \frac{1-x_n}{1-a}, & a < x_n \le 1 \end{cases} \quad (1)$$

where $a \in (0,1) \setminus \{0.5\}$ is the control parameter of tent-map, x_n is the n^{th} value of the chaotic sequence generated using the tent-map and x_0 is the initial value from $(0,1)$ range. Binary sequences Z_i are generated using the X_i real value sequences generated with the tent-map, and binarization threshold c.

$$z_{i,j} = \begin{cases} 0, & 0 \le x_{i,j} \le c \\ 1, & c < x_{i,j} \le 1 \end{cases}, \quad (2)$$

where $z_{i,j}$ is the j^{th} element of the chaotic binary sequence Z_i and $x_{i,j}$ is the j^{th} element of the chaotic non-binary sequence X_i.

A running-key procedure is applied for typical Z_i binary sequences in order to obtain binary i.i.d. sequences compatible with the fair coin model.

The enciphering key used for the proposed image hashing algorithm is a binary sequence based on five additions of typical sequences Z_i, as shown in equation 3.

$$Y = \sum_{i=0}^{4} Z_i \bmod 2 \quad (3)$$

According to [8], the binarization threshold was considered equal to the control parameter $(c = a)$. The security of the method was theoretically and experimentally proven for a control parameter a in the range $(0.39, 0.61) \setminus \{0.5\}$ for 5 modulo 2 additions.

The secret key K of the system is given by the initial values of each non-binary sequence X_i and the control parameter:

$$K = (x_{00} \| x_{01} \| x_{02} \| x_{03} \| x_{04} \| a) \quad (4)$$

Note: As already suggested in [8], the additions number could be increased, extending the range of the control parameter a. This result leads to a larger selection of the secret key. The construction principle of the chaotic system used to generate the pseudo-random key to encipher the feature set is presented in Fig. 1.

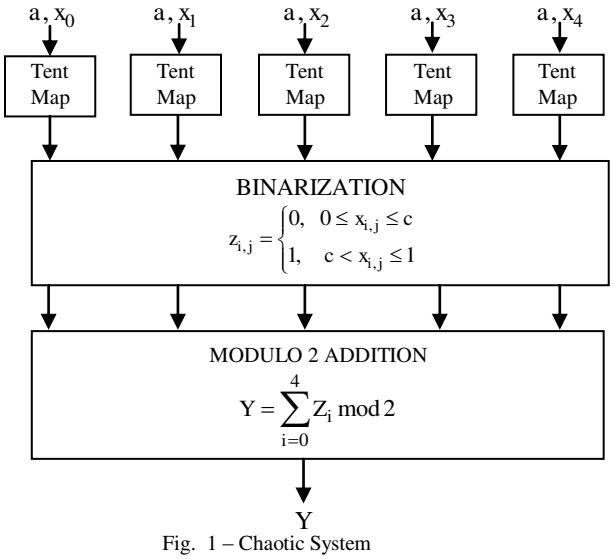

Fig. 1 – Chaotic System

The step-by-step construction of the perceptual image hashing scheme according to the description is next presented:

1. The input color image is transformed to grayscale.
2. The grayscale image is resized to a standard mxm dimension using the bicubic interpolation.
3. A n –level DWT Haar decomposition is applied on the grayscale image.
4. LL_n sub-band is divided in non-overlapping kxk blocks and DCT transform is applied on each block.
5. DC coefficients are extracted from all DCT blocks and the vector V containing the features of the image is built. The

length of the feature vector V is given by the formula:

$$l = \left(\frac{m}{k \cdot 2^n} \right)^2 \quad (5)$$

6. The mean value m_{dc} of the feature vector is computed.

7. The feature vector V is binarized and a new binary feature vector W is obtained according to the formula:

$$w_i = \begin{cases} 0, & v_i < m_{dc} \\ 1, & v_i \geq m_{dc} \end{cases} \quad (6)$$

where $V = (v_i)_{i=1...l}$ and $W = (w_i)_{i=1...l}$

8. A pseudo-random sequence $Y = (y_i)_{i=1...l}$ is generated using the chaotic system presented in Fig. 1, with the secret key K.

9. The binary feature vector W is enciphered using the pseudo-random sequence Y and the final hash value $H = (h_i)_{i=1...l}$ is obtained, where: $h_i = w_i \otimes y_i$, $i = 1...l$

At the end of all steps, a hash value with $l-$ bits length is obtained. The proposed system is illustrated in Fig. 2.

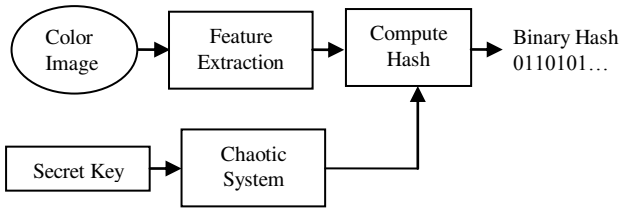

Fig. 2 – Proposed Hashing System

IV. Experimental Results

A. Simulations description

Several parameters were tested during the simulations. This parameters were the dimension of the resized image (M), the $n-$ level of the DWT transform and the block size kxk of the DCT transform. In this paper we illustrate the performances of the proposed algorithm for the following parameters:

a) $M = 256,\ n = 1,\ k = 8,\ l = 256$

b) $M = 256,\ n = 2,\ k = 4,\ l = 256$

The investigation of the proposed scheme was performed for hash values with constant binary lengths $l = 256$. All feature sets were encrypted using the 256–bit length chaotic sequences generated according to [8]. Each bit error from the binary hash contributes to the final error with the value $\frac{1}{l}$ (i. e. $err \approx 0.0039$).

For our purposes we used three different databases with resized images between 512x384 and 1024x1024. The investigation of the proposed algorithm was conducted using the following databases: Uncompressed Color Image Database (UCID) (color images), Break Our Steganographic System (BOSS) database (color images) and Break Our Watermarking System (BOWS) database (gray images). 1000 uncompressed images with different formats (tif, bmp and pgm) were randomly chosen from each database to create our testing set containing 3000 images. Images from BOSS database were converted from CR2 (Cannon Raw file format) in bmp format.

To define the similarity between the reference hash and the target hash, we use the Bit Error Rate (BER) as a measure of number of differences. The BER value for two hashes is given by the ratio between the number of erroneous bits and the total number of bits. A perfect similarity equates with a 0 BER value and two completely different images should provide a BER value close to 0.5 (not similar).

B. Robustness against JPEG Compression

Our tests for the proposed hash function aimed primarily the resilience of the method to the JPEG compression with different quality factors $(Q = 10, 20...100)$. A number of 1000 uncompressed digital images from each database were compressed with different quality factors, from 10 to 100. All hash values computed from uncompressed images were compared with hash values calculated for the corresponding JPEG image compressed with quality factor Q. The robustness achieved under JPEG compression for all three databases are independently illustrated in Fig. 3. Our results prove the robustness of the proposed method for both color and gray images at compression factors down to $Q = 10$. A DWT 2-level decomposition of the image jointed with the DCT 4x4 decomposition proved slightly better results in terms of robustness against JPEG compression for all three image sets.

C. Robustness against other image processing attacks

The proposed hashing algorithm exploits the advantage of transform domain and also provides some robustness against common image processing attacks such as filtering, noise addition and some geometric transforms. The BER value calculated between the hashes was also used as metric to measure the similarity between the original and attacked images. Several attacks were applied on the Lena image stored in JPEG format compressed with $Q = 90$ and with size 512x512. All attacks were conducted using the Checkmark framework [11] with the specific parameters and the results are presented in Table 1. The proposed hashing scheme performed well under filtering, noise addition and some geometric attacks. However, the method proved to be vulnerable against geometric manipulations such as rotations greater than 2^o and certain cropping attacks.

Scale 40%	0.0117
Crop 40%	0.1796

(1) This test is available in Checkmark Benchmark in several variants. Worst result is presented.

D. Robustness against malicious attacks

An attacker may perform two types of malicious attacks. The former implies the counterfeiting of both digital image and hash value. A second type of manipulation is by direct modification of the image content, while retaining the hash value of the image. The first class of attacks is unfeasible for the proposed scheme due to the secrecy of the enciphering key of the chaotic system. The resilience of the proposed algorithm against this class of attacks is given by the strength of the chaotic system and the secrecy of the key. For the latter class of attacks, the image may be maliciously distorted using the following techniques: object addition, object removal and object altering. Our block based hashing scheme is less sensitive to local modifications. Changing small parts of the image is reflected by the DC coefficients obtained for the DCT transform applied for the LL sub-band. However, these changes are not fully reflected in the binary feature vector. This is because the averaging procedure used to collect the feature set is not always sensitive to this type of modification. The use of a threshold very close to 0 may assure a partial robustness against this class of attacks.

A feasible solution for images containing text elements (letters, numbers, visible watermarks etc.) is using character identification techniques. All extracted text elements may be hashed using a robust cryptographic hash function. This hash value is concatenated to the perceptual hash value and a final hash is built. The use of SHA-256 as cryptographic hash function assures a 512 bit length of the final hash value.

E. Collision Resistance

A perceptual hashing scheme should provide different hashes for dissimilar images. The proposed algorithm complies with this requirement and provides different hash values for different images. In order to illustrate the collision resistance property of the proposed image hashing scheme an example is illustrated in Fig. 4 for images AudiA4_1.jpg and AudiA4_2.jpg (source: www.autovit.ro) The BER value calculated for the images presented in figure 0.5078 indicates the total difference between the hashes of the two distinct images.

Fig. 4 – a) AudiA4_1.jpg b) AudiA4_2.jpg
BER = 0.5078

However, the BER value of dissimilar images is not always close to 0.5. In Fig. 5 we illustrate the discriminative capability of the proposed algorithm, by computing the probability density function of BER values for dissimilar images. This result was obtained for 1000 image pairs, randomly extracted from the test databases. The BER values calculated between perceptual hashes of distinct images have a Gaussian distribution, with the mean 0.4763, which is close to the theoretical value 0.5.

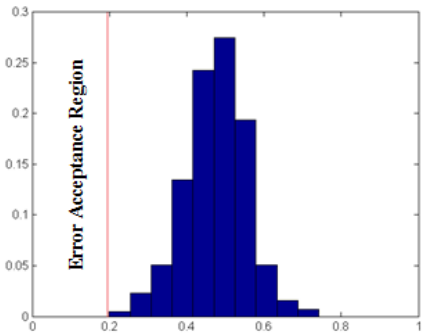

Fig. 5 – Probability density function for 1000 dissimilar image pairs

The minimum value (i. e. 0.1992) is far enough from most of the values obtained for Lena image and its attacked versions using Checkmark Benchmark. A BER threshold value fixed at 0.05 assures very good performances for our perceptual hashing method.

III. Practical Applications of the Proposed Hashing Scheme

The goal of the proposed image hashing system was to cover the following three topics: image authentication, image retrieval and copyright protection. In all three cases the reference image is required. For each target image the hash value is computed using the same secret key as for the reference image. Two hashes are computed at the bit level in order to determine the similarity level.

The verification system is built according to Fig. 6.

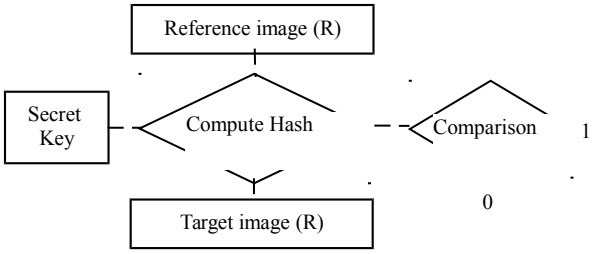

Fig. 6 Verification System

After comparing the two hashes at bit level, a *BER* value is computed. Depending on the sensitivity of the application integrating the image hashing scheme, different threshold value of the BER should be chosen. *BER* values above the threshold outputs a binary 0 (non-authentic image) and *BER* values under the threshold outputs 1 (authentic image). A *BER* value should be close to 0 when very high sensitivity is required (e.g. authentication of tampered images) and the may be increased when the application is not very restrictive (e.g. applications with content identification such as *TinEye*, *Google Images*).

IV. Conclusions and Future Works

In this paper we investigated the concept of image hashing in frequency domain secured with the aid of chaotic sequences. Our feature points are extracted using jointed *DWT* and *DCT* transforms. The feature set is enciphered using a robust chaotic map. A large set of natural images was tested in order to measure the performances of the proposed method. Experimental results illustrated a good robustness of the proposed method against known attacks such as compression, filtering, noise addition and slight geometric transformations. The proposed scheme may be applicable for image authentication, copyright protection and image retrieval. In part of future research, we will concentrate on an alternative approach which is more robust against geometric transforms and tampering attacks.

Acknowledgment

The author thanks Professor Adriana Vlad for the guidance concerning the use of the chaotic system from this work and for all technical advices and discussions about chaos based cryptography.

2nd Workshop on Scalable Computing in Distributed Systems and 7th Workshop on Large Scale Computations on Grids

The Large Scale Computing in Grids (LaSCoG) workshop originated in 2005, and when it was created we have stated in its preamble that:

"The emerging paradigm for execution of large-scale computations, whether they originate as scientific or engineering applications, or for supporting large data-intensive calculations, is to utilize multiple computers at sites distributed across the Internet. In particular, computational Grids are collections of distributed, possibly heterogeneous resources which can be used as ensembles to execute large-scale applications. While the vision of the global computational Grid is extremely appealing, there remains a lot of work on all levels to achieve it."

While, it can hardly be stated that the issues we have observed in 2005 have been satisfactorily addressed, a number of changes has happened that expanded the world of large-scale computing. Today we can observe emergence of a much more general paradigm for execution of large-scale applications, whether they originate from scientific or engineering areas, or they support large data-intensive calculations. These tasks utilize computational Grids, cloud-based systems and resource virtualization. Here, collections of distributed, possibly heterogeneous resources, are used as ensembles to execute large-scale applications.

This being the case, we have decided to keep the LaSCoG workshop tradition alive, but to co-locate it with a conference which will have an appropriately broader scope. This is how the Workshop on Scalable Computing in Distributed Systems (SCoDiS'14) emerged.

The LaSCoG-SCoDiS'14 pair of events shares a joint Program Committee and is envisioned as a forum to promote an exchange of ideas and results aimed at addressing sophisticated issues that arise in developing large-scale applications running on heterogeneous distributed systems.

Topics

Covered topics include (but are not limited to):

- Large-scale algorithms and applications
- Symbolic and numeric computations
- High performance computations for large scale simulations
- Large-scale distributed computations
- Agent-based computing
- Data models for large-scale applications
- Security issues for large-scale computations
- Science portals
- Data visualization
- Performance analysis, evaluation and prediction
- Programming models
- Peer-to-peer models and services for scalable Grids
- Collaborative science applications
- Business applications
- Data-intensive applications
- Operations on large-scale distributed databases
- On-demand computing
- Computation as a service
- Federation of compute capacity
- Virtualization supporting computations
- Self-adaptive computational / storage systems
- Volunteer computing
- Large scale computation with GPU
- Cloud computing architectures and models
- Load Balancing in large-scale distributed systems
- Intelligent resource allocation
- Cloud Security, Privacy, Confidentiality and Compliance
- Mobile Cloud
- High Performance Cloud Computing
- Green Cloud Computing
- Economic, Business and ROI Models for Cloud Computing
- Performance, Capacity Management and Monitoring of Cloud Configuration
- Cloud Interoperability and Portability
- Cloud Application Scalability and Availability
- Big Data Cloud Service

Event Chairs

***Abstract*—This paper presents the methodology for the synthesis of real-time applications for the Infrastructure as a Service (IaaS) model of cloud computing. We assume that the function of the application is specified as a set of distributed echo algorithms with real-time constraints. Then our methodology schedules all tasks on available cloud infrastructure minimizing the total costs of the IaaS services, while satisfying all real-time requirements. It takes into account limited bandwidth of communication channels as well as the limited computation power of server nodes. The optimization is based on the iterative improvement algorithm, which has the capability of escaping from the local extrema, giving better results than greedy algorithms. The method starts from the fastest solution and in the next steps modifies the solution to reduce the cost of hiring the cloud infrastructure. We also present a sample application, that shows the benefits of using our methodology.**

***Index Terms*—cloud computing, Infrastructure as a Service, real-time system, distributed systems, system synthesis.**

I. Introduction

CLOUD computing recently has received significant attention as a new computing infrastructure. A cloud environment often has hundreds of thousands of processors with numerous disks interconnected by dedicated high-speed networks. There are three deployment models of cloud computing [1]. The first is the private cloud, it works specially for organization with private security and exclusive network. The second is the public cloud, it gives the maximum efficiency level in shared resources and it is protected by the cloud service provider. The third is the hybrid cloud, it combines the private and public. Cloud computing supports three types of services [2]:

- IaaS (Infrastructure as a Service) offers end users direct access to processing, storage, and other computing resources. IaaS allows users to configure resources, to run operating systems and to run application software on them. Examples of IaaS are: Amazon Elastic Compute Cloud (EC2), Rackspace and IBM Computing on Demand,
- PaaS (Platform as a Service) offers an operating system as well as suites of programming languages and software development tools that customers can use to develop their own applications. Examples of PaaS are: Microsoft Windows Azure and Google App Engine. PaaS gives end users control over application design, but does not give them control over the physical infrastructure,
- SaaS (Software as a Service) offers final applications that end users can access through a thin client (web browser). Examples of SaaS are: Gmail, Google Docs. The end users (customers) do not exercise any control over the design of the application, servers, networking and storage infrastructure.

Cloud computing is really changing the way, how and where the computing is going to be performed. More and more Internet-enabled devices are now available (mobile phones, smart TVs, navigation systems, tablets, etc.). It is expected that in a few years, almost each product may be identified and traced in the Internet using RFID (Radio Frequency IDentification), NFC (Near Field Communication) or other wireless communication methods. Smart device not only incorporates sensing/monitoring and control capabilities, but also may cooperate with other devices and with Internet applications. For example an adaptive car navigation system may interact with an Internet system, controlling and monitoring the traffic in a city, to avoid traffic jam. In such case cloud applications are used to process requests sent by smart devices implementing client applications. Usually responses to the device should be sent during the limited time period. Therefore, this class of application is a real-time system.

Distributed Internet application requires an expensive network platform, consisting of servers, routers, switches, communication links etc., to operate. The cost of the system may be reduced by sharing the network infrastructure between different applications. This is possible by using the Infrastructure as a Service (IaaS) model [3] of the cloud computing services [4]. IaaS together with a real-time cloud environment [5] seems the ideal platform for many real-time cloud applications. But to guarantee the quality of service

978-83-60810-58-3/$25.00

and minimize the cost of the system, efficient methods of mapping real-time applications onto IaaS should be developed.

Some studies [6], [7] consider resource allocation for cloud applications. The common focus of these works is the optimization of resource allocation from IaaS in respect of the cost. One of the previous method selecting resources from a cloud is based on the conception of the game theory [8]. The method optimizes the cost and the performance. This conception reflects the common characteristics of the physical position and bandwidth available between job and resources, and emphasizes on establishing a scheduling relationship between near entities. In resource scheduling, a choice of near and low-cost resources is a key criterion. Paper [9] also describes the scheduling algorithm for cloud computing. In this cost-based method, the set of computing resources with the lowest price are assigned to the user, according to the current supplier resource availability and a price. Another method, proposes scheduling of resources, based on genetic algorithm [10]. In this method, scheduling scheme is coded using integer sequence and a fitness function is based on influence degree. The genetic operations include selection, crossover, mutation and elitist selection. None of the above methods consider real-time requirements.

The use of the cloud infrastructure for real time computing is a quite new concept. Current work concerning Real Time Cloud Computing mainly concentrates on 2 domains: adopting existing web technologies to this new paradigm and developing software architectures for real-time applications. Recent studies [11]–[14] have been performed on the allocation of resources for real time tasks. Aymerich *et al.* [11] developed an infrastructure for a real-time financial system based on cloud computing technologies. Liu *et al.* [12] showed how to schedule real-time tasks with different utility functions. The real-time tasks are scheduled non-preemptively with the objective to maximize the total utility by using time utility function (TUF). Tsai *et al.* [13] discuss about a real-time database partitioning on cloud infrastructures. Kim *et al.* [14] investigate power-aware provisioning of resources for real-time cloud services. In their work the real-time constraint is specified in a Service Level Agreement (SLA) between customers and cloud providers. SLAs specify the negotiated agreements, including Quality of Service (QoS), such as deadlines. In such cloud models the service provider is responsible for the allocation resources. Their work examines power management while allocation of resources should meet the SLA. None of these studies consider a cost-efficient selection, from a set of different types of resources available in clouds, for real-time tasks.

The closest work to ours is that of Kumar *et al.* [15]. They develop an algorithm of resource allocation for applications with real-time tasks. They propose an EDF-greedy scheme and a scheme considers temporal overlapping to allocate resources efficiently. Unfortunately an EDF-greedy strategy may not give the lowest total cost, because of their tendency to be trapped in local minima of the cost.

In our work, we consider the IaaS model of the real-time cloud computing, where the user pays the cost of using the resources supported by the service provider. We present the methodology for the synthesis of reactive, real-time cloud applications specified as a set of distributed echo algorithms. The goal of our methodology is to find the distributed architecture of the application which will satisfy all user requirements. We developed an iterative improvement algorithm, which is able to escape from the local extrema, giving much better results than constructive algorithms. Presented method also minimizes the cost of IaaS services required for running the real-time application in the cloud environment.

The next section presents our assumptions and it defines the concept of real-time cloud computing used in our methodology. In section 3 the method of synthesis will be described. Section 4 presents example and experimental results demonstrating the advantages of the methodology. The paper ends with conclusions.

II. Problem statement

System synthesis is a process of automatic generation of the system architecture, starting from the formal specification of functional and non-functional requirements. Functional requirements define functions that should be implemented in the target system. Nonfunctional requirements usually define constraints that should be fulfilled, e.g., time constraints define the maximal time for execution of the given operations, cost requirements define the maximal cost of the system, etc.

Functions of distributed systems are usually specified as a set of communicating tasks or processes. Since we consider real-time systems, hence time constraints are the main set of requirements. The model of the system specification used in our methodology will be described in p.1.

We use existing network infrastructure, hired from a cloud (IaaS), consisting of servers, routers and connections. If the current architecture does not guarantee that all time requirements will be met, the infrastructure should be extended by adding some components, i.e. additional resources should be hired from cloud providers. Thus, it should be possible to specify architectural requirements that have to be satisfied by the target system. The model of the target architecture will be described in p.2, while requirements that are used in our methodology will be presented in p.3.

1. Functional specification

We assume that a real-time cloud application will process requests received from clients. The system should be able to process all requests during the required time period, i.e., for each real-time request a response should be sent before the specified deadline. We consider soft real-time processing [16], ensuring that the process will be completed at a given time depending on the constraints of quality of service. In

case of a large number of requests and a long time of processing, real-time processing will be possible only if massive parallel computing will be applied. Therefore, the functional specification of the system should represent the function as a distributed algorithm [17], developed according to the following requirements:

(1) parallel model of computations: system should be specified as a set of parallel processes using message passing communication,
(2) parallel request handling: huge number of requests may cause the communication bottleneck, to avoid this, simultaneous requests should be handled by different processes.

We assume that the system is specified as a collection of sequential processes coordinating their activities by sending messages. Specification is represented by a graph $G = \{V, E\}$, where V is a set of nodes corresponding to the processes and E is a set of edges. Edges exist only between nodes corresponding to communicating processes. Tasks are activated when required set of events will appear. As a result, the task may generate other events. External input events will be called requests (Q), external output events are responses (O) and internal events correspond to messages (M). The function of the system is specified as finite sequences of activation of processes. There is a finite set of all possible events

$$\Lambda = Q \cup O \cup M = \{\lambda_i : i = 1, \ldots, r\} \quad (1)$$

For each event λ_i communication workload $\omega(\lambda_i)$ is defined. System activity is defined as the following function:

$$\Phi : C \times V \rightarrow \omega \times 2^{\Lambda} \quad (2)$$

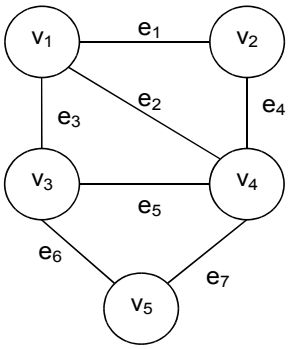
where C is an event expression (logical expression consisting of logical operators and Boolean variables representing events) and ω is the workload of the activated process.

Using function Φ it is possible to specify various classes of distributed algorithms. Fig. 1 presents sample echo algorithm [18] consisting of 5 processes. The algorithm consists of 10 actions. Each action is activated only once, when the corresponding condition will be equal to true. All actions except A_1 and A_6 contain alternative sub-actions. Only the first action, for which the condition will be satisfied, will be activated. According to the echo algorithm specification, process v_1 is the initiator, messages $m1_1$, ..., $m14_7$ are explorer messages, while $m15_1$, ..., $m25_7$ are echo messages (indices are added only for readability, mx_i means that message mx is associated with edge e_i in the graph, for the same reason, edge names in the event expressions mean any received message corresponding to this edge, e.g., $e_1 = m1_1 \mid m4_1 \mid m15_1$, $e_2 = m2_2 \mid m9_2 \mid m20_2$, etc.). Events x_1, ..., x_{11} are internal events, used for storing the state of processes between successive executions.

Since different requests may be processed by distinct algorithms, the function of a system may be specified using a set of functions Φ sharing the same processes. Each function has only one initiator (process activated by the request). Processes may be activated many times, but the algorithm should consists of the finite number of actions and infinite loops are not allowed.

2. Real Time IaaS Architecture

The proposed architecture of RTCCI (Real Time Cloud Computing Infrastructure) is composed of two layers (Fig. 2): Network Layer (*NL*) and Server Layer (*SL*).



A_1: $\Phi(v_1,\{q_1\}) \rightarrow (5, \{m1_1,m2_2,m3_3\})$

A_2: $\Phi(v_2,\{m1_1\}) \rightarrow (4,\{x_1,m5_4\}) \mid \Phi(v_2,\{m10_4\}) \rightarrow (4,\{x_2,m4_1\})$

A_3: $\Phi(v_3,\{m3_3\}) \rightarrow (7,\{x_3, m7_5,m8_6\}) \mid \Phi(v_3,\{m11_5\}) \rightarrow (7,\{x_4,m6_3,m8_6\})$
$\mid \Phi(v_3,\{m13_6\}) \rightarrow (7,\{x_5,m6_3,m7_5\})$

A_4: $\Phi(v_4,\{m2_2\}) \rightarrow (6,\{x_6,m10_4,m11_5,m12_7\})\mid$
$\Phi(v_4,\{m5_4\}) \rightarrow (6,\{x_7,m9_2,m11_5,m12_7\})\mid$
$\Phi(v_4,\{m7_5\}) \rightarrow (6,\{x_8,m9_2,m10_4,m12_7\})\mid$
$\Phi(v_4,\{m14_7\}) \rightarrow (6,\{x_9,m9_2,m10_4,m11_5\})$

A_5: $\Phi(v_5,\{m8_6\}) \rightarrow (5,\{x_{10},m14_7\}) \mid \Phi(v_5,\{m12_7\}) \rightarrow (5,\{x_{11},m13_6,\})$

A_6: $\Phi(v_1,\{e_1\&e_2\&e_3\}) \rightarrow (10, \{r_1\})$

A_7: $\Phi(v_2,\{x_1\&e_1\&e_4\}) \rightarrow (4,\{m15_1\}) \mid \Phi(v_2,\{x_2\&e_1\&e_4\}) \rightarrow (4,\{m16_4\})$

A_8: $\Phi(v_3,\{x_3\&e_3\&e_5\&e_6\}) \rightarrow (3,\{m17_3\}) \mid \Phi(v_3,\{x_4\&e_3\&e_5\&e_6\}) \rightarrow (3,\{m18_5\}) \mid \Phi(v_3,\{x_5\&e_3\&e_5\&e_6\}) \rightarrow (3,\{m19_6\})$

A_9: $\Phi(v_4,\{x_6\&e_2\&e_4\&e_5\&e_7\}) \rightarrow (5,\{m20_2\}) \mid \Phi(v_4,\{x_7\&e_2\&e_4\&e_5\&e_7\}) \rightarrow (5,\{m21_4\}) \mid \Phi(v_4,\{x_8\&e_2\&e_4\&e_5\&e_7\}) \rightarrow (5,\{m22_5\}) \mid$
$\Phi(v_4,\{x_9\&e_2\&e_4\&e_5\&e_7\}) \rightarrow (5,\{m23_7\})$

A_{10}: $\Phi(v_5,\{x_{10}\&e_6\&e_7\}) \rightarrow (2,\{m24_6\}) \mid \Phi(v_5,\{x_{11}\&e_6\&e_7\}) \rightarrow (2,\{m25_7\})$

Fig 1. Sample specification of the echo algorithm

Layer *NL* consists of Communication Channels (*CC*) composed of routers and communication links. For each CL_i the available bandwidth $B(CC_i)$ is defined.

Layer *SL* contains servers (*S*) consisting of computational nodes N_i. Each N_i is characterized by performance P_i reserved for RTCC system, and it may be equipped with a network interface. Thus, each computational node may be connected to another communication link.

The goal of our methodology is to find the cheapest system architecture for an application that fulfills all time constraints and uses the existing network infrastructure available in a cloud. All servers (nodes) and communication channels, that are used in the target architecture $\Pi_T = \{S, CC\}$ of the system, will be outsourced to the cloud provider.

The method starts from the initial architecture $\Pi_I = \{S', CC'\}$ consisting of the fastest resources. Next, the architecture is optimized by performing some modifications of Π_I, only resources supported by cloud providers are considered here. Our methodology minimizes the cost of hiring the network infrastructure by achieving the maximal utilization of all resources and by allocating cheapest components that satisfy all time constraints. Each available resource is characterized by properties defining the performance and the cost of the corresponding IaaS service. Specifications of all available resources constitute the database of resources $L = \{CC'', S''\}$.

Communication channels $cc_i \in CC''$ are characterized by the maximal available bandwidth $B(cc_i)$, bandwidth $B_r(cc_i)$ reserved for the application and the price of communication service $Cr(cc_i)$ for each available bandwidth. Communication channel connects any pair of network interface ports. Thus, the time of transmission of packet D_i through communication channel cc_j is the following:

$$T(D_i)=\frac{l(D_i)}{B_r(cc_j)} \tag{3}$$

where $l(D_i)$ is the length of packet D_i.

We assume that each server s_i may consist of any number of nodes, i.e., a multiprocessor or a cluster architecture of the server. Each node may execute all assigned tasks sequentially. Thus, the following properties characterize the server:

– n_S - the number of nodes, hence server s_i may be represented as a set $\{N_1, ..., N_{ns}\}$ of nodes,

– $Cr(s_i)$ - the cost of the computing services, the cost depends on the number of nodes allocated to the application, usually the cost function is not linear.

– $\{P_1, ..., P_{ns}\}$ - performance of each node.

The time required for executing process τ_i by the node N_j equals:

$$T(\tau_i)=\frac{w(\tau_i)}{P_j} \tag{4}$$

where $w(\tau_i)$ is the workload of task τ_i.

Fig. 2 presents a sample target architecture of RTCCI.

3. Requirements and constraints.

Let $\rho(\lambda_x,\lambda_y)$ be a sequence of actions $A_1,...,A_s$ such, that λ_x is the request, λ_y is the response, and:

$$A_1:\Phi(v_i,\lambda_x)\rightarrow\{\omega_1,\{\lambda_1\}\},\ A_s:\Phi(v_j,\lambda_s)\rightarrow\{\omega_s,\{\lambda_y\}\},\ \underset{1<k<s-1}{\forall} A_k\rightarrow A_{k+1} \tag{5}$$

where v_i, v_j are any processes and $A_k \rightarrow A_{k+1}$ means that action A_k generates events activating action A_{k+1}. Then, the time of execution of the given sequence of actions is defined as a sum of the execution times of all processes and a time of inter-process communication:

$$t(p(\lambda_x,\lambda_y))=\sum_{i=1}^{s}\frac{\omega(A_i)}{P(A_i)}+\sum_{i=1}^{s}\frac{\omega(m_i)}{B_r(m_i)} \tag{6}$$

where: $\omega(A_i)$ is the workload of the process activated by action A_i, $P(A_i)$ is the performance of the server executing this process, $\omega(m_i)$ is the communication size, $B_r(m_i)$ is the reserved bandwidth of the channel used for sending the message. If processes activated by actions A_k and A_{k+1} are executed by the same server, then $\omega(m_k) = 0$ for any message sent between these processes.

The time constraint is the maximal period of time that may elapse between sending request and receiving the response. Since the request may activate different sequences of actions until the response will be obtained, therefore the time constraint (deadline) is defined as:

$$t_{max}(\lambda_x,\lambda_y)=\underset{i}{MAX}(t(p_i(\lambda_x,\lambda_y))) \tag{7}$$

During the synthesis, processes and transmissions are scheduled and assigned to network resources. The method first assigns processes and transmissions to the fastest re-

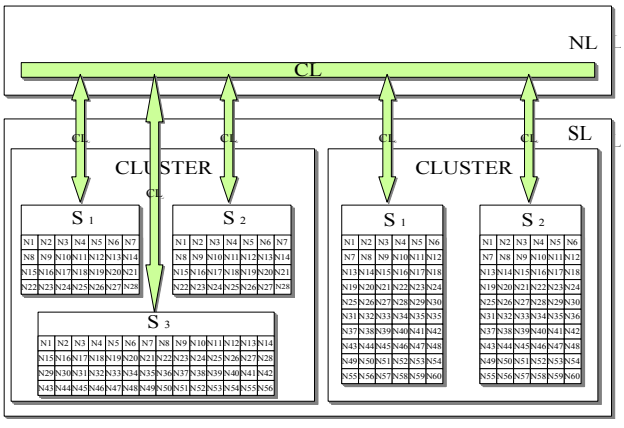


Fig 2. Sample target architecture

sources supported by cloud providers. This step verifies if it is possible to find the network infrastructure which fulfills all time constraints. Next, the cost is minimized by performing the following modifications:

- change communication channel to cheaper one, decreasing bandwidth $B_r(cc)$, for any allocated communication channel, in this way the cost of communication service $Cr(cc)$ may be reduced,
- change server s to cheaper one or reduce the number of allocated nodes, in this way the cost of computing services $Cr(s)$ will be reduced.

Only modifications that do not violate time constraints are considered. The optimization process will stop, when each considered modification of the architecture will cause violation of time requirements. Hence, the total cost of the IaaS service will be the following:

$$C_M = \sum_i Cr(cc_i) + \sum_j Cr(s_j) \tag{8}$$

The goal of our methodology is to minimize C_M.

III. Synthesis

Our method of synthesis starts from the formal specification of the system (as described in p. II.1) and tries to produce the optimal target architecture of the system, that satisfies all constraints. The method minimizes the cost of outsourcing the network infrastructure to the IaaS cloud provider.

1. Assumptions

The method is based on the worst case design. We assume that the workload of each action and sizes of all transmissions are estimated for the worst cases. All time constraints should also satisfy the following condition:

$$t_{max}(\lambda_q, \lambda_o) \leq \frac{1}{f_{max}(\lambda_q)} \tag{9}$$

where $f_{max}(\lambda_q)$ is the maximal frequency of requests λ_q, λ_o is response to the request. Otherwise, the system will be not able to process requests in real-time.

The system specification consists of a set of distributed algorithms (tasks). Our scheduling method is based on the assumption that the worst case is when all tasks will start at the same time, this corresponds to the simultaneous appearance of all requests. Thus, all tasks are scheduled in a fixed order and are activated in certain time frames. When the system will receive new request, it will be processed during the next activation of the corresponding task. Therefore, time constraints should include this delay, i.e., task should be scheduled with period equal:

$$\frac{t_{max}(\lambda_q, \lambda_o)}{2} \tag{10}$$

The goal of optimization is the minimization of the cost of outsourcing the network infrastructure to cloud providers. The method schedules tasks and transmissions on available cloud resources. We use an efficient iterative algorithm for finding the (sub-)optimal solution.

2. Dynamic task graph

The algorithm should be able to verify if after scheduling next task, it is still possible to obtain the valid system. For this purpose the dynamic task graph (DTG) is created. All tasks are simultaneously analyzed according to their order of execution, assuming that processes and transmissions will be executed by the fastest resources. Since in the system specification only the first message received by a process is relevant, all other messages are temporarily neglected. In this way the specification is converted into task graph. Next, the task graph is scheduled using ASAP (As Soon As Possible) method.

3. Algorithm of the synthesis

In our earlier works [19], [20] synthesis is performed using the greedy algorithm, that schedules processes according to their priority. However, it is constructive algorithm and the obtained results are far from optimal, because the method is prone to be trapped in the local minima of the cost. In this paper, we present the iterative improvement algorithm, which is able to escape from the local minima, giving better results than constructive algorithm. An outline of the algorithm is shown on Fig. 3.

Gain is the difference of quality of the new solution and the current one. The quality of the solution is determined on the basis of several features of the target architecture. In our case, the quality of solutions is based on the cost of the system that satisfies all time constraints, i.e., the optimum is the cheapest system that meets the time constraints.

The algorithm starts from the initial architecture where all processes are assigned to resources with the highest performance, according to the rule: the biggest task to the fastest processor. For transmissions, also communication services with the highest bandwidth are reserved. Next, while any time constraint is not violated, the method tries to reduce the cost of IaaS services by modifying the network infrastructure using iterative improvement methods (refinement of the current result). The methodology repeats the following steps:

- remove the node or replace the resource with a cheaper one,

```
Generate initial solution Π^CUR
do{
  Π^BEST = Π^CUR;
  gain = 0;
  while((Π'=refine(Π^BEST)) != Φ){
   gain = Q(Π') - Q(Π^CUR);
   if(gain > 0)
     Π^CUR = Π';
  }
}while(gain > 0);
```

Fig 3. An outline of the iterative improvement algorithm.

- create a dynamic task graph,
- schedule all processes and transmissions.

The solution giving the best gain is chosen to the next step. The algorithm terminates when there is no solution that can improve the total cost of the system.

The quality of the solution determines the gain of the improvement. The aim of the algorithm is to minimize the cost, thus the main system feature determining the gain should be the cost of the system. However, driving refinement only according to the optimisation goal usually leads to trapping the algorithm in local minima (the greedy approach). Hence it is appropriate to define the quality of the solution using also other features of the solution. It should inhibit the greed of the algorithm. For this purpose laxity L is introduced. The laxity is defined as follows:

$$L = t_{max} - t_{cur}, L \geq 0 \tag{11}$$

where t_{cur} is the execution time for the current solution.

At each step, various modifications of the current system are considered. Each modification may change the cost and/or the latency of the solution. Quality (Q) of the modified system is defined as follows:

$$Q = \begin{cases} \frac{C_{BEST} \cdot L_{CUR}}{C_{CUR} \cdot L_{BEST}}, when\ \Delta C < 0 \text{ and } L_{CUR} \geq 0 \\ 0, when\ \Delta C > 0 \text{ or } L_{CUR} < 0 \end{cases} \tag{12}$$

where:

$$\Delta C = C_{CUR} - C_{BEST} \tag{13}$$

L_{CUR} and C_{CUR} are the features of the current result, L_{BEST} and C_{BEST} are the features of the best result, found in the previous iterations.

The quality is defined as the ratio of the previous cost to the cost after modification. If the latency is also changed, then the quality is modified by the percentage of the latency increase. If there is no reduction of the system cost, then the quiality equals 0, i.e., modification will be rejected. This condition guarantees that the algorithm is convergent. The quality is also equal to 0 when a time constraint is violated, i.e., $L_{CUR} < 0$.

Solutions that do not lead to a gain greater than 0 are rejected. The quality prefers solutions with the greatest reductions of cost and greater increase of the performance of the system. If all modifications do not reduce the cost of the system ($\Delta C=0$) then the solution with the greatest increase of the system performance is taken as the best to the next step.

At each step of the algorithm, various modifications of the current solution are considered and solution that gives the highest quality is chosen to the next step. Since the quality Q depends also on the increase of laxity, therefore the greed of the algorithm will be reduced, i.e., instead of the modification reducing cost the algorithm may select modification that more reduces the laxity. Higher laxity means more possiblilities of improvements in the next steps.

In order to minimize the cost of the system, in the algorithm the following modifications are considered:

(1) Change the node from the cloud to cheaper one and move tasks to it.
(2) Replace the communication link to cheaper one.
(3) Remove one node and move all assigned tasks to other nodes.

In the case where more than one task is allocated to the resource, it is necessary to schedule tasks. The FIFO scheduling method is used for this purpose. The refinement process is presented on Fig. 4. It consists of 3 loops, each loop evaluates all possible modifications of the system architecture. Only systems with quality greater than 0 are taken into consideration. We assume that the process *refine* returns the architecture, then after next activation it continues its execution. The process terminates after analyzing all possible modifications of the initial architecture. Architecture with the highest quality is taken as an input to the next step of the algorithm.

IV. Example

As an example demonstrating our methodology we present the design of an adaptive navigation system for a smart city [19]. We assume that all cars are equipped with GPS navigation devices (GD), that are able to communicate with the Internet using wireless communication (we assume that the network of access points covers the whole city). GD devices send requests to RTCC system. Requests contain information about current position, the destination and user preferences. Then, the system finds the optimal route and sends response to GD device. Since GD expects the response in a reasonable time, then the system should satisfy real-time constraints. We assume that the time in which the GD device has to get an answer must be no longer than 5 seconds. The idea of such system is based on the adaptability, i.e., the system may take into consideration traffic information, traffic impediments (e.g., car accidents) and it may construct different routes for the same destinations to avoid traffic jams.

Since the system may receive thousands of requests per second the centralized system may not be able to handle all requests due to the communication bottleneck. Therefore, we propose the distributed system. The city is partitioned into sectors, routes through each sector are computed by different processes. Each process also receives requests and sends responses from/to positions in the corresponding sector. Thus, the function of the system may be specified as a set of distributed algorithms, similar to the echo algorithm. In our example the specification consists of 6 to 12 tasks, in each task another process is the initiator. The initiator receives all requests coming from the corresponding sector, computes all possible routes to adjacent sectors and sends the information about routes to adjacent processes. When messages will reach the destination sector, then the best route is selected and information about it is sent back to the initiator.

```
refine(Π^CUR){
    for each X_i ∈ Π^CUR do {
      Π′ = Π^CUR − X_i;
      for all X_j in IaaS do
         if C(X_j ) < C(X_i) then {
           Π″ = Π′ + X_j;
           for each v_k ∈ X_i do  //transfer tasks from X_i to X_j
             Assign v_k to X_j;
           if Q(Π″) > 0 then
              return Π″;
         }
    }
    for each CL_i ∈ Π^CUR do {
      Π′ = Π^CUR − CL_i;
      for all CL_j in IaaS do
        if C(CL_j ) < C(CL_i) then {
           Π″ = Π′ + CL_j;
          for(cl_k ∈ CL_i){  //transfer transmission from CL_i to CL_j
             Assign cl_k to Cl_j;
           if Q(Π″) > 0 then
              return Π″;
        }
    }
    for each X_i ∈ Π_CUR do {
     Π″ = Π^CUR − X_i;
     for each v_k ∈ X_i do {  //transfer tasks from X_i to other resource from Π^CUR
       Find resource X_j ∈ Π″ such, that L(Π″)is maximal after
          assigning v_k to X_j;
       Assign v_k to X_j;
     }
     if Q(Π″) > 0 then
       return Π″;
    }
   return Φ;
}
```

Fig 4. Synthesis algorithm for cost minimization.

Assume that a cloud provider offers 13 servers and 4 bandwidths for communication services (Fig. 5), and assume that parameters of available resources are known. In Table I available bandwidths of communication links and the cost of IaaS communication services are presented. Table II shows parameters of servers available in the cloud and costs of IaaS computing services are presented. The time constraint t_{max} equals 5 s.

Some dynamic tasks graph constructed for the best solution are presented on Fig 6. On Fig 7 the Gantt chart presenting the scheduling of all processes is presented. We may observe high utilization of all servers.

TABLE I COST OF AVAILABLE IAAS COMMUNICATION SERVICES

Link	Bandwidth (Mbps)	Per hour
Lx1	1	0.0001$
Lx2	5	0.0010$
Lx3	10	0.0028$
Lx4	20	0.0069$

TABLE II: COST OF AVAILABLE IAAS SERVICES FOR ONE SERVER.

Server	Processor	Per hour
S1	1.7 GHz	0.004 $
S2	2.4 GHZ	0.008 $
S3	2 × 1.7 GHz	0.007 $
S4	2 × 2.4 GHz	0.014 $
S5	4 × 1.7 GHz	0.013 $
S6	4 × 2.4 GHz	0.025 $
S7	4 x 1.5 GHz	0.012 $
S8	4 x 1.2 GHz	0.01 $

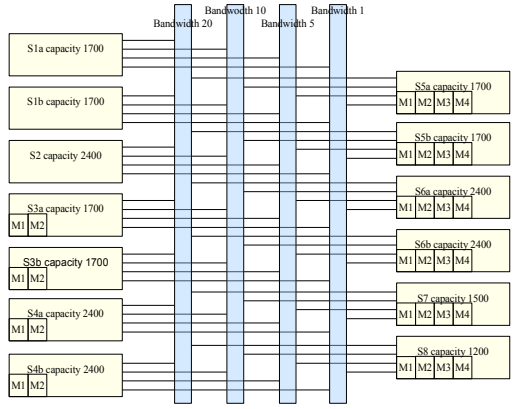

Fig 5. Database of resources available in the cloud.

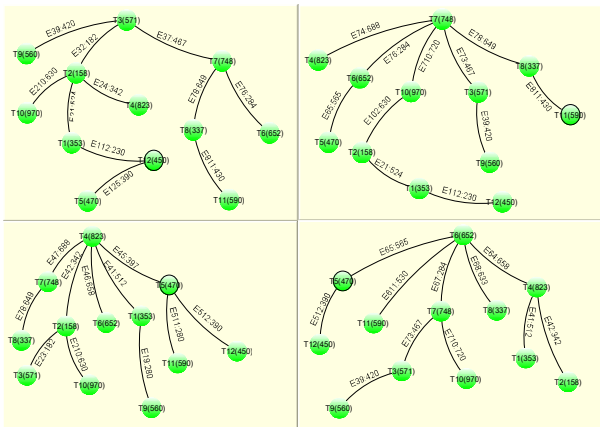

Fig 6. Several sample tasks graph

The frequency of task activation depends on the number of requests appearing during the given time period. For a large number of requests the system will require more computing power. Thus, the cost of IaaS services strongly depends on the maximal estimated traffic in the city. Fig. 8 and Table III present the dependence between the number of requests and the cost of IaaS services for greedy and iterative improvement algorithm. To allocate resources from the IaaS, iterative improvement algorithm produced much better results than greedy algorithm. The comparison is shown in Table III. Our algorithm allows the end users of IaaS to reduce the cost of hiring cloud resources by over 50%.

V. CONCLUSIONS

We analyze the problem of allocating resources for real-time tasks such that the cost is minimized and all the deadlines are met. In this paper the methodology for the synthesis of reactive, real-time cloud applications accordant with the Cloud Computing concept, was presented. We developed the architectural model of the reactive RTCC system and we proposed the method of specification for such systems, in the form of a set of distributed Echo algorithms.

Next, the method of synthesis that guarantees the fulfillment of all time requirements was proposed. The method schedules all processes and transmissions on network resources supported by cloud providers, while the cost of IaaS services is minimized. Finally, we presented the design process of the sample RTCC system, which underlines the advantages of our methodology above greedy algorithm.

In our approach we use iterative improvement algorithm for scheduling and allocation of new resources and we show its advantage over the heuristic greedy algorithm. In the future work we will consider developing a more sophisticated method of optimization as well as more advanced methods for the worst case analysis. Reactive RTCC systems are a new challenge for future Cloud Computing. We believe that in the future, RTCC systems will constitute an important class of Cloud Computing systems, thus efficient design methods will be very desirable.

***Abstract*—Cloud architecture has the ability of sharing hardware resources and services among multiple tenants. In this paper we measure the performance for the multi-VM (multiple virtual machines) cloud architecture and compare it with the single-VM architecture. Renting resources on a cloud usually comes with a variety of options, such as use of more and smaller virtual machines or use of less and bigger virtual machines. The objective of this research is to find out which scenario gives better performance for the same price of rented resources. This will be done by comparing the following attributes: Average response time, Pages per second, Average page time, Requests per second, CPU time. We setup a hypothesis that the multi-VM approach would be better, and the best architecture is the one offering the highest number of small virtual machines, predicting that the computational demands will spread to different virtual machines in a balanced manner. The results confirm the hypothesis and lead to a recommendation for an optimal architecture of a cloud based solution for a common transactional web solution.**

***Index Terms*—Cloud; Web Services; Windows Azure.**

I. Introduction

CLOUD computing has a growing trend in the past few years and companies increasingly understand its benefits [1]. Gartner [2] determined that the size of the cloud market is $150 Billion by 2013 and predicts that virtualised server workloads will reach a high of 60% in 2014. This trend pushes companies to migrate their services and applications in the cloud.

Benchmarking the cloud and multi-tier applications that are hosted within will help the developers to determine the most appropriate architecture, services, and settings [3]. In this paper we present results of the performance analysis of different approaches in building possible cloud architectures and solutions of the Ticket Management System (TMS).

The objective of this research is to find out which scenario performs the best for the same price of rented resources. We assume that a single processor with four cores has approximately the same price with 4 CPUs with one core, 8 GB RAM has roughly the same price with two RAMs of 4 GB etc.

Traditional distributed approach claims that the best performance is achieved when the workload is distributed to a huge number of processing units executing balanced tasks. However, it is very hard to organise the tasks with perfect load balancing in a distributed system. The cloud, on the other hand, initiates new challenges, such as predicting server CPU utilisation and resource under-provisioning. In addition, scalability and elasticity are main concerns when the customers desire to deploy their solutions on the cloud. Client expectations are very important, due to the recent huge offer of cloud providers. Summarising the above, a typical customer challenge is selection which architecture performs the best, renting more and less powerful Virtual Machines (VMs) or a smaller number of more processing powerful VMs.

We have set a hypothesis that the best performance will be achieved if the processing is distributed to more less powerful VMs. The testing environment is deploying the ticket management SaaS solution on various Windows Azure configurations with approximately the same cost.

The rest of the paper is organised as follows. In Section II, we discuss the related work and in Section III describe the testing environment, ticket management web service and test data. Section IV presents the results and Section V compares the results and evaluates the performance. The final Section VI is devoted to conclusion and future work.

II. Related work

This section presents the recent research in the area of cloud performance benchmarking, resource allocation and multi-tier transactional cloud web application.

A. Cloud performance discrepancy

Renting the same amount of IaaS (Infrastructure as a Service) resources on the Azure cloud [4] costs the same, regardless whether they are all provisioned in a single huge virtual machine or into several smaller virtual machines. This pricing scheme also follows the other most common public clouds [5], [6].

An orchestration of hardware resources on the cloud impacts the performance of the hosted cloud application or web service. Allocating the resources among many concurrent instances of virtual machines is better than using VM with multiprocessors using parallelization [7].

Gusev et al. [8] determined a region where response time is up to 10 times better if web services are spread among several small VMs, rather than in a single VM. This phenomenon motivated us to analyse how orchestration impacts the performance of the real cloud N-tier application in Azure.

Cloud multitenant virtual environment also provides discrepant performance during the time and therefore, a performance isolation is required [9]. Koh et al. reported that a VM

978-83-60810-58-3/$25.00

provides different performance on the same physical machine during the time, if it is instantiated among the other active VMs [10]. Jayasinghe et al. [11] reported that a configuration that provides the best performance in one cloud can provide the worst performance in another. Iakymchuk proposed a method to improve the performance with underutilization of physical resources by adding more nodes [12].

B. Windows Azure performance

Many authors have conducted research on Azure's performance. It is most suitable for application with small amount of communication [13] and it does not work well for tightly-coupled applications compared to Amazon EC2 or cluster [14]. Hill et al. [15] provided a performance analysis of VMs, storage services and SQL services in Azure. Azure also can decrease the costs and time for deployment, as well as support efficient TCP data transfers [16].

C. Multi-tier performance benchmarking

Today's web applications are usually 3 or 4-tier applications, commonly identified as multi-tier (n-tier) applications. Each tier is usually hosted on a separate machine or VM. These architectures are usually interesting due to several bottlenecks that can appear, which will decrease rapidly their performance.

Several authors propose benchmark tools and methodologies to simulate the multi-tier cloud web applications to analyse their performance and determine their deficiencies.

Turner et al. [17] propose a C-MART benchmark, which emulates a modern web application hosted in a cloud environment. Rubis [18] is another benchmark application that simulates an auction site and evaluates design patterns and the performance scalability of application servers. However, it cannot be used as a modern application benchmark because there are many flaws for Web 2.0 applications [19]. Also it requires a lot of effort to install, which outweighs its usefulness [20]. TPC-W is also a transactional web benchmark, which emulates an online bookstore [21]. But, it also has deficiencies [3]. In this paper, we use a real cloud SaaS application hosted in Azure to determine the scalability and user load impact on different customers' and cloud service provider's parameters.

Apart from benchmarking tools, several methodologies for benchmarking the N-tier applications are proposed and evaluated with them. Wang et al. [22] proposed a method for bottleneck detection, which correlates throughput and load. Chen et al. [23] proposed a predictive performance model that analyses cloud based N-tier web applications and determines appropriate resource allocation to each tier of an application.

III. Methodology

This section describes the architecture of the system and the environment used for testing, including the testing tools, hardware architecture, test cases and implementation procedure.

A. TMS Architecture

As a testbed-application we use our TMS SaaS solution [24] as a scalable and elastic multi-VM cloud solution. This benchmark has all features to evaluate performances of a typical transactional based SaaS solution, such as, simple operations for each transaction, and variable and huge number of users that generate different workload.

The benchmark TMS solution consists of three code modules and one optional module [24]. Core modules are: System management module (SMM), Company management module (CMM) and Core functions module (CFM) and optional is Additional functional module (AFM).

The core of this TMS cloud solution is the SMM module, shared for all companies. All resource provisioning in the cloud are managed by this module. It is always active to provide company subscription management, authentication, authorisation etc.

CMM is a company specific module, personalised and customised by TMS users. Each company offers this module as a service to its end customers. This module is responsible for all general configurations within a company.

Another company specific module is the CFM module, responsible for all essential processes to realise ticket management (bug reporting) within a company. It enables a connection between companies (providers) and their customers. This module provides functionalities such as: ticket creation, responds by a resolver, customer approvals of the responses, creation and execution of test-cases etc.

The only optional module is the AFM module, dedicated for add-on functions, such as enabling a possibility to create and execute test cases, especially useful for bug reporting systems.

All modules in this TMS solution are divided in two groups: static and dynamic modules. Static modules are always active modules, unlike dynamic modules that are activated only when some company needs them. From the modules we mentioned above SMM is a static module and the other three are dynamic modules.

This system integrates a very important Broker module in order to communicate with different company specific modules and acts as a role of system service orchestrator. Fig. 1 [24] presents three agents that are a part of the Broker module.

Let us explain shortly how this system organisation works. As we mentioned before SMM is the main module of the system and it is always active to provide features for "pay-by-use" cloud concept, including authentication, authorisation, accounting with management of the company, its' contracts and subscriptions etc. This module is realised by two agents:

- *Admin agent*, which provides the accounting features for the company.
- *Infrastructure agent*, which instantiates and closes various instances, providing the optimal resource utilisation and reducing the overall cost for renting the hardware resources.

The dynamic modules of this system have the opportunity to be hosted on the same machine or on different virtual machines, which is essential for our testing of the elasticity, because we want to analyse and compare the performances obtained in a single-VM and multi-VM environments.

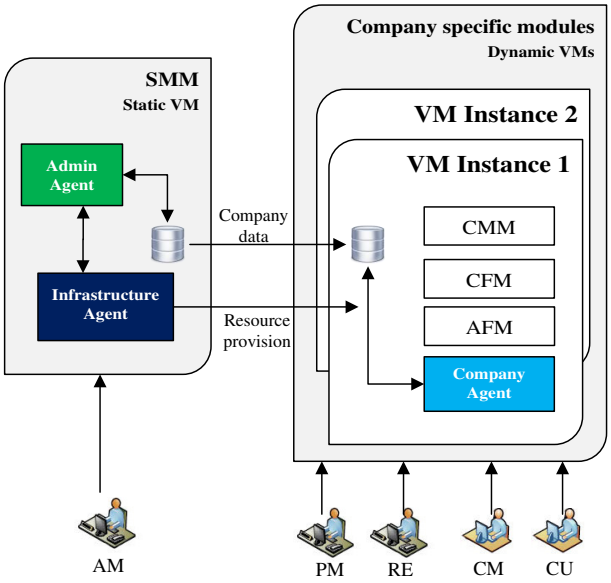

Fig. 1: Architecture of benchmark TMS SaaS solution

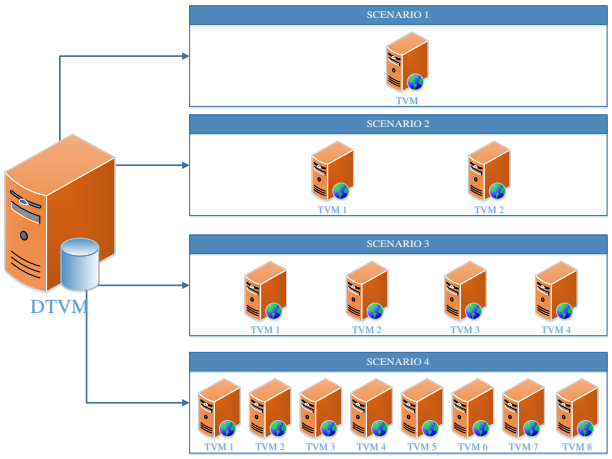

Fig. 2: Architecture of testing environment and scenarios.

TABLE I: Test case specification

Scenario	VM Type	Cores	RAM	Resources
All	DTVM	8	14 GB	8 Cores 14 GB
Scenario 1	1 TVM	8	14 GB	8 Cores 14 GB
Scenario 2	2 TVMs	4	7 GB	8 Cores 14 GB
Scenario 3	4 TVMs	2	3.5 GB	8 Cores 14 GB
Scenario 4	8 TVMs	1	1.75 GB	8 Cores 14 GB

Each dynamic VM hosts two core software modules: the CMM and CFM modules, independently for each company. Additionally dynamic part of the AFM module is hosted on each dynamic VM.

The Company agent is hosted on the same VM, to enable a communication with SMM and data synchronisation between the SMM and VM.

B. Testing environment

The testing environment consists of VMs and Windows Azure Cloud [4]. Windows Azure provides on-demand infrastructure that scales and adapts to the user ever changing business needs. With Windows Azure, the user can spin up new Windows Server and Linux VMs relatively fast and customise the environment. To create fast robust deployment, Windows Azure allows using custom images or building on the pre-configured images.

To realise the experiments we have created architecture for four different scenarios that use one *Database and Testing VM* (DTVM) and a set of *transactional VMs* (TVMs). All of them are deployed on Windows Azure as presented on Fig. 2.

The testing machine is used to run the tests for all experiments. The DTVM consists of AMD Opteron 4171 HE 2.10 GHz CPU with 8 cores and 14GB RAM. It hosts the SQL database for all scenarios. Windows Server 2012 Datacenter is running on the DTVM. The installed testing tools are selected from the Visual Studio 2012. The experiment results are measured with the *Web Performance and Load Test Project*, as a powerful tool for this kind of research.

The main function of the DTVM is to run all the tests for predefined scenarios. The first scenario is predefined as a single-VM, while the rest of them concern the multi-VM approach. The TVMs are configured to have equal cost in each scenario using resources on a machine with AMD Opteron 4171 HE 2.10 GHz CPU with 8 cores and 14GB RAM. Therefore, the first scenario is defined by one TVM that uses 8 CPU cores and has 14 GB of RAM. Two TVMs are used in the second scenario, each of them with 4 CPU cores and 7 GB of RAM. The third scenario uses 4 TVMs with 2 CPU cores and 3.5 GB of RAM, while the fourth scenario 8 TVMs with 1 CPU core and 1.75 GB of RAM.

All scenarios use VMs with same type of CPU and RAM. Windows Server 2012 Datacenter is preinstalled on TVMs including IIS and Application roles. Detailed features of the DTVM and TVMs in all scenarios are shown in Table I.

Experiments are tested by simulating two types of network: Cable DSL 1.5Mbps and Cable DSL 768Mbps. All experiments are realised with the use of a web browsers. To enable platform independence we have tested the experiments by equally using all of the following web browsers: Internet Explorer versions 9 and 10, Firefox, Chrome and Safari.

C. Web Service Description

TMS [25] is a cloud solution realised as a transactional web based software, where a user can access a dynamically created web page, browse the site, list page details and update a selected information, as most of typical web solutions.

The objective of this research is to find the best architecture when analysing the performance for the same price of rented resources. Our hypothesis is based on an assumption that multi-VM approach would be better and the best performance will be obtained renting the largest number of small VMs

for different companies. Note that the database is deployed on a separate VM in all experiments and the testing mostly relates to selecting a proper configuration for a web server that realises functions of web browsing and database update.

We define two test cases to analyse the performance. The first test case is based only on a web service providing a functionality of browsing through the application and the second uses update functionality with data store in database.

In the first test case, the user logs into the system, opens a page with presented tickets and selects a ticket to display relevant information. The user can browse the site and list the content of a given page. In the second test case, despite the previous steps realised for browsing and listing the required information, the user responds on the information by entering an additional information and changing the ticket status. It finishes with database update.

These web services are hosted by all VMs defined by each scenario. Note that the DTVM does not deploy these web services, but hosts the testing tools and the database required by the web services. The 4 scenarios realise both the single-VM and multi-VM approaches using the same amount of available resources. Hosting the web service and database on separate VMs may reduce the overall performance, because of communication needed between the VMs. But in case of large user loads all requests for a web service and interaction with the database will be distributed between VMs. Database operations are more expensive than the communication in Windows Azure, where all VMs are connected in virtual network with stable network connection between them.

D. Testing procedure

Visual Studio 2012 Web Performance and Load Test Project is a tool that offers many testing options. We decided to use the test "Tests based of the number of virtual users" for the purpose of this research providing relevant information about throughput and achieved speed.

We choose Visual studio because this tool provides a lot of possibilities for parametrisation. With Visual Studio 2012 we can choose different types of tests, depending of the number of the users or number of tests. Also we can choose the type of networks, type of browsers that we use for testing. Tests can be executed on different ways depending of number of tests or time span. A very important issue is that the results from tests are specified with sufficient details.

Visual studio 2013 provides a new option to run tests in Windows Azure without new configuration. Administrators do not have to deploy any VM or to configure different services. Through Load Test Web Service, Visual Studio 2013 loads the tests on the cloud. Behind this service is a pool of test agents that is used to run the tests. All results from a test, along with other performance counters are available.

Four experiments are defined, each for a test case defined by a corresponding scenario:

- *Experiment 1* - a single-VM with a DTVM and 1 TVM
- *Experiment 2* - a multi-VM with a DTVM and 2 TVMs
- *Experiment 3* - a multi-VM with a DTVM and 4 TVMs
- *Experiment 4* - a multi-VM with a DTVM and 8 TVMs

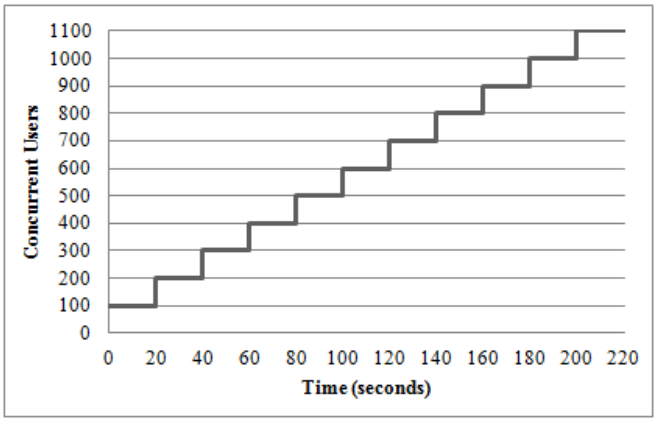

Fig. 3: Test plan for each experiment

All experiments use two VMs with 8 cores and 14GB RAM each. The first experiment simulates a single-VM environment, while the remaining a multi-VM environment with different configuration of TVMs enabled by renting the same cloud resources. Experiments perform different tests based on different loads defined by a various number of virtual users of the system per test.

The selected test runs every test for 3 minutes and 40 seconds. Certain number of users is defined per each testing interval to simulate increased load, as shown in Fig. 3. Our workload generation for multi-tier web application in the cloud is similar to other similar approaches [26]. The initial load configuration starts from 100 concurrent users and this is increased by a step of 100 users every 20 seconds, ending with a maximum of 1100 users.

All test case scenarios are executed for each experiment. To ensure good results, the tests started only after a 2 minutes warm up period of Visual Studio.

E. Test data

The selected testing tool measures and calculates a lot of parameters. For the purpose of our research, the following five different parameters are analyzed:

- T_r - Average response time,
- P - Pages per second,
- T_p - Average page time,
- R - Requests per second, and
- CPU_U - CPU utilisation.

The values of each of these criteria are based on the selected load defined by the number of users.

The performance factors for measured times are calculated as reciprocal value and indicated as throughput and speed, by the following measures:

- T - Overall throughput calculated as $T = 1/T_r$,
- S - CPU speed calculated as $S = 1/CPU_U$.

Each experiment (for a different scenario) results with different performance factors. Let $i, j \in \{1, 2, 3, 4\}$ identify

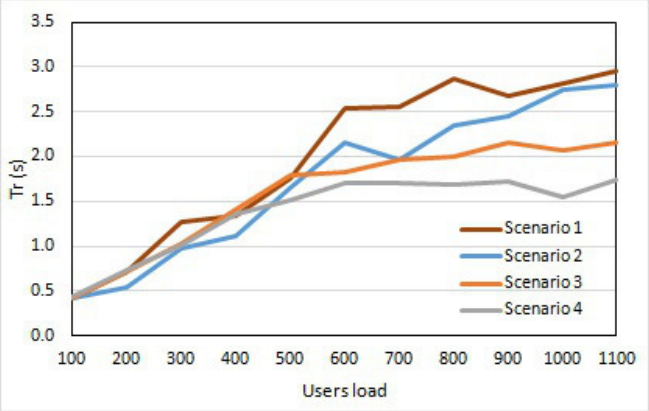

Fig. 4: Average response time as a function of user load

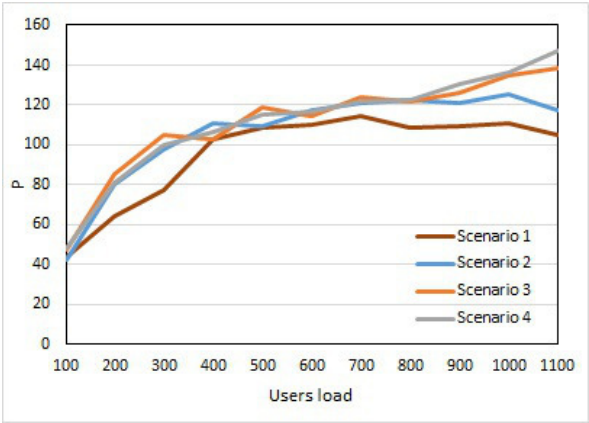

Fig. 5: Pages per second as a function of user load

two experiments. Their relative index as presented in (1) gives the relative comparison value for performance factor F, which stands instead of T, P, R, or S, corresponding to overall throughput, page throughput, request throughput and achieved processor speed. The higher the relative performance factor is, the better performance.

$$F_{ij} = \frac{F_i - F_j}{F_j} \tag{1}$$

In addition, when compared to Experiment 1 we obtain relative performance increase of multi-VM vs single-VM approach for the same number of users.

IV. Experiments and Results

This section presents the results achieved for each performance criteria: average response time, pages per second, average page time, handled requests per second and CPU utilisation. Parameters are analysed as a function of user load.

The brown line in each graph presents the results for scenario 1, the blue line scenario 2, the orange line scenario 3 and the grey line scenario 4.

A. Average Response Time T_r

Response Time refers to the average time that is necessary to receive the entire response to a request, starting from the moment when a request is sent to the web server. The difference between the Response Time and Transaction Time is in think time that occurs during a transaction. Transaction Time includes think time, but Response Time does not [27].

Fig. 4 presents the average response time results for all experiments. The average response time proportionally depends on the load increase defined by the number of concurrent users. Two different regions are observed with different behaviors. In the left region ($N \leq 500$) all four scenarios provide similar average response times. However, Scenario 1 is the worst, while Scenario 2 is slightly better than others for all test cases in the region. Scenario 1 also provides the worst performance in the right region ($N > 500$), but now Scenario 4 has the smallest average response time. All curves in the left region have a trend for linear increment until the value $1.5s$, which saturates in the right region in the range of $[1.5s, 3s]$.

B. Average pages per second P

Average pages per second refers to the number of pages that are sent per second during the load test run [27]. Fig. 5 displays the results for the performance factor P defined by achieved average pages per second.

Single-VM (Scenario 1) also shows the lowest performance for this parameter for each user load. Multi-VM scenarios provide similar performance for smaller load ($N \leq 500$), but the results are similar as the previous parameter for greater load. That is, using greater number of smaller TVMs is better than having smaller number of greater TVMs.

All curves in the left region also have a trend for linear increment starting from 40 to 110, which saturates in the right region in the range of $[100, 150]$.

C. Average page time T_p

Average page time refers to the average response time for all requests for a single web page [27]. The results of the average page time are shown in Fig. 6. Also in this case, the results show that the multi-VM approaches perform better than the single-VM scenario. Scenario 4 performs the best for a large number of concurrent users higher than 700, while Scenario 2 for smaller loads.

The curves follow the similar trend as the previous two parameters, in the regions divided with $N = 500$ concurrent requests. The average page time increases starting from 0.5 to 2.5s and saturates in the range [2.0s, 3.5s] for all scenarios.

D. Handled requests per second R

Requests per second consist of details for individual requests that are sent during a load test. This includes all HTTP and dependent requests such as images. *Request per second* refers to the rate per second of a request during the load test run [27].

Results for the overall handled requests per second are presented in Fig. 7. The obtained behavior and performance

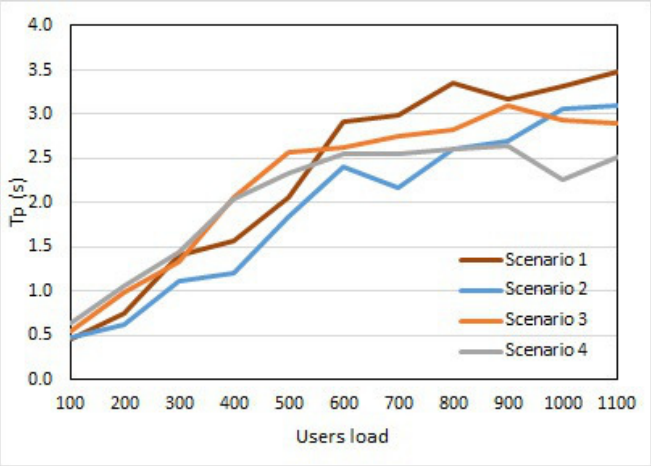

Fig. 6: Average page time as a function of user load

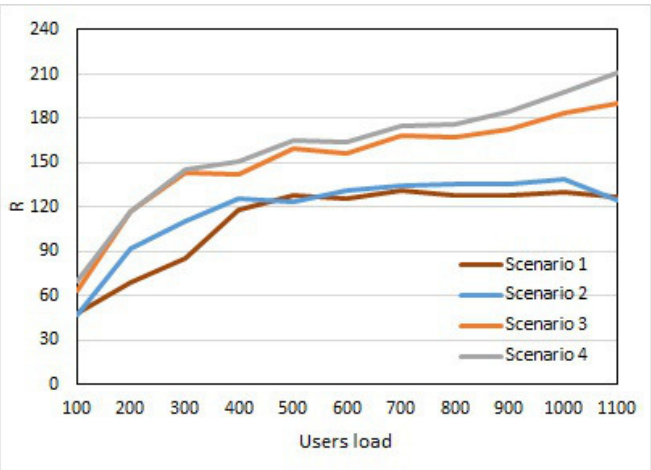

Fig. 7: Requests per second as a function of user load

trend is similar to the cases with previous analysed parameters. That is, the scenarios with greater number of smaller TVMs (scenarios 4 and 3) are better than having smaller number of greater TVMs (scenarios 2 and 1).

We observe small discrepancy compared to other parameters. That is, the curves start to saturate for different user load. Scenarios 1 and 2 increase the values for the handled requests starting from 50 to 120, while scenarios 3 and 4 provide increase from 70 to 140.

Scenarios 3 and 4 slightly saturates for $N > 300$ (they continue to increase, but with smaller intensity) in the range $[140, 210]$, while scenarios 1 and 2 saturate for $N > 400$ and their curves are almost constant in the right region around the range $[120, 140]$.

E. CPU Utilization R

Processor time denotes the percentage of time that a VM instance charges against the processor user time for individual request issued during a load test. The theoretical maximum for this parameter is $number\_of\_processors \cdot 100$.

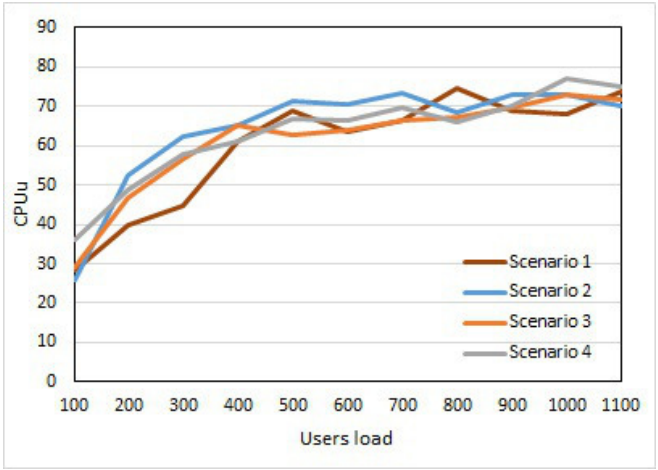

Fig. 8: CPU utilization as a function of user load

CPU utilisation is very important parameter for cloud service provider because it is directly connected with cost for power supply and cooling due to increased heating. The results for this parameter are shown in Fig. 8. Although all scenarios are very similar, lower CPU utilisation is noticed for the single-VM environment, while Scenario 2 mostly utilizes the CPU.

Similar two regions are observed, which are divided with $N = 400$. The curves increase in the left region until 65%, and then the CPU utilization saturates in the range of $[65\%, 70\%]$.

V. Discussion

This section compares the results achieved from the four cloud approaches and discussed relevant explanations for analyzed behavior and performance trends.

A. Parameter correlations

This section presents the correlations between the response time and page throughput and between the response time and CPU utilization.

1) Response time vs page throughput: The parameters T_r, P, T_p, and T_R are correlated among each other, as shown in figures 4, 5, 6, and 7. The results show that user loads for $N = 400$ or $N = 500$ are borders of two different regions. The parameters behave the same in a single region, i.e., increasing trend in the left region (smaller load) and saturating trend in the right region (heavy load).

2) Response time vs CPU utilization: Figures 9 and 10 present the overall throughput and CPU speed. We can conclude that both figures are very similar, which confirms that both parameters are very correlated as a function of user load.

B. Scenario comparisons

In most cases, especially for increased loads, we concluded that Scenario 4 performs the best compared to the others.

The load defined by the number of concurrent users has noticeable impact on the results. All performance factors lead

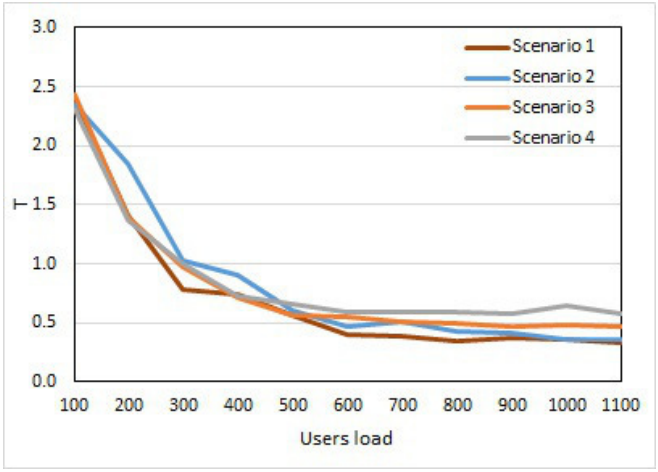

Fig. 9: Overall throughput T as a function of user load

Fig. 11: Relative throughput T_{12}, T_{13} and T_{14}.

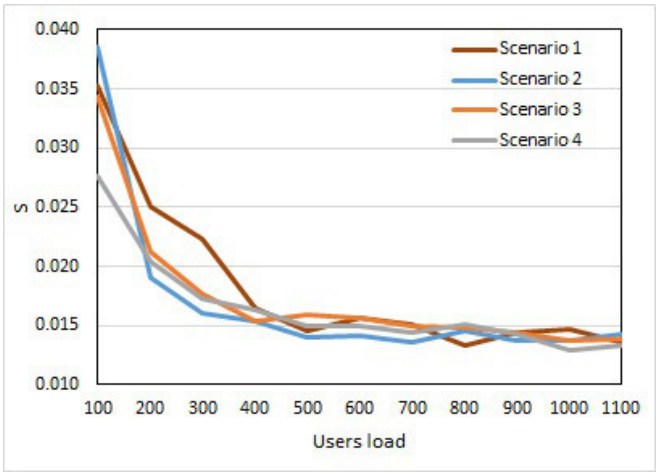

Fig. 10: Achieved CPU speed S as a function of user load

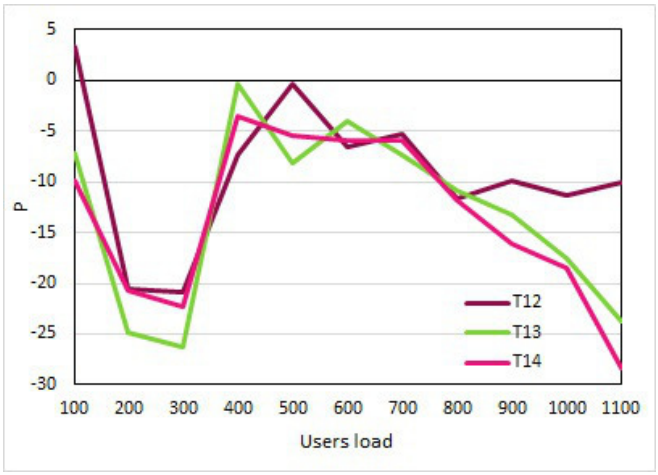

Fig. 12: Relative pages per second R_{12}, R_{13} and R_{14}.

to a conclusion that our hypothesis is proved for increased loads higher than 400 users.

Figures 11, 12 and 13 present the relative values of parameters for the three multi-VM scenarios compared to the single-VM scenario. They confirm the previous conclusions that the scenarios with greater number of smaller VMs is better than smaller number of bigger VMs as TVM.

VI. Conclusion

Performance is critical when choosing appropriate configuration for rented cloud resources. Cloud providers offer a variety of options, so the users get confused when selecting the optimal configuration. This research brings conclusion about a typical behavior in transactional web solutions for expected small and medium number of concurrent users. The ticket management solution is a transactional-based dynamic web site where a lot of information fluctuates among users, and information update is a frequent task. It uses a lot of users which access a dynamic web site.

Fig. 13: Relative page time between multi- and single-VM

The presented architecture for the cloud solution is based on separating the database layer form the business logic and presentation layers on different VMs. This solution uses a database allocated to a single and powerful VM, and distributing the transactional business logic and presentation layer to a set of other VMs. An intended user may choose whether to host a new powerful VM or to distribute the load to more less powerful VMs using the same cloud resources.

We have performed load testing with increasing number of users, testing the performance of 4 different configurations that use the same rented resources. We were motivated by the challenge to find the most optimal configuration that performs the best. This research proves our hypothesis that using a higher number of small VMs performs better than other configurations, confirming the traditional distributed concept to distribute tasks on more balanced processing units.

This result suggests an architecture for cloud based solutions that performs the best for transactional web sites, which do not perform complex computations and are mainly based on page browsing and database update operations. The recommendation is to separate the database layer from other layers, allocating the database layer to a powerful VM and distributing the business logic and presentation layers to more less powerful VMs.

Creating portable TOSCA archive for iKnow University Management System

Magdalena Kostoska, Ivan Chorbev and Marjan Gusev
University Ss. Cyril and Methodius, Faculty of Computer Sciences and Engineering,
1000 Skopje, Macedonia
{magdalena.kostoska, ivan.chorbev, marjan.gushev}@finki.ukim.mk

***Abstract*—Portability of developed solutions is a huge challenge for both the customers and cloud providers. A typical customer would like to realize a flexible software solution which can be easily deployed on a selected infrastructure or transferred on a cloud environment. Finally, the idea of a software environment independent of a specific cloud provider enables preferable conditions for customers.**

These portability issues are analyzed for a case study of a custom University Management System - iKnow, used by the University Ss. Cyril and Methodius in Macedonia. This paper presents implementation of a Topology and Orchestration Specification for Cloud Applications (TOSCA) specification to enable a software solution to be deployed on a flexible and portable environment.

The motivation to consider the implementation of such a platform is initiated due to the rising number of students that use the iKnow system, reaching the peak during the enrollment periods. A possible solution is to consider the possibility of moving the iKnow system (or its part) to a cloud environment and balance the workload using flexible resources. We conducted research to describe the iKnow system using the TOSCA specification and to enable a rather easy deployment and maintenance.

This paper presents the challenges and issues regarding the TOSCA specification while implemented on the iKnow system.

I. Introduction

IKNOW is the University Management Information system that provides electronic services for both university management and students [1]. It is deployed in most of the universities in Macedonia, including the University Ss Cyril and Methodius, where this research is conducted.

Our analysis shows peak usage of the iKnow system during the enrollment period. More than 7 000 applicants use it to register, fill applications, overview ranked lists, submit appeals and perform similar activities in the applying process. From the other side, more than 400 administration users within committees of 27 different faculties work on data checking, evaluation, ranking and similar processes. At the same time more than 25 000 enrolled students use the iKnow system for course enrollment and exam application. Along with the students, this system is also frequently used by the administrative staff of the faculties.

Heavy workload only in a short time period is a problem that motivates us to find an alternative solution to increase the bandwidth and processing power in the enrollment period, without buying additional hardware. Although, the natural solution for our needs is the cloud, there is one more demand, the University Management does not prefer ”lock in” to a specific cloud provider and would like a flexible platform that can be easily ported from one cloud provider to another or return to the existing University server.

A solution to these portability demands initiated our research on how to create easily portable, reusable and maintainable system specification, that we can use on any cloud provider, flexible enough to choose the provider offering the desired highest performances. We propose the usage of Topology and Orchestration Specification for Cloud Applications (TOSCA), a new standard for description of applications and services [2][3].

The main goal of the realized research was to explore the possibility of using TOSCA to describe the iKnow system and to address all the challenges of moving this system to the cloud, or changing the cloud provider. As a result, the research identifies TOSCA features and drawbacks of such an implementation.

The rest of the paper is organized as follows: Related work about cloud portability and TOSCA analysis is presented in Section II. Background about the TOSCA specification and the iKnow system (architecture and current deployment) is given in Sections III and IV respectively. The TOSCA model of the iKnow system is presented in Section V. Section VI describes the challenges and issues we have met during this research. Finally, in Section VII we evaluate the significance of each of the found challenges and we conclude with future work.

II. Related Work

The main problem in Cloud computing is the lack of unified standards [4]. Several standards are on the way of their development, approval of the community and wider adoption [5].

Latest research considering the portability of cloud services in each of the layers of the service stack, tackle the portability problem from three different perspectives. One perspective is the usage of standards to accomplish this task. In this direction they try to identify current challenges, efforts and options [6], [7] or to extend open standards for this purpose [8]. The second perspective searches for other proprietary solutions like the abstraction-driven approach where abstract languages are used to specify solutions [9] or to create a storage abstraction layer (CSAL)[10]. The third perspective consists of other approaches that focus on exploiting the semantic technology to create semantic interoperability framework [11],

978-83-60810-58-3/$25.00

to automatically analyze cloud vendor APIs [12] or to use mOSAIC for this intention [4], [13].

OASIS (Organization for the Advancement of Structured Information Standards) introduces a new cloud standard called TOSCA (Topology and Orchestration Specification for Cloud Applications). The TOSCA technical committee has published the first version of a standard for "*interoperable description of application and infrastructure cloud services, the relationships between parts of the service, and the operational behavior of these services (e.g., deploy, patch, shutdown)*" [2]. This initiated a spread of research activities in different directions, such as IBM efforts to implement this standard [14], [15], creation of environment for execution [16], [17], modeling tools [18], [19] and attempt to create this type of specification [20].

III. TOSCA

This section presents a brief overview of the language, the structure and the usage of TOSCA.

Topology and Orchestration Specification for Cloud Applications (TOSCA) is developed by OASIS, a non-profit, international consortium. The main goal of the OASIS TOSCA Technical Committee is to enhance the portability of cloud applications and services by enabling interoperable description of application and infrastructure cloud services, the relationships between parts of the service, and the operational behavior of these services [2].

This specification utilizes open standards to describe a service and explain how to manage it independently from the supplier and the cloud. The current release of this specification is Version 1.0 and defines services by using a Service Template document. The TOSCA language introduces a grammar for describing service templates by means of Topology Templates and plans. TOSCA utilizes XML Schema 1.0 and WSDL 1.1. It also contains non-normative references to BPEL 2.0, BPMN 2.0, OVF and XPATH 1.0.

The specification defines a meta model for defining the structure of an IT service and its management. The core of TOSCA is the Service Template, depicted in Fig. 1. It consists of two logical parts: service topology description and management plans. The Topology Template defines the structure of a service. Plans define the process models that are used to create, terminate and manage a service.

The structure of the services is defined by the Topology Template. This template consists of Node Templates and Relationship Templates. The Node Template describes the required components and their properties, operations and interfaces, while the Relationship Template describes connectivity between components (Node Templates) by stating the direction of the relationship (source and target) and can have additional parameters. The Node Type and Relationship Type templates formally describe nodes and relationships (in terms of properties, interfaces etc.), while the templates are created and set concrete values based on these types definitions. The purpose of Plans is to interpret the templates and execute appropriate actions. They are defined as process models and they rely on BPMN (primarily) and BPEL. In addition, this specification allows nesting (ex. One Service Template to be part of another).

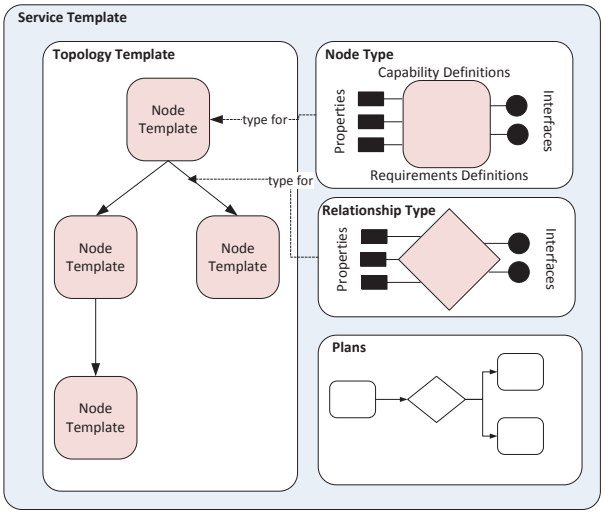

Fig. 1: TOSCA Service Template (adapted from [2])

In order to allow automatic deployment or build of services TOSCA specification also defines Artifacts' installable or executional types and objects like scripts, libraries, installation binaries, installation images and other objects.

IV. iKnow University Management System

The architecture and current deployment of the iKnow University Management System is presented in this section.

The main goal of the iKnow system is to provide electronic services and to store and exchange electronic information among students, professors, administration, university management and the Ministry of Education.

A. Architecture

The system consists of two main components, each consisting of modules: the new students Enrollment Student Services (ESS) and the Core Student Services (CSS) [1].

The Enrollment component consists of the faculty enrollment functionalities like enrollment wizard, manual entry of candidate's data and candidate's data processing, ranking and results publishing.

The Core student services component includes modules for administration, management of study programs and schedules, student activities, personal identification and access control, electronic payment and migration of legacy data.

The main architecture used to construct the system is NTier, depicted in Fig. 2. The two main components (Enrollment and Core) are almost independent of one another, except for several business processes (like transferring enrolled students into the core module). Although they use the same database server, physically they use two databases (enrollment and core

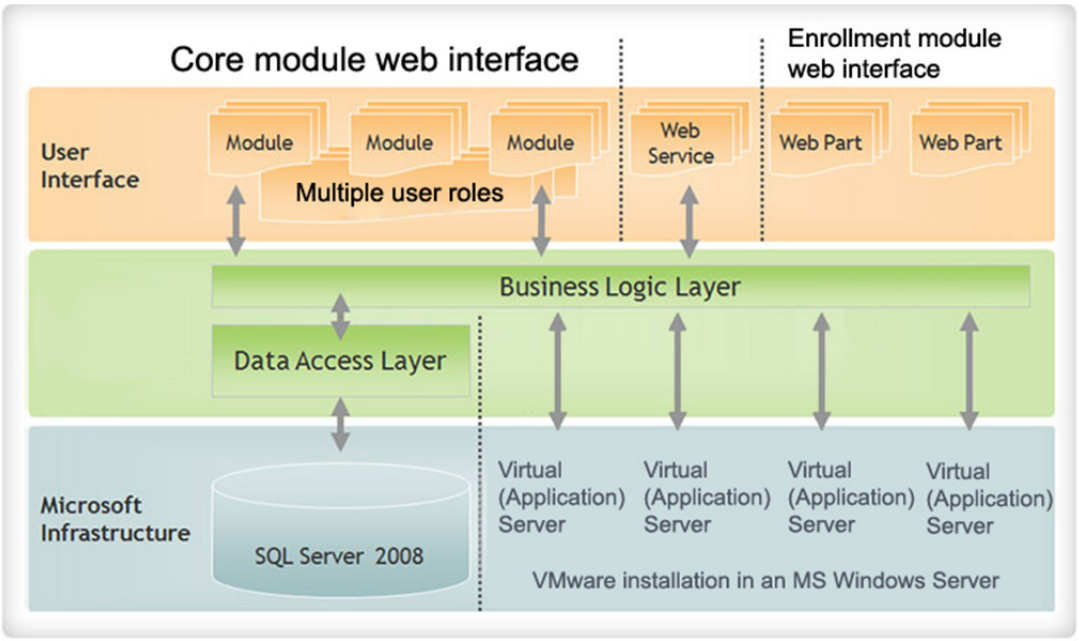

Fig. 2: iKnow architecture [1]

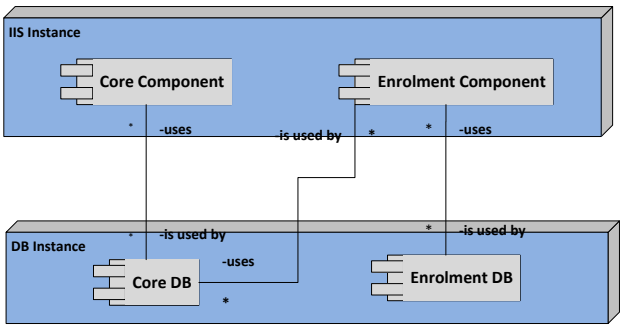

Fig. 3: Modules and database interactions

database). Fig. 3 shows the interactions among modules and databases.

The current solution consists of several project and both modules use some of them, like UniSS.DataModel, a Class library project containing the Entity framework model of the data as well as the audit log component. The UniSS.Repositories project is a Class library project storing the classes for implementation of the Repository template. The UniSS.Logic project contains the implementation of the MVP template, while UniSS.Forms is a Web Forms application project in which all forms are separated according to their functionalities.

The Model-View-Presenter (MVP) is used for all the modules [1].

B. *Current Deployment*

The current deployment includes two physical servers with implemented virtualization approach and an independent storage system. The first server is used as SQL server with Microsoft SQL Server installed and the second is used as an application server. The application server is upgraded by installing 4 virtual Windows servers using VMware. Additional Load Balancer balances the workload of each instance of the application. Both servers have an Intel Xeon e5630 2.56 GHz CPU and 16GB of RAM, 1 TB storage. The system is supported by additional backup internet link in case of failures of the primary link. In addition, a third fully synchronized server is installed on remote location and can take over in case of failure of the primary servers. All communications are encrypted using SSL protocol and a digital certificate.

V. iKnow TOSCA specification and artifacts

The TOSCA specification for the iKnow University Management System will be presented by specification of corresponding nodes, relationships, artifacts and plans.

A. *Nodes*

The first step is to identify the logical set of component services that the application is both composed of, as well as those services that the application relies upon for deployment, installation, execution and other lifecycle operations [21]. Each of these basic components, their interfaces and properties are described as TOSCA *Node Types*. TOSCA recommends creation of three node types: base, specific and custom. Fig. 4

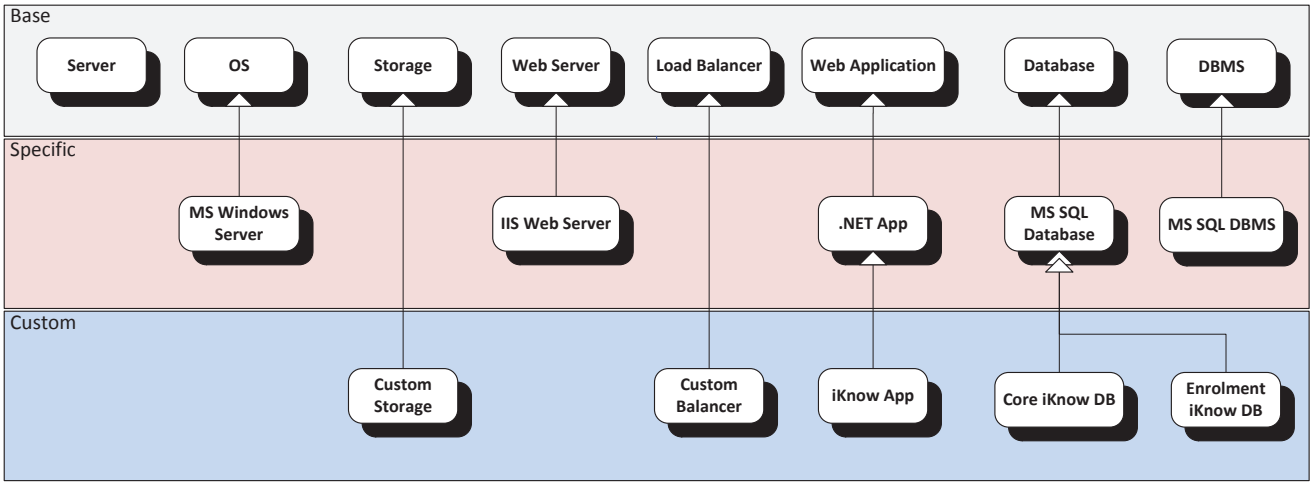

Fig. 4: Node Type Modeling and Node Type Inheritance Hierarchy for iKnow

illustrates all node types and inheritance hierarchy for the iKnow system.

The *Base Node Types* describe the basic set of components services needed for the proper functioning of the application. All Base Node Types are directly derived from a generic TOSCA root node type. Listing 1 shows part of the definition, due to the large specification. For the same reason the name spaces are removed.

```
<NodeType name="Server">
      <DerivedFrom typeRef="RootNodeType"/>
    <RequirementDefinitions>
      <RequirementDefinition lowerBound="0"
          name="container"
requirementType="ServerContainerRequirement"
upperBound="1"/>
    </RequirementDefinitions>
      ...
</NodeType>
<NodeType name="WebServer">
      <DerivedFrom typeRef="RootNodeType"/>
      <Operation name="install"/>
      <Operation name="configure"/>
      <Operation name="start"/>
      <Operation name="stop"/>
      <Operation name="uninstall"/>
      ...
</NodeType>
<NodeType name="LoadBalancer">
      <DerivedFrom typeRef="RootNodeType"/>
         <Operation name="install"/>
      <Operation name="configure"/>
      <Operation name="start"/>
      <Operation name="stop"/>
      <Operation name="uninstall"/>
      ...
</NodeType>
<NodeType name="WebApplication">
      <DerivedFrom typeRef="RootNodeType"/>
        <Interfaces>
     <Interface name="lifecycle">
      <Operation name="install"/>
      <Operation name="configure"/>
      <Operation name="uninstall"/>
     </Interface>
   </Interfaces>
      ...
</NodeType>
<NodeType name="Database">
      <DerivedFrom typeRef="RootNodeType"/>
      <Interfaces>
     <Interface name="lifecycle">
      <Operation name="install"/>
      <Operation name="uninstall"/>
      <Operation name="start"/>
      <Operation name="stop"/>
     </Interface>
   </Interfaces>
      ...
</NodeType>
<NodeType name="DBMS">
      <DerivedFrom typeRef="RootNodeType"/>
      <Interfaces>
     <Interface name="lifecycle">
      <Operation name="install"/>
      <Operation name="configure"/>
      <Operation name="start"/>
      <Operation name="stop"/>
      <Operation name="uninstall"/>
     </Interface>
   </Interfaces>
      ...
</NodeType>
```

Listing 1: Definitions of Basic Node Types

The next step is to extend the base types to represent specific instances (to define *Specific Node Types*). They are derived directly from the base types. In our use case, we define five

specific node types: MS Windows Server, IIS Web Server, .NET Application, MS SQL Database and MS SQL Database Management Service. Listing 2 shows the definition for IIS Web Server.

```
<NodeType name="IISWebServer">
   <DerivedFrom typeRef="WebServer"/>
   <Interfaces>
     <Interface name="lifecycle">
       <Operation name="install"/>
         <InputParameters>
              <InputParameter name="httpport"
                  type="integer"/>
              <InputParameter name="username"
                  type="string"/>
              <InputParameter name="password"
                  type="string"/>
       ...
     </Interface>
   </Interfaces>
</NodeType>
```

Listing 2: Definition of IIS Web Server Specific Node Type

Furthermore we can extend the specific node types to *Custom Node Types*, which are the custom build elements of the solution. In the iKnow system use case we define five custom node types for the storage, the balancer, the iKnow application as well as the two databases (Core and Enrolment). Listing 3 shows the definition for the Core database.

```
<NodeType name="CoreiKnowDB">
   <DerivedFrom typeRef="MSSQLDB"/>
   <Interfaces>
     <Interface name="lifecycle">
       <Operation name="install"/>
       <Operation name="start"/>
       <Operation name="stop"/>
       <Operation name="uninstall"/>
       <Operation name="backup"/>
     </Interface>
   </Interfaces>
</NodeType>
```

Listing 3: Definitions of Core DB custom node types

The final step in the node definition is to create *Node Templates*, based on the defined node types, which can be instantiated with specific properties. Node types only describe properties, requirements and capabilities, while Node Templates provide specific property settings to be applied when the specification is deployed on the cloud provider. Listing 4 shows the definition for the IIS Web Server Node Template.

B. Relationships

TOSCA uses *Relationship Types* to describe how these TOSCA node relate to each other in the cloud deployment. The same as node, the relationship type can be base, specific and custom. Some of the relationship types are shown in Listing 5.

Similar to Node Templates, TOSCA *Relationship Templates* are describing the logical relationships and other dependencies between the application's node templates and are needed for deployment. It describes the source and target Node Templates. Listing 6 describes the relationship between iKnow Core Database and MS SQL by using the Requirement and Capability properties defined in this node templates.

```
<NodeTemplate id="IISWebServer"
      name="IIS Web Server"
      type="IISWebServer">
   <Properties>
      <httpport>80</httpport>
      <username>sa</username>
      <password>sa</password>
   </Properties>
</NodeTemplate>
```

Listing 4: Definitions of IIS Web Server Node Template

```
<RelationshipType name="DeployedOn">
   <DerivedFrom
       typeRef="RootRelationshipType"/>
   <ValidSource typeRef="WebApplication"/>
   <ValidTarget typeRef="WebServer"/>
</RelationshipType>

<RelationshipType name="ConnectsTo">
   <DerivedFrom
       typeRef="RootRelationshipType"/>
   <ValidSource typeRef="WebApplication"/>
   <ValidTarget typeRef="Database"/>
</RelationshipType>

<RelationshipType name="HostedOn">
   <DerivedFrom
       typeRef="RootRelationshipType"/>
   <ValidSource typeRef="Database"/>
   <ValidTarget typeRef="DBMS"/>
</RelationshipType>

<RelationshipType
    name="CoreDBHostedOnMSSQLDBMS">
   <DerivedFrom typeRef="HostedOn"/>
   <SourceInterfaces>
     <Interface name="HostedOn">
       <Operation name="hostOn"/>
     </Interface>
   </SourceInterfaces>
   <ValidSource typeRef="CoreiKnowDB"/>
   <ValidTarget typeRef="MSSQLDBMS"/>
</RelationshipType>

<RelationshipType
    name="iKnowAppDeployedOnIISWebServer">
   <DerivedFrom typeRef="DeployedOn"/>
   <SourceInterfaces>
     <Interface name="DeployedOn">
       <Operation name="deployOn"/>
     </Interface>
   </SourceInterfaces>
   <ValidSource typeRef="iKnowApp"/>
   <ValidTarget typeRef="IISWebServer"/>
</RelationshipType>
```

Listing 5: Sample of iKnow Relationship Types

```
<RelationshipTemplate
    id="CoreDB_HostedOn_MSSQLDBMS"
    name="hosted on"
        type="CoreDBHostedOnMSSQLDBMS">
    <SourceElement ref="CoreDB_container"/>
    <TargetElement ref="MSSQLDBMS_databases"/>
</RelationshipTemplate>

<NodeTemplate id="CoreDatabase"
      name="iKnowCoreDB"
      type="CoreDB">
   <Properties>... </Properties>
   <Requirements>
    <Requirement id="CoreDB_container"
        name="container"
              type="MSSQLDBContainerReq"/>
   </Requirements>
   <Capabilities>...</Capabilities>
</NodeTemplate>

<NodeTemplate id="MSSql" name="MS_SQL"
    type="MySQL">
   <Properties>... </Properties>
   <Requirements>... </Requirements>
   <Capabilities>
    <Capability id="MSSql_databases"
        name="databases"
             type="MSSQLDBContainerCap"/>
   </Capabilities>
  </NodeTemplate>
```

Listing 6: Sample Relationship Template for Node Templates

C. Artifacts

Artifacts are needed in order to deploy and install the cloud application. The may vary from scripts, files to packages and virtual images.

```
<ArtifactType name="FileArtifact">
   <DerivedFrom typeRef="RootArtifactType"/>
</ArtifactType>

<ArtifactType name="ScriptArtifact">
   <DerivedFrom typeRef="RootArtifactType"/>
   <PropertiesDefinition
       element="ScriptArtifactProperties"/>
</ArtifactType>

<ArtifactType name="ArchiveArtifact">
  <DerivedFrom typeRef="RootArtifactType"/>
   <PropertiesDefinition
       element="ArchiveArtifactProperties"/>
</ArtifactType>

<ArtifactType name="PackageArtifact">
   <DerivedFrom typeRef="RootArtifactType"/>
   <PropertiesDefinition
       element="PackageArtifactProperties"/>
</ArtifactType>
```

Listing 7: TOSCA Primer Artifacts Types used for iKnow[21]

The installation of the iKnow system on the cloud environment requires careful setting of the environment, artifact to set the service components (like the required web application and database servers) and packages and file to deploy and host the custom solutions. All of the element must be orchestrated and set in a predefined order.

The basic artifacts types for the iKnow use case are: file, script, package and archive artifacts. Since the TOSCA primer already defines these types, we use the same. Listing 7 shows the basic artifacts defined by TOSCA primer [21].

The archive artifacts are used for packaging a collection of files and can contain additional metadata. In the iKnow use case these types are used for packaging the storage files. The package artifacts contain collections of software application or service files and in our case are used for the application deployment code. Listing 8 shows the created archive artifact for this intention. The script packages are used for deployment, configuration and similar activities.

```
<ArtifactTemplate id="iKnowApp"
   name="iKnowApplication-archive"
       type="ArchiveArtifact">
   <Properties>
    <ArchiveArtifactProperties>
     <ArchiveInformation
         archiveReference="files/iKnowApp.zip"
         archiveType="zip"/>
    </ArchiveArtifactProperties>
   </Properties>
   <ArtifactReferences>
    <ArtifactReference
        reference="files/iKnowApp.zip"/>
   </ArtifactReferences>
</ArtifactTemplate>
```

Listing 8: Archive Artifact used for iKnow application

D. Plans

Plans are defined as process models. TOSCA relies on BPMN or BPEL languages to define a plan. There is no official support for creation of management plans. For that reason we have created diagrams that can be transformed into one of the offered languages. At this moment the plans for iKnow system include deployment and server instantiation management in case of increased workload of the system. Fig. 5 depicts the deployment topology plan this application.

VI. Discussion

TOSCA is a recent proposal for standard and it is still in its early stage of adoption, presented by the current version 1.0. There are no commercial environments that enable usage of this specification, besides the several efforts made in this area for open-source solutions [17], [16]. Although it is promising, there is no guarantee of a wider acceptance by major cloud providers and software developers; and further standard commercialization.

Another possible approach is the usage of BPMN to define plans that will manage the life cycle of the application, especially for more complex management. BPMN is a general-purpose language and does not offer support for creation of

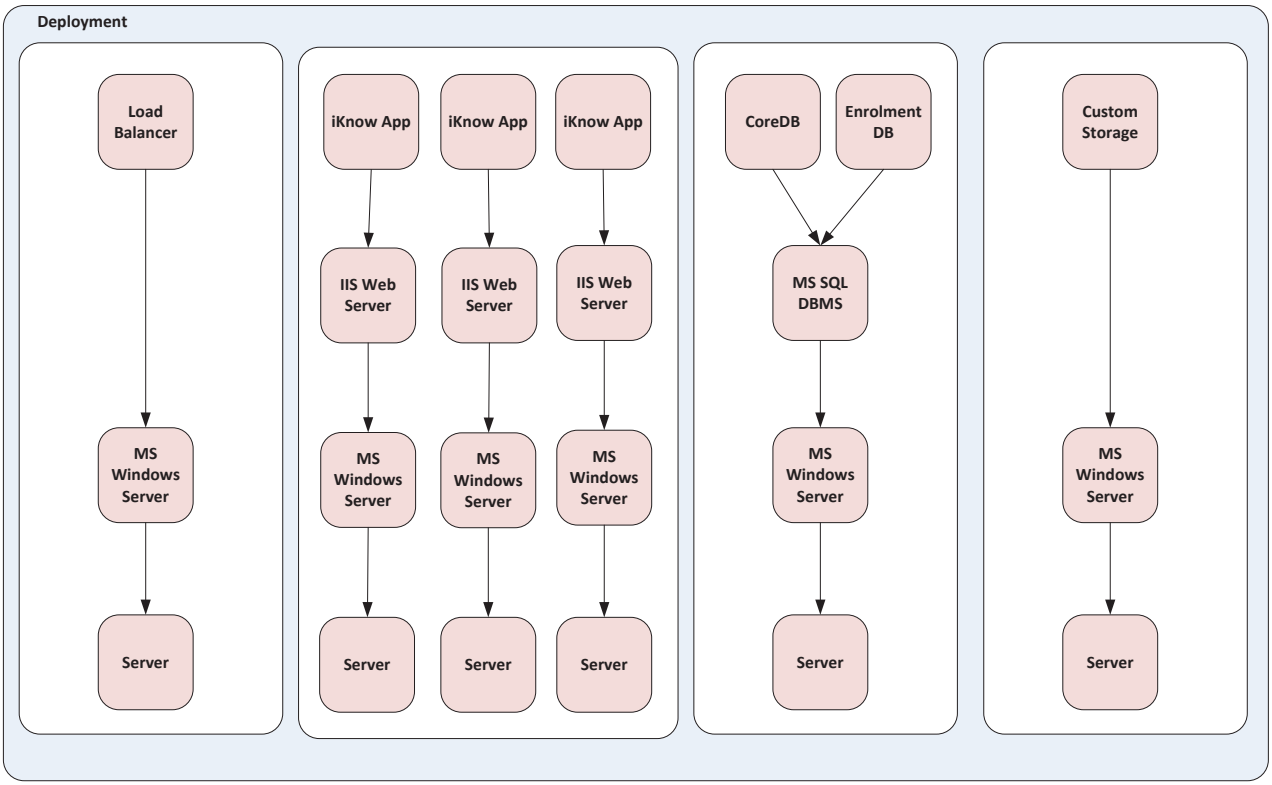

Fig. 5: Deployment Topology for iKnow

management plans. An effort in this direction is in process [22], but without commercial environment to support this effort, the results are not visible yet. This is the reason why the plans for the iKnow use case are still work in progress.

On the other hand TOSCA offers flexible definition of a software application. For smaller applications it offers straightforward way of definition, but for more complex applications, the specification may become very large and complex. In this paper we have analyzed the iKnow case study, as a mid-size project, where the specification grows fast. Usage of modeling tools like Winery [18] can ease this process. The greatest benefit is the promise of re-using the same specification by different cloud providers and environments. Another benefit, in this moment, is the formalized specification, which can be transformed in future and used for other purposes.

To create a TOSCA specification for a given application is a huge challenge at this time, since there is only one published primer [21] and it does not offer a lot of details. Creation of some parts of the iKnow TOSCA specification was based on assumptions considering the absence of concrete environment to test, like proper configuring of the environment with scripts, ability to convert the plans for installation and instantiation management into BMPL, etc.

An important concern is the usage of commercial solutions (in the case of iKnow it is based on Microsoft solutions, such as MS Server, MS SQL Database etc.). Due to the closed environment it is not always possible to properly configure all the necessary data with scripts or APIs. Other main concern is the security definition and settings. This is still a crucial work-in-progress area in the cloud.

Initial steps towards specifying an automated general procedure to extend the TOSCA specification and enable portability of SaaS applications has been reported by the authors in [23]. Automated portability was analysed in [24]. We have also demonstrated how a general procedure can be applied on a simple SOA transactional-based service example [25].

VII. Conclusion

In this paper we have presented a TOSCA specification of the iKnow University Management System, which is so far a unique example and case study to apply this new standard for university management software solutions. The proposed specification and challenges we have faced are not specific only for the given software solution, but can be rather used as a case study to ease the process of TOSCA specification of similar solutions.

Besides the benefits that TOSCA offers, we have pointed current drawbacks of this specification. This work contributes to support the future progress of TOSCA as a developing

standard with bright future in the area of cloud provision of interoperable services.

As future work we plan to continue working and expanding this specification with plans and to help creating an environment where this specification can be tested. We also plan to redefine and rework the iKnow system to create two independent modules (Core and Enrollment) so they can be independently transferred to separate platforms.

ACKNOWLEDGMENT

This work was partially financed by the Faculty of Computer Science and Engineering at the "Ss. Cyril and Methodius" University, Skopje, Macedonia through the project XaaSin-Cloud (Everything-as-a-Service in Cloud). All testing was performed on facilities at the Laboratory of Innovative Internet Technologies.

The iKnow project has been developed as a part of the Tempus JPGR 511342 Project.

***Abstract*—The paper presents creating web system models. The aim of the work was to develop models of the distributed Internet system that allow the performance evaluation. From many possible methods we have selected Queueing Petri Nets consisted of two classes of formal models (Queuing Nets and Petri Nets). In the paper web systems are modeled by Queueing Petri Nets tool. The paper includes the selected results of models simulation. Our approach predicts the performance of distributed Internet system.**

I. Introduction

THE Internet system consists of a set of distributed nodes to provide up-to-date data in set time frames. Groups of nodes (clusters) are organized in layers conducting predefined services (e.g. WWW service).

Nowadays, Internet systems modeling and design develop in two ways. On the one hand, formal models which can be used to analyze performance parameters are proposed [1], [2], [3], [4], [5]. To describe Internet systems such formal methods like Queuing Nets and Petri Nets are used. Sometimes elements of the control theory are used to manage the movement of packages on web servers [6]. Experiments are the second way [7]. Applying experiments and models greatly influences the validity of the systems being developed. The convergence of simulation results with the real systems results confirms correctness of the modeling methods. The following mathematical models are used to describe Internet systems:

- analytical models: obtained on the basis of systems observation for the queuing systems with significant assumptions regarding the requests arrival and service process,
- simulation models of qualitative and quantitative analysis: Time Coloured Petri Nets, Queuing Petri Nets [8] or generalized queuing models based on the queuing theory (e.g. CSIM software libraries [9], [10]).

Our earlier works [9], [11] are based on Queuing Nets (QN) and Timed Coloured Petri Nets (TCPN). A distributed Internet system model, initially described in compliance with Queuing Net rules, is mapped onto Timed Coloured Petri Net structure by means of queueing system templates. We have used two types of formal models that have been exploited in the industry. In our elaboration we created separate system models using Queuing Nets and Petri Nets, which allow the performance analysis. We used experiments to check real distributed Internet system parameters. We verified some constructed models with the real experimental environment as a benchmark (Performance Engineering analysis). The validation results show that the model is able to predict the performance with error about 20[%] [9].

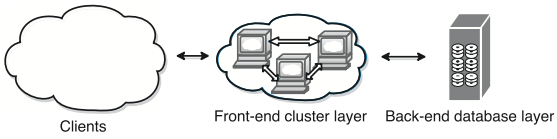

Fig. 1. Distributed Internet system architecture

Distributed Internet systems analysis based on Quality of Service metrics: performance (utilization, throughput, response time), availability, reliability. In these studies the performance is measured in terms of the mean response time of business transactions.

The remaining work is organized as follows. Section II presents distributed Internet system architecture. In the next section, we describe used formal methods. Section IV presents models and simulation analysis. The final section contains concluding remarks.

II. Distributed Internet System Architecture

Distributed Internet system architecture is made up of several layers. In our approach the presented architecture has been simplified to two layers (Fig. 1) based on [8] results:

- Front-end layer is based on the presentation and processing mechanisms.
- Back-end layer contains one or - in the case of replication [9] - several databases. This layer keeps the system data.

Architecture composed of these layers is used for e-business systems. The presented double-layer system architecture realizes Internet system functions. Access to the system is realized through transactions. Proposed in the paper our approach may be treated as an extension and continuation of solutions presented in [9].

In the paper we consider one class of Internet systems. In these systems a started transaction may be cancelled as a result of a system offer change. Not all transactions will be successfully finished. We shall consider cases in which the number of requests per second is hundreds or thousands.

978-83-60810-58-3/$25.00

Such a situation may cause the rejection of a large number of requests, due to timeliness loss. Therefore, partial processing of unrealized requests, also increases the response time for requests processed correctly. Transactions realization related to the system offer must take into account the results of previous transactions associated with this offer. Such systems are known as Interactive Internet Systems with Dynamically Changing Offers [9]. The presented systems class is interesting from the practical point of view. A stock exchange system (e-trading), where transactions are carried out on-line, could be their representative. The study considers the class of interactive Internet systems, for which the rate of offer change is equal to clients' time of interaction with the system. It is assumed that the offers are submitted by a seller or a broker. The offer change may cause that a transaction started earlier, is interrupted and unfinished. It is also assumed that transactions are realized immediately and they apply a common set of resources (such as sale of goods). It is assumed that the buyer can buy a collection of shares in a single transaction. The following features distinguish the described systems from others:

- short response time required - a necessity to transfer results to a client in a short time,
- sequence processing - a large part of transactions requires sequential processing,
- peak of intensity processing - processing a large number of client requests at the same time.

The Internet systems have different response time requirements. The response time for different Internet system types divided into three main groups. The major group, from the viewpoint of our study, is a group of systems, for which the required response time is the shortest. On-line auctions, sports betting, on-line ticketing and e-trading are distributed Internet system examples [9]. Within the Internet system classes we can distinguish a class for which the service is heavily dependent on the offers' time variability.

The characteristic feature of many Internet systems is a large number of customers using the Internet services at the same time. In the case of the described systems class, customers are often focused on one event related to the same system offer (the same database resources). Based on these futures we used e-trading system as a benchmark with two-layered architecture (cluster in front-end layer and one database instance in back-end layer).

III. Mathematical Models

In our solution we propose a very popular formal method - Queueing Petri Net (QPN). This method is based on Queueing Nets and Petri Nets.

A. Queuing Theory

Queuing Theory deals with modeling and optimizing different types of service units. Queueing Net usually consists of a set of connected queuing systems. The various queue systems represent computer components. Queueing Nets are very popular for the quantitative analysis. To analyze any queue system it is necessary to determine:

- arrival process,
- service distribution,
- service discipline,
- scheduling strategies.

B. Petri Nets

Petri Nets are used to specify and analyze the concurrency in systems. The system dynamics is described by the rules of tokens flow. The net scheme can be subjected to a formal analysis in order to carry out a qualitative analysis, based on determining its logical validity. Petri Nets are referred to as the connection between engineering description and theoretical approach. Petri Nets are well-known models used to describe and analyze the service units. Petri Net cannot be used for a quantitative analysis due to lack of time aspects. Some Petri Nets, such as Stochastic Petri Nets or Time Coloured Petri Nets, try to meet the requirements of quantitative analysis. The studies focus on incoming load measuring, e.g. measure of the response time or presentation of an overall modeling plan.

C. Queueing Petri Nets

In our solution we propose Queueing Petri Net formalism [12]. There is a very popular formal method of functional and performance modeling (performance analysis). These nets provide sufficient power to express modeling and analyzing of complex on-line systems. The choice of Queueing Petri Net was caused by a possibility of obtaining the different character information. The main idea of Queueing Petri Net is to add queueing and timing aspects to the net places.

Queuing Nets - quantitative analysis - have a queue and scheduling discipline and are suitable for modeling competition of equipment. Petri Nets - qualitative analysis - have tokens representing the tasks and are suitable for modeling software. Queueing Petri Nets have the advantages of Queuing Nets (e.g., evaluation of the system performance, the network efficiency) and Petri Nets (e.g., logical assessment of the system correctness).

Queueing Petri Net consists of queueing places (resource or state) which contain two components: a queue and a depository for tokens that completed their service at a queue. Input transitions are fired and then tokens are inserted into a queueing place according to the queue's scheduling strategy. Tokens are entered into the queueing place in the same way as in other Petri nets. After service, the tokens are not available for output transactions. They are immediately moved to a depository, where they become available for output transitions. Queueing places can have variable scheduling strategies and service distributions or impose a scheduling discipline on arrival tokens without a delay. [8]

The response time for analysis was chosen from many Performance Engineering parameters. The response time is a sum of residences and queues time and service demand.

TABLE I
PARAMETERS OF EXPERIMENTAL ENVIRONMENT

	Parameter	Value
Software	Application server threads pool per node	30
	Database server connections pool per node	40
Client workload	Number of requests per second	5-20
	Number of clients	220
	Experiment time [s]	300

IV. PERFORMACE ANALYSIS

Queueing Petri Net models are used to predict the distributed Internet system performance.

A. Experiments

First we present the results of our experimental analysis. The goal is to check the service demand parameters for front-end and back-end nodes.

Deployment details are as follows: Gbit LAN network and three front-end nodes and one back-end node. Software environment is based on Linux and consists of: workload generator, load balancer (Apache Tomcat Connector), application server (GlassFish) and database server (Oracle). All important configuration parameters were described in the table (Table I).

Modern distributed Internet systems are usually built on middleware platforms such as J2EE. We use DayTrader performance benchmark which is available as an open source application. Overall, the DayTrader application is primarily used for performance research on a wide range of software components and platforms. Experimental system helps to identify configuration parameters. DayTrader is a suite of workloads that allows performance analysis of J2EE application server. DayTrader is a benchmark application built around the paradigm of an online stock trading system. It drives a trade scenario that allows to monitor the stock portfolio, inquire about stock quotes, buy or sell stock. The load generator is implemented using multi-threaded Java application connected to DayTrader benchmark. By client business transactions we mean the stock-broker operations: Buy Quote, Sell Quote, Update Profile, Show Quote, Get Home, Get Portfolio, Show Account and Login/Logout (Table II). Each business transaction emulates a specyfic class of client session.

Experiments (one node in front-end and one node in back-end layer) have shown that the mean number of requests per second (DayTrader was able to complete) for front-end layer is about 1300. The figure (Fig. 2) shows among others the mean number of requests per second (DayTrader was able to complete) for front-end layer (maximum 1309 requests per second for 220 clients and 15 requests per second workload). Respectively the mean measured number of requests per second for back-end layer is about 7500 requests per second.

Starting the server cluster in the front-end layer requires a mechanism that would allow an equable distribution of load. It must also be a gateway that transfers requests and responses between a user and an application. In such a

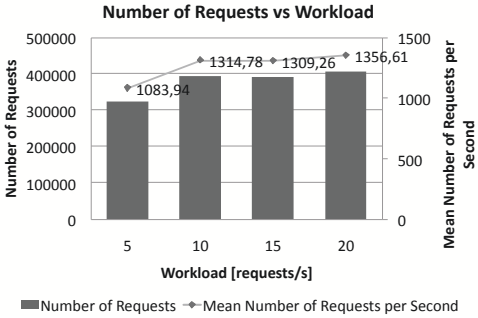

Fig. 2. Number of requests vs load (number of requests and mean number of requests per second)

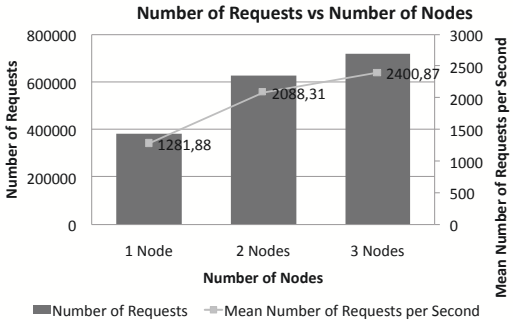

Fig. 3. Number of requests vs number of nodes (number of requests and mean number of requests per second)

scenario, only a gateway is visible from the outside and - on the basis of the request - it determines which part of the system (application server), and how, will be used to perform the request. Built-in load balancer is not available in the free version of the GlassFish server. Apache Tomcat Connector (mod_jk) has been used as the load balancer. Exampled client Uniform Resource Identifier query (Table II): http://[DayTraderApp]/daytrader/app?action=query.

Also cluster (three nodes in front-end and one node in back-end layer) experiments (Fig. 3) have shown that the mean number of requests per second (DayTrader was able to complete) for the front-end layer is about 2400 (for three front-end nodes, 220 clients and 15 requests per second workload). The mean measured number of requests per second for the back-end layer is the same as earlier.

One of the most important requests - Buy Quote (Requests class, which has a bigger impact on the behavior of the system (Fig. 4)) is used in simulations, because we have one class of requests in simulations. Simulations are only an approximation of reality. Buy Quote is only a few percent of all requests (Table III), because the experimental system is based on the real system workload.

B. Models

Multiple front-end nodes and one back-end node are the main configuration scenario. The Queueing Petri Net models (Fig. 5) are used to predict the system performance. We use the Queueing Petri net Modeling Environment [8] tool. Queueing

TABLE II
VALUE OF ACTION PARAMETER IN UNIFORM RESOURCE IDENTIFIER ADDRESS

Query	Transaction	Parameters	Description
buy (GET)	Buy Quote	$symbol$ – stocks symbols; $quantity$ – number	Buy and return the number of specified stocks
$sell$ (GET)	Sell Quote	$holdingId$ – stocks ID, which will be sold	Sell indicated stocks
$update\_profile$ (GET)	Update Profile	$password$ and $cpassword$ – new password; $fullname$ – name and surname; $address$ – address; $creditcard$ – credit card number; $email$ – email address	Update the logged-in user profile
$quotes$ (GET)	Show Quotes	$symbols$ – comma-separated stocks to display	Display information about the required stocks
$home$ (GET)	Get Home	–	Generates a logged-in user's homepage
$portfolio$ (GET)	Get Portfolio	–	Display a list of stocks held by the user
$account$ (GET)	Show Account	–	Display the logged-in user profile
$login$ (POST)	–	$uuid$ – user ID; $password$ – user password	Log the user in the system (session is created on the server side and its identifier returned in cookie)
$logout$ (GET)	–	–	Close the user session

TABLE III
PERCENTAGE OF QUERIES

Query	[%]
buy	5
$sell$	5
$update\_profile$	4
$quotes$	40
$home$	20
$portfolio$	12
$account$	10
$login/logout$	4

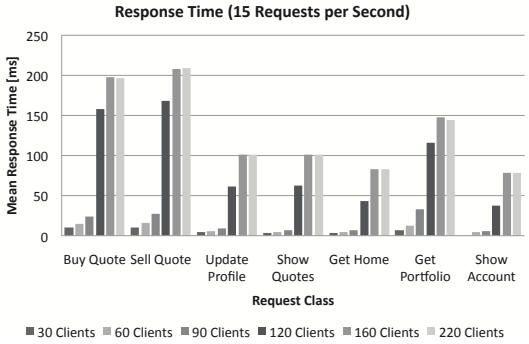

Fig. 4. Exampled real system response time for 15 requests per second workload (one node in front-end layer and one node in back-end layer)

Petri net Modeling Environment is an open-source tool for stochastic modeling and analysis based on the Queueing Petri Net modeling formalism was used in many works [13], [8], [2], [3], [4]. Total response time (Eq. 1) is a sum of all individual response times of queues and depositories in a simulation model without the client queue response time (client think time).

$$R = R_{QPN\_PLACES_{(QUEUE)}} + R_{QPN\_PLACES_{(DEPOSITORY)}} + R_{PLACES_{(QUEUE)}} + R_{QPN\_CLIENTS\_PLACE_{(DEPOSITORY)}} \quad (1)$$

Servers of the front-end layer are modeled using the Processor Sharing (PS) queuing systems (FE_CPU places). The back-end server is modeled by First In First Out (FIFO) queue (BE_I/O place). $PLACES$ (Eq. 1) represent the places (FE and BE) used to stop incoming requests when they await application server threads and database server connections respectively. Clients think time is modeled by Infinite Server (IS) scheduling strategy ($CLIENTS$ place). Application server threads and database server connections are modeled respectively by $THREADS$ and $CONNECTIONS$ places (Fig. 5).

Software and client workload parameters are the same as in the experiment environment. Service in all queueing places is modeled by an exponential distribution (λ parameter). Service demands in layers are based on experimental results in Sect. IV-A: $d_{FE\_CPU} = 0,714$ [ms] and $d_{BE\_I/O} = 0,133$ [ms]. Initial marking for places corresponds to the input parameters of the cluster experiment: number of clients (number of tokens in $CLIENTS$ place), application server threads pool (number of tokens in $THREADS$ place), database server connections pool (number of tokens in $CONNECTIONS$ place). In these models we have three types[1] of tokens: requests, application server threads and connections to the database server. The process of requests arrival to the system is modeled by the exponential distribution with the λ parameter (client think time) corresponding to the number of client requests per second.

C. Simulation Results

Many simulations were performed for various input parameters (Table IV).

The number of clients was increasing in accordance with the values presented in the table (Table IV). We used scenarios in witch we have a single requests class, the Buy Quote transactions. The first scenario involves a certain number of clients, a variable number of nodes and a variable number of requests per second for the entire system. The second scenario involves the response time of the entire system (Sys), the response time of the front-end layer and back-end layer (FE+BE) and the response time of the back-end layer (BE). In both scenarios the number of application server nodes is 1, 3, 6 and 9. The distributed Internet system model is used to predict the performance of the system for the scenarios mentioned above.

[1]A color specifying the types of tokens that can be resided in the place.

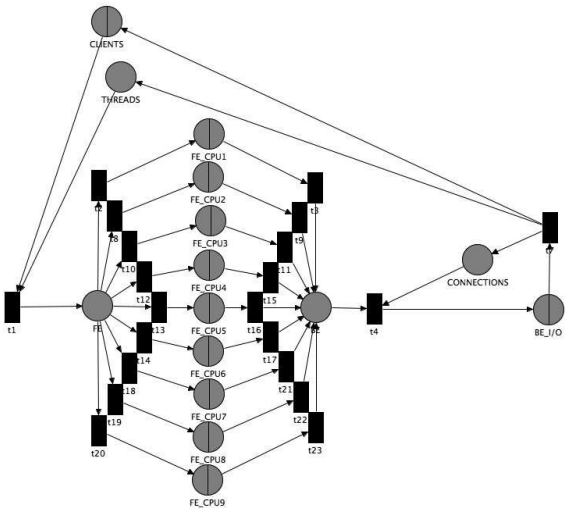

Fig. 5. Model of Internet system with front-end cluster (example for 9 nodes)

TABLE IV
PARAMETERS OF SIMULATIONS (ONE CLASS OF REQUESTS CORRESPONDS WITH BUY QUOTE REQUESTS)

	Parameter	Value
QPME	FE queue[a]	FE_CPUn
	BE queue	BE_I/O
Software[b]	THREADS place	30[c]
	CONNECTIONS place	40[d]
Client workload	λ	0,015[e]
	CLIENT place	30; 120; 210; 300; 390; 480
	Simulation time [s]	300

[a] n - number of front-end nodes
[b] Initial marking per node
[c] 30 threads for one front-end node, 60 threads for two front-end nodes, etc.
[d] 40 connections for one front-end node, 80 connections for two front-end nodes, etc.
[e] Client think time equals 66,67 [ms]

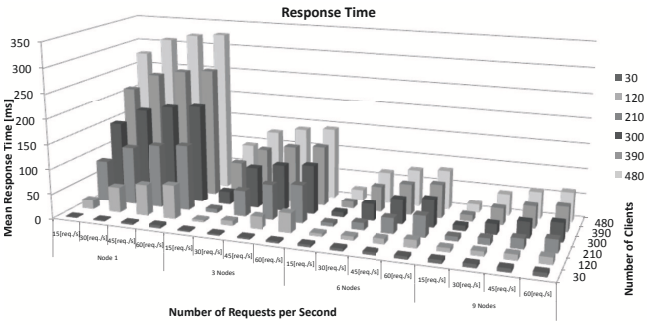

Fig. 6. Mean response time simulation results (system, fron-end and back-end layer, back-end layer) for different number of nodes (1, 3, 6 and 9), requests per second (15, 30, 45 and 60) and clients (30, 120, 210, 300, 390 and 480)

The figure (Fig. 6) reports the analysis results for all scenarios. In all cases, the model predictions are understandable. We investigate the behavior of the system as the workload intensively increases. As a result, the response time of transactions is improved for cases with a higher number of front-end nodes. As we can see increasing the number of nodes while simultaneously increasing number of application server threads and connections to the database is a good solution.

The overall response time decreases while the number of nodes increases (the change of requests per second (15, 30, 45, 60)). The response time of one front-end node architecture for all cases is the biggest. The response time difference between the 6 and 9 nodes is much smaller than that between 1 and 3 nodes in the front-end layer. When more nodes in the front-end layer are added the analysis of their impact on other elements of the system should be preluded.

In the second scenario the changes of the number of requests per second (1 and 3 nodes) do not have an impact on the back-end layer response time (BE). In the next cases with a higher number of nodes in the front-end layer (6 and 9) we can observe an increasing response time for the back-end layer. It can be seen already at 30 and more requests per second (Fig. 7). Overall system response time increases with increasing workload, even with a larger number of nodes (Fig. 7).

V. CONCLUSIONS

We can not always add new devices to improve performance, because the initial cost and maintenance will become too large. Also not every system can or should be virtualized or put in the cloud computing. Because the overall system capacity is unknown we propose the combination of benchmarking and modeling solution. Our earlier works propose Performance Engineering frameworks to evaluate performance during the different phases of their life cycle. Our present approach predicts performance for the distributed Internet system. The benchmark used in our work has got realistic workload.

We analyze the response time characteristics of different configurations. We develop a framework that helps to identify

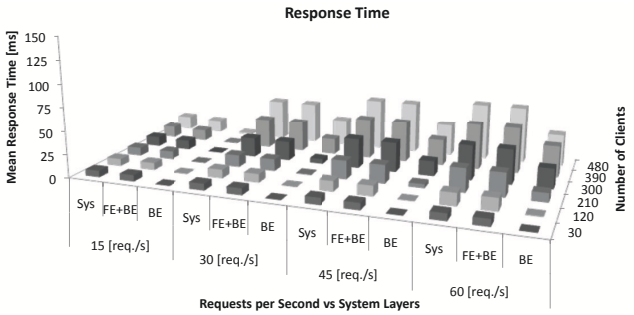

Fig. 7. Mean response time simulation results (system, fron-end and back-end layer, back-end layer) for different number of requests per second and clients (9 nodes)

performance requirements. The study demonstrates the modeling power and shows how the discussed models can be used to represent the system behavior. We used Queueing Petri Net models to predict the system performance for several different workloads and configuration scenarios. We used simulations because available analysis techniques are useless. It was not possible to predict the system performance under a large workload and a large number of nodes.

A number of different models of realistic size and complexity were considered. The benchmark was run for 300 seconds per test and each test was repeated 10 times to improve the reliability of results. The QPN model was simulated using the method of non-overlapping batch means method to estimate steady state mean token residence times. The average predicted response times are within the 95[%] confidence interval of the measured average response times. For all the simulations the confidence intervals were sufficiently small for the results to be reliable. Our analysis showed that the data reported by SimQPN is very stable.

The convergence of simulation results with the real systems results confirms the correctness of the modeling methods and their theoretical values. The validation results show the main advantage of this model (Table V). The relative error is lower than 15[%]. QPN model is a better than QN or TCPN models.

TABLE V
MODELING RESPONSE TIME ERROR FOR SCENARIO WITH 300 CLIENTS (EXAMPLE FOR 60 [REQUESTS/S])

Number of nodes	Model [ms]	Measured [ms]	Error [%]
1	198,48	229,65	13,5
3	99,47	114,96	13,4

Energy consumption in information and communications technology is growing annually by 4[%] despite efficiency gains in technology. It is therefore important to study ways of reducing energy consumption [14]. Power consumption depends on the load and on the number of running nodes in the cluster-based Web system. We shall study the compromise between a perceived average response time and energy consumption (practical value).

The future research will focus on verification of the system behavior in the case of a higher number of requests classes used in simulations. We shall provide a larger-scale analysis using hundreds of nodes.

***Abstract*—Cloud service providers offer their customers to rent or release hardware resources (CPU, RAM, HDD), which are isolated in virtual machine instances, on demand. Increased load on customer applications or web services require more resources than a physical server can supply, which enforces the cloud provider to implement some load balancing technique in order to scatter the load among several virtual or physical servers. Many load balancers exist, both centralized and distributed, with various techniques. In this paper we present a new solution for a low level load balancer (L3B), working on a network level of OSI model. When a network packet arrives, its header is altered in order to forward to some end-point server. After the server replies, the packet's header is also changed using the previously stored mapping and forwarded to the client. Unfortunately, the results of the experiments showed that this implementation did not provide the expected results, i.e., to achieve linear speedup when more server nodes are added.**

I. Introduction

THE dynamic way of living enforces the companies to be more adaptive to changes. A lot of new companies are emerging and growing fast, thus taking the market share ruled of the leading companies. Therefore, services in each company must be prepared for dynamic changes and cope with increasing or decreasing the load [1]. If a company wants to save costs and buy a smaller amount of resources, then those resources cannot handle the load peaks. Nevertheless, buying huge amount of resources will increase the costs and the resources will be underutilized most of the time [2].

A possible solution is to migrate the services in commercial clouds. This process requires a dynamic strategy for a given company, to enable efficient acquiring or releasing the cloud resources. Additionally, increasing the resources requires a sophisticated load balancing strategy to maximize the effective and efficient usage and utilization of the rented resources. The final effect is to maximize the cost, performance and utilization ratio.

Recently, we have proposed an architecture for a Low Level Load Balancer (L3B) [3]. This architecture provides a scalable cloud environment, which can distribute server load among several active virtual machines that are integrated over the communication link [4].

In this paper, we present a new load balancer, realized on a network level. It dynamically balances the incoming network packets among all active virtual machines and returns the responses to the clients that send the requests. This balancer adds a small latency, which does not impact the total response time. The balancer also increases the security of the services since the client cannot see the internal cloud network.

The rest of the paper is organized as follows. Section II presents the related work in the area of load balancing. In Section III, we briefly describe the architecture of L3B. The development and the performance of the L3B balancer implementing the proposed architecture is presented in Section IV. Finally, Section V concludes the work and presents future work.

II. Related Work

Load balancing is an inherited feature from grids onto clouds. It may have various uses in cloud computing, such as:

- *Failover*, as continuation of a service after the failure of a cloud resource;
- *Energy conservation and resource consumption* kept to a minimum; and
- *Scalability*, as a feature of cloud computing requirements.

Rimal et al. [5] give an overview of load balancing techniques used by various cloud providers and solutions, including Amazon, Google, SalesForce, Azure, Eucalyptus, OpenNebula, etc. Most of these techniques are implementations of a conventional Round Robin schema, weighted selection mechanisms, HAProxy, Sticky session, SSL Least Connect, Source address, cluster server load equalization, high performance protocols over EC2, hardware load balancing, cloud controllers, etc.

A lot of load balancing techniques have existed long time before the introduction the cloud computing paradigm and the virtualization technique, which can be grouped in three groups [6]:

- Session switching at the application layer;
- Packet-switching mode at the network layer; or
- Processor load balancing mode.

978-83-60810-58-3/$25.00

Heinzl and Metz [7] classified the load balancers in two groups: Hardware and software, and commercial and open source.

In this paper we propose a network based load balancer, realized by packet-switching mode at the network layer of OSI model.

However, load balancing is not the only sufficient essential part for realization of the cloud. Resource brokering is also important, which is known as elastic load balancer (ELB), such as Amazon's ELB. Hu-Sheng et al. [8] proposed TeraScaler ELB, which is able to dynamically adjust the processing capacity of back-end server cluster with the applied load.

In our previous research, we proposed an architecture of a L3B balancer [3]. We have developed the load balancer and in this paper we present the architecture and design. A set of experiments is also conducted in order to prove the performance of our solution.

Load balancing in the cloud was analyzed by several authors, with corresponding surveys about performance of various load balancing algorithms [9], [10].

Load balancing techniques can be either centralized on a specific server or distributed by content aware policy. The centralized load balancing techniques are controlled by a single central node and all the other nodes communicate with this node, such as the Central Load Balancing Policy for Virtual Machines (CLBVM) solution proposed by Bhadani and Chaudhary [11], or the CLBDM solution proposed by Radojevic and Zagar [12], which takes into consideration other parameters as server load and application performance on top of the Round Robin Algorithm.

Centralized load balancing approaches in cloud computing do not offer full scalability features due to design limitations and communication overhead [13].

III. Proposed Architecture

This section describes the architectural design of the new proposed L3B balancer.

A. Overall model

The overall system architecture is presented in Figure 1, presenting the position of all items and their external interconnections. L3B is placed in front of a pool of virtual machine instances on the cloud, communicating with the Internet clients from one side and with physical or virtualized servers from the other side. The main function is to realize the load balancing of the clients' requests for services on various servers.

The latency that the L3B adds to the client requests should be compensated with the reduced response time by the servers due to reduced number of requests.

The internal architecture of the L3B balancer [3] consists of two modules: *Resource Management Module (RMM)* and *Packet Management Module (PMM)*, as presented in Figure 2 [3]. The purpose of these modules is to realize accounting functions, which is essential for load balancing.

The main objective of the RMM module is to manage the provision of cloud resources with dynamic accounting of the current load and utilization of active virtual machine instances. Whenever the accounting shows a need for more resources, the RMM module communicates with the cloud controller, by sending a command to initiate creation of a new virtual machine instance. If there is an information of underutilization, a corresponding command is sent by the RMM module to shut an existing virtual machine instance.

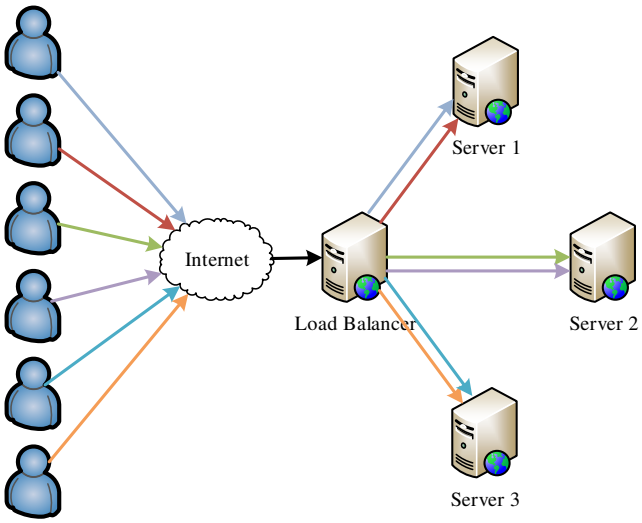

Fig. 1. L3B System architecture

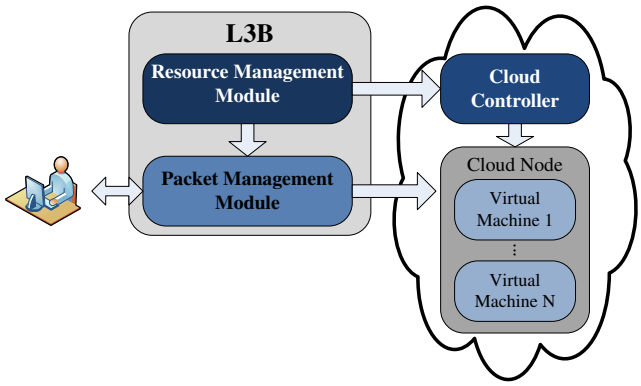

Fig. 2. Modules in the internal L3B architecture

Besides the connection to the cloud controller, the RMM also communicates with the PMM module. Particularly, the RMM module sends an information to the PMM module about active virtual machine instances to enable quality information about the work balance and to enable conditions for the PMM to realize the load balacing. The PMM module's main task is to redirect the input packets to some of the active virtual machine instances and then to forward the responses to the client that has sent the request.

This paper presents an extension of this idea, with details on the development of the PMM module, since we are interested

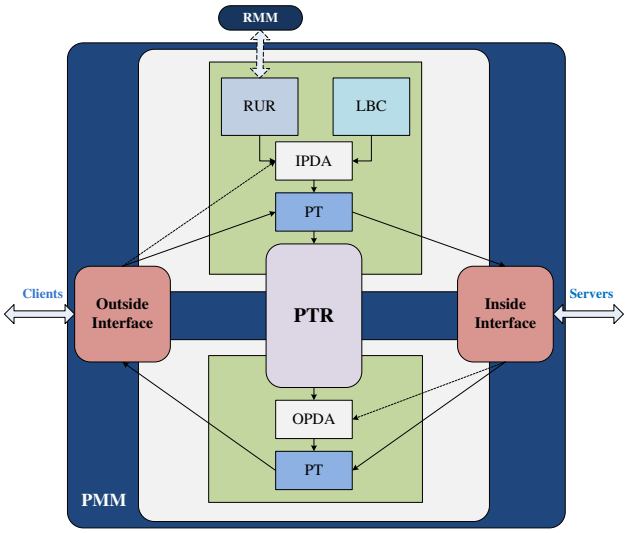

Fig. 3. Design of the PMM module

in presenting a proof that it will be efficient for load balancing of client requests among several active machines (or virtual machine instances in the cloud). The development of the RMM module is out of scope of this paper since it directly depends on the cloud controller and its APIs and interfaces.

B. Design of the PMM module

The PMM module is the core of the L3B balancer. The main functionality is to enable intelligent management of all the inconsistent traffic coming from the clients.

The design of PMM module is presented in Figure 3. It is used to manage the client's requests, i.e. to forward particular incoming packet to a particular virtual machine instance, enabling an environment to balance the load of all virtual machine instances. When the target virtual machine responds back, PMM forwards the response packet to the client that has sent the corresponding request.

The PMM module consists of two interfaces to establish a communication to:

- the *clients*, presented by the client machines that sends requests and
- *virtual machine instances*, presented by the Cloud Nodes.

Figure 3 shows the two internal modules for communication with the external parts:

- *L3B Outside Interface (OI)* that communicates with the clients, and
- *L3B Inside Interface (II)*, responsible to communicate with the virtual machine instances.

The main part of the L3B, realized as a core processing unit is the

- *Packet Translation Repository (PTR)* responsible for receiving the packets in both directions, their processing and forwarding to the destination.

The other internal PMM modules, which are designed to establish communication in direction from outside LAN to inside LAN, (direction from OI to II) and information exchange with the RMM module are the following:

- *Input Packet Decision Agent (IPDA)*, a part that realizes the most important agent, which implements the intelligent algorithm to derive smart decisions in assigning the requests to appropriate resources,
- *Resource Utilization Repository (RUR)* is a part that stores information about utilization of the physical resources, by sensing the active virtual machines and communicating with the RMM module;
- *Load Balancing Configuration (LBC)* is dedicated to store the information about configuration for the load balancing;
- *Packet Translation (PT)* agent is the part that realizes the low level networking on IP level in direction from OI to II.

The PMM module contains also parts responsible for low level network communication in direction from inside LAN to outside LAN (direction from II to OI), as follows:

- *Output Packet Decision Agent (OPDA)* is the agent responsible to make decisions and assign responses to the requestors, realized by appropriate communication with PT and PTR.
- Inverted *Packet Translation (PT)* agent realizes the low level networking on IP level in direction from II to OI.

The OI arbitrates among the clients and the PMM inner agents. Its function is based on a decision making and triggering some actions.

A typical scenario, when a new packet arrives, the OI instantly sends information to the IPDA. The IPDA agent uses a sophisticated intelligent algorithm to realize smart decisions needed to assign the requests to appropriate resources. The decision can be made only by using relevant information by the RUR and LBC about current utilization of the physical resources and load balancing configuration. Finally, after IPDA has analyzed the real time information of the hardware utilization, it determines which virtual machine can handle the request in order to preserve sustainable performance. The realized decision is sent to the PT agent, which receives the packet from OI and uses it to proceed with the IP header translation using the NAT/PAT (Network Address Translation / Port Address Translation). This functionality enables an environment to translate internal and external network addresses for each packet. These translations are then stored in the PTR and finally the corresponding transformed packet is forwarded to the II part, as inside interface to forward it to the target virtual machine instance.

As soon as the packet reaches the II part, it is forwarded to the corresponding cloud node and the target virtual machine instance. The packet has modified header to be transmitted in the network. The information stored in the header can be efficiently used for packet flow in the opposite direction. In this case the II receives the packet with responses from the

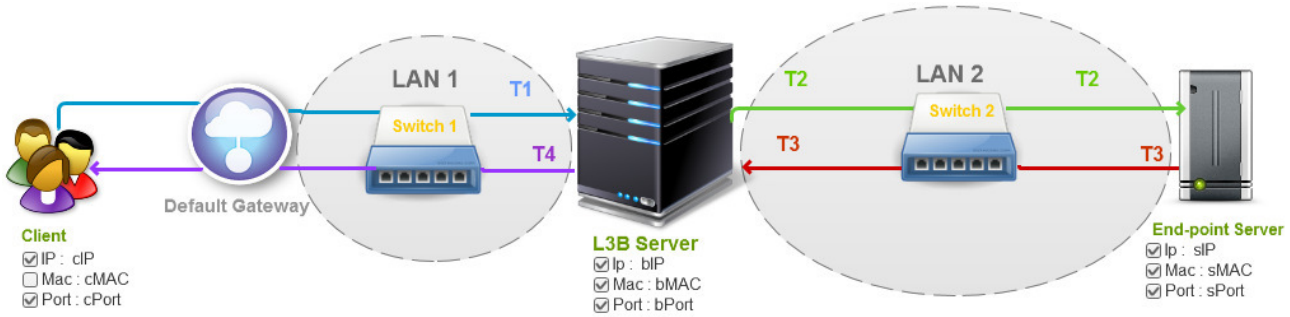

Fig. 4. The L3B implementation

virtual machine. The packet encapsulated in data link frame contains the corresponding MAC addresses of the source and target. Now the packet is sent to OPDA, which communicates to the PTR to receive detailed PT instructions. Note that there is an inverted PT in this section, which repeats the inverse NAT/PAT procedure to translate the external IP address into the original destination IP address. Then the packet is sent to the OI to forward the response to the client.

IV. The Implementation of L3B

This section presents the implementation of L3B according to the architecture described in Section III. The results of the experiments to determine its impact to the end-service's performance are also presented.

A. L3B functional requirements

The efficient and effective load balancer should comply with the following functional requirements:

- To balance all incoming packets that are sent by the clients to the active end-point servers;
- Must have a configuration file where a specific port can be configured where the clients should sent their requests;
- Must have a configuration file to specify the IP addresses of active end-point servers where the incoming packets will be balanced; and
- Introducing L3B between the client and more end-point servers must reduce the overall response time of the client requests.

B. The Architecture

The L3B is implemented in JAVA to be platform independent. This feature compensates the small JAVA deficiency, manifested as a reduced performance. Recently, this is not emphasized a lot, since modern Java virtual machines' performance do not fall behind other solutions such as C or C++ [14].

The architecture of the L3B implementation is depicted in Figure 4. Only one end-point server is presented in order to simplify the explanation. The participants in this communication scenario are the client, L3B server and end-point server (virtual machine hosted on the cloud). There are two LANs identified in the figure, LAN1 as a network segment between the default gateway and the L3B server, and LAN2, as a network segment between the L3B server and the end-point server (virtual machine hosted on the cloud). We assume that these LANs are supported by corresponding fast switches. In addition, this organization allows the end-point servers and L3B to be in the same subnet to decrease network latency. Considering the L3B modules, actually OI communicates with default gateway in LAN1 and II communicates with virtual machines hosted in LAN2. The participant' parameters (IP address, Mac address, Port) are presented below each participant, as presented in Figure 4.

TABLE I
Header values of a request in different states in the L3B implementation

Header Value	T_1	T_2	T_3	T_4
Source IP	cIP	bIP	sIP	bIP
Destination IP	bIP	sIP	bIP	cIP
Source port	cPort	obPort	sPort	bPort
Destination Port	bPort	sPort	obPort	cPort
Source MAC	Def. Gateway	bMac	sMac	bMac
Destination MAC	bMac	sMac	bMac	Def. Gateway

Lets discuss a typical scenario in this L3B architecture and implementation. When a client sends a request, it is routed through Internet until the L3B default gateway, identified as T_1 state in LAN1. Now, the incoming packet is received by the OI module in the L3B balancer. This packet is processed, as discussed in Section III.

The packet header processing, transforms its Ethernet, IP and TCP headers. More details for the scenario presented in Figure 4 are specified in Table I. Besides transformation, the old and new headers are stored in corresponding repository (PTR). As explained in the previous Section, IPDA is the agent that makes the decision to select the end-point server as a destination where the packet should be sent. In the figure, this is labeled as T_2 in the LAN2.

When the end-point server processing is finished, a response packet starts to be sent in the opposite direction in the analyzed architecture. The end-point server replies back to the L3B, by sending the packet in the LAN2, labeled with T_3 in the figure. Similarly to the previous explanation, II unit from the L3B balancer receives the packet, and OPDA uses the

information stored in PTR repository to make a decision about the header translation. Then the inverse PT agent transforms the corresponding Ethernet, MAC and IP addresses, according to the decision made by OPDA, and updates the configuration in PTR. After header translation, PT sends the packet with changed headers to the OI unit, which forwards it to the relevant client, which originated the counterpart request.

C. Implementation challenges

Our implementation of the architecture uses jNetPcap library [15] to sniff the network traffic and alter the incoming packets. Using the jNetPcap library made some problems during the packet forwarding.

The packet sniffer Wireshark [16] showed that a regular packet arrived at the server T_2, with correct values for appropriate fields in Ethernet and IP header. However, the server did not respond back to the L3B balancer and T_3 was not initiated.

The solution to this problem, acquired more experiments and programming. We redeveloped the L3B to open a new socket to the end point server for each packet. However, although this change solved the problem and the packet was sent back to the L3B balancer, and then from L3B to the client, the results were not promising. The following two sections present the testing methodology and the results of the experiment to determine the L3B performance.

D. Testing methodology

Four workstations with the same hardware resources and platform are used as a testing environment. Each workstation has Intel(R) Xeon(R) CPU X5647 @ 2.93GHz with 8GB RAM memory, installed with Ubuntu 12.04. The client is on the same LAN as the L3B workstation and two end-point workstations to reduce the network latency.

A client requests a packet with constant web page content, which size is $56KB$. The different number of concurrent requests are then initiated to create various loads. We choose this page size in order to be smaller than the IP packet limit of 64KB. Usually the web requests and responses are smaller than $64KB$.

The concurrent requests are simulated with SOAPUI. Each test case consists of sending N concurrent requests per second, such that N varies in each test case starting from $N = 5$ until $N = 100$ requests, by increasing N with step 5. Each test case lasts 60 seconds.

E. Performance analysis of the L3B implementation

The defined test cases were executed in order to check the impact of the L3B balancer to the end-point web server. Both experiment scenarios are examined, with and without L3B.

Figure 5 presents the results of the experiments. We observe that the last functional requirement is not satisfied for neither test case, meaning that the most important feature is not realized. In reality it shows that introducing the L3B balancer made the response time even worse, compared to the scenario without L3B.

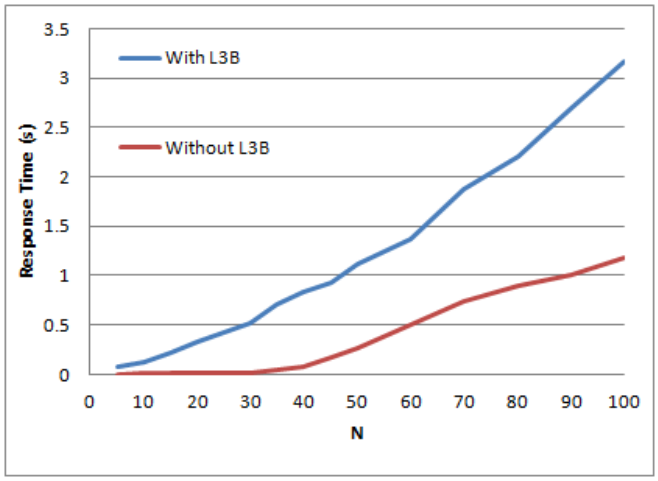

Fig. 5. Results of the experiments for the L3B implementation

The results show that although opening a new socket for each incoming packet was a solution to reply the server, it is performs worse and overall it is a bad solution.

This motivated us to analyze various proposals how to make the L3B more efficient. The main idea was to try to open one or several sockets from the L3B server to the servers in order to reduce the overall response time.

V. Conclusion and Future Work

In this paper we have presented a new approach for a load balancer, that is, the low level load balancer that works on a network layer of OSI model. The balancer is developed according to the L3B architecture [3], but its implementation have even reduced the performance when two end-point servers are used compared to the case when only one end-point server is used without the L3B balancer.

Since this implementation of the L3B balancer did not yield the expected results, we will proceed to improve the L3B architecture and implementation. Creating a new socket for each arrival packet reduced the performance of the L3B balancer and the architecture will be improved by creating a virtual client.

Supporting job-level secure access to GPGPU resources on existing grid infrastructures

John Walsh, Jonathan Dukes

Email: John.Walsh@scss.tcd.ie, Jonathan.Dukes@scss.tcd.ie

***Abstract*—Grids provide secure, utility-like access to a wide variety of large-scale, distributed computational and storage resources. In particular, the European Grid Infrastructure (EGI) and Open Science Grid (OSG) have excelled in processing vast workloads of independent jobs for the research community.**

Researchers demand increasingly faster processing speeds to solve increasingly larger and more complex problems. To meet this need, attention has shifted over the past decade away from single-core processing models towards the use of multi-core, many-core and massively parallel computational accelerators. The increasing availability and use of General Purpose Graphic Processing Units (GPGPUs) are an example of this.

This paper addresses many of the challenges that exist in the integration of resources such as GPGPUs into Grid infrastructures. Specifically, solutions are proposed for discovering and describing GPGPU Grid resources, specifying multi-GPGPU job requirements, performing multi-GPGPU allocation to jobs, dynamically updating publicly-readable GPGPU usage information and enforcing GPGPU access control to prevent distinct jobs from inadvertently accessing the same device. The proposed solution is fully compatible with widely-used and accepted standards and middleware including the GLUE 2.0 schema and EGI Unified Middleware Distribution. A prototype implementation is also described.

I. Introduction

GRID Computing [1] developed out of the need for geographically distributed scientific communities to co-operate in order to investigate scientific problems with increasing computational complexity. The most famous example of such a community is the Particle Physics community investigating the existence of the Higgs Boson using the Large Hadron Collider (LHC). Not only do such large-scale problems require a given scientific community to share vast amounts of data among its (distributed) users, it may also be unfeasible to to process this data at a single location (known as a "Site" or "Resource Centre") – hence distributing the data processing tasks and storage to multiple locations is often required. Such grid-systems draw upon distributed computing, resource discovery and sharing, distributed data-management, authentication and authorisation, role-based access control and process accounting.

Grids developed around a "single program/single CPU" execution model. However, since 2005 the exponential growth of CPU speed and processing power has plateaued [2], and this has generated some questions about the future of computational-based scientific research using this "single program/single CPU" approach. *Parallel Processing* taking advantage of emerging multi-CPU cores (multicore) or many processing cores (many-core) on General Purpose Graphic Processing Units (GPGPUs) or Intel's Xeon Phi Computational Accelerator is regarded as a "white-knight" like solution to this problem. Indeed, the trend towards the extensive usage of GPGPUs and Intel's Xeon Phi, commonly known as "Computational Accelerators" (CAs) [3], in High Performance Computing environments can be seen in the twice-yearly "Top 500 Supercomputer" lists [4].

Support for grid-based parallel applications using Message Passing Interface (MPI) [5] has been available for a number of years [6]. No such support currently exists for the emerging CA-based parallel-processing architectures despite indications that many grid resource-centres and users were planning to incorporate CAs into their future work-plans [7] [8].

The core objective of the work presented in this paper is to address the challanges of integrating GPGPU resources into grid infrastructure in such a way that there are no changes (or minimal changes) to how the user works. In addition, there should there be no significant changes to the grid infrastructure itself. The approach taken to solve this integration problem is to first consider the more general problem of integrating any new resource. A set of *Grid Resource Integration Principles* is developed (Section III) that take these constraints into account.

In this paper: Section II reviews some of the key concepts in Grid Computing, including service-discovery (the Grid Information System) and the job submission lifecycle. Section III introduces the multi-layer abstract achitecture that seperates GPGPU job resource requests from the GPGPU allocation and access protection layers. Section IV presents a realisation of this model in the form of a prototype execution-model that extends the architecture and capabilities of a grid based on the popular Unified Middleware Distribution (UMD). This extension provides new services that address four key grid components, namely: (i) GPGPU service discovery; (ii) multi-GPGPU resource allocation through a grid job description language and batch system integration; (iii) dynamic updating of publicly-readable status information describing the GPGPU resource usage that complies with current standards; and finally, (iv) per-job access controls that prevent distinct jobs from inadvertently accessing the same GPGPUs. Section V looks at related work, and when applicable, discusses how and why the approach taken here differs. Finally, Section VI

978-83-60810-58-3/$25.00

reviews the current implementation and the scope for future work in this area.

II. Grid Computing

The terminology "Grid" and "Grid Computing" has a wide and varied interpretation [9]. With this in mind, there is a need to clarify these terms in the context of this work and thus define the scope of the work. This section introduces key concepts in Grid Computing – specifically Grids such as the European Grid Infrastructure (EGI) and Open Science Grid (OSG) that primarily provide computing and storage resources to researchers. A high-level overview of the lifecycle of a user's job, from job submission through to execution using a Grid resource, will be presented. Grids are, by nature, large-scale, distributed infrastructures and accessing Grid resources relies on maintaining a uniform, structured, global view of the Grid. An overview of the systems that maintain this information will also be presented.

Key Concepts

A Grid is a distributed collection of computational and storage resources where (i) each resource is controlled and managed solely and independently by its owner or *resource-provider* (for example a University, research centre, company or private individual) and (ii) each resource-provider has some level of control over how the resource is accessed and used. This definition is sufficiently general to include both large-scale Grids, such as EGI or OSG, and also "compute-cycle" volunteer donation systems such as BOINC [10].

The work described in this paper is concerned with large-scale Grids, such as EGI or OSG, that are composed of multiple *resource-centres*, each operated by their owner or *resource-provider*. Each resource-centre provides one or more *Compute Elements* (CEs). These are services that provide access to computational resources such as a cluster of worker nodes accessed through a batch system. A *Grid Information System* is used to publish the capability of each resource-centre, in the form of a description of the resources that it provides, the current utilisation and availability of those resources and a description of the mechanisms for accessing them. To make use of the computational resources provided by a Grid, users submit *jobs* that are described using a formal *job description language* (JDL) (or *resource-specification language* (RSL)). In simple terms, a job consists of an executable program, a specification of the software environment in which the program must run, any input parameters and data required by the program and the files that will contain the outputs from the job. Users are grouped into *Virtual Organisations* based, for example, on their research area and these groupings are used to control access to – and account for the usage of – grid resources.

Grid users can request that their jobs be executed on a specific resource, based on *a priori* knowledge of the capabilities of a resource-centre. However, ideally Grids such as EGI and OSG will allow users to submit a job and let the Grid "decide" where that job should execute. To facilitate this, as well as capturing basic information about the job (e.g. executable program, input parameters and data), a JDL description of the job can also describe the job's resource requirements (e.g. number of CPU cores, minimum CPU specification, minimum memory requirement, software environment). In this scenario, instead of submitting a job directly to a resource-centre, the job is submitted to a Grid *Workload Management System* (WMS). The WMS acts as a broker, using the information published about each resource-centre through the Grid Information System, together with the description of the job, to find all resources that match the job's requirements. Furthermore, the broker can select one of the matched resources (e.g. using pre-defined policies or heuristics) and orchestrate the execution of the job on the chosen resource.

The Grid Job Life-cycle

The usual starting point when submitting a job to the grid is the User Interface (UI). This is a service node that contains the necessary command tools to interact with other grid services. The UI is configured to interact with one or more Workload Management Systems (WMS).

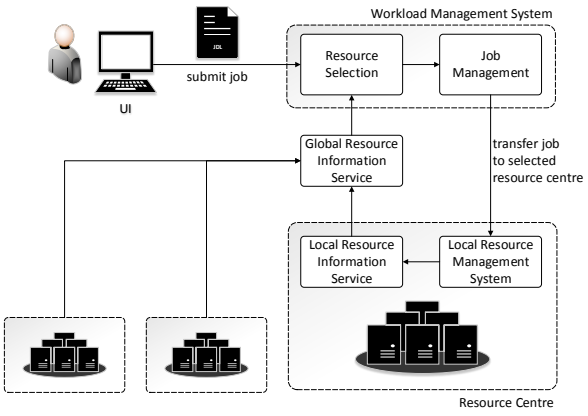

Fig. 1: The Job Submission Chain

Figure 1 illustrates the life-cycle of a single grid job, from the submission of the job in JDL on the UI, through its orchestration by a WMS, to its eventual execution at a resource-centre. A high-level outline of the flow of a grid job through the WMS includes the following stages:

1) When the job is submitted to the WMS, a copy of the JDL file and any input files specified in it are copied to the Workload Management System (WMS).
2) The WMS will determine all locations where the job can possibly run. This is the "match-making" process. The potential locations are then *ranked* in preference. The user can also influence the rank ordering by specifying a *RANK* expression in the JDL.
3) Once a target CE at a resource-centre is chosen, the WMS will engage with the CE.
4) The CE builds a *JobWrapper*. This executable is built taking into account the local batch system, also known

as a *Local Resource Management System* (LRMS), on the CE. Some of the roles of the JobWrapper are to build a job submission script for the batch system, transfer all input files from the WMS, and then submit the job to the batch system.

5) The batch system is responsible for scheduling the execution of the user's job on one or more *CPU-Cores* on a *worker node* (WN).
6) After execution, the output files specified by the JDL description are transferred back to the WMS and can be retrieved by the user.

The match-making process requires knowledge of the overall state of the distributed set of resources. This state information is managed by a "Grid Information System".

Grid Information System

The Grid Information System is a critical component required for discovering services, determining the status of resources and selecting resources for submitted jobs. This system is composed of an information model (a *schema*) for describing entities (such as computational resources and available software) and the relationship between those entities, as well as a "presentation layer" that publishes this information as a frequently-updated queryable service (a *realisation*).

The *Grid Laboratory Uniform Environment* schema (*GLUE schema*) was developed as an Open Grid Forum (OGF) "reference standard" for multi-disciplinary Grids. There are currently two major (incompatible) versions of the GLUE schema in common use – GLUE 1.3 [11] and GLUE 2.0 [12]. Grids such as EGI are currently transitioning from GLUE 1.3 to GLUE 2.0 by running services that can utilize both standards. GLUE 2.0 offers many improvements over GLUE 1.3, including a richer description of grid entities and their state and the ability to easily publish extra details about grid-entities (using "OtherInfo" attributes). Moreover, GLUE 2.0 was developed to improve inter-grid interoperability [13].

Information in a Grid Information System originates from *Information Providers*. The services that are used to access and manage grid resources (e.g. a batch system for a set of worker nodes) should provide an interface that allows the Information Provider for that resource to determine the properties and current state of the resource, transform this information into an appropriate GLUE entity and publish the information (Figure 2).

Propagating GLUE entities so that they are visible "globally" in a Grid Information System follows a natural hierarchical structure (Figure 3): GLUE entities are generated by Information Providers; the set of Information Providers (info-providers) on a particular node publish their state as a *local resource*; the set of local resources form a *domain*; and the combined set of entities from each domain yield a global view.

The GLUE information "presentation layer" is typically managed by the *BDII*([14], Sec. 3.3.5). This is an implementation of a the hierarchical Grid Information System model with three BDII "types" and a set of "information providers" that generate information about the Grid entities. As per

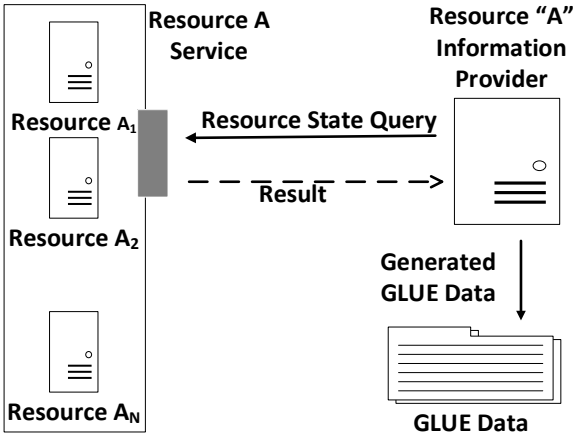

Fig. 2: Abstract Information Provider Model. An Information Provider queries a service that manages a set of Resources of type "A" at a resource centre. The Information Provider transforms the response into one or more GLUE entities.

Figure 3 the Resource-BDII (lowest BDII level) aggregates the state of a grid service node by executing a set of Generic Information Providers (GIP) plugins; the Site-BDII aggregates all the Resource-BDIIs belonging to the given site; and the Top-level BDII aggregates all the Site-BDIIs. Information is "pulled" from the lower to higher levels. In general, all queries about the state of the Grid are made through the Top-Level BDII.

III. Integrating GPGPU resources into Existing Grid Infrastructures

Many grid resource centres have already deployed GPGPU resources [7]. There is, however, no support in place for users to discover these GPGPU resources or submit jobs that specify a dependency on GPGPUs. Currently, users wishing to use these resources rely on *a priori* knowledge of the location and properties of available GPGPUs and the job submission mechanisms required to use them. Furthermore, after inspecting GLUE data published by the Top-Level BDII *lcg-bdii.cern.ch*, it was determined that from a sample of 2887 unique GlueCEUniqueID entities (i.e. interfaces to queues on the grid-connected batch systems), over 58% of these GlueCEUniqueID reported that the Torque/PBS (excluding PBSPro) batch system was used (Table I (a)). In particular, 779 GlueCEUniqueIDs (27%) used Torque/PBS 2.5.7 (Table I (b)). This is indicative of the default UMD Torque/MAUI installation that does not correctly handle generic consumable resources. From this data, it is reasonable to conclude that a significant percentage of grid systems on the EGI grid infrastructure do not support GPGPUs as consumable resources.

This paper addresses the challenge of integrating GPGPUs as first-class grid resources. From a user's perspective, these resources should be easy to discover without relying on *a*

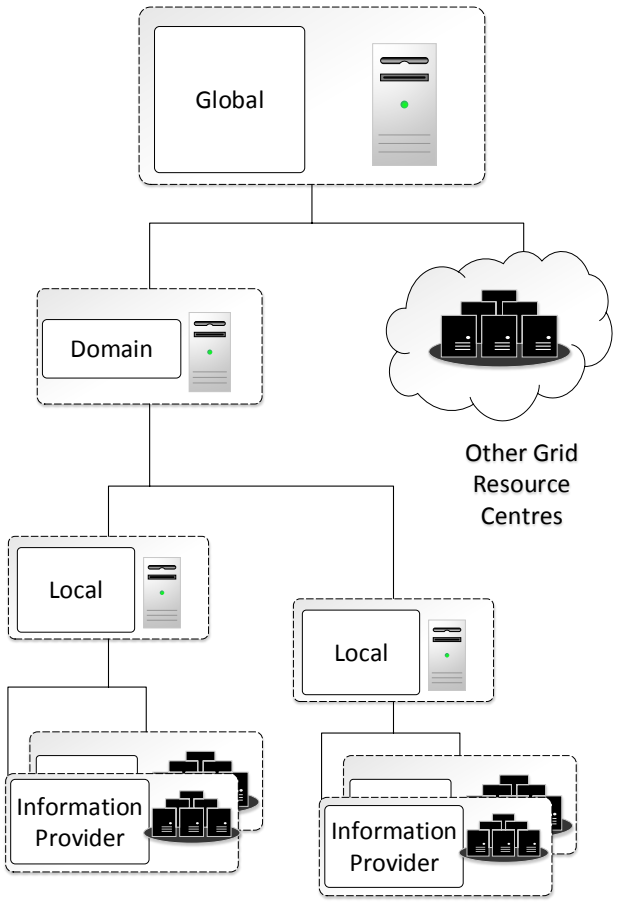

Fig. 3: The Grid Information System. GLUE data is propagated from the lowest level (generated by Information Providers) up to Global level.

TABLE I: Reported LRMS Types

priori knowledge (*discovery*); the specification, requirements and ranking of these resources should be independent of how the resources are locally managed (*independence*); and the user should have some assurance of exclusive access to the resource (*exclusivity*). Rather than considering GPGPUs specifically, the challenge is viewed as a generic consumable resource access problem. The approach proposed for addressing this challenge is summarised by the following *Grid Resource Integration Principles*:

- **Discovery:** The resource should be published as one or more GLUE entities. The act of publishing the resource into the Grid Information System makes the resource discoverable by users and services. An entity should, where possible, contain attributes that reflect the resources properties, and also where possible, these attributes should be *quantitative*. This allows resources of the same type to be compared and ranked against each other. (For example, the vendor, model and performance characteristics of a GPGPU may be of importance when selecting appropriate resources for a job.)
- **Independence:** There should be a method through which the required resource can be specified using a job description language. The specification should be independent of the way in which the resources are locally managed. (For example, the mechanism used to specify GPGPU requirements to the Torque/MAUI scheduling system differs from that used by SLURM.)
- **Exclusivity:** A resource allocated to a job by a batch system should be available as if it were exclusively allocated to the job. (For example, a GPGPU allocated to a job should not be available or even visible to another job running on the same worker node.)

Case Study – GPGPU integration

As an example of the application of the above *Grid Resource Integration Principles*, the use-case of GPGPUs as grid resources is considered. This use-case is interesting not only because of their parallel-processing capabilities, but because they are also representative of the class of LRMS *Generic Consumable Resources* - a class of non-CPU resources that can be managed by the LRMS.

Discovery: The salient properties that help describe a GPGPU are similar to those used to describe CPUs: vendor, model, memory, speed, benchmarked performance, number of physical GPGPUs per worker node. LRMS properties that can influence WMS orchestration and ranking include, the total number of installed GPGPUs and the number that are currently allocated through the batch system. Users may also be interested in the software required to access the resource, and basic installation details. These properties could be advertised in the Grid Information System as one or more GLUE entities and optionally used as a filter during resource selection.

Independence: The user needs an LRMS-independent way to specify the number of GPGPUs required or the number of GPGPUs that the job needs per-CPU core (this implies a minimum number of GPGPUs per worker node).

Exclusivity: The user needs assurances that two or more jobs concurrently executing on the same worker node cannot use the same GPGPU. In the absence of batch-system support for such exclusivity, an additional mechanism must be provided.

In the next section, a prototype extension of a Grid that integrates GPGPU resources is presented. This prototype introduces a GLUE 2.0 entity and GPGPU Information Providers that provides for the discovery of GPGPU resources; a means to specify GPGPU resource requirements that is independent of the batch system used; and, finally, a new mechanism to ensure that GPGPU resources are allocated exclusively to each job.

IV. Prototype Implementation

As shown in section II, the mechanism for orchestrating the execution of a grid job follows a complex chain of events. As a result, providing access to new grid resources, such as GPGPUs, is non-trivial. In particular, if these resources are to be provided by *existing* grid infrastructures that are *in-production* and in continuous use by an extensive community of users, the challenge becomes more acute. Adding support for new resources cannot be dependent, for example, on architectural changes, the replacement of core services or modifications to the GLUE schema. Instead, the approach taken must integrate with existing infrastructure, while adhering to the principles of *discovery*, *independence* and *exclusivity* (Section III).

The approach taken in this prototype is to provide a set of modular *hooks*, that in principle can be applied to many other resource types, other than GPGPUs. In this section, it will be shown that this approach requires relatively small changes to existing grid middleware.

A. Prototype Infrastructure

The focus of this prototype on the integration of Nvidia GPGPUs using the CUDA runtime and application development framework. (Nvidia GPGPUs are the most widely used GPGPU in High Performance Computing centres.) The prototype was developed using the UMD gLite grid middleware, and consists of a User Interface (UI), a Workload Management System (WMS), a Top-Level BDII (BDII), grid-security infrastructure services, and a Resource Centre using the CREAM CE. The CREAM CE uses Torque 2.5.7 as the batch system server and the MAUI batch scheduler. (MAUI was modified with a publicly available patch to enable Generic Consumable Resources.)

B. Discovery: GPGPU Schema and Information Providers

Section III considered what information about GPGPU resources should be represented through the GLUE-schema. In this prototype, a simple representation of these details is realized by using the GLUE 2.0 *ApplicationEnvironment* entity [12]. This entity is primarily used to describe the properties of software installed on worker nodes. However, a key feature of the ApplicationEnvironment is that it supports non-mandatory attributes that relate to software capacity and utilisation. This feature is used to publish installed GPGPU capacity and utilisation. Furthermore, the definition also allows for other arbitrary information to be published, such as the GPU vendor, model and speed and benchmarked performance.

(An alternative and perhaps superficially more obvious approach would have been to use the GLUE 2.0 *ExecutionEnvironment* entity, which provides for attributes such as CPU vendor, model and speed which may also used to describe GPGPUs. This approach, however, would describe an architecture in which the GPGPUs are independent of – rather than reliant on – the CPUs on the same worker nodes. In contrast, using the ApplicationEnvironment entity to describe GPUs allows the relationship between CPUs and their attached GPUs to be captured by the Grid Information System.)

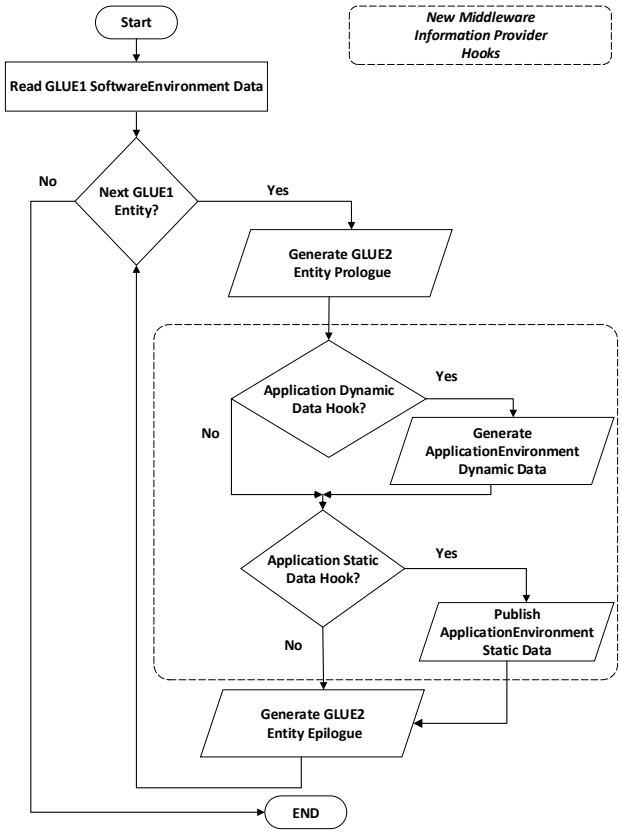

Fig. 4: Workflow of Modified ApplicationEnvironment Information Provider

The current gLite implementation of the GLUE 2.0 ApplicationEnvironment Information Provider already generates ApplicationEnvironment entities by converting GLUE 1.3 SoftwareEnvironment entities into their minimal GLUE 2.0 equivalents. In this prototype, this existing Information Provider is replaced with a new Information Provider that facilitates per-application *hooks*. For each application, separate hooks can be provided to generate static and dynamically changing GLUE data. This is illustrated in Figure 4.

In particular, the prototype uses new CUDA ApplicationEnvironment hooks that publish static data pertaining to the GPGPU hardware and CUDA software properties as well as

dynamically gathering and publishing previously unavailable GPGPU capacity and utilisation data from MAUI. Listing 1 illustrates an example of some of the output generated by the execution of a modified Information Provider where both dynamic and static hooks for the CUDA environment have been added.

Listing 1: An example of the output from the static and dynamic GLUE 2.0 CUDA ApplicationEnvironment hooks

```
...
objectClass: GLUE2ApplicationEnvironment
GLUE2ApplicationEnvironmentMaxJobs: 32
GLUE2ApplicationEnvironmentAppName: CUDA
GLUE2ApplicationEnvironmentFreeJobs: 30
...
GLUE2EntityOtherInfo: ↩
    GPUCUDAComputeCapability=2.1
GLUE2EntityOtherInfo: GPUMainMemorySize=1024
GLUE2EntityOtherInfo: GPUCoresPerMP=48
GLUE2EntityOtherInfo: GPUCores=192
GLUE2EntityOtherInfo: GPUClockSpeed=1660
GLUE2EntityOtherInfo: GPUECCSupport=false
GLUE2EntityOtherInfo: GPUVendor=Nvidia
GLUE2EntityOtherInfo: GPUPerNode=2
```

Table II indicates where the CUDA ApplicationEnvironment hooks provide additional Attribute-Value pairs that are part of the GLUE2 standard (but not generally used), and where the ApplicationEnvironment schema has been further extended (as allowed by the standard) by adding GLUE2 *OtherInfo* values. Furthermore, Table II lists the data-type of each value, the source of the data, and whether the data is generated dynamically or provided statically.

TABLE II: Extended GLUE2 CUDA ApplicationEnvironment

Standard ApplicationEnvironment		**Source**	**Creation**

New EntityOtherInfo Attributues		**Source**	**Creation**
ApplicationArea	String	System	Static
GPUCUDAComputeCapability	Float	GPGPU	Static
GPUMainMemorySize	Integer	GPGPU	Static
GPUMP	Integer	GPGPU	Static
GPUCoresPerMP	Integer	GPGPU	Static
GPUCores	Integer	GPGPU	Static
GPUClockSpeed	Integer	GPGPU	Static
GPUECCSupport	Boolean	GPGPU	Static
GPUVendor	String	GPGPU	Static
GPUModel	String	GPGPU	Static
GPUPerNode	Integer	LRMS	Static

C. Independence: Specifying and Handling GPGPU Job Requirements

Independence implies that the grid user should be able to specify required GPGPU resources within the existing job submission framework in a manner that is independent of any CE batch system implementation. By considering how jobs are orchestrated through a WMS, the changes required to the grid infrastructure to achieve this goal are outlined below.

JDL GPGPU requirements specification: The prototype allows a user to request GPGPUs by adding the following JDL specification:

```
GPUPerNode=X;
```

Here, *X* is the number of GPGPUs to be allocated *per node*. This specification requires no changes to the JDL Language definition syntax. As well as specifying the number of GPUs required, the JDL should also specify the ApplicationEnvironment entity that advertises the availability of the required GPGPU. An example of the complete JDL for a job requiring two GPGPUs and using the CUDA framework is shown in Listing 2.

Listing 2: Example GPGPU Job for gLite based Grids

```
[
Executable = "myScript.sh";
StdOutput = "std.out";
StdError = "std.err";
InputSandbox =  {
                 "GPGPU_acquire_prologue.sh",
                 "GPGPU_job_script.sh",
                 "GPGPU_release_epilogue.sh"
                };
OutputSandbox = { "std.out","std.err"} ;
VirtualOrganisation = "gputestvo";
Requirements = (Member("CUDA",other.↩
    GlueHostApplicationSoftwareRunTimeEnvironment)↩
    );}
GPUPerNode=2;
]
```

Once the job is submitted to the WMS, the set of potential resource-centres is filtered to include only those that advertise that they support the specified ApplicationEnvironment entity (CUDA in the above example). After applying some further job requirements, the WMS will select a matching CE, transfer the job *workload*, and then orchestrate its execution.

Resource Centre Job Execution: The orchestration of the job on the chosen resource centre CE can be classified into three stages: (i) job preparation; (ii) job submission; and (iii) job execution on the selected worker nodes(Figure 5). The *job preparation* stage is used to convert the JDL GPGPU resource specification into an LRMS specification.

During the Job Preparation phase, job input files and executable programs are transferred from the WMS to the CREAM CE. A "JobWrapper" script is created by CREAM. The JobWrapper is executed on the CE, and is responsible, among other things, for constructing a job execution environment appropriate to the LRMS. The JobWrapper script created by CREAM already contains a mechanism to pass or "Forward" job requirements to the LRMS [15]. This prototype exploits this mechanism by implementing a JobWrapper "batch requirements forwarding" script that will parse a copy of the JDL to determine if the $GPUPerNode$ value is defined and, if it is, return a suitable resource request, the format of which will be dependent on the specific batch system.

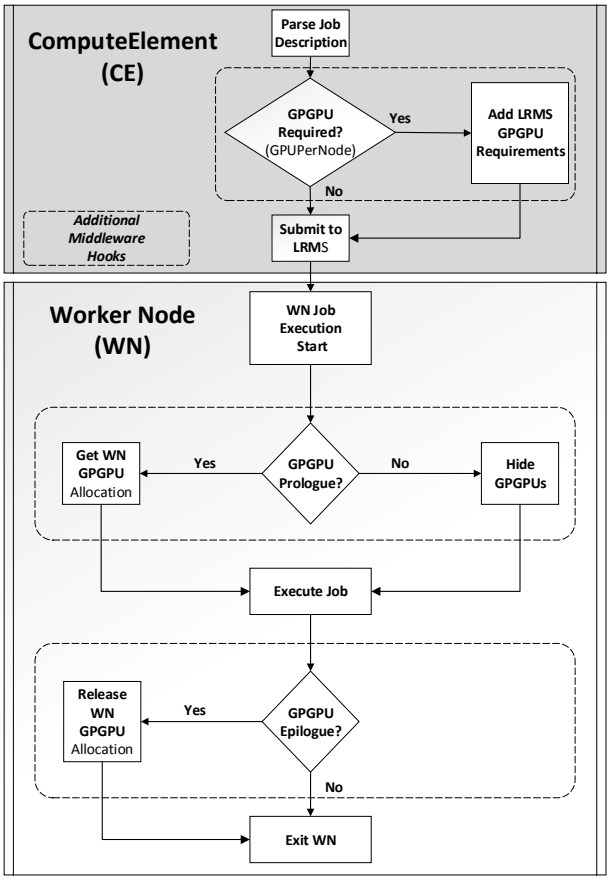

Fig. 5: Batch System GPGPU allocation process.

D. Exclusivity: Restricting Visibility of GPGPU Resources

Multi-core worker nodes allow many independent jobs to execute simultaneously. These independent jobs are protected from each other by executing in their own private disk-area, and by using file-access and process protection enforced by the operating system kernel. GPU (and consequently GPGPU) resources are designed to be accessible by all worker node users. In the case of GPGPUs exposed through a batch system, it is desirable to control access to them. Nvidia supports a number of ways in which access to its GPGPUs can be controlled:

1) the CUDA_VISIBILE_DEVICES environment variable can be used to restrict the visibility of a set of GPGPU devices in a process,
2) the Nvidia *Compute Modes* can permit/deny sharing of a GPGPU between multiple processes.

The handling of GPGPU allocation on common open-source batch systems, such as Torque/MAUI, is still problematic, in particular with mid-range GPGPUs where Nvidia-SMI tools do not report a full complement of utilisation data. A simple prototype service was developed that allows Torque/MAUI batch jobs to request a set of free GPGPUs on the worker node, and to release those GPGPUs back to the service when no longer required. Furthermore, the allocated GPGPUs are not visible to other user jobs on the worker node.

The service, which executes on each worker node, implements a lightweight web-server using the Tornado [16] framework. To improve the security of the service, it runs as an unprivileged user, GPGPU allocation states are maintained in a lightweight persistent database, and the service is internal to the worker node (i.e. it is not available to other nodes).

The server responds to two types of requests: *requestGPUS* and *releaseGPGUs*. These requests are respectively called from the within the *GPGPU_acquire_prologue.sh* and *GPGPU_release_epilogue.sh* Job Hook scripts, specified in the JDL (Listing 2).

Requests to the prototype tornado server must adhere to a strict syntax, and all malformed requests are dropped by the server. In the case the Torque implementation, a request is generated by sending a copy of the "PBS_JOBCOOKIE" and a list of *Universally Unique Identifiers* (UUIDs) - one per requested GPGPU. The PBS_JOBCOOKIE was chosen because, unlike the batch system "jobid", this value is not exposed to other users or processes.

The server manages the allocation of GPGPUs to jobs by using a single database with two tables: *UUID_JOBID* and *GPU_UUID*. The GPU_UUID table associates GPGPU devices with a job-generated UUID. The UUID_JOBID table associates UUIDs to a suitable unique value, such as the $PBS\_JOBCOOKIE$.

1) Initialisation: The GPU_UUID table is initialized at node start-up. A row is added for each physical GPGPU. Similarly, the UUID_JOBID table is created, but remains unpopulated until a GPGPU is requested by a job. Table III shows the initial state of the database tables for a node with two GPGPUs.

TABLE III: Initial State

(a)

GPUID	UUID
0	
1	

(b)

JOBID	UUID

2) Allocation Request: A GPGPU allocation request (Figure 6) should be sent to the server before the job attempts to execute any GPGPU code. When the server receives an allocation request message, a "Request Handler" will attempt to validate it. If the request is valid, then the string is converted into two component values: a JOBID (PBS_JOBCOOKIE) and a list of UUIDs. The request handler then iterates over the list of UUIDS and adds (UUID,JOBID) tuples to the UUID_JOBID table. The handler will also iterate over the list of UUIDs, selecting the first free GPGPU (i.e. rows where the UUID cell is NULL) from the GPUID_UUID table. The selected row is the updated with a new (GPUID,UUID) tuple. Changes to the database are committed. Finally, the server returns a text string to the client in the form of a comma-separated list of integers. This is the list GPGPU devices that

the the job has been allocated. This value is assigned to a *read-only* CUDA_VISIBLE_DEVICE environment variable, thereby ensuring that the user or process can no longer (inadvertently) update its value.

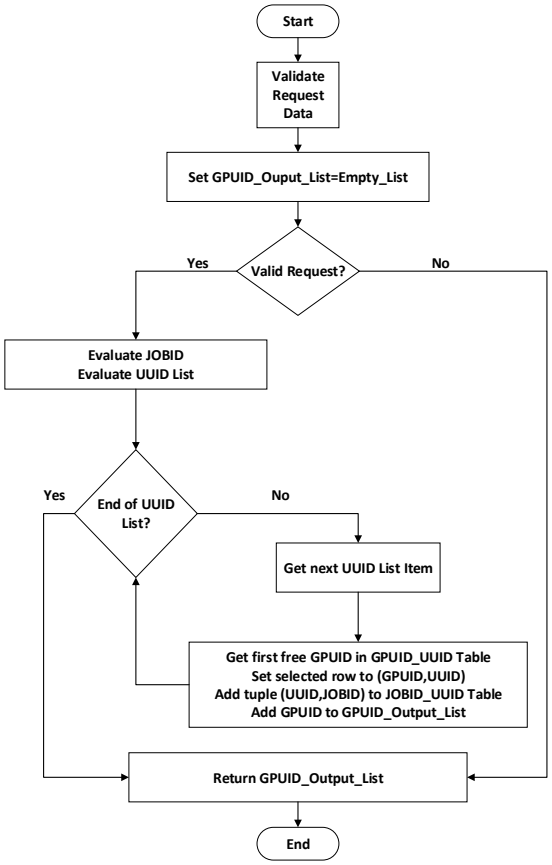

Fig. 6: Worker Node GPGPU allocation subsystem

TABLE IV: Example of a single job running on a node with two GPGPUs

(a) GPGPUs paired to UUIDs

GPUID	UUID
0	$UUID_1$
1	$UUID_2$

(b) $JOBID_1$ linked to $UUID_1$, $UUID_2$

JOBID	UUID
$JOBID_1$	$UUID_1$
$JOBID_1$	$UUID_2$

3) Release Request: A GPGPU "Release" request should be executed during the job's epilogue. This request is complementary to the "Allocation" request. As with the allocation request, the input is validated. If the request is valid, the server's "Request Handler" will remove all tuples matching the UUIDs from the UUID_JOBID table, and all the specified UUIDs from the GPUID_UUID table.

E. Results

Job submission was tested using different values for $GPUPerNode$. Sample output of a job that requested a single GPGPU but executed on a worker node with multiple GPGPUs is listed below (Listing 3):

Listing 3: Example GPGPU Job resricted to a single GPGPU

```

```

V. Related Work

CUDA_wrapper

CUDA_wrapper [17][18] was developed to help facilitate secure and controlled access to Nvidia-based GPGPU resources on multi-user GPGPU clusters. The wrapper acts by intercepting normal CUDA API fuction calls and overloading them with additional methods that transparently provide additional key-based access-control to the raw GPGPU device.

The approach taken in this paper avoids some drawbacks with the CUDA_wrapper method, namely: (i) Each API interception imposes a latency to handle each CUDA function call; (ii) CUDA_wrapper must be recompiled for each new version of CUDA; (iii) CUDA_wrapper did not work under testing with CUDA 5.5; and, (iv) The wrapper is vendor and LRMS (Torque) specific.

GPU resources on the Grid

There are several examples of current work where GPGPU resources have been partially integrated into Grids. These take the form of both non-virtualised GPGPU resources [19] and virtualised GPGPU resources [20]. In both cases, the grid-users job is given exclusive access to the GPGPU resource. However, both of these implementations lacks resource and service discovery and therefore require *a priori* knowledge of the existance of the resources. Moreover the virtualisation methodology imposes about 5% overhead on GPGPU access and runtimes.

BOINC and Desktop Grids

BOINC has support for multi-disciplinary computational sciences using GPGPU. For example, the *Einstein@Home* project uses GPGPUs to search for weak astrophysical signals from spinning neutron stars (also called pulsars) using data from the LIGO gravitational-wave detectors, the Arecibo radio telescope, and the Fermi gamma-ray satellite [21]. Furthermore, the EDGI Desktop Grid provides a mechanism [22] to bridge between EGI and BOINC-enabled resources. However, such combinations do not address the specific GPGPU service-discovery requirements.

HTCondor GPGPU Support

HTCondor [23] supports advanced GPGPU resource publication, service-discovery, per-job GPGPU match-making, and job-management [24]. Indeed, HTCondor is central to the the UMD WMS match-making service. However, some of the major differences between HTCondor and the work presented

in this paper include: (i) the solution is intended to be compatible with Grids using the OGF GLUE 2.0 information model; and (ii) The approach taken treats GPGPUs as an instance of generic consumable resources.

Application Hook Method

The design and implementation of the presented execution model used in this work follows a pattern similar to that used by MPI-Start [25]. In particular, this is evident in how software hooks are used to build an appropriate site-local application runtime-environment. The major differences in the implementation are: (i) MPI enabled resource centres currently publish information about the local MPI environment as a set of GLUE 1.3 SoftwareEnvironment tags. This information is inefficiently converted into a set of discrete and seemingly unrelated GLUE 2.0 ApplicationEnvironment entities; (ii) The GPGPU implementation attempts to exploit many of the newer features of the GLUE 2.0 ApplicationEnvironment definition. This includes the ability to publish GPGPU resource capacity and utilisation information.

Token based access-control

The use of UUIDs as tokens in the GPGPU allocation and release process is partially based on the use of time-limited UUID tokens in the *Puppet* [26] fabric managent system - a system used to install, configure an maintain machines on a network. In Puppet the token is used as a "shared-key" between the Puppet server and the client machine. The shared-key is used to authorise the download of the client's installation configuration file.

EGI GPGPU Working Group

The European Grid Initiative (EGI) is currently considering the GPGPU resources into grid infrastructures and one of the authors is a member of the EGI GPGPU Working Group [27]. The results presented in this paper represent independent work that may be contributed to this community effort in the future.

EGI Grid Federated Cloud Working Group

The EGI Federated Cloud Working Group uses the GLUE 2.0 ExecutionEnvironment to advertise diverse sets of (virtual) resources [28]. The authors had considered this appraoch, but deemed it to be unsuitable as a way to describe *Consumable Resources*.

VI. Conclusions and Future Work

This work shows how a GLUE 2.0 based multi-disipline scientific grid can be extended to support new models of parallel computing using GPGPUs. A methodology was developed that applied three abstract principles to this resource integration problem, namely: *Discovery*, *Independence* and *Exclusivity*.

The presented prototype is one of the first examples of where a GLUE 2.0 ApplicationEnvironment entity has been extended to include additional attributes that describe the capacity, utilisation and other properties of hardware used directly by the application itself. These attributes can be generated either statically or dynamically. The example use-case demonstrates a CUDA ApplicationEnvironment that is extended to include the total number of installed Nvidia GPGPUs, their current utilisation, and some selected hardware properties. This conforms to the *Discovery* principle.

A method was developed that allows a grid user to specify a GPGPU requirements in the Job Description Language. In particular, the prototype allows the user to specify the number of GPGPUs required per allocated Worker Node. The job requirement is converted into the native LRMS resource specification once the job enters the choosen Resource Centre. The method can also be applied to other resources made available through an LRMS. This is an application of the *Independence* principle.

Ensuring that users have guaranteed and isolated access to GPGPUs in a multi-user system can be difficult. This problem is compounded in the cases where multiple GPGPUs on the same machine can be accessed by multiple users - many batch systems do not indicate what GPGPU has been assigned to each user job. The worker node GPGPU Access Control system discusssed in Section IV-D can assuage this problem. The development of the GPGPU allocation handler for these systems ensures the *Exclusivity* principle.

Work is in progress to support enhanced job specifications, allowing the user to make job placement decisions based on a wider range of published GLUE 2.0 ApplicationEnvironment data. This allows for greater control over the resource discovery and selection process. An example based on published CUDA ApplicationEnvironment (Table II) is illustrated in Listing 4.

Listing 4: Example JDL using CUDA attributes

```
Requirements = GPUVendor=="Nvidia" && (↩
    GPUMainMemorySize >= 512);
```

Although the service demonstrated used Nvidia and CUDA, other environments such as AMD GPGPU and OpenCL can also be trivially accomodated - for example, AMD uses GPU_DEVICE_ORDINAL environment variable to restrict user visibility of AMD GPGPU devices [29]. In addition, this system can work in non-grid Torque/MAUI environments, and requires minor changes to work with other batch systems.

Finally, although the prototype implentation was tested with GPGPU resources, the model can be adapted to cater for wider range of resources, such as Intel's Xeon Phi, FPGAs and Licence controlled software. Said resources are difficult to integrate into grids based on GLUE 1.3. The prototype shows that: (i) there are cases where hardware resources can easily be treated like an ApplicationEnvironment; (ii) arbitrary information can be published about these resources - and this can be generated statically or dynamically; and (iii) job-requirements can be specified in a Job Description Langauge and transformed into batch-system directives without any major changes to the grid middleware.

ACKNOWLEDGMENT

This work was carried out on behalf of the Telecommunications Graduate Initiative (TGI) project. TGI is funded by the Higher Education Authority (HEA) of Ireland under the Programme for Research in Third-Level Institutions (PRTLI) Cycle 5 and co-funded under the European Regional Development Fund (ERDF). The authors also acknowledge the use of additional support and assitance provided by the European Grid Infrastructure. For more information, please reference the EGI - InSPIRE paper (http://go.egi.eu/pdnon).

Education, Curricula & Research Methods

ECRM is a FedCSIS conference area aiming at interchange of information, ideas, new viewpoints and research undertakings related to university education and curricula as well as recommended methods of doing research in all computing disciplines, i.e. computer science, computer engineering, software engineering, information technology, and information systems. This area spans typical FedCSIS events (conferences, workshops, etc.) with rigorous paper submissions and review processes as well as panels, PhD and research consortia, summer schools, etc. Events that constitute ECRM are:

- DS-RAIT'14 – 2nd Doctoral Symposium on Recent Advances in Information Technology
- ISEC'14 – 3rd Information Systems Education & Curricula Workshop

3rd Information Systems Education & Curricula Workshop

ISEC goal is to promote the discussion about the convergence between Computer Science and Information Systems topics, so that researchers can present a complete and detailed specification of their educational curricula by means of these two topics. We inspect papers that contribute to the better understanding of emerging and important educational fields of Computer Science (CS) and Information Systems (IS). Authors are invited to submit their papers in English, presenting the results of original research or innovative practical applications in the field.

Regarding the selection process, we plan to perform a triple review process.

Topics

Key issues in this workshop will focus on (but are not limited to):

- Convergence between IS & CS in higher Education
- Specification of IS Education Curricula
- General IS Theory
- IS Scope
- IS Educational Fields
- Student participation in research
- Adaptation to the European Higher Education
- Assessment of students
- Innovative teaching methods
- Training for career and skills development
- Definition of "knowledge" in IS
- Quality and evaluation of teaching
- Social and environmental commitment
- Curriculum organization and curriculum
- The Fundamental Concepts Underpinning IS
- Merge from IS to CS and vice versa in higher Education

Event Chairs

***Abstract*—Computer Science (CS) classes have been supported for ten years by multimedia materials in the form of podcasts. Even such materials did not improve quality of learning outcomes. In order to change this the idea of flipped classroom (FC) was used but situation did not change radically, so survey concerning students opinion on FC was conducted. Comparison of results of survey show big differences in attitude to FC and learning between students in Poland and students in United States or Canada. Conclusion of this research is sad—it is very difficult to motivate Polish digital natives to learn..**

I. Introduction

IDEA of inverting education is already nearly fifteen years old. One of the first papers in that field was published in 2000 [1]. This paper describes two parts of subject taught at Miami University while using the inverted classroom concept and analyzes the outcomes. Numerous technologies offered completely new possibilities for students to learn away from the classroom, while school period was used to perform collaborative experiments and worksheets. Authors of the paper concluded that the idea of inverted classroom offers alternatives for various learning styles and report that students favor that strategy. A different outline and evaluation of flipped education within a huge, primarily based on lectures, computer science course was published in 2002 in [2]. In this project new multimedia and video streaming application eTech was employed to change a course. In-class lectures were substituted by recorded lectures and auxiliary materials which could be viewed by students in the Internet independently. This make it possible to utilize the live period in the class for team problem solving facilitated by tutors. Another interesting paper in that field was published one year later in 2003 [3]. Within a series of five experiments hundreds of students from two different universities supervised by three different professors and six different teaching assistants took one semester long course in the field of casual and statistical reasoning in both traditional or online format. Within the frame of this project pre and post test results were compared. Features of the online experience which were helpful and which were not helpful were identified as well as most and least effective student learning strategies. Three years later a paper evaluating a web lecture intervention in a human–computer interaction course was published [4]. By utilizing lectures available in the Web before class more in-class period was used engaging students with hands-on tasks. Class time was spent on learning by doing rather than learning by listening. In 2007 Gannod presented his work in progress on how to use podcasts in an inverted classroom [5]. One year later Helmick presented integrated online courseware for computer science courses [6]. Last but not least in 2008 a paper describing how to use the inverted classroom to teach software engineering was published [7].

The present paper summarizes results of investigation presented in [8] and [9]. Starting from academic year 2012-2013 in some of groups podcasts (mainly software animations in the form of screencasts) were used in different way. Students were asked to watch podcasts at home. During classes students were supposed to be prepared to use software without any difficulties and to solve using it typical problems. First results of this experiment were to some extend promising. Students gained better scores in this case, but they were not very keen to spend additional time at home watching podcasts. They do prefer to be taught during classes. This problem was easily solved by adding simple point to subject regulations – students should be prepared to computer laboratories and this fact is checked by means of test before the class. In academic year 2013-2014 idea of flipped classroom was used for all groups – nine studying in Polish and two studying in English but only for part of material covering Computer Algebra System MathCAD Prime 3.0. Result of survey concerning students' satisfaction will be presented in the paper.

II. Flipped Classroom

It is much more effective to watch, passive by nature, screencasts at home and solve problems with tutor in class than the other way round. This observation leads to idea to revert the situation. Why not to ask students to perform

This work was supported by Warsaw University of Technology and grant no. 504/00713/1088/40.000103

easier tasks at home and learn from podcasts independently and why not to solve during classes more difficult problems. Such situation is in agreement with Bloom's Revised Taxonomy [10], [11].

Blooms Taxonomy proposed in 1956 by panel of educators chaired by Benjamin Bloom is a categorization of learning objectives as well as activities split up into three areas: cognitive (mental skills, knowledge), affective (feelings, emotional areas and attitude) and psychomotor (manual and physical skills). The cognitive domain, the most significant in higher education, requires mental abilities and also knowledge. Within this domain one can find six major categories outlined from the most straightforward one: knowledge, comprehension, application, analysis, synthesis and finally evaluation. In the middle of 1990's cognitive domain has been modified. Titles associated with different types have been transformed from nouns to verbs. Moreover their order has been somewhat changed. Bloom's Revised Taxonomy demonstrates to a greater extent active way of thinking and also consists of six different categories: remembering, understanding, applying, analyzing, evaluating and finally creating. This taxonomy much better accounts for completely new behaviors and multimedia technology innovations (Fig. 1). Lower order thinking skills like remembering, understanding and applying are gained at home from podcasts which can be treated as recorded classes. Higher order thinking skills like analyzing, evaluating and creating are gained at the university. Such situation requires change of the role of academic staff – from teachers to tutors. This idea was fully described in three books recently published by Bergmann and Sams [12], Bretzmann [13] or Walsh [14].

One of the best definitions of flipped class is given by Bergmann, Overmyer and Willie in The Daily Riff entitled The Flipped Class: Myths vs. Reality. "The traditional definition of a flipped class is: where videos take the place of direct instruction; this then allows students to get individual time in class to work with their teacher on key learning activities; it is called the flipped class because what used to be classwork (the "lecture" is done at home via teacher-created videos and what used to be homework (assigned problems) is now done in class."

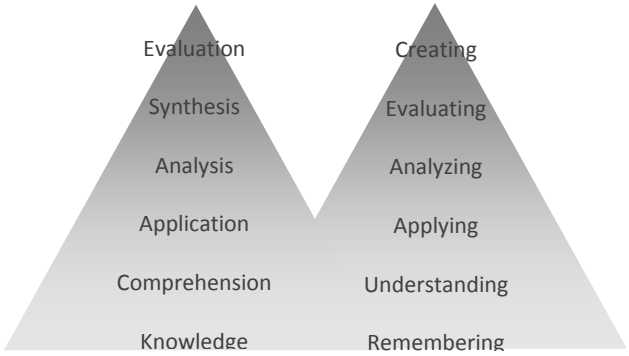

Fig. 1 Blooms Taxonomy and Revised Blooms Taxonomy

They also answered to the question what the flipped Classroom is. "A means to increase interaction and personalized contact time between students and teachers. An environment where students take responsibility for their own learning. A classroom where the teacher is not the "sage on the stage", but the "guide on the side". A blending of direct instruction with constructivist learning. A classroom where students who are absent due to illness or extra-curricular activities such as athletics or field-trips, don't get left behind. A class where content is permanently archived for review or remediation. A class where all students are engaged in their learning. A place where all students can get a personalized education."

III. Computer Science in Civil Engineering

The place and role of Information Systems (IS), which can be treated in narrow sense as a term referring mainly to ICT, and Computer Sciences (CS) in curricula of Civil Engineering (CE) studies was described in previous paper [9]. Hardware and software information revolution has changed radically modern engineering workplace. The exact description of how transformation and circulation of information in the construction industry can and should look like can be found in [15]. In this work there are distinguished three groups of information: about the function, about the structure and about structure's behavior (Fig. 2). In all stages of transformation, it is important to use computer tools. The process of analyzing the structure is invariably dominated by computer programs using the finite element method. In the process of synthesis, where there is room for optimization, there are also available computational tools, such as for example a spreadsheet Solver.

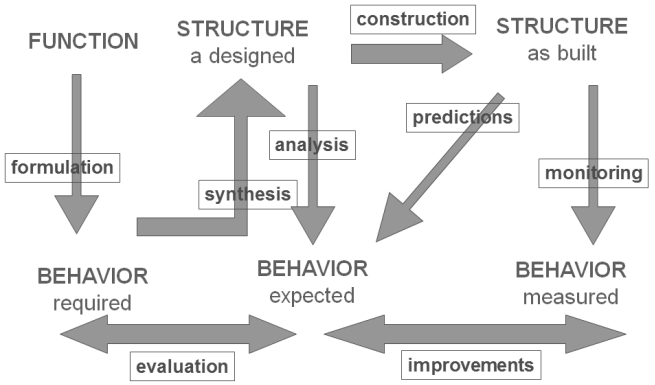

Fig. 2 Information flow in Civil Engineering

The last and the biggest block of classes is devoted to Computer Algebra System (CAS) namely to MathCAD Prime 3.0 which is described in books like [15] and [16]. Previous version of this program is better described in literature [17], [18] and [19]. Its presence in curricula of studies is a source of never ending discussions. In the opinion of many teachers students overuse MathCAD while preparing their design homework. It is enough that one

person creates a file and all remaining can simply enter only the input data.

First part of MathCAD classes is devoted to solving classical mathematical problems like symbolic calculations, defining variables and functions, calculus (integrals, derivatives, limits), matrix and vector operators and functions and solving problems like linear and nonlinear equations, minimization and maximization. Second part is devoted to programming. In the beginning basic instructions (if, for, while) and control statements (return, continue, break) are introduced. The idea of this subject was inspired by the book [20]. Detailed list of screencasts for that part of the subject is in Table I.

All course materials are stored on learning platform Moodle. Taking into account different learning styles [21], [22] learning materials are available in different forms ranging from PDF files to screencasts (Fig. 3). The vast majority of materials are in the form of screencasts which are recordings of traditional classes (Fig. 4).

IV. Survey

The research concerning students' satisfaction with flipped classroom was conducted in academic year 2013/2014 on a group of 222 students studying in Polish (PL) and a group of 51 students studying in English (EN). Out of 222 PL students the questionnaire was filled by 211 students. Similar data are for students studying in English. Questionnaire was filled by 49 out of 51 students. One third of students studying in English were foreigners.

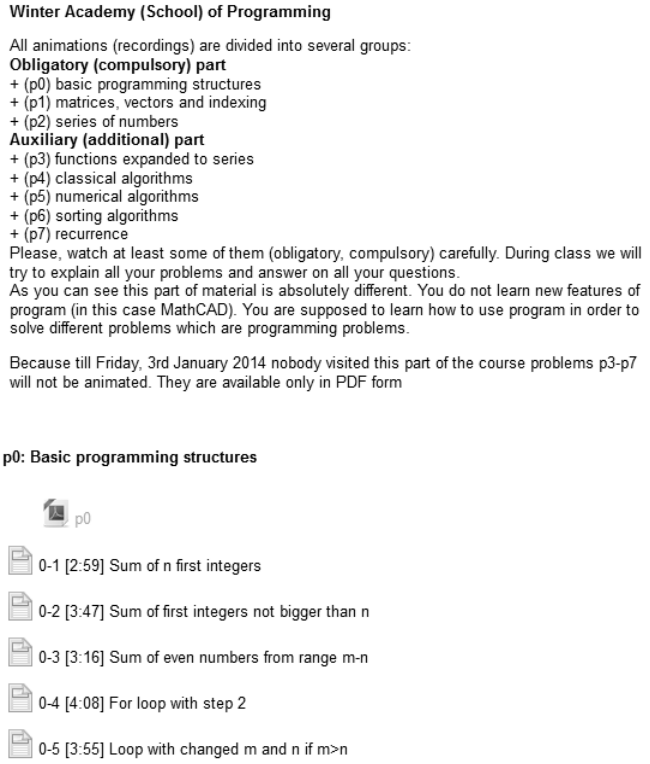

Fig. 3. Sample Learning Materials on Moodle platform

Four weeks of classes during which material covering text editor Word and spreadsheet Excel was discussed were

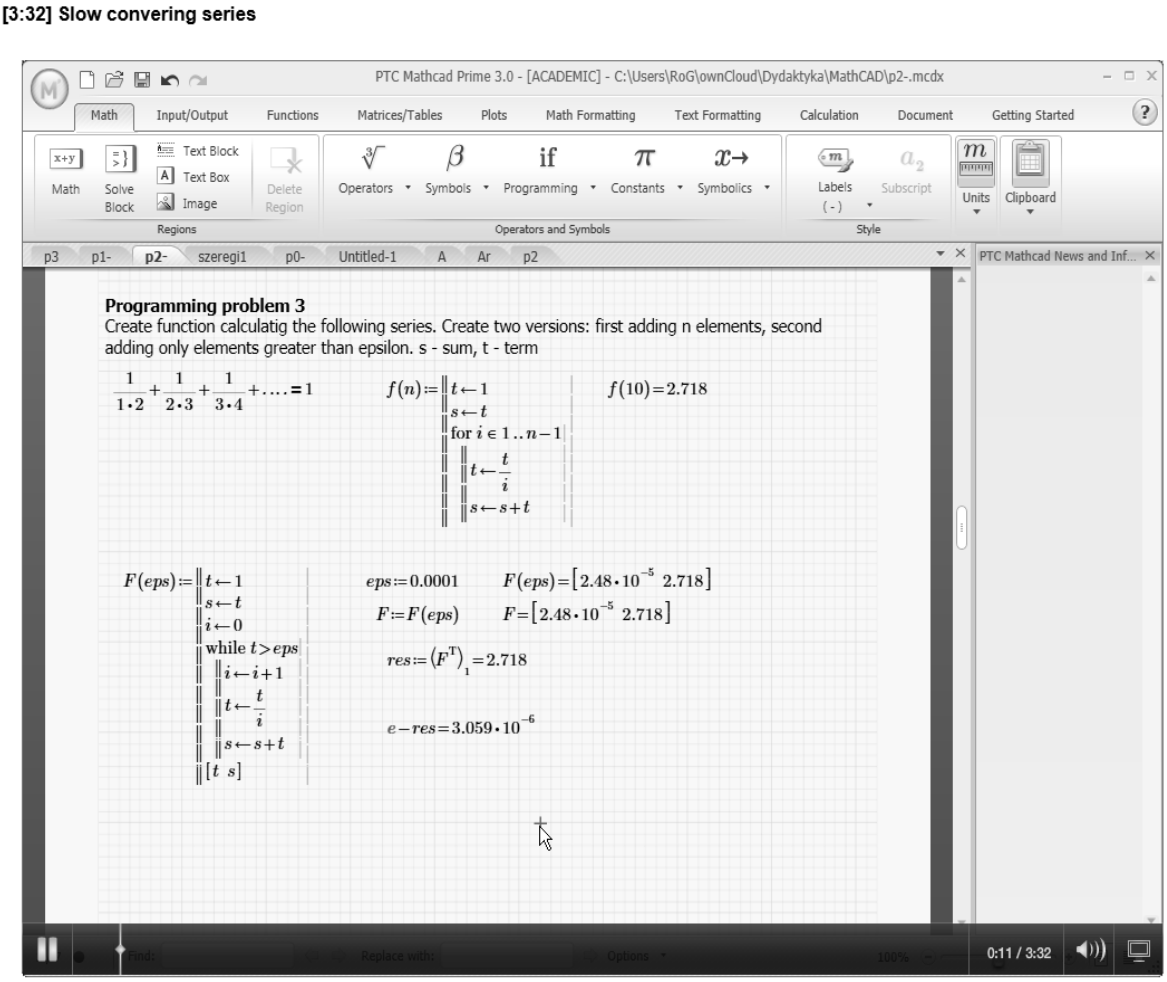

Fig. 4. Sample Screencast – Slow Converging Series

carried out in the traditional manner. In the computer laboratory equipped with 30 workstations there were two teachers. One of them demonstrated with multimedia projector solutions of the sample problems. The second teacher assisted students.

In order to perform survey Google Docs were used (Fig. 5, Fig. 6).

Fig. 5. Survey for Polish language students

Questionnaire used in this survey consists of fifteen closed form questions and 6 opened form questions. Due to the nature of answers all questions were divided into three groups. In order to compare results of survey with other outcomes some of the questions were based on similar surveys: first one conducted in Canada [27] and second one described in blog Flipping with Kirch conducted by Mary Kirch from United States.

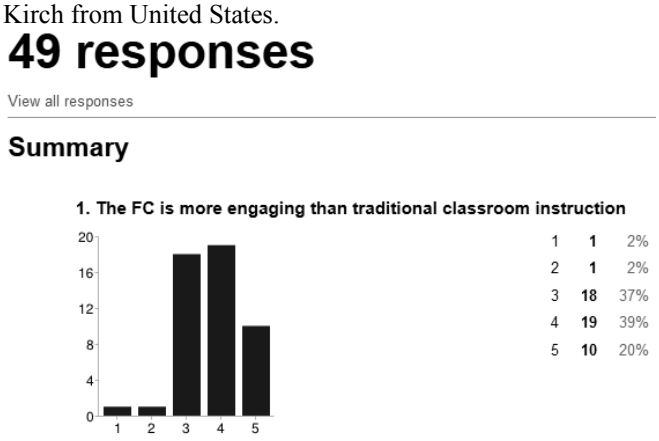

Fig. 6. Survey for English language students

Observations from traditional classes were rather pessimistic. More than half of the students did not follow the presentation and did not perform similar tasks to those presented by the teacher. As presented in previous article [9] this material was rather unknown for students but they were simply not interested in learning new things. It is rather difficult to motivate digital natives to learn [23]. This is still a very important and significant problem even there were many books written on that subject [24]. The answer to this question is difficult when we consider digital natives who don't care and who also think that they know everything [25] in the field of subjects like Applied Computer Sciences and Computing in Civil Engineering. Mendler presents one of the existing solutions – five key processes that motivate: emphasizing effort, creating hope, respecting power, building relationships and expressing enthusiasm. But digital natives being real partners for learning [26] are difficult and demanding partners.

V. Results of Survey

Scale of answers for all first five questions is from "strongly agree" to "strongly disagree". Results for Polish language and English language students were compared with surveys from Canada. First of the asked questions was about level of engagement in traditional classroom instruction and flipped classroom (Fig. 7).

40% of students studying in Polish language strongly disagree or disagree with the statement what is in accordance with the observation, that nearly half of the students was not interested in traditional classes. Answers of students studying in English language are closer to the answers from survey conducted in Canada.

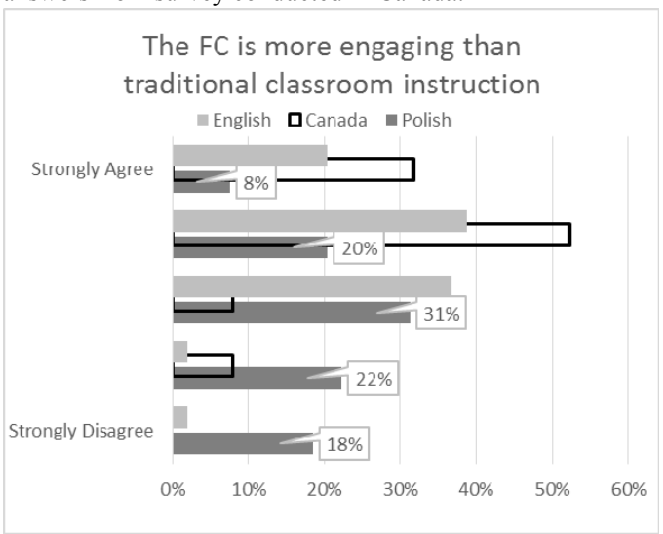

Fig. 7. Answers on question 1.1

Second question from that group was about potential recommendation of flipped classroom to a friend (Fig. 8).

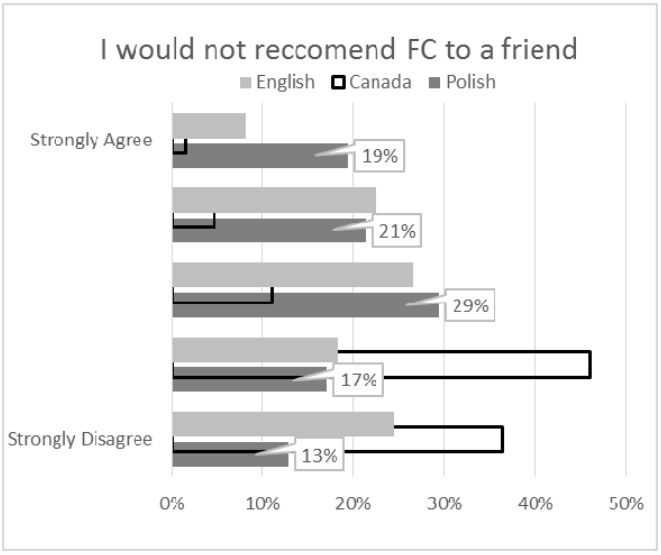

Fig. 8. Answers on question 1.2

For this question answers of students studying in Polish and English languages are similar but they definitely differ from the results of survey conducted in Canada. Nearly six times more students studying in Polish language in comparison to Canadian agree or strongly agree with the statement that they would not recommend flipped classroom to a friend.

Next question (statement) was very simple – I like watching lessons on video (Fig. 9). In this case answers for all three groups were very similar.

Fourth question in this group of questions was about bigger motivation to learn in the flipped classroom mode (Fig. 10).

In the case of this question answers of students studying in Polish language differ from the answers of two other groups. Nearly 40% of them strongly disagree or disagree with that statement that they are more motivated to learn in flipped classroom mode.

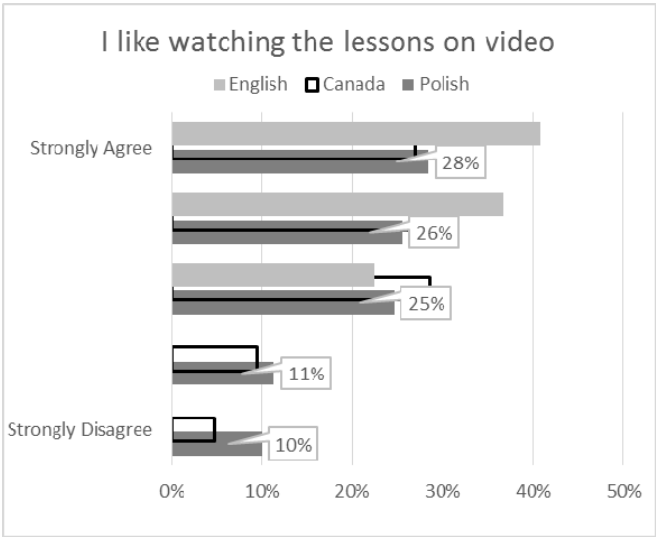

Fig. 9. Answers on question 1.3

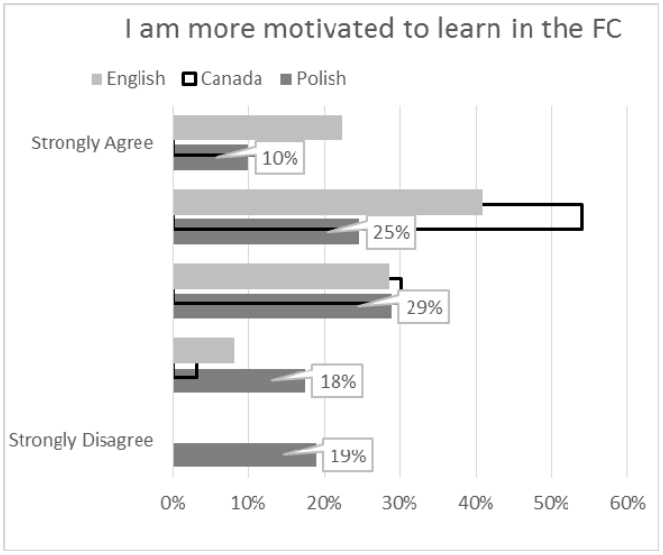

Fig. 10. Answers on question 1.4

The last question in this group is about improvement of learning in flipped classroom mode (Fig. 11).

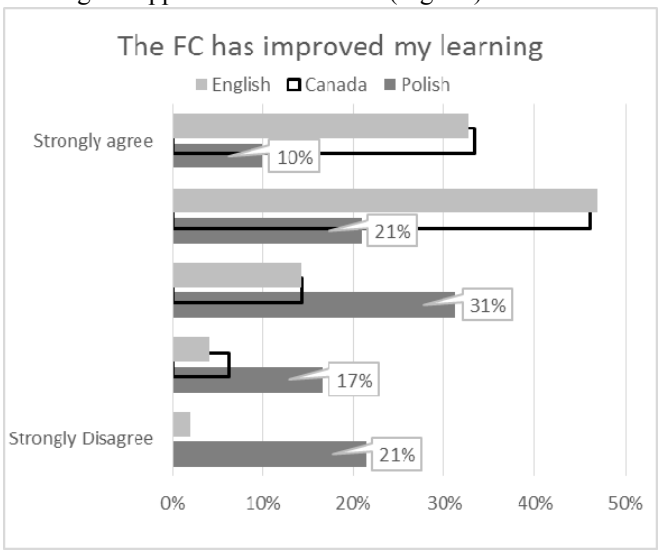

Fig. 11. Answers on question 1.5

Also in the case of this question answers obtained for students studying in Polish language are definitely different from results for two other groups. Nearly 40% of them strongly disagree or disagree with that statement. Answers for students studying in English and answers from survey in Canada are nearly the same. Nearly 80% agree or strongly agree with statement that flipped classroom has improved learning.

Second group of five questions is based on research conducted by Mary Kirch. Also in this case answers are on scale but they differ from question to question.

First question in this group is about rating flipped classroom. Scale of answers is from “very bad” to “very good” (Fig. 12).

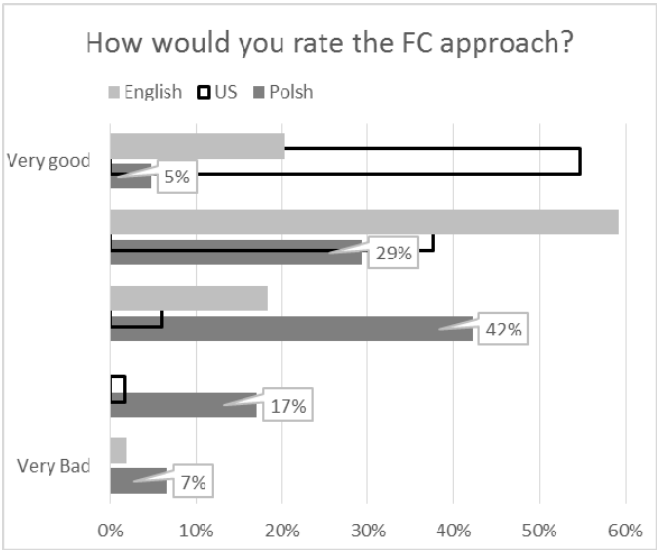

Fig. 12. Answers on question 2.1

Also in the case of this question answers for all groups are different. American students are most enthusiastic – more than 90% rated flipped classroom approach as very good or good. Students studying in Polish are definitely less enthusiastic and more skeptical – nearly 25% of them rated flipped classroom approach as very bad or bad.

Next question in this group compared feelings how flipped classroom helps to learn the material in comparison to traditional approach (Fig. 13).

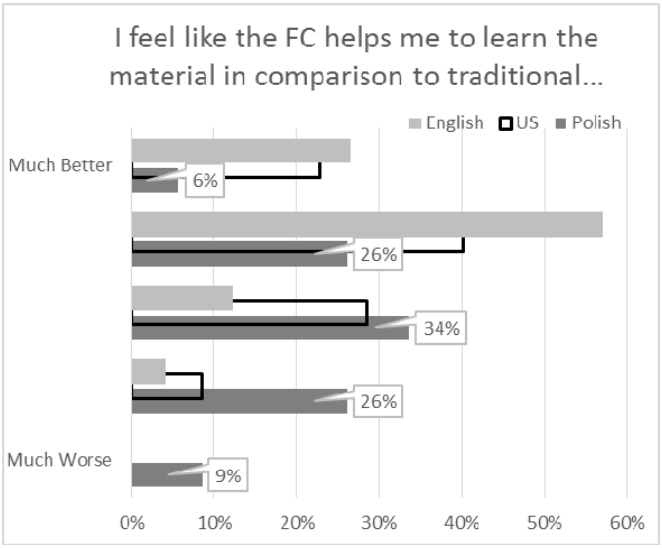

Fig. 13. Answers on question 2.2

Answers to this question are to some extend surprising. Number of answers much better or better is among students studying in English the highest – nearly 85% of such answers. Traditionally students studying in Polish gave the highest number of negative answers – 35% of them answered that flipped classroom helped them to learn in comparison to traditional approach much worse or worse.

Fourth question was about feelings towards flipped classroom approach. Scale of the answers was from “I hate it” to “I love it” (Figure 14). Results in this point differ also

because American scale was four point scale without neutral answer. Students were supposed to express only negative or positive feelings.

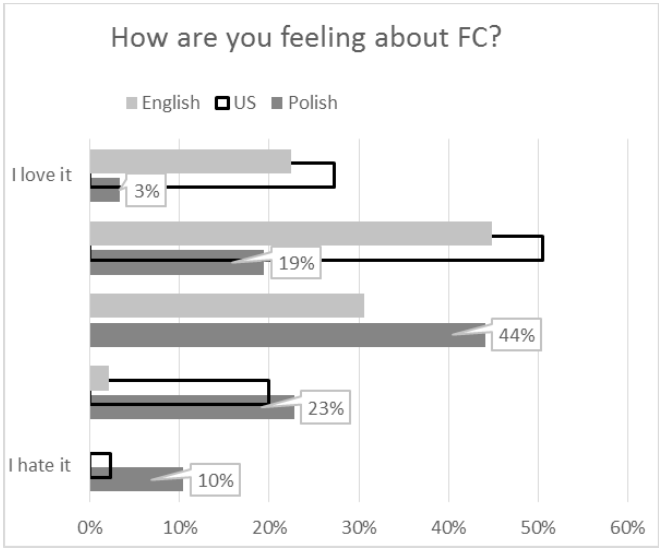

Fig. 14. Answers on question 2.3

As in the case of previous questions for students studying in Polish language the number of definitely positive answers I love it is the lowest – only 3%.

In next point question how much did you learn in flipped classroom in comparison to traditional was asked (Fig. 15).

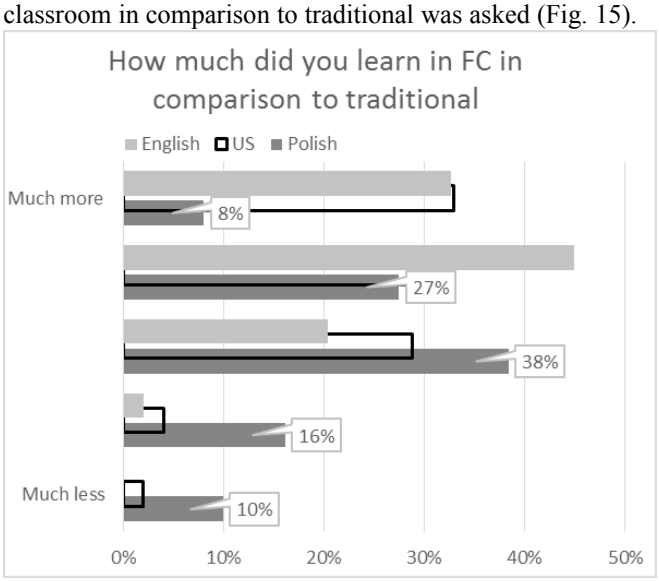

Fig. 15. Answers on question 2.4

More than 25% of Students studying in Polish language answered that they learned much less or less while more than 30% of students studying in English language or American students answered that they learned much more.

The last question was: how much were you challenged as a student in flipped classroom comparing to traditional one (Fig. 16).

Results for all three groups are in the case of this question very similar.

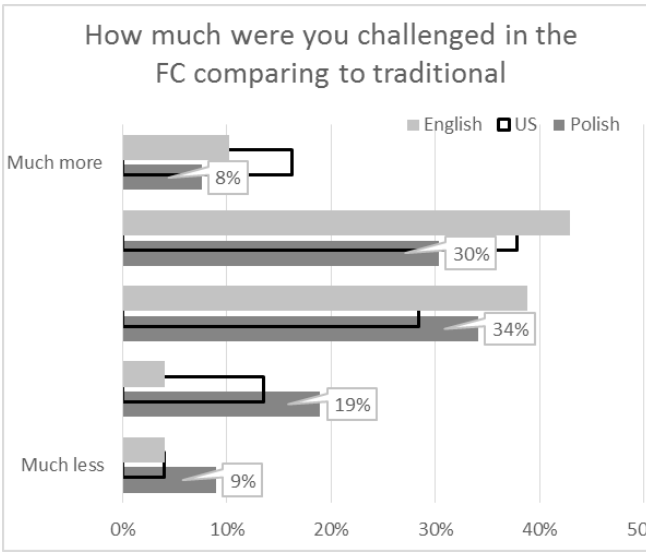

Fig. 16. Answers on question 2.5

I. Final Remarks

One of the pressures on universities is the rapid development of new information and communication technologies for the provision of education and training. Wide opportunities in open and distance learning create new markets. Moreover the principle of life-long learning extends the age groups to which university can offer education. Additionally the principles of new techniques can be applied to traditional markets – regular intramural students. All Polish universities willing to use modern information and communication technologies face common opportunities, threats and constraints. A constant struggle between pressure to change and fear and resistance to change is visible in Poland. Teachers' attitudes are a major obstacle to the introduction of change. There is an internal brake on the efforts to make changes through using new technologies: resistance from people. Reference can be made to a "frozen middle" resisting attempts to change from both the top of the institutions (authorities) and from the bottom (students). Students' demands are a powerful factor forcing universities to exploit the potential of new technologies to improve learning experience. But the question "how to change the unchanging" is still open [28]. Moreover one should add to this question a new one – "how to motivate digital natives to learn?" [23].

Flipping the classroom is not the only way in which "how to change" and "how to motivate" problems can be solved. One of them is classification of learners using linear regression [29], because proper classification of learners is one of the key aspects in e-Learning environments .Second possibility is to enhance online educational environment what can be obtained by providing platform side intelligent functionalities in the shape of a recommender system or learning path builder [30]. Another possibility is to use system that allow the organization of a set of teaching and learning activities and meets, at its highest level of detail all the elements that compose the curriculum: setting goals and content, design and development of activities and

evaluation, organization of space and time, and providing the necessary resources [31]. Next chance is to implement a Learner-centered learning which is constructivism based and Competence directed in which we define general competencies, domain competencies and specific course competencies [32]. Last but not least there are also another innovative teaching methods for blended learning like for example Drawer [33] or recognizing different learning styles while designing e-courses [34].

ACKNOWLEDGMENT

The authors wish to thank L. Wlasak, T. Dubilis and T. Warda for their support during flipped classroom experiment and survey. Thanks are also due to Dean of Faculty of Civil Engineering Professor H. Zobel who allowed us to conduct this educational experiment. Last but not least the authors wish to thank all students who filled very long questionnaire at the end of semester.

***Abstract*—This article shows our research oriented towards improving doctoral theses by publications. This process is justified by John Dewey's knowledge theory and various phases of Kilpatrick's work. After a theoretical foundation, the research work set the steps in a thesis by publications, which is both validated by members of the scientific community and created from the knowledge of the experience of the candidate in the field of study. Validation of the PhD thesis in this case is found by members of the scientific community in a research validation along publications.**

I. Introduction

THIS article proposes a didactic technique using John Dewey's knowledge theory as the starting point. With experience as key factor, theory and practice have a strong relation and focus education on an experimental and pragmatic approach.

Pragmatism is a school of philosophy originated in the United States in the late 19th century. The term comes from the Greek work praxis, which means action. Pragmatism is not really a philosophical theory but a "mindset" that includes different theories that can be applied to different disciplines. Pragmatism is also regarded as a theory of human beings from the cognitive perspective.

John Dewey's theory of knowledge [1] in conjunction with William Heard Kilpatrick's technique of project-based work produces an improvement of the teaching-learning process.

The combination of both is a different approach to the project-based method from many perspectives: epistemological, psychological, educational purpose, and curriculum development. This article shows how to apply the project-based work to doctoral theses by publications, namely theses composed of a compendium of publications, where there is a project-based work as well as a team that supports the PhD student. By applying a didactical methodology, the study tries to get PhD work and students closer.

A doctoral thesis is usually an original idea from the author. This idea is a consequence of a series of individual and smaller ideas coming from other authors involved in previous scientific researches, with a set of problems to solve.

The development of a thesis then involves the creation of a team aimed at solving a problem using a project-based approach. This team is often comprised of tutor, co-director, supervisor, collaborators and the student. This makes the final results are validated both by the team and the publications, which are a form of validation.

This approach is innovative and unusual, but we think it is necessary to begin the development of scientific research methodologies closer to reality, as teamwork in an interdisciplinary thesis is common. Also, there is a constant exchange of ideas among scientists through published articles, workshops and forums that are a way to provides both corrections as validating the research since its inception.

II. Objective

The aim of this article is to begin research and start a discussion on how to make a thesis by publications around ICTs in education. The starting point is knowledge methods of recognized educators, which are the source of the didactic-scientific methodology nowadays.

The team based the research on its previous three-year period of work on educational curricular organization and classroom methodologies. This experience was vital to develop this research and create a methodology for theses by publications, targeted at the application of theory to the productive, research or corporate sectors, thus creating theses applied to real environments such as industry, education or health.

III. State of the art

John Dewey sees education as the sum of processes by which a community or social group transmits its acquired powers and objectives, to ensure its own existence and its continued growth. He built an entire pedagogical philosophy with experience as a base, defining education as "a reconstruction or reorganization of experience, which gives meaning to experience and increases ability to guide subsequent experiences" [3].

The main element related to Dewey's theory of knowledge is the concept of experience. This concept is also the most important of his theory. Dewey proposes defines experience as a dynamic concept, an exchange between humans and

978-83-60810-58-3/$25.00

their physical and social environments, not simply a matter of knowledge. Moreover, experience entails a series of actions and affections, and cannot therefore be as a simply subjective term. Dewey states the experience is based on connections and continuities, implying processes of reflection and inference and linking experience and thinking [4].

Summarizing Dewey's proposal, the key element of knowledge and also the most important is a progressive education. The general method is an aim-driven action that takes into account activities such as artistic activities, past, tradition, and techniques that development that activity. The management of the scientific method must be guided by scientific knowledge. Because of this, Dewey believes educative methods must derive from the scientific method, adding any necessary adaptations. This is the so-called "Dewey method" or "problem method", a sequential process used to outline learning as a research activity. With this method, learning becomes a chapter in the general research method [5], comprised of five stages [6]:

- The student has a situation of authentic experience. In other words, there is a continuous activity in which the student is interested.
- A real problem arises in this situation as a stimulus for thought.
- The student posses the information and performs necessary observations to tackle the problem.
- Suggested solutions make the student realize she is responsible for developing them in an organized way.
- The student has the opportunity and the chance to test his ideas for their application, to clarify its meaning and to discover their validity.

Alternatively, Kilpatrick created the following method that "arises from a proposal made for the purpose of teaching the Dewey's concept of thought. This method became a more concrete way of acting in the field of practice than in theory [7]:

- First stage: students choose a topic from a set proposed by the teacher.
- Second stage: once students reveal their interest, we must assess their prior knowledge about the topic. This phase is called "What Do We Know?"
- Third stage: the following question is asked: "What do we want to know?" The answer is objectives and contents the students should acquire through analysis and research on the chosen topic.
- Fourth stage: "How can we know it?" phase or "investigate and learn." Here we must take into account the elements of the methodology (organization of space and time, materials and resources to use, people who will help us, sources of information and activities).

• Fifth stage: "What Have We Learned?". This stage corresponds to the evaluation. Students tell about what they liked most, the least, specially difficult tasks... and will reflect our work in a final document to provide greater value to our work (reports, letters, drama, book project) that will be stored in the classroom library.

The project-based method leads to a significant and globalizer learning process where students assume more responsibility for the own learning and use acquired skills and knowledge in real problems. We therefore need to take into account the theory of significant knowledge by David Ausubel [8], which states that significant knowledge occurs when new information "connects" with relevant concept a ("subsunsor") that already existed in the cognitive structure. Thus, new ideas, concepts or relevant propositions can be meaningfully learnt, as others are clear and available in the cognitive structure of the individual, working as an anchor.

Once we have justified the cognitive perspective of project-based work, with Dewey's theories of knowledge and Kilpatrick's project-based work, we need to evaluate the research methodology in order to adapt it to research on the use of ICTs in classroom education.

IV. Thesis Methodology: summary of publications

At the point of state of the art we have developed the necessary starting points for this item, we will develop as they could be the steps for developing a thesis by publications, adapting the method steps for projects Kilpatrick, is a methodology for creating and decorating that could be adapted to their needs, we must also note that we have to take into account the meaning of a thesis by publications where doctoral dissertation develop through the articles achievement of previously set objectives.

The figure presented below find the different phases of the period of creation of the thesis, there are five stages in white, these phases are designed to obtain the different phases that are the definition, validation of ideas, the specific development, application of the results and final phase of integration and evaluation of results. The blue line found the feedback from the doctoral thesis of companies, researchers conducting a review of exports and the items made. These sections in conjunction form a series of phases, as described below.

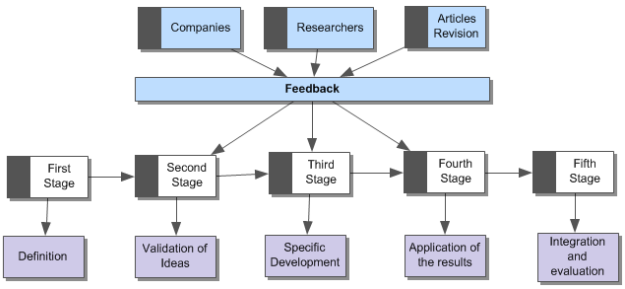

Fig. 1 Stages

A. First stage

In this first phase the doctoral student must select the subject of the thesis, this process must be from the starting point of the knowledge of the candidate, director of the thesis proposes possible research. In this first phase of the doctoral student must submit inquiries to define their own line of research. This period is a period of reflection, which must be accompanied by a practical part, this practical part must include a period of experimentation must also include scientific methodologies a practical part that is as close as possi-

ble to the productive sector which will intended research. This PhD received feedback both the method and the specialized staff working in these sectors may thus incorporate new elements of judgment and experience by providing both solutions and establish the objectives, hypothesis and problems.

We are therefore faced with the definition of the research of the thesis as we see include the problems that you are encountering in the productive sectors, this is a way of bringing doctoral reality and allow the implementation of doctoral thesis the productive sectors of the industry, thus bringing research computer schools, both companies like the different sectors, since the computer is a highly interdisciplinary and cross science, in which the approach to the problems from companies improve the concept of applied computer science.

The starting point for the hypothesis may be that hypotheses are possible solutions to the problem are expressed as generalizations or propositions. These are statements that consist of elements expressed as an ordered system of relationships, which are intended to describe or explain conditions or events not yet confirmed by the facts. [9].

The PhD student may pose for a series of scientific articles that should culminate in the precise definition of objectives that will develop and what the scope of the investigation.

In this first part of the doctoral student should perform a series of articles in order to ensure the research and thus allow other members of the scientific community to review the established line, this series should end with the completion of A final item that we could call "Phd Thesis Objectives Article" which clearly embodying the following points:

- Problem
- Hypothesis.
- Objectives.
- Scope of the problem
- Development methodology of the thesis

It is therefore a series of articles that trigger at the origin of the research and the idea of the author is protected from the start by posting the same and its transmission to the members of the scientific community in the concrete explanation that general solutions can be a bear to achieve the objectives.

B. Second stage

In the previous phase have described that we do, through a process of validating ideas and methodology publications, in this second phase begins developing the doctoral thesis, verifying and enhancing their knowledge, this knowledge is not science specific on which the PhD is done, but the novelty here ye must learn and see what knowledge and must be purchased on the implementation of the thesis, dissertation that apply to a specific production sector.

In this case depending on the possibilities the director of the thesis, shall perform a work accompanying the doctoral candidate in the search for work experience in a company of the productive sector, as in the formation of this in the field, thus we get that you obtain a better view doctoral researcher field applied to the reality of the productive sector, in turn the doctoral student must complete the items necessary for the realization that solutions can be, how it will be if your metodolgoia7y seen an increase and modification of the objectives, hypotheses and the emergence of new problems.

This phase must be completed with the creation of an article in which the objectives will be translated and how they will achieve these goals, technologies and designs all the justification necessary in order to introduce the members of the scientific community and its progress if need help from a researcher in validating their results or have an investigator which states something. This is the turning point where the work really begins, once the revision of the article from which the solution begins with the objectives.

C. Third stage

Once validated and completed the objectives, problem and methodology doctoral students proceed from scientific publications a specific development for each of the objectives, i.e. scientific publications will be aimed at the solution of each of its objectives separately, where maintaining a classical structure of the article, abstract, introduction, aim of the thesis being treated, points of development and verification of the aim of the thesis.

During the review process these items reviewers may seek clarification on these items or possible improvements for sharing the results thereof, such information shall be forwarded to the director of the thesis in order to recapitulate the development data items if necessary a greater realization of the objectives or a breakdown thereof, the doctoral student must retake these changes and make publications in order to clarify and modify the changes that reviewers indicate.

D. Fourth stage

At this stage we continue the exploration of the research, it is time to validate the objectives and whether the solution is true, for it would have to perform the doctoral an article of inclusiveness, we might call integrator article dissertation, this article must integrate items developed in previous phases, this is where the doctoral student researchers and will see the entire investigation.

This point is important because the overall view can offer both weaknesses and strengths in the investigation thereof, is another as another feedback point of the thesis. This can be done by hand, a redefinition of the objectives or the appearance of new targets to be treated as a whole, at this stage the direct application of the results obtained in a case of direct application is also included.

There are multiple options for an application of the results obtained, we believe that such validation items that have been made, it would be interesting for the creation of articles, presentation application sectors of the thesis, we thus validate Objectives from the IT point of view but from the point of view of the application of research. This is an analysis of the results expose these results to anyone who will use and proceed to the validation of these from the point of view of the application.

E. Fifth stage

The evaluation process, feared by all doctoral candidates, one way to do this is to make a final scientific article in which the doctoral drafted the level of achievement of the objectives and the solution of the problem has been achieved, this can be done many forms depending on the subject of the thesis, a way is made an article with realizer integrative conclusions based on the main items of a solution to the whole problem, in this paper besides an integration under one thread should capture the level of achievement of the objectives through the articles, a section that can clarify this situation is the main product, a case study in which the solution to be integrated, this has been developed in different scientific papers but is a way to facilitate an understanding of their research as a whole.

The combination of the phases can be performed the same research methodology, we highlight one hand the organization of the work we have previously pointed out the phases and other research methodology, this methodology must also develop in the realization of the articles, the reason for this is that the development of the items directly affects a good realization of the final conclusions and also have to have external factors as shown previously described. In the figure below we present such as the research methodology within each of the phases.

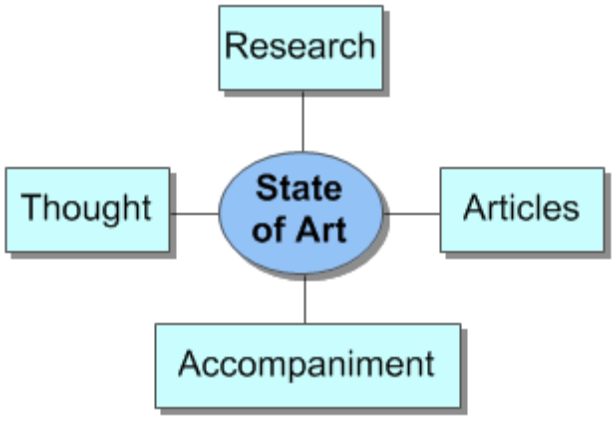

Fig. 2 Research methodology

From the state of the art, a research by the scientific articles that tries to find solutions to the objectives and problems encountered in the translation of the thesis is done, the presentation of scientific papers in international journals and conference allows the option to review other researchers, we put in the focus state of the art, this state of the art is not that we are used to now, is to make a state of the art in two parts, first we make a study of what the needs or as the productive sector which is destined. It is also important accompaniment of the thesis supervisor and the doctoral student in situations where you will apply the final result of the thesis in order to produce feedback to the thesis.

Once the sections of the thesis done we can think of the following index for the thesis, as these consisted of a doctoral thesis by publications is necessary to capture very specific things, and a good way to see it is through an index, which it can be shown below:

1) Problem Hypothesis and Objectives.
2) Scope of the problem.
3) Theoretical Framework: State of the art where
4) Need.
5) Articles published, plus should consist of the full text article for a description of the stage at which it is and has been achieved with this article.
6) Conclusions inclusive, this point should in addition to the final conclusions of the thesis describe, ideally write a case study integrating papers made in order to see an overall solution to the problem described in another section and the level of achieving the objectives through the items.
7) Future work.

V. Centralized research resumé

Once we have described the methodology and the different phases, in previous research we have described as the centralization of student resume is performed [10] [11]. In this section, we plated the goals of our future research in order to extract information from the presentation of this publication will be a starting point for a series of articles in which we set the following objectives.

Centralize the doctoral curriculum, depending on the work done during the development of the doctoral thesis, in which it is to storing all the work done, this main objective we can be subdivided into:

- Classification of the knowledge of the candidate technologies starting with handles and transverse fields has been working.
- Targets developed on each of the items, giving a score by the reviewers as to the level of achievement of the objectives in the articles.
- Search for researchers under a similar profile, in order to enable collaborative research work with similar objectives, although these are in a different line of research
- Communicate with companies achieved the objectives in research; this would open the way to the outside research in the investigation periods.
- Curriculum vitae researcher from the milestones it has been marking the researcher, making unique and validated cataloging items.
- Integration of the resumes of researchers in a body that also lend credibility to this research allow feedback, this organism can be for example the top universities, can use this feedback to generate other lines of research.
- Recognize the idea of the researcher in scientific forums, in order to ensure that the PhD was who came up with the idea and avoid potential problems in the development of research that can last five years.

These objectives are the beginning of a new line of research and here with comments from reviewers and members of this conference can be a start to know the real possibility of whether a line of research is possible or necessary.

VI. CASE OF STUDY

In this section we will make the assessment objectives which would be a summary of the findings and integrating validation of submitted articles for my doctoral thesis, the starting point was 4 years ago when the computer was working doctoral technician for School 2.0 program [12] in Spain, the field of application of the thesis is the use of ICT in classroom education, so we set from the beginning to facilitate the tasks of the teacher through a system that allows the creation, maintenance curricular programming for the educational stages of Primary, Secondary and Vocational Education, from:

1. Creating curricular schedules that allow teachers to structure their programming following the official curriculum, divided into teaching units have a distribution in sessions over time, justification, objectives, core competencies, provide content, materials needed, activities, qualification students, attention to diversity for students with special needs, methodology.
2. Structuring and preparing the working sessions within their curricular programming, taking into account the learning unit wherein said working session is located.
3. Track the teaching-learning process of their students in collaboration with parents, attending the assessment, rating and monitoring of the student in this process, which will also improve mentoring.
4. Ensure a flexible system that allows the inclusion of activities and creating them from existing educational platforms, including such activities in the lesson plans the teacher develops within its programming.
5. Centralize the educational curriculum vitae student, taking into account the results and the level of achievement of the objectives in addition to basic skills attained.
6. Improve the interaction between students in the classroom by Distributed Graph User Interfaces (DUI), thus improving the teaching methodology in the classroom.

These objectives we have worked throughout the research time and have been monitoring the level of achievement of the objectives through the items, as you can see in the summary of the conclusions, which we integrate below:

First we defined the cloud services necessary for the development of curricular schedules of teachers, including the creation of curriculum schedules following the official curriculum and following a structured work sessions where the teacher indicates the activities to resolve considering objectives, core competencies and the specific needs of each student [25].

Once you have developed these services is necessary to establish the curricular structure of the official curriculum and curricular programming that allows storage managers of database systems with the information associated with each of these [14] [15].

One of the most important aspects is to track student evaluation. In this respect we track the teaching-learning process based on objective and core competencies of the contents worked by students in activities and assessment tests have been conducted, establish a system to score each of the activities taking into account basic objectives and the teacher determined the creation of each one of the activities that make up the didactic units that form the annual teacher curricular programming skills. The inclusion of activities in curricular programming allows teachers to better development of their daily work and provides flexibility that is possible thanks to the integration capacity of the systems in the cloud and the ability to leverage interoperability of Web services [16] [20] [21] [23] [24].

On the other hand improving student resume and centralization is possible because the system on which the assessment is made is a score of basic skills that students obtained in academic courses [10] [11].

The teaching methodology is achieved by improving the interaction, by using the graphic user interfaces distributed (DUI, Distributed User Interfaces) and insertion patterns of education as a service in the cloud, allowing the inclusion of teaching methodologies in programming and that the teacher can adapt these methodologies to the student group [19] [22] [24].

In the research process is important also apply learning, which is why publications have made a different line of research to validate what we are doing and allow us to continue our research in the future to other lines of research [17] [18].

VII. CONCLUSIONS AND FUTURE WORK

The development of doctoral theses by workers compendium also includes collaborative work we must also give a definition and approach to achieve specific objectives, these objectives must abide by and comply to reach a good end development, these goals are dismembered objectives pertaining for each item in order to perform a better specification of problems to solve. Surely many of these objectives will be converged with other researchers so flexibility is important and here comes the opening teamwork among researchers, so it will be important to re plan, refocus and rediscuss the scope and needs from know the real development of the doctoral thesis.

The Director of the thesis is a fundamental task as it must ensure the best options for the doctorate and the completion of the thesis in a while possible, this teamwork between different doctoral can make different lines appear very close research so the director of the thesis may take this opportunity to look for new and continuing doctoral research.

The type of evaluation process is enclosed in a unstructured learning environments, with specific objectives but flexible and open, conducted by a research activity that encourages told and team learning environments between different doctoral research and also took the research experience to the production system in real contexts, experiential learning theory of John Dewey suggests in his theory of knowledge.

***Abstract*—This paper presents an adaptation of the Brousseau method. The concepts of didactic variations and interactions are introduced by using didactic and a-didactic situations. With the main aim of guaranteeing alumni improvement and evaluation processes, a case study application was development founded on a cloud architecture, which is also based in previous research, curricular organization and interaction processes within the class.**

I. Introduction

GUY Brousseau introduced theory of situations, didactic contracts and didactic and a-didactic situations in 1998. This is a teaching theory seeking the conditions for artificial genesis of mathematical knowledge. Brousseau says that "knowing mathematics" is not only about knowing definitions and theorems to recognize the opportunity to use and apply them, but also about "dealing with problems" in a broad sense, which means finding good questions and solutions.

Computer science professors and researchers play an important role at first stages of the computer science teaching process and should be able to start asking questions about the process of teaching and learning that is used with their students in their daily work.

Curriculum development in university subjects lacks structure focused on the student evaluation process. Evaluation and assessment is an inexistent process, since in most cases it consists of an evaluation of the practical part of the subject, accompanied by a short presentation by the student, and a final exam to asses theoretical contents.

This teaching and learning process does not apply any clear pedagogical basis, with the exception of objectives achievement and is often subject to the teacher's decision. For example, in a Master thesis, the final evaluation is done in a presentation where the student talks about her work during a fixed time.

Sometimes, didactic methods are not used due to either ignorance or lack of transversality among subjects. However, there exists a wide use of teamwork [1] or project work [2], mainly because these methodologies adapt perfectly to work that students will perform in their professional future.

Didactic adaptation of subjects at the university level is likely to grow over time. One of the goals of educational outreach is the university of education, which will lead to an increment of the population percentage with higher education. Universities will need to include teaching methods that allow curricular adaptations, significant [3] and not significant [4].

Furthermore, the enhancement of students creative thinking from the Brousseau perspective can lead to the creation of new products and creative solutions to solve complex problems. In this way, students of Computer Science can improve their abilities to solve problems with training and adaptation methods. On the other hand, university teachers could use these methods autonomously and adapt their needs over time.

II. State of the art

During our research work, we have carried out the adaptation of the Montessori method [5] and the leverage of social networks in educative environments [6]. This paper presents an adaptation of the Brousseau method.

Brousseau developed the "Situation Theory", in which he searches conditions for an artificial genesis of mathematic knowledge. Under the assumption that they are not built spontaneously, it is based on the constructive conception of thought.

Pedagogic constructivism is to equip students with the necessary tools, allowing them to create their own procedures to solve problems.

There are four essential features of a constructivist action [7]:

1) It is based on the conceptual structure of each student: part of the ideas and preconceptions that students bring to the classic topic.
2) Anticipates conceptual change is expected from the active construction of the new concept and its impact on mental structure.
3) Confront the ideas and preconceptions related topic of education, with the new scientific concept being taught.
4) Applies the new concept to concrete situations and relates to other concepts of cognitive structure in order to expand its transfer.

Necessary conditions to boost constructivist teaching are the following:

978-83-60810-58-3/$25.00

1) Generate dissatisfaction with prejudices and preconceptions, allowing students to identify their mistakes.
2) The new concept begins to be clear and distinct to the previous.
3) The new concept shows its applicability to real situations.
4) The new concept generates new questions and expectations.
5) The students observe and understand the causes of their prejudices and misconceptions.
6) Create a climate for free expression of student, without coercion or fear of making mistakes.
7) Foster the conditions for the student as a participant in the teaching-learning process: planning, selection of activities, sources of information queries, etc.

In the Brousseau theory of constructivism, students learn to adapt to an environment that is a factor of contradictions, difficulties and new knowledge is acquired through responses that are evidence of learning. This is achieved with didactic and a-didactic situations.

A didactic situation is a set of relations explicitly and / or implicitly established between a student or group of students in an environment, including, eventually, instruments and objects, and an educational system (teacher). Student work should, at least in part, reproduce the characteristics of scientific work itself, to guarantee an effective construction of relevant knowledge. Each didactic situation is governed by a certain type of training contract, i.e. a set of implicit and explicit obligations, namely an action between teacher and students.

An a-didactic situation is essentially characterized by the fact of representing certain learning moments in which the student works independently, not subject to any direct control of the teacher. In this situation, the student becomes able to reuse the knowledge that he is acquiring, in a situation not covered in any teaching context and in the absence of any teacher.

Summing up, a didactic situation is one that inherently contains the intention of someone to learn something. This intention does not disappear in a-didactic situation, where the lack of intention means that the student must address the problem by replying to it based on his knowledge, motivated by the problem, not by the desire to please the teacher [10].

Brousseau establishes a didactic contract. The didactic contract was defined by Rousseau [11] and there are several functions performed:

1) Promotes student autonomy and responsibility.
2) Attends to the particularities of the student.
3) Facilitates the interest and motivation of students in their own learning process.
4) Academically guides student work.
5) Democratizes the education to take into account instances of negotiation in setting learning objectives, course content and assessment process.
6) Stimulates the ability of self-reflection on the student's own learning enhancing critical thinking.

Brousseau also adds that the training contract refers to the actions established between teacher and student, thus comprising the set of behaviors that the teacher expects from the student and the set of that the student expects from the teacher.

The didactic contract, along with educational and a-didactic situations, can be modified by the didactic situations are theoretical objects whose purpose is to study the set of conditions and own a well-defined relations knowledge. The contract can use values that enable students to understand and resolve the situation with their prior knowledge, and then make them face the acquisition of new knowledge by setting a new value of a variable.

The contract has a structure similar to a teaching unit that we developed in prior research. In this previous research we also included a study on how to evaluate and assess students in conventional curricular situations [12] and in social networks [13]. Also, we studied the necessity of curricular organization in rural environments [14]. The outcome from this research showed that evaluation and assessment should be done by taking into account the whole teaching and learning process. Student evolution should be registered and logged during the process.

III. Definition and objectives

This article shows an adaptation of the Brousseau method, developed in order to improve the learning of Computer Science and change the approach of subject from a raw contents perspective. The starting point is to be able to address problems from the computer science point of view. These capabilities involve the use of techniques and technologies designed for problem resolution. Furthermore, this approach can improve students' creativity in the development of new products and particular solutions to problems.

IV. Didactic methodology

Teaching methods drawn from this technique are a part of a master class [15], where the teacher presents concepts and takes the approach to solving problems in addition to the qualification criteria (training contract). At this point, students should start having doubts regarding these content. These doubts or questions are contract breakers. To avoid, the contract breaking, the teacher interferes with the development of problem proposing new situations for the student to solve. At this point project work, collaborative work, or individual work can be used.

The introduction of educational variables in this methodology complements a problem during the teaching-learning process, creating milestones in the teaching methodology and turning points that allow students to obtain new solutions from these variables.

These variables can be adapted by the teacher for students with learning and teaching needs with significant or not significant curricular adaptations, thus adapting the activity of students to the specific needs of these or group level students each time.

These educational variables are milestones, which must be solved by the students. These new standards raise new

questions for students to be overcome and entail the creation of new solutions to the problem proposed completing its complexity or making new methods to its solution.

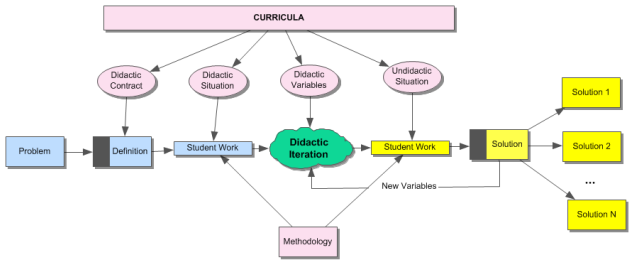

Fig. 1 Didactic Methodology

The above diagram depicts the operation of this methodology. The methodology starts with a problems and ends with a solution. This solution is not unique because during that modify variables included.

• Blue boxes represent the beginning of the process. The teacher defines the problem and the students begin working on its definition. During this process, students adapt the problem to their academic interests, mainly based on the knowledge acquired in previous experience of other activities.

• Didactic Iteration is in green. The teacher introduces variables that cause the a-didactic situation in students and create confusion enabling them to continue the development of the solution. This a-didactic situation can cause various solutions the problem.

• Yellow boxes highlight the iterating process where the teacher introduces new and triggers a process where different teaching methodologies are applied.

• Purple boxes represent the curricular part of the technique described above. This requires access to information in the official curriculums, which are created on the teacher's teaching schedule.

Summing up, the teacher develops a problem statement, which is completed by the students in the teaching-learning process. Then, by creating the conflict, students learn and develop complex problems, from their own knowledge, while teacher supervises the development of the activity and the achievement of objectives.

V. Models and States

The design of models for a solution to this teaching methodology is defined by the following:

• Problem: The problem statement must be constructed from the knowledge gathered from the student group considering transversality and curriculum contents. The process must take into account the objectives and core competencies the activity will be based on.

• Definition: In this model, the teacher helps students continue with the development and realization of the problem statement, using knowledge acquired in other subjects (transversality of education).

• Student Work: The "individual student" work, influenced by the different teaching methods that teachers adopt. These methodologies entail personal, individual work and collaboration, and should be applied after periods of discussion that generate ideas, thus achieving greater articulation of such proposals or solutions as appropriate.

• Didactic Variable: Within the process of learning the teacher can add new challenges to the student. These challenges are raised by questions, which are asked in order to break the didactical contract and sow doubt in the chosen solution, allowing the student progress in this process.

• Teaching Iteration: Starting from the doubt created by the a-didactic, the teacher introduces didactic variables so that students can continue their work. These didactic iterations can last until the teacher considers the objectives are met.

These models must be accompanied by states, which are changes produced by the introduction of a model. In this way, the teaching-learning process is configured and can modify the behavior of the model itself. It is a way to introduce a change in the model by autonomic self-employment in a situation that produces a change in both solution and in the definition.

• Didactic Situation: Not a model itself, but a state in the process where the teacher creates the curricula through the objectives of the practice or problem statement. In this state, the student collects information about what to do and how to do it. The end of the situation is the acquisition of a training contract containing the work to be performed, which may be modified posterity.

• A-didactic situation: This situation is a state of reflection on the proposed problem in which students develop their cognitive elements of an evolution problem. More restrictions to the problem are raised, thanks to the introduction of didactic variables added before.

For the development of this methodology, we consider the situation of the student group and the level of achievement of the objectives. Therefore there is a direct relationship with the official curriculum [12] and in teaching methodology used the classroom [15] [16] hence the need for data collection of the teaching-learning process.

VI. Method Application

The structure we have for the development of the subject of IT projects is a matter that also needs the support of other subjects in the field of software engineering, database management systems and data programming.

From the learning outcomes and assessment criteria the teacher proposes the problem:

Problem: short form corresponds to the problem statement. "...Create a management application that allows professionals to manage their company store..."

Definition: Students begin to define the problem and begin to questions arise that will lead to the creation of the didactic contract. This methodology can be accomplished by collaborative work and well predefined roles.

Didactic contract made by the students and the teacher, which is the result of acquired learning and assessment crite-

ria (goals to achieve). The contract provides students with the ability to get that learning outcome, according to the curriculum of the course:

1. **Identify needs of the productive sector, relating them to projects that can satisfy these needs.** The following results are obtained:

a) Related companies were classified according to their organizational characteristics and the type of product or service they offer.

b) Firms were characterized indicating the organizational structure and functions of each department.

c) Most demanding business needs were identified.

d) Predictable business opportunities in the sector were assessed.

e) Type of project was identified in order to meet the anticipated demands.

f) Specific characteristics of the project were specified as required.

g) Tax, labor and risk prevention and implementation conditions of obligations were determined.

h) Potential aid or subsidies for the incorporation of new production technologies were identified.

i) A roadmap was developed for the project.

2. **Design projects related to the competences described in the statement, explicitly developing the phases that compose it.** The following results are obtained:

a) Information was compiled on the aspects that will be addressed in the project.

b) Technical feasibility study of the project was done.

c) Project stages were defined, specifying its content and deadlines.

d) Targets by scope were set.

e) Development supporting activities were determined.

f) Necessary resources and personnel to complete the project were predicted.

g) Funding needs were identified.

h) Project documentation was defined and created.

i) Aspects that must be controlled to ensure project quality were identified.

3. **Schedule the execution of the project, determining the intervention plan and associated documentation**, The following results are obtained:

a) Tasks were scheduled according to implementation needs.

b) Logistics and resources required for each task were determined.

c) Roles and permissions to carry out each tasks were identified.

d) Procedures have been identified for implementation of tasks.

e) Risks were defined, defining the risk prevention plan and means.

f) Allocation of material and human resources were planned.

g) Economic assessment that responds to the conditions of the project implementation was carried out.

h) Documentation necessary for project implementation was defined and developed.

Once the teacher has presented learning results, objectives and assessment criteria, students define the problem they want to solve, through collaborative work or moderated discussion. The definition of the problem is done following these points

• Conduct a marketing job.
• Conduct a study of economic feasibility.
• Create a project plan.
• Create an implementation plan for the company.
• Specify a requirements document.
• Study legal legislation in the creation of a software project
• Balance project risks
• Perform an economic assessment of the project.
• Characterize the productive sector. Students decided that it would be garage to and a car parts store.
• Establish the garage modules: warehouse management, repair management, billing and online sales.
• Establish phases of application design and make the application requirements in order to ensure the success of it.
• Create a testing phase.
• Tighten the planning of project duration and resources required for its development.
• Perform a marketing study of the developed product.
• Teamwork: Create teams in the initial phase to enable the design, analysis and implementation of the project, also defining the role of each team:

- Design team: system design, databases design, UML and database management systems.

- Analysis Team: conduct the analysis of the final creation of a requirements document, also will perform market research and project feasibility.

- Implementation Team: initially undertake technological evidence necessary for the implementation of the subject and phase necessary to select databases and programming languages needed to implement tests.

Once the didactic contract with students is done, we can see the challenge that students have been established, as there is a considerable lack of order and some aspects remain undefined. At this point, the teacher plays an important role as a project leader, providing the students a pseudo-real situation as close as possible to a corporate project, without forgetting the academic taking into account that the a-didactic situation should let students progress on their own.

A. Introduction to syntactic variables and interaction production

Students showed their findings in a presentation to the group. During the questions and answers time, the teacher asked questions to the group of students from each team. These questions should make students question their own activities and complete their work.

For example, the following are questions made to the different teams. This was asked to the analysis team was: “Is all your work aimed to find the customer's needs, divided into different types of requirements, as you specified in the anal-

ysis phase?" The following comment was made to the design team: "You have decided which technology to use, I see you chose a language taught in other subjects (Java), but I do not see how the analysis team could use that work, you must design thinking to support the analysis team. Should the customer to see something during the requirements phase?" The implementation team was asked the following: "You carried out stress testing, you designed a database cluster and client-server communication, but what if I have to offer an external service such as sending data to a central provider or upgrade fees from the central shopping?"

At the end of the class, a student from the analysis team points out the following: "How should we organize the staff? This is a mess; it took us a week and we have nothing, we can not offer a joint solution for business… in software engineering classes the teacher told us about CASE tools, should we use them?"

A member of the design team questioned this decision and indicated they already had the Rational Rose tool at their disposal, which could be integrated with Requisite Pro tool, a specific tool for requirements definition, also saying that they could create database table in the design stage.

A member of the implementation team showed the possibility of defining a logical structured to develop a modular application. Another member said that they could create the accounting module with an ERP and save time.

The teacher finally decided to step in this chaos, with the sole purpose of moderating, and also indicating that he wanted to see them at his office the next morning. Next morning, only one member of each team showed up. Groups had just defined the team leader role without the teacher intervention.

During this mentoring sessions, issues discussed the day before are solved. Students established a modular structure and decided to continue using Rational Rose and Requisite Pro, as their combination is a way of linking design and analysis phases, finishing up with the definition of use cases. Regarding requirements definition, students decide to start developing IGU prototypes in order to achieve a better definition of requirements and ease the creation of a database. The also decided to do a reverse engineering process on industry applications, to includes industry data in the analysis, which is a good way to make an analysis and design when software teams do not have own data.

In this interaction, with the introduction of variables, the progress was considerable in terms of project organization. Students made decisions based on prior knowledge and sought appropriate solutions to problems, creating a project development methodology.

VII. Architecture

We need to create architecture for incorporating the method of Brousseau. This architecture is focused on the cloud to ensure the possibility of growth and integration of services built on previous research. It is essential to consider the organization the teacher does in the academic environment, the documentation of teaching the set of objectives that the student has reached. Also, the teacher has to conduct the evaluation and monitoring of the goals of the students. This requires the creation of a workspace.

Figure 2 depicts the cloud architecture that enables this work, as we will now need a part that facilitates interaction and creation of workspaces based on the teaching methods and other assessment and preparation activities for the teacher.

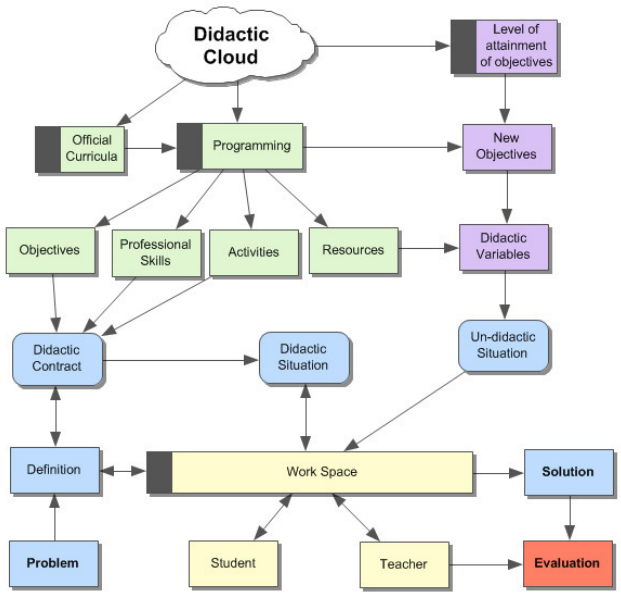

Fig. 2 Architecture in the cloud

We set a conceptual level architecture in the cloud, as we can see there are several parts.

Green modules represent the organization that the teacher created for the subject. Data is gathered from the subject curricula, divided into objectives, skills, activities and resources. The curricular organization that the teacher has developed for a subject must be adapted to the Brousseau methodology, thus conducting a curricular inclusion in the method we are developing.

Parts of the method are depicted in blue. They are some of the patterns and conditions described in the previous section. Data is collected both from the didactic plan and transversality necessary for the advancement of the data. The method begins by defining the problem and creating a learning contract that allows the teacher to start the process. Once the student work and under a teaching situation, the a-didactic situation comes into play, which should finish with the solution of the problem.

In purple, we highlight didactic variables selection that create the a-didactic situation and break the didactic contract. These educational variables are defined by the teacher based on the objectives of the students obtained in other subjects and also new goals. In both cases, the student level of objectives achievement is taken into account, thus guaranteeing transversality and the fact that students will be able to come up with an overall solution.

For the evaluation, the teacher needs objectives developed by each student and the student group as a whole in order to ensure a quantitative assessment of the objectives developed in the problem statement. At this point the teacher needs to

change the perspective to see entire process. This means that activities performed by the students must be complete and must be exported to the teacher assessment notebook.

The workspace or interaction space for students and teachers is where they perform the work. The workspace must conform to the methodology that the teacher has selected and also have access to resources, this can be achieved with the CSchool Interactive Design tool [17] and use a cloud application environment [18].

VIII. Conclusion

The method of Brousseau, raises the goal that students should learn to solve problems. We use this method for computer courses. A case study was presented in which students develop the problem by introducing variables. Teacher's work in such situations is to guide students through the educational variables and produce iterations in each stage of the process. On the other hand, it is important to set limits to ensure the achievement of the objectives of the course and also control the development of the sessions. Course planning comes from the subject curriculum and, in this case in particular, needs other subjects to achieve the same goals. Currently the problem is the inhibition for students to enroll in certain courses if they have not passed previous more basic courses. This is not a problem with our approach, as there is a possibility that students review the lessons learnt in other subjects. This suggests that future work on this methodology should be directed towards improving students' curriculum and promotes the objectives of subjects from others that require such knowledge. For example, if a student does not have the minimum knowledge to pass the programming databases course, he could be placed in a team with another student who masters this subject, supporting the other student. Activities like this one would need to know what to do with interdisciplinary work between subjects, how to evaluate it and how allow academics the student profile improvement.

***Abstract*—We propose a Global Unification Model of Studies where the subjects, which follow a same educational plan inside of a specific state or country, can be selected by students from any place inside of that state/country. This proposal increases the university's flexibility providing to the students the option of selecting subjects given for teachers of other universities. In addition we promote the unification of studies' plans to facilitate the subjects' selection and to step forward for a future global unification.**

I. Introduction

WE have to take into consideration the current trend to a high education studies globalization to allow students of different places to work in a foreign country without problems derived from their curricula or previous studies. Therefore, a particular student that had done his/her studies in Spain could go to any country of the European Union without to normalize the degree or the titles obtained previously. It facilitates a fluent movement of prepared people inside of the continent. At the same way that frontiers and different kinds of currency made difficult the transactions and emigration, different kinds of studies make that students of separated areas don't have the flexibility and freedom needed to continue promoting a globalization.

To contribute to continue with a studies' globalization, we propose an approach that consists of unifying most of the subjects of a specific degree, which will allow students to choose among different universities the subjects that they think is better for them. In other words, a student will be able to have many subjects of different universities.

At the following sections we are going to explain the content of this approach, where will take into account the current state of the high education studies, the benefits of our proposal and other interesting issues related with it.

II. Current state of higher education

The most common way of doing a high education degree is to study all the subjects proposed by the university's plan for that degree, and doing it assisting to the classes of that specific university. However, the current trend of e-learning is updating the existing model, mixing the face to face classes with online lessons [1][3]. Indeed, some degrees allow students to perform their practices and to read material from their homes through an e-learning platform. In addition, there are diverse kinds of agreements to send students to other countries for studying there, and after that, their passed subjects will be ratified with the local ones in their base university. This program is called Erasmus (European Community Action Scheme for the Mobility of University Students), and as its name says, it consists in generate a mobility environment for students who want to study some of their subjects out of their country to improve their foreign language among other characteristics. It is a beginning of globalization outside of the frontiers, but it still continues being so far to reach what we are talking about.

Therefore, with the introduction of new technologies and the current bandwidth of internet connection we are able to modify our style of doing learning [2]. Thus, everyone can take advantage of the benefits provided by the new models and the new trends.

III. Global Unification Model

The first step to achieve a globalization of higher education contents is to unify the contents into the own country. Once unified inside of a particular country, it is easier to talk about unification outside of it because there are not too many different studies' plans to discuss. Therefore, we are going to start with a local unification to reach a future global unification. However, our main goal is more focused on the students, which will be able to select subjects from many universities to promote the choice freedom and a more flexible learning.

If we take a specific degree from two different places into a specific country like Spain, we can find some changes among them. For this example we are going to take the studies' plan from the University of Castilla-La Mancha and from the University of Barcelona related with the Computer Science degree.

This work was not supported by any organization

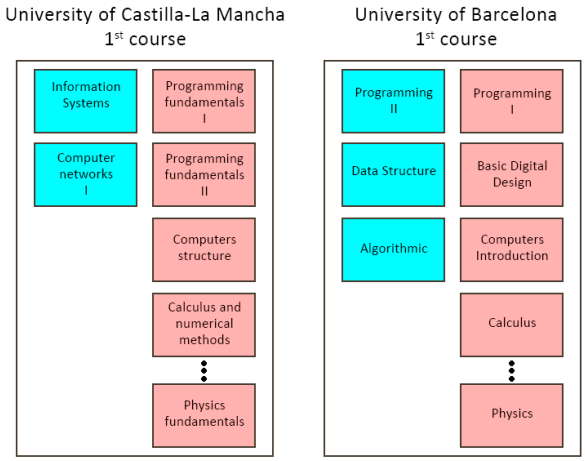

Figure 1. Studies' plan for the first course at the UCLM and UB.

As we can see at the previous figure (Figure 1) there are similar subjects but with different nomenclature. It could confuse students when they want to compare among universities' plans to choose a specific subject. The first approximation to reach the globalization is to unify the subjects, in other words, we have to allow that subjects of different universities but which correspond with the same degree, can be ratified on any university with the same degree. It is the beginning to let the students to choose a specific subject from other university. Therefore, if we get the goal, students will have the freedom to choose in case they want a subject of another university because of the teacher's quality or the methodology followed.

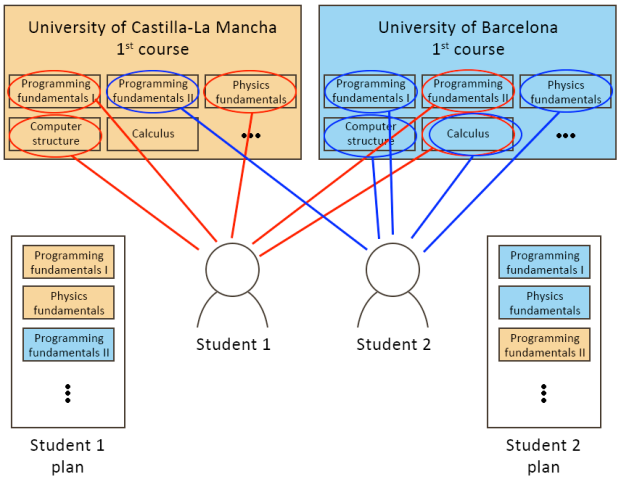

Figure 2. Unification model.

At the figure 2 we can see how two different students (one enrolled in the University of Castilla-La Mancha, and another one enrolled in the University of Barcelona) choose the subjects that they think better for them due to particular circumstances. One aspect to take into consideration is that any student enrolled into a specific university has to select always at least a minimum percentage of subjects of that university, for example the fifty percent. Thus, the student will belong to that university and s/he will be able to take advantage of the benefits promoted by it.

Obviously, each university will have their own specialties, but we are talking about a unification of the bases and main subjects of a specific degree. Thus, the common aspects, which form the degree, will be kept; and each university will propose their own specific areas that make it different [6].

Once we have unified the subjects of a determined country, we can face the challenge of unifying the subjects and plans of the European Union in an easier way. However the scope of this paper is focused firstly on local universities, but in the future we will step forward to reach the European scope [7].

IV. Benefits of the Global Unification Model

The unification of subjects' nomenclature and studies' plans makes easier for students to select them from each university. But the question could be, Why would a student want to choose the same subject from a different university?. Each student has a diverse set of motives that could bring him/her to a determined decision. For example:

- Could happen that a subject is taught by a teacher of another university that explains very well the content.
- Maybe the practices performed in another university are clearer than the practices provided by the current university.
- Due to that more content is explained at the other subject, or in the opposite side, due to that less content is explained at the other subject.
- Maybe the relation with a specific teacher is not as good as a student would want to have and s/he prefers to take the lessons from another person.
- If the student prefer an online learning, it is possible that a subject from another university provides a better experience with that kind of contents.

Previous sentences are related with possible reasons that a determined student could have in mind. However, the student could study the whole set of subjects at the university where s/he is enrolled. This model provides to the students with the possibility of choice, which makes universities' plans more flexible and adaptable to each student [5]. Moreover, depending of the amount of students in a determined subject, it can show that something is happening in relation with that subject. It gives the possibility to the educational institution to pay more attention on it and to find out more about the motives of the lack or excess of students. Therefore, universities can get a lot of conclusions in relation with the enrolments and all the aspects related with them.

This solution is in line with the current trend of emerging technologies and new models of learning related with the online learning [4]. Therefore, it is a modern model that facilitates the access to the university to people that cannot deal with the expenses related with housing or another issues

related with higher studies. In other words, students have the possibility of studying from their homes, saving a big amount of money. Something to take into account is that obviously they have to go sometimes to the university to perform exams or other necessary aspects that cannot be made from home.

The result of promoting the e-learning offers some benefits for both students and university. Some of them:

- A bigger amount of enrollments, due to opening the possibility of studying to more people. It gives more money to the university.
- Less people at class due to the division among offline and online students. It facilitates the personal learning and the university doesn't need big classes to perform the lessons. Fewer students at class allows them to have more attention from the teacher and the labor of teaching is easier for him/her.
- In case of necessity of computers or another type of hardware, with less people the quality of the practices is better because those students have more possibility to use those elements.

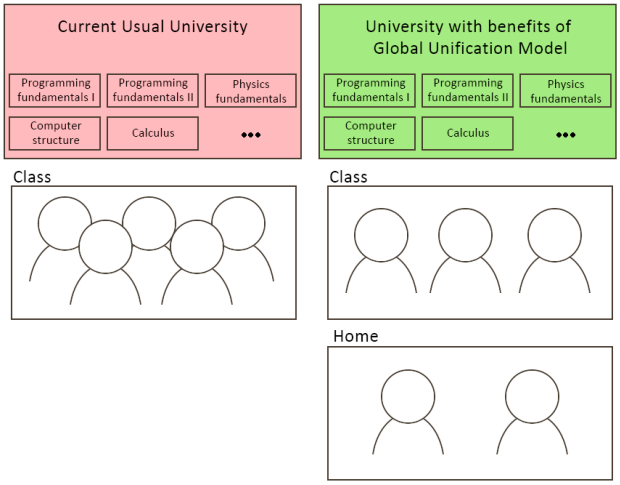

Figure 3. A benefit of the Global Unification Model based on the e-learning.

At the figure 3 we can observe how the density of people at class is lower, which benefits to students and teachers. We also have to take into consideration that each of the students of the university with the Global Unification Model can use his/her right to use the e-learning with his/her own university and obviously it becomes necessary when we talk about the classes of the other university.

However although this model provides some benefits, we have also to take into consideration that teachers have to pay more attention to the online platforms because a part of students use them to make the learning labor. Therefore, they have to get used to the use of these platforms and to the interaction with people outside of the class.

V. Conclusion

Technologies, methodologies and models are evolving to improve the learning; therefore educational institutions have to do the same and don't leave aside this trend. Moreover, the current trend is focused on the globalization and unification of studies plans into the higher education, for that reason we have proposed this model, which pays special attention to improve the flexibility and quality of educational institutions. Students will have more options to choose what they want to study and where they wish to do it. In addition, students that have fewer resources or that don't have the possibility to study in a different place where they live, will be able to make higher studies through internet connection and the e-learning platforms provided by the university. Therefore we are not only globalizing and unifying the subjects and studies' plans, but we are extending the education to the student's home.

In future studies we are going to face the challenge of adapt the model to the European scope. Once unified the model at local scope, the adaptation and unification in a wider environment is easier. However, it will create new issues that have to be faced through negotiations among affected countries inside of the continent. Into these negotiations, the best statistics and results derived from the application of the model proposed will have more weight. Thus, we will have real feedbacks to take into consideration and to improve both the model and the learning methodology.

***Abstract*—Most of today's computer systems, including rapidly emerging embedded ones, rely on an operating system. Consequently, the development of embedded systems and related software often requires a deeper understanding of operating systems. This paper presents a new incrementally built operating system and a learning course formed around it. Each increment builds on the previous one and introduces new system elements, new concepts and solutions, and a new set of assignments for improving or extending operations or simply demonstrating its use. Increments and assignments are designed to extend theoretical and practical knowledge in the operating system domain, give experience with non-trivial software systems and their development tools, familiarize the learner with basic computer hardware components and demonstrate device driver construction. The audience targeted by this operating system and course materials includes advanced students with (basic) knowledge of computer architecture, programming and operating systems. In addition, materials may be used individually as part of a lifelong learning process.**

I. Introduction

EMBEDDED computer systems are ubiquitous and have become increasingly integrated into our environment, thus increasing the need for engineers with appropriate skills. Developing and maintaining such systems involves hardware and software considerations. The software complexity inherent in embedded systems may vary from a simple controlling program running on a small micro-controller to a complex distributed system. Furthermore, complexity and logical correctness are not enough. For embedded systems, software (as well as hardware) must conform to additional requirements, such as deterministic behavior, dependability, security, low power consumption, long term operation and connectivity. To fulfill such requirements, an engineer must have appropriate skills and expertise. Computer science is a fast-developing domain, and it is common for computer science engineers to expand their skills long after getting their degrees, qualifying them for new challenges. Some of the challenges for the embedded system software developer are discussed in the following.

Software development for a new project may start from scratch or may reuse code from existing projects. Some simple systems may be built from scratch in a short period, but to achieve the required functionality in shorter periods, it is usually better to start with existing elements, e.g., a similar system or a collection of components. If there are no similar systems or useful components to reuse, one may start by selecting the operating system and appropriate development tools that will be used as a base. The operating system and development tools might be selected from the available commercial off the shelf tools (COTS), such as μC/OS-II [1], QNX [2], VxWorks [3], or from freely available tools, such as Linux [4] and and FreeRTOS [5]. Possible disadvantages of COTS systems may include price and possible problems with customization because all system details and internal component sources might not be available. The main problem with freely available systems lies in the absence of technical support (except in the form of free community forums). Whether we use COTS, freeware or a custom-built system, at some point of development, customizing the core system is likely to be required. The reason for customization might be a change in system requirements or a hardware change (e.g., a new or changed device, part or system, prior to the existence of official support). When system customization is required, even if we have the complete source code, an operating system (as for the core of any system) is a complex system, and changes are difficult to implement. Deep knowledge of operating systems is required if the desired change is to be made without compromising the existing functionality.

To be a successful embedded system engineer, one must understand computer architecture, have programming skills and have a deeper understanding of operating systems. The basics of those skills are usually acquired through education. Improvement of these skills is possible with practice and experience. While knowledge of computer architecture and programming language skill is usually improved through courses, operating system expertise is harder to attain. Depending on the instructor and the available options, operating system exercises usually concentrate only on using operating system operations through its interface (and improving understanding in this way). Knowledge obtained in this fashion may be adequate for a regular software engineer but is not sufficient for an embedded systems engineer who might be asked to customize some (operating system) core component.

A deeper knowledge of operating systems might be acquired individually, using the literature and resources from the Internet or through special seminars or courses. In this paper, we present the educational system, Benu, whose source code is freely available [6]. Benu was built primarily for

978-83-60810-58-3/$25.00

education on operating systems in embedded and real-time systems (RT), but it is generic enough that it can also be used for education on operating systems in other areas. The source code is accompanied by a textbook (currently only in Croatian), as Benu is used in the course "Operating systems for embedded computers" (OSFEC) [7].

Remainder of this paper is structured as follows. A comparison with similar systems is made in Section II. Section III presents the basic concepts and ideas behind Benu. The main part of the paper details the contents of the Benu increments, which are presented in Section IV. Benu usability is discussed in Section V. Conclusions are presented in Section VI.

II. Related work

Creating an operating system for education is an old idea and has been performed many times in the past because examples are the best educational tools, especially those examples that the teacher is comfortable using. A review of many such systems, often called "instructional operating systems," has already been presented in several papers, e.g., [8] and [9]. A large number of such educational systems indicate the complexity in teaching this subject and the possibility of many different approaches, emphasis on different aspects of operating systems, different abstraction levels, influences of teacher preferences and the number of students in groups and their competences, i.e., their previous education. In this section, we compare only a few instructional operating systems, primarily highlighting features that are important for those systems when comparing them to Benu.

MINIX [10] is a well-known instructional operating system, modeled on UNIX, which was first introduced in the early 1980s and has since evolved to version 3. In addition to educational use, mostly for understanding UNIX system architecture and micro-kernel concepts, MINIX was later developed for systems with minimal resources, embedded systems, and systems requiring high reliability. A classical operating system textbook [11] details MINIX internals, providing its usage for education.

Linux [4] is not built to be an educational tool. However, because it was free from initial release, it has become fairly popular in academia, and it is often used as a base for student assignments in operating system courses. Because of the magnitude of the Linux source code, the assignments are mostly concentrated on utilizing operations that Linux provides, not on modifying its internal coding. Linux is a complete operating system, built to be effective and used on a variety of computers, primarily targeting personal computers, workstations and servers. Therefore, Linux source code, while freely available, in authors view is too vast and complicated to be used as an educational system for begginers. Only highly persistent students can master Linux complexity and use its internals as part of assignments.

The operating system μC/OS-II [1] is a small system, designated for embedded and real-time systems, with very limited hardware resources. It comes with a companion book, and it is free for educational use. μC/OS-II was primarily created for use in real-time systems, but because it is simple, it is also adequate for education, perhaps more for individual use by enthusiasts than in coursework.

Nachos [12] is a system skeleton prepared for student assignments (in C++) that complete some of the Nachos functionalities. Topics covered by Nachos include thread and process management, paging, file systems and network subsystems. Because solutions from previous assignments are used in the next ones, students are highly motivated to do their best in every assignment. Nachos comes with a MIPS processor emulator for the UNIX environment, which somewhat limits its use. Similar ideas used in Nachos are behind PortOS [13]. PortOS runs in an emulated environment, as a process in a Windows operating system. Assignments prepared for PortOS include multithreading, network and file subsystems.

Nachos and PortOS start with threads and are therefore on a higher abstraction level than Benu. In addition, Benu highlights the building process, building tools and advanced features using C. MINIX, and especially Linux, are complete operating systems, made to be used in more than one role, while Benu is built just for education and research. μC/OS-II is specifically designed for embedded and real-time systems and has many mechanisms for low-level system control exposed directly to user programs. For example, a user program may temporarily disable some kernel components, such as interrupts and scheduling. Although a few of such mechanisms can be found in Benu, we do not encourage their usage; we prefer accomplishing all such operations through the kernel.

III. Benu basic concepts

Benu is a collection of increments that uses a step-by-step presentation of the core operating system operations, data structures and algorithms, where each new increment introduces only a few new subjects. Other educational operating systems, while presenting a single topic, still use the complete system, highlighting related elements from it. In Benu, using increments, the student can focus better on only the subjects introduced in that increment, thus simplifying the learning process of an otherwise very complex system. The evolution of operating system components is roughly presented through increments, starting with the basic functionality in one increment and adding extended functionalities as they are needed. In addition to operating system topics, using Benu in education might improve the other skills required for embedded system development. These skills include the advanced use of the C programming language, experience with development and debugging tools and methods, and familiarization with POSIX for real-time and embedded systems.

For education, Benu can be used without supervision, simply progressing through prepared assignments. Better results can be achieved faster if assignments are preceded with some theoretical introduction, e.g., that presented in [7], with topics covered, such as those presented in [14], or any operating system textbook, e.g., [15], [11] or [16]. Source code dissection, assignments and other experiments should follow theoretical

introductions to broaden students' understanding. Every increment in Benu is associated with example assignments. New components, methods or principles are carefully chosen and added such that each new major increment brings the proper number of new elements for ease of understanding. Some concepts that are more radical and complex, such as threads and processes, are introduced in several smaller increments. Changes from one increment to the next can be easily tracked using text or graphical tools, such as Meld [17].

The current version of Benu is prepared for both Intel i386 and ARM platforms. Although the i386 platform is not typical for embedded systems, it has the advantage of providing educators with access to development tools, emulators, computers and documentation. Adding support for other processors is supported by the layered architecture of Benu, with a separate hardware abstraction layer. As a development platform, Linux is selected because all of the required tools, i.e., GNU development tools [18], are freely available and easy to install on Linux. Linux itself may be run as a development platform in an emulated environment, requiring only the emulator to be installed on the host computer (if the host computer is not already Linux-based).

Based on our experience in teaching computer architecture, programming languages and operating system basics as well as using Benu in an advanced operating system course, we observed that using Benu accomplished the following:

- A deeper understanding of the operating system, its components, data structure, operations, algorithms and limitations,
- Improvement of advanced programming skills, which in turn produces shorter, more efficient, extendable and more readable (and thus reusable) code,
- An understanding of the capabilities of developing and debugging tools and computer emulators,
- The ability to build embedded system software from scratch, not relying on any operating system interface, and preparing images to be loaded into systems with variety of memory configurations,
- Expertise with POSIX interfaces for timers, threads and signals for real-time and embedded systems,
- The ability to navigate within and use larger source code projects (written by others), the discovery of usual concepts and practice in source code naming, file structure and management tools, and
- An improvement in the student's problem-solving skills.

We do not claim that Benu is the best choice in the field of embedded operating system education, but it may be among the easiest for beginners. Starting increments are simple and do not require preparation. Students can start early, familiarize themselves with the development environment and be prepared for the more demanding increments that follow.

IV. Contents of increments

Benu is created using basic operating system principles as a base [15], [16] and is modified to better suit the embedded system environment, simplified for educational purposes, and built for incremental topic introduction. Benu contains eight major increments in the source code, which, for the rest of this section, are just "increments" or "chapters". Each chapter has several minor increments, depending on the complexity of the subjects presented in the chapter, as shown in Table I. Details about each chapter, its purpose, the components it presents, and possible assignments, are presented in the following sections.

TABLE I
Major and minor increments in Benu

Major increments – chapters	Minor increments
Chapter_01_Startup	01_Startup
	02_Example_clock
Chapter_02_Source_tree	01_Source_tree
	02_Console
	03_DEBUG
	04_Debugging
Chapter_03_Interrupts	01_Exceptions
	02_PIC

	04_Interrupts
Chapter_04_Timer	01_Time
	02_One_timer
	03_Timers
Chapter_05_Devices	01_Devices
	02_Keyboard
	03_Serial_comm
Chapter_06_Shell	01_Shell
	02_Arguments
	03_Programs
	04_Makepp
Chapter_07_Threads	01_User_threads
	02_Threads
	03_Ext_context
	04_Synchronization
	05_Messages
	06_Signals
	05_Sched2
Chapter_08_Process	01_Syscall
	02_User_mode
	03_Programs_as_module
	04_Programs_as_process
	05_Static_processes
	06_Processes

A. Chapter 01 – Development environment

The goal of Chapter 01 (with related materials from the textbook) is to present the environment used for developing system software, i.e., Benu, which will run on bare-bone hardware (real or emulated). Compiling and running system software requires special steps during the compilation and linking phases, supported with appropriate configurations, and is thus significantly different from compiling and running application programs. Because of this straightforward goal, the code is purposely simple; it just displays the "Hello World" message on the console.

There are only three files in Chapter 01: two with source

code (one in assembly and one in C) and one with shell script used for compiling. The assembly code is small, but it is required for processor initialization (stack pointer and status register). The assembler then transfers control to a function written in C. A single function is placed in a C file, i.e., a function that writes a text string into video memory, thus displaying it on the console. While low-level operations implemented in assembly code and device drivers might be interesting to some, they are not essential for using and understanding Benu and the principles it describes. It is possible to learn most operating system concepts without a knowledge of assembly language or device driver details; therefore, assembly and device drivers are placed into a separate directory (from the next chapter) to isolate them from the other increments and lessons. To compile and link the source codes into an executable and run it, a shell script is used only in this chapter. A shell script better reflects the necessary steps involved and therefore better serves the purpose of this chapter, which is to show how the appropriate tools are used. The script illustrates how to start the compiler and linker and how to create the system image and start emulator, using all necessary flags and parameters. Beginning with the next chapter, Benu uses standard build tools, i.e., `make` with appropriate definitions across `Makefiles`.

The second minor increment of the first chapter demonstrates how very simple systems can be implemented without having an OS in a traditional sense. For that purpose, a simple clock is implemented that uses hardware timers and displays a counter on the screen.

Assignments for the first chapter should include only the preparation of the development environment, e.g., installing the required tools, downloading Benu, and compiling and running it in an emulated environment. The first few assignments should also focus on using a revision control tool, such as Git [19] or Subversion [20].

B. Chapter 02 – Layered structure

The instructional goal of the second chapter is to demonstrate the modular and layered approaches to operating system design. To reduce complexity, systems are often developed modularly, using the "divide and conquer" approach. A single module or component is simpler than an entire system, and it is thus easier to develop and test. Furthermore, modules can be concurrently developed by different programmers, reducing development time.

Operating systems are designed and built in a modular manner; each module is a "subsystem". Typical subsystems include input-output, memory management, thread and process management, network, security and file subsystems.

Operating systems are also layered, and the layers communicate with one another using strictly defined interfaces in a top-to-bottom fashion, i.e., a higher layer uses the services of the immediately lower layer only. One of the purposes of introducing layers is to separate smaller, architecture-dependent code that sits immediately above the hardware, often called the "hardware abstraction layer" (HAL), from the larger architecture-independent code in the layers above. This separation makes it easier to port the operating system across different architectures because only the HAL has to be modified or rewritten. The architecture-independent code consists of several layers, one built upon another. The first layer, called the "kernel", is immediately above the HAL and provides the core operations for system resource management. System resources include hardware components, such as devices, and software components, such as synchronization objects and the task scheduler. The kernel implements fine-grained operations that manipulate system resources and provide an interface for accessing them from the layer above, i.e., the application programming interface (API) layer. The API layer (henceforth referred to as "api") uses the kernel layer to implement any designed interface (e.g., POSIX [21]) for user programs, i.e., the next higher layer. User programs use the "api" to implement operations that are required by the user (which is the highest layer of the operating system).

Benu adheres to the described layered approach with four layers, named after directories where their code is placed: arch (HAL), kernel, api and programs. There is also an additional pseudo-layer, the library layer ("lib"), which captures the utility functions used by the other layers, e.g., string manipulation and list operations. A list of all of the layers as well as their containing directories in Benu is shown in Fig. 1.

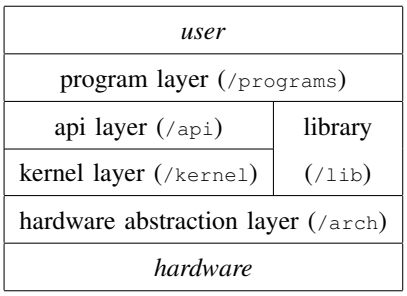

Fig. 1. Layers in Benu

In Chapter 02, the layers contain no functionality: the corresponding directories are mostly empty, and they are just placeholders for the components that will be implemented in subsequent chapters.

Each layer has a clearly defined interface for the higher layers. Fig. 2 shows an interface example introduced in Chapter 04, when the user program uses the `clock_nanosleep` operation. The function `clock_nanosleep` is defined in api as a system call to the kernel function `sys__nanosleep`. The kernel function uses the HAL interface `arch_timer_set` which calls `i8253_set_time_to_counter` from the device driver (via the timer interface function `set_interval`).

```
programs: [api]     clock_nanosleep
kernel:   [kernel]  sys__clock_nanosleep
          [kernel]  ktimer_settime
          [arch]    arch_timer_set
arch:     [arch]    timer->set_interval
          (=>i8253_set_time_to_counter)
```

Fig. 2. Interface chain for operation `clock_nanosleep` (in Chapter 04)

Interfaces that one layer provides for the next one are defined in header files placed in the `include` directory (placed in top level, same as those from Fig. 1).

The naming convention used throughout Benu follows certain prefix rules. Kernel functions that provide the interface to the higher layer (i.e., to api) have the prefix `sys__`; internal kernel functions (i.e., the ones used only within the kernel) are prefixed with `k_` or just `k`; functions that are part of HAL are prefixed with `arch_`; and the device driver's functions are prefixed with a short device name.

Devices and subsystems are used through a predefined interface. Chapter 02 defines the interface for printing characters on the console, i.e., `console_t` (defined in `include/types/io.h`) with the following elements:

```
int (*init)(void *p);
int (*clear)();
int (*gotoxy)(int x, int y);
int (*print)(int attr, char *text);
```

Each structure element is a function that implements a specific operation. The same functionality may be achieved by different devices or components. For example, for simple console display, a graphics card can be used, as in Chapter 02, or a serial port connected to a terminal, as in Chapter 05. Switching from one console to another is accomplished using different objects (variables) that implement the same interface. In Chapter 02, in `kernel/startup.c`, consoles for kernel and user programs are selected using variables `k_stdout` and `u_stdout`, both referencing variable `vga_text`, defined in the device driver file `arch/devices/vga_text.c`.

The same principle for defining an interface is frequently used in Benu, i.e., using the structure with functions and parameters like `console_t`. Interfaces are defined for the interrupt device (Chapter 03), timer devices (Chapter 04), general devices (Chapter 05), and dynamic memory allocators (Chapter 03). Interfaces make separations easier, replacing one device or component with another simpler and source code more readable.

Chapter 02 also presents possibilities for tracing and debugging. Because the system being created uses (emulated) hardware directly, debugging is harder than debugging a traditional program which can be paused and inspected at any moment. One primitive debugging method is to insert print commands in the source code, e.g., with the `printf` operation or with `LOG` and `ASSERT` macros that will be executed only in the `DEBUG` mode. Another method is to use the appropriate tools that enable the developer to stop (and examine) the system while executing, such as the GNU debugger and the QEMU emulator [22], which are used in the demonstration example.

Assignments for Chapter 02 can be focused on layered architecture and on debugging. For example, the assignment can be to divide the console into two parts, one for kernel messages and the other for program output. Implementation through two different `console_t` objects, almost the same as the one provided, will require little coding but will need implementation in nearly all layers. Debugging can be practiced by requesting stops and system inspections at defined points or by discovery of covertly inserted bugs that cause system failures.

C. Chapter 03 – The interrupt subsystem

Interrupts are very important mechanisms, not only for managing devices but also for other purposes, e.g., protection from system calls, thread scheduling (timer interrupts), memory management and program failure detection. The instructional goal of this chapter is the presentation of interrupt handling methods in the operating system. The presented material is, by necessity, simplified and therefore has some limitations, but it also offers space for possible extensions using student assignments.

The primary function of the interrupt subsystem is to provide an interface for connecting the interrupt handler functions (which might be part of other subsystems) with interrupts, i.e., the functions that will be used as interrupt handlers. The interface for registering the interrupt handler function `hnd` with an interrupt identified by number `id` is defined in HAL as follows:

```
arch_register_interrupt_handler(id, hnd);
```

For every source of interrupts identified by an interrupt number, at least one handler function can be defined. When the interrupt occurs, all handlers for that interrupt are called sequentially.

Benu uses an Intel 8259 programmable interrupt controller (PIC) in HAL through the `arch_ic_t` interface, making future replacements with other interrupt controllers (e.g., APIC) easier. Chapter 03 defines the interrupt subsystem but handles only the processor's interrupts because no other device driver is used in Chapter 03. Device drivers are added in ensuing chapters, i.e., the timer in Chapter 04 and the keyboard and UART in Chapter 05.

Registering more interrupt handler functions for a single interrupt number can be accomplished using a static data structure (i.e., an array with predefined size for each interrupt number) or a dynamic data structure, such as a list. A list provides more flexibility and less overall memory consumption, but requires dynamic memory management. Because dynamic memory management will also be required for other subsystems, it is introduced in this increment. Two algorithms for dynamic memory management are presented: the simple "first fit" (FF) method with a "last in, first out" list of free blocks and the more complex "two level segregated first" (TLSF) method [24]. FF is simpler, and, on average, faster than TLSF. However, TLSF provides reduced fragmentation; and more importantly, the execution time complexity of TLSF is $O(1)$, while the worst case for FF is $O(n)$, where n equals the number of free blocks. Therefore, TLSF is a candidate for use in real-time systems.

Student assignments for Chapter 03 include improvements to the interrupt subsystem, such as adding priorities to existing interrupt handlers. Then, when multiple interrupts overlap,

they can be handled according to their priorities. Other assignments can be focused on implementing additional dynamic memory management algorithms, such as "best fit".

D. Chapter 04 – Time management

Most program activities, especially in embedded systems, must be executed in a timely manner. Therefore, the operating system must provide support for time management through a timer subsystem. Most required operations include system time control ("set" and "get" system time), thread execution delays and programmable future actions, i.e., alarms. The operating system also uses time for managing input/output devices, scheduling and maintenance.

The timer subsystem implemented in Benu consists of two components: a lower-level component implemented in HAL and a higher-level component implemented in the kernel. The component implemented in HAL uses an Intel 8253 programmable interrupt timer (PIT) through the `arch_timer_t` interface. The primary operations provided by that interface include keeping system time and a single alarm, which, upon alarm expiration, forwards a call to the kernel. The component implemented in the kernel extends capabilities to multiple alarms available to the kernel and programs and provides operations for program delays.

Assignments for Chapter 04 may include extensions of the timer subsystem. For instance, absolute times can be changed to relative times or the sorted list of alarms may be replaced with some more efficient structure; monotonic clock can be added to the system, a clock that can't be changed with `*set*` interface (as current real-time clock can); a software watchdog timer can be implemented; other more advanced hardware devices than the Intel 8253 can be used to achieve better resolution for time management.

E. Chapter 05 – Device interface

Every device in a computer has its own specifications. To simplify device management, devices are grouped into classes, and an interface is defined for each class. When creating a device driver for a device, the appropriate interface must be implemented. The simplest device driver interface must include functions for sending data to the device and functions for reading data from the device. Such an interface may not be as efficient as a more complicated interface that, for example, uses direct memory access capabilities of the devices, but it is a good starting point for illustrating the integration of device control into an operating system. For that reason, Benu uses a simple interface defined by the structure `device_t` (defined in `include/arch/device.h`) with the following functions:

```
int  (*init)(uint flags, void *parm, device_t *dev);
int  (*destroy)(uint flags, void *parm, (...) );
int  (*send)(void *data, size_t size, (...) );
int  (*recv)(void *data, size_t size, (...) );
void (*irq_handler)(int irq, void *dev);
int  (*callback)(int irq, void *dev);
```

The usage of the `device_t` interface is demonstrated on three devices for which the device driver is prepared within Benu: the display driver (replacing `console_t`), a keyboard driver using the Intel 8042 controller, and a serial port using the 16550 UART device. The interface `device_t` is intended for use only within the kernel. The kernel allows programs to access these interfaces indirectly through `sys__device_*` system calls (`*open`, `*close`, `*read`, and `*write`).

Assignments for this chapter may include introducing the program (thread) blocking state to read/write operations until they are completed on a device. Other assignments include adding device drivers for other devices or improvement to current devices, e.g., adding scroll history capabilities to the console display driver.

F. Chapter 06 – Command shell

The interfaces offered to users on today's computer systems range from graphical interfaces, with buttons or menus, to console-oriented interfaces, such as the command line interface, where the user types commands to be executed. Because Benu only has a text-based console, a command-line interface is implemented and presented. From an educational point of view, the implementation of a command line user interface is useful for two reasons: parsing the command line and sending parameters to programs (as strings, without interpretation).

The second novelty introduced in Chapter 06 is in the compile script (`Makefile`). Every program from the `programs` folder may be independently included in or excluded from compilation. This change further distances the program layer from the kernel, making the kernel (and thus HAL and api) potentially usable for many purposes.

Assignments for this chapter may include improvements to the shell program, e.g., adding history and auto-complete features.

G. Chapter 07 – Thread management

The systems presented in the previous chapters or the systems based on them (e.g., created as assignments) are very simple. Still, they may be sufficient for numerous embedded systems. More complex systems require additional features, such as multithreading and processes. Introducing those features has a strong impact on all of the system components, making the system significantly more complex and larger, and thus it is not recommended if those features are not required by the embedded system.

Multithreading support simplifies complex system implementation. Independent tasks may be run independently as threads, with their own timings and resource requirements that are more easily coded and satisfied at runtime.

Based on our teaching experience, we believe that multithreading programming is one of the most difficult subjects in computer science education. Thinking "in parallel" is required, and any shared resource must be considered and properly protected. Synchronizations via semaphores and monitors have to be carefully designed to achieve desired sequences and avoid deadlocks or simultaneous changes on

any shared resource. Multithreading is increasingly important because modern processors are multicore and manycore and require multithreading for using all of the processing power the processors can provide. Thus, many operating system and programming courses emphasize multithreading with the other subjects.

The multithreading covered in Benu includes both lower-level kernel operations, such as thread creation with resource allocation and context switching, and higher-level operations, such as scheduling, synchronization and communication. A priority scheduler is used with "first in, first out" as the second level scheduling criteria (for threads with equal priority). Semaphore and monitor synchronization mechanisms are included, and communication is provided through messages and signals.

Many assignments can be created for Chapter 07. Threads can be used for kernel operations, e.g., in an interrupt subsystem for processing individual interrupts. Existing thread operations can be improved or extended. Semaphores and monitors may be extended with "try-wait" and "timed-wait" operations or improved with priority inheritance protocols. New synchronization and communication mechanisms could be added, such as barrier, read/write locks and pipes. Program assignments that solve some synchronization problems can also be created.

H. Chapter 08 – Process Management

Programs, especially more complex ones, may have bugs that might compromise the system. In a multitasking environment, there should exist mechanisms that protect the kernel and other tasks from a malfunctioning task. The usual protection mechanisms include processor operation modes and memory protection, both requiring hardware support from the processor. If the system is running in unprivileged processor mode, the thread may not be able to execute instructions that could compromise the entire system. For example, if a thread cannot disable interrupts but must instead use a synchronization function for a critical section, the eventual error that leads to an infinite loop in a critical section will only affect that thread and other threads that use the same critical section object, while the rest of the system will be unaffected. The same reasoning is true with memory separation methods, such as memory protection and virtual memory. If a thread cannot change memory locations outside its defined boundaries, it cannot compromise kernel data or other programs.

Grouping threads that work on the same operation into a single process (i.e., threads that are created within the same instance of a single program) will isolate them from other threads, and vice versa. An error in one thread will usually have only a local effect on threads in the same process. Errors that compromise a shared system resource, like a device, will, however, still be an issue for the entire system.

Chapter 08 brings a further separation of programs and the kernel by introducting the privileged and unprivileged processor modes, forcing software interrupts as mechanisms for calling kernel functions (syscalls). Additionally, memory protection is introduced using segment registers of the Intel 80386 processor family for simple virtual memory implementation. Threads use logical addresses and cannot reach outside the boundaries of their processes. Any attempt to do so will trigger an interrupt, and the thread will be terminated. Compiling programs using logical addresses complicates the building process. Since kernel and programs must be prepared for different locations (physical and logical) they are separated into different objects after compilation. To simplify emulation in those increments GRUB was used as boot loader where program objects can be prepared and loaded as modules.

Assignments for Chapter 08 might be same as those for Chapter 07 because major differences in the chapters are in the implementation of the syscall mechanism via a software interrupt with the address space changing from the user to the kernel, from logical (process) to physical address space. Both changes require special syscall parameter handling, which provides a sufficient challenge to adopt.

V. Using Benu

Even in the last increment (that includes all) there are 56 source code files (.c) and 73 header files (.h) (including the 16 example programs). Furthermore, about half of them are only for layering purposes (parameter checking and forwarding call to lower level function). The combined source code of the kernel, HAL, library and api (all except headers and example programs) have approximately 7,500 lines of code (as counted by the `cloc` program). A system this small cannot have advanced components, such as paging, file systems and networking, which are required in more complex systems. However, some simpler systems, such as the ones used in embedded computers, may use an operating system like Benu because they may not need advanced components at all. Future work on Benu includes developing those advanced components, though in some minimalistic form that has yet to be devised. Otherwise, such complexity will significantly reduce its educational value. The components present in Benu are built on basic principles, avoiding too many complexities that may have better properties. From an educational viewpoint, this approach leaves the basic course straightforward and allows for advanced student assignments and projects.

Although Benu is built on somewhat different ideas than Linux and MINIX, it can be a good prelude to studying them. Because Benu is not a complete operating system, it can provide a simpler example for embedded systems that do not need advanced components. Due to their simplicity, Benu source codes do not have as complex interconnections in their kernel as real systems have (e.g., Linux). Compared to other systems, the components in Benu are easier to change and replace, and new components are easier to integrate and evaluate, thus making Benu also usable in operating system research. For example, current synchronization mechanisms can be changed and extended with other models (e.g., [23]), priority inheritance and priority ceiling protocols can be embedded, deadlock detection can be implemented, thread scheduling can be upgraded, and interrupts can be processed

with threads [24]. As example extensions, "round robin" (RR) and "earliest deadline first" (EDF) schedulers are implemented and presented in Benu.

In addition to Benu source code, a companion textbook is available to students (currently only in Croatian). The textbook is tightly coupled to Benu but includes theoretical explanations of operating system topics, excluding advanced components such as networking and file systems. A quick start with Benu is possible with a basic knowledge of computer architecture and operating systems, and a moderate knowledge and experience in the C programming language. Therefore, a Benu course should best be placed after courses that cover fundamentals. In addition, Benu could be learned as a post-graduate, as part of the lifelong education process. Benu targets students interested in operating system internals and experimentations with it and students interested in software development for embedded computers.

Benu has been used as a teaching tool since the 2009/2010 academic year, when OSFEC was offered as an elective course in master computing science studies. Most students who take this course show much interest, and most of them successfully complete the exams. However, for some students, the assignments and exams are harder to complete. After an analysis, it was found that the students who had problems did not have the recommended prerequisite courses in bachelor studies, especially the courses that exercise C programming skills.

VI. Conclusion

Mastering operating system topics, including theory, implementation details, tools and common practices, can be faster and more interesting for students if a simple system such as Benu is used in teaching and assignments. The uniqueness of Benu among other instructional operating systems is in its incremental build structure, allowing gradual introduction of operating system components. Each increment logically extends the previous one with only a few new elements, which are, consequently, easier to adopt.

An operating system is a complex system, and, even with simplifications, as in Benu, many students may find it difficult to master. However, the majority of students do not need to master all of the components of an operating system. For some, it will be enough to master the kernel layer or even just a specific components, like the interrupt subsystem, timer subsystem and threads. For others, Benu may be just a starting point, one step toward understanding more complete and complex systems.

A quantitative comparison of Benu with other (instructional) operating systems is not performed. To perform such a comparison, we cannot just use the other systems, but we would also need to prepare teaching materials and assignments closely coupled with them, as the current OSFEC materials are coupled to Benu. Nevertheless, based on our experience with Benu, we can conclude that Benu offers a great deal for independent study and exercise and provides a base for faster learning, not only in the operating system domain but also in embedded system software development.

***Abstract*—Student software projects are often focused on training coding skills and on model-driven software system design. The projects rarely develop skills needed for the proper formulation of system visions and requirements specifications. To solve this issue the projects must deal with real-life software projects issues. The projects should solve main commercial aspects of real-life – they must include looking for project topics in practice and there should be possible to communicate and collaborate with future project users. Successful projects should be rewarded (optimally paid) by the users like other commercial products. We discuss here the quite successful experience with a "prototype" implementation of the concept.**

I. Introduction

THE SOFTWARE development is a risky process. The proportions of failed and challenged projects is about 1/4 and 1/2 respectively [1], [2], [3]. It is known that it is due to poor quality of project visions (aims) and project requirements specification. Late stages of software development processes are seldom the source of the issues.

The development issues are besides the management failures caused by underestimation of the complexity of the vision and specification stages.

A detailed analysis of the problem indicates that the development team members are in fact not aware enough of the software engineering aspects of the projects, i.e. that the development of software systems is a technical (engineering) problem. It holds, surprisingly enough, not only for users (project sponsors and project stakeholders inclusive) but also for IT experts taking part in the projects. They all must be aware that a seemingly simple requirement need not be implemented and used due the technical aspect easily.

Our experience from academia as well as form industry shows the reasons for failures and challenges in software projects are often caused by IT experts unable to effectively and properly take part in project vision and requirements specification.

Young people are often excellent in coding. It especially holds for young people active in theoretical disciplines. They know very well that their coding skill is difficult to overcome. This fact is overemphasized. Soft software development skills are difficult to develop. It holds especially for the people trained in hard skills needed for academic or scientific career. They are excellent coders but usually not excellent in design and especially in requirements specification. They are often proud on their intellectual abilities and scorn the users being unable to write and test programs. They underestimate or disregard the importance and the complexity of real-life problems. They are unable to take part in such agile software development processes when they must take users as partners. They even do not admit that they should take part in reqirements specification. They are unable to tune specifications in cooperation with users. We will discuss our experience with student projects aimed to solve the above issues at IT side. The projects were a part of postgradual studies.

The issues can be solved if IT students take part in team projects covering very early stages of software development – marketing, vision formulation, and requirement specification. The students should cooperate with prospective users of the developed systems. It implies that the students project can fail. We know that real-life projects fail frequently.

We will discuss here the structure of student projects we have used to solve the issue and present experience with them.

The paper is structured as follows: First, we discuss the problems discussed above in details. Then we describe two variants of the projects intended to train analytical skills. Finally, we summarize the experiences gained in the projects.

II. The Soft Facts on Project Failures and Challenges

The proportion of failed projects is remarkably stable, the proportion of failed projects remains very high for decades – see the surveys Why Projects Fail [4] or the Chaos Report [3]. The reasons are not solely at project stakeholder and project management side.

Our experience indicates that the issue is a bit more difficult and complex. People involved in software system development, maintenance, and use are not aware enough that software systems are complex technical entities requiring engineering attitudes. All developers, IT experts inclusive, are not ready to apply software engineering knowledge, attitudes and processes. IT experts are then not able to convince users

978-83-60810-58-3/$25.00

and managers that the application of software engineering is necessary and that requirements specification is no straightforward matter.

We must conclude that the project failures are in this sense due to IT experts more frequently than it is presented in project failure analyses. It is quite difficult to change this attitude as developers, especially coders, dislike developing and applying needed skills. Model-driven architecture and related attitudes are helpful partly only.

Our experience with the students' projects indicates that our students like and are able to propose an elegant solving of technical problems. They are often not interested in seemingly boring problems of real life. They, for example, are able to design a very complex SQL statement but they are not aware that a small modification of it could be substantially more usable in real-life projects.

We also experienced that people tending to be managers underestimate the fact that a more detailed technical knowledge could be very useful for them too. It concerns especially the cases when managers make decisions having important technical consequences.

III. Education and Analytical Skills

We can conclude that the education and mastering of soft knowledge and skills necessary for analytical tasks in software development is of growing importance but it does not meet needs. IT students and even some of their teachers do not understand the importance of the issue. They often consider analytical documents to be something like gossips whereas the only valuable thing is a big piece of (good) code. This attitude is supported by the fact that young people are often very good coders.

The poor understanding of the importance of the early stages of software development is the crucial reason of lower quality of analysis oriented student knowledge. The issue is further strengthened by the fact that the needed development skills are not trained enough. It leads to the lack of good project management and to poor results of agile methods of software development.

We discuss here possible ways of solving this issue. The training of necessary social skills is a key issue here. The training can be realized only if the requirements specification and, if possible, the vision and market analysis are trained in students' team projects. The goals of the projects should be the development of small information systems or the development of their autonomous parts.

The projects should be designed so that they meet the needs of real-world people and in collaboration with them, i.e. they should be small commercial projects. The development process should have as much common as possible with standard development of information systems in small software firms – market analysis, business, and technical risks inclusive.

We present below the main principles of the implementation of the above requirements and the experiences with the projects at two Czech universities. We further discuss issues of our attitude to be still solved. The most important problem of the projects is the trend to the fragmentation and extreme specialization of scientific knowledge and of education processes, and a growing gap between hard a soft knowledge of our alumni. They are not trained to be good project managers as recomended, e.g., by Ebert [5].

IV. Information Systems and Professional Knowledge

The basic goal of the postgradual study of IT experts is the education of professsionals being able to propose, develop, maintain, and execute software, usually information systems. The development of such systems are enhanced variants of classical waterfall model [6] consisting of:

1) Analysis done in cooperation of the system developers with future system users: by formulation of visions (answering the question "why?" and outline of the basic requirements) and by requirements specification,
2) design,
3) coding,
4) testing:
   - unit testing,
   - integration testing,
   - function testing,
   - system testing;
5) integration,
6) deployment.

The scheme can be enhanced and modified in various ways, see iterative development (agile development, scrum [7], XP [8]) and incremental development (various SOA methodologies [9], [10], [11] inclusive). The variants of development can be viewed as repeated and integrated waterfalls.

Knowledge and skills needed in the initial stages of software development are often missing. It is known [3], [12] that the user involvement and management issues are crucial for the success of information systems development. The faults in these stages of the development can cause more than 80% costs spent to remove development errors in not failed projects. Almost half of software projects significantly overrun expenses and terms.

The overall losses caused by the errors are significantly higher. For example conceptual errors are the main reason of most project failures. According to [3], [13] it happens to about $1/4$ of projects. These misconceptions usually stay behind poor maintainability of software systems and behind their early or permanent obsolescence [14].

There are yet other snags: The conceptual errors can hiddenly lead to a user discomfort or can even reduce their long-term wellness feeling and even their health. It reduces productivity and worsens social climate in firms. It destroys firm culture and threatens its future.

Coding and testing are usually without substantial issues. The education of the skills needed for coding and testing is therefore successful.

It is the reason for looking for new methodologies and development paradigms like the concept of SOA ecosystem by

OASIS. The stages 1, 2, and partially 5–7 require according [15], [1], [3] and the experience of software developers:

- collaboration of developers with users,
- support by management,
- requirements specifications specific abilities of the involved team,
- etc.

It requires a collection of soft skills and, what is more important, the skills must be trained.

The students should take part in the early development stages of projects designed so that they are "approximations" of real-world projects usually for small to medium enterprises (SME). The knowledge (often even sole information) collected in books need not be sufficient. The needed knowledge should be broad open and flexible to be usable for the specification of user needs.

Some services in SOA can be developed (may be as prototypes) as students projects. It is also possible to use sprint subprojects of SCRUM or XP methodology. It is a crucial proposition as real world projects must be able to bring some real world effects. They should incorporate the vision and even some marketing. It is a very hard task in academia environment. We must cope with the fact that such projects can face real-world risks. The existence of the risks contradicts the concepts and organizational principles of the IT education. It, together with the trends in the academic research, leads to the overspecialization and fragmentation of student knowledge. It further tends to grow contempt of social and generally soft knowledge at the students' side. The study plans must cope with the fact that some of our projects may fail.

V. Basic Requirements on the Real-World-Like Projects

The analysis of the problems of our alumni is strongly restricted by data privacy protection. The data collection requires explicit approval of the students with the data collection and use. Even in the cases when alumni are successfully contacted, that their approval will not cause selective/choice effects. Based on the facts and our experience with students projects there can be made the following conclusions:

The students overestimate the importance coding skills. They are partially right as they are in such skills peerless. One perfect coder (people from the top 5% quantile) can replace some 20–30 average coders ([16], [17]). It leads to some conceit and underestimation of soft and social skills, to unacceptable team attitudes and to some negative aspects of hacking – see the Corncob Antipattern [18].

It is more important that such individuals strengthen the feeling of exclusivity and underestimate the necessity of good relations with users and ability to understand their knowledge and needs. It is not easy to communicate with them what is strengthened by the fact that they underestimate knowledge outside IT. Persuasion that it is neither good nor simple is usually a hopeless task. The only way is to create situation showing explicitly that they are not right.

Let us note that social and organizational skills are getting obsolete significantly slower than the knowledge and skills necessary for coding where within 5 years about one half of them get obsolete. Partial solution of this issue is possible if project aims are properly selected. We have tried two main variants of the projects:

1) Projects having features typical for SME/SMB projects. They train especially the skills of vision setting and requirement specification.
2) Projects solving partial tasks in software development in and for large enterprises. Such projects improve skills necessary for cooperation in such environments and enable understanding the environment and its processes.

VI. Involvement of students in commercial projects of large software vendors

Large vendors, e.g. IBM, have started a close collaboration with some Czech universities. The collaboration is implemented as the engagement of selected students in development teams of the vendors. The students often take part in the development of information system of the commercial partners as assistant analysts.

The students successively take up relevant roles in analysis and negotiation with a vendor client. He/she is induced to use vendor policies, processes, and tools. The students often take also part in design, especially in model building. In the cases when the students prove themselves useful they can be rewarded and have quite often opportunity to become gradually the employees of the firm.

The firms hire in some sense the students. It follows that it is applicable for some students only. The results and experiences with the concept are surprisingly good. The students are often warmly accepted by the enterprise team members. They are pleased to collaborate with the students.

The development of excellence centers supported e.g. by Europe grants enables further enhancement and a broader use of this concept. It simplifies the involvement of start-up firms and open new possibilities for master and dissertation projects.

The main advantage of these forms of studies is the training of analytical and design skills in the real world environment (ecosystem). The main disadvantage is that the students do not come in contact with the formulation of visions (aims) and marketing.

VII. Small to medium business oriented projects

Small-to-medium enterprises (SME) are a frequent domain where our alumni get good jobs. Most of our alumni get job in SME. SME need people having skills enabling to take part in all phases of software life cycle starting with market analysis, looking for a client, vision statement, negotiation, business agreements, and requirements specification.

These skills must be trained. We have trained the necessary skills in projects designed and implemented in the following way:

1) The projects are implemented as team seminary works being an optional part of a postgradual study. There are usually about 20 seminary participants.
2) The participants are required to propose themes of possible projects. The themes should have the potential to be commercially successful. The student must therefore, using their contacts market analysis formulate project proposal containing project name, the specification of possible user(s), and a (abstract of) vision. It must be based on the analysis of a real-word organization (partner).
3) The proposals are presented and defended.
4) The most promising proposals are chosen and the participants form teams having three to seven members.
5) Each team choose tools (e.g. an information system) supporting its work. An open source/free project support systems are preferred. The team members present their professional profiles, CVs and experiences.
6) The project name and abbreviated name is fixed. A project logo is welcome. The visions are refined and included into project home page. Achieved results are presented and defended using data projectors. The presentation should include the testable project effects.
7) The teams develop requirements specifications and system models. The involvement of the partner experts or intended end users is welcome.
   a) The teams can use open source software or free systems.
   b) The integration of the system into the partner ERP is highly appreciated.
   c) The team must do market analysis, especially the detection and study od the properties of similar systems.
8) There are at least two progress reports for each project. They have the form of reviews in the software engineering sense.
9) The final project defense at the end of seminary consists of:
   a) Presentation of the proposed system capabilities in the form understandable for users.
   b) Review of the technical properties a concise description of development processes, prototypes, and models.
   c) Interesting experiences.

The projects cover the software development stages at least up to design. There should be a well-founded hope that the project development could be continued and implemented on commerce basis (payment inclusive).

VIII. Schedule of the Seminary

A. Initial Meeting

- The teacher specifies the aims (vision) of the seminar. He/she shows that the main challenge of software project, especially of the project at SME, is the poor formulation of aims/visions and requirement specification of software project. The challenges are strengthened by the fact that the aims and requirements specifications are seemingly easy to understand and therefore easy. It is not the case but to understand the problem the students must take part in real-life projects needed collaboration with people from practice (future system users).
- A seminary support system specified (offered) rules of seminary students communication are specified in cooperation with the lecturer and the student.
- The overall schedule is specified see the points below.

B. Looking for Project Topics and Possible Business Partners

- Looking for Project Topics and Possible Business Partners
- Parallel activities:
  - Students present themselves, their experience, knowledge, and skills. Aims:
  - training the skills applicable during job seeking and for taking part in seminary project

C. Presentations and Competitive Choice of Project Proposals

- Choice of project leaders. The leaders are usually the students bringing the successful project proposals. They usually serve as project contact people. Involvement of the teacher in the choice is possible but not preferred.
- The leaders choice team members.
- The roles in the teams are tentatively defined.

D. Aims and Main Specifications

The aims and main specifications should be formulated in cooperation with business people – tentative users of the system.

E. Organizational Data

- Project identification;
- Project topic;
- Team structure and team roles – minimal team size is 3, maximal 7 members;
- Project supporting system (open source);
- The chosen development tools;
- Semiformal risk analysis.

F. Initial Outputs of the System Development

- the system full and short names;
- the specification of business partner;
- tentative vision.

G. First Presentation of the Project

First presentation of the projects (after a month) is in the form of a review:

- Presentation of project homepage.
- Main outputs.
- Control of the contents and documents in project support system, especially the team meeting reports, reports from negotiation with partners, and other project reports.

H. Closing Customer-Oriented Presentation

- presentation of project home page;
- presentation of goals/visions and final capabilities;
- possible use of prototypes.

I. Closing Technical Presentation

- Project schedule;
- Derived technical models (diagrams);
- Experience, positive and negative aspects.

J. Final Session

- Evaluation of the projects and students activities;
- Informal evaluation of individual students;
- Common personal $+$ and $-$.

The structure should be accommodated to the expertise of the students. Sometimes happens that there are students being professional software development team or software company leaders. In such cases the other students can take significant advantage of it.

IX. Issues Common for all Team Student Projects

Some students' projects can be done individually but in a team it is possible to collect some additional experience.

A. The Team

The students should build the teams independently. The students should fulfill their other study duties in parallel to the project. The team therefore faces the risk that some team members could be busy with other study duties or that their study can be for other reasons terminated. It can lead to one of the following situations:

- The students can close the ranks and start to help each other also in other (not project related) duties to keep the team at full strength.
- The students start to protect themselves by decomposing the project into relatively autonomous parts (or even by choosing projects that are naturally divided in this way) implementable by individuals. It allows them to show that they fulfilled their partial duties. Sometimes the finished components could provide at least basic functionality of the desired system.

We succeeded in some projects to set up the policy that every team member got assigned some development labor (preferably several tasks) in both primary and secondary role in pair programming. The role of a buddy (secondary developer in the pair) means that the person is informed what the primary developer does and why it does and that it could be asked to consult some issues or even to help. Such teams were quite reliable even when a team member was for some (even longer) time out of service (due other school duties or an illness).

A creation of such pairs requires some minimal tolerance and mental compatibility of the involved people. It is moreover advantageous, is a person has different shadows for his/her different tasks or if it plays a shadow of someone else than he/she is shadowed. If someone get into troubles, the shadow could take his/her work over and can delegate some of the shadow's work to his/her own shadows. The load for individual people than could grow by a part only what gives better chance that the person will be able to finish the work without induced troubles.

It has also approved itself if the project has been designed to change its extent (it is, there was a kernel that must be finished and multiple extensions that were optional – developed when nothing bad happened). Such projects could be finished successfully, reliably, and without fatal rushing.

Creation of a good team and tuning the extent of the project is a nontrivial task. It shows that it could take even several weaks yet before the project officially starts.

Side Effects

Working on a project may bring further benefits for the students:

- a deeper familiarization with the topic handled by the project;
- mastering tools for team work;
- act and negotiate with people (it is necessary to get on with other team members as potential team break could usually harm all its members);
- often also the discovery that a teacher can be true even if the student is thinking that he/she know it better (and then it shows that the hint given by the teacher and rejected by the student(s) could save a lot of work and avoid a lot of troubles).

B. Experience with the Projects

We practiced "real-life" student projects for eleven years at two Czech universities in two different cities (Prague and Brno). There were 4–6 projects a year at each university. There were interesting trends. The students in Prague tended to prefer coding. It caused the falling interest of the students in taking part in the projects. There are no active projects of this type in Prague now. There are less visible reasons for it. For example, a limited number of small enterprises developing information systems in Prague and a strong preference of theoretical computer science. Last but not least, it is possible to finish the study in other study branches with less effort and risk.

The trend in Brno has been towards a broad use of free or open software systems (project management tools, modeling tools, documentation tools) used to support the vision, requirements specification, and the team organization. It substantially enhanced the quality of the project processes. There were no project failures provided that their initial defences were successful. The reason was that the project vision must be successfully defended at the beginning of the project. An unsuccessful defense implied an immediate project cancellation. It was rather an exception.

The best projects in Brno were further positively influenced by the following aspects:

- There are many medium-sized firms in Brno employing the students.

- Some students have their own firms.
- There is a well-working collaboration of big firms (e.g. IBM) with Brno universities.
- SOA and Scrum methodologies can provide enough small-to-medium real-life projects.
- Some projects (usually 1–2 a year) were not only accepted and partly paid by the software firms but they were enhanced, commercially finished, and used for several years.

C. Students Projects and Curricula

The students' projects introduce many issues. They are of organizational, financial, and juridical nature. Let us mention some of them:

- Inclusion of project supervision into teachers load (good project supervision takes significantly more time than what corresponds to assigned/scheduled hours).
- Taking time complexity of the project into curricula design (to avoid time coexistence of critical parts of the project with other crucial study duties).
- Maintenance of successful projects. Good projects should be continued after the project evaluation. The issue here is that the evaluation is long term and laborious and the students that developed the application or system have also other study duties. It can also happen that they leave the university. Such projects could be used to train maintenance. There is a risk that an improper maintenance could break the well-working system.
- Turning the project into its commercial phase (in the case of its success) – requires having a procedure making from study result a commercial project (it includes transfer of the rights between the university and the company that will care about the project further). Some universities have this procedure stable and simple, for other universities it is a very hard (if not impossible) task.
- Not every teacher/lecturer is able to properly supervise students projects. It is necessary to find them and to prepare them. It requires some skills and experience that not every professor must have.

X. Conclusions

Majority of our student projects were quite successful. Their participants were as a rule able to find viable topics, contact people from firms, form student teams, find and apply team work supporting software, develop needed diagrams, and present the results. Some projects led to successful commercial products. It was probably partly due to the fact, that almost all the students were part-time employees of software firms. As a valuable byproduct the students discussed their experiences from the firms where they were employed.

The main contribution of the seminaries is a better understanding of the importance of a proper combination of soft and hard knowledge by all students, not only by the ones taking part at the seminaries. The information is spred spontaneously via social networks It is appreciated ex post by our alumni being in practice for several years.

Our seminary model has been successfully applied at Faculty of Informatics, Masaryk University Brno and partly at Faculty Mathematics and Physics, Charles University Prague.

We can conclude that the seminaries described above were successful. The weak point is that their concept is difficult to be applied massively. An implicit precondition of project success is that some of the seminary participants are quite excellent programmers and that some of the students have moreover a broader knowledge and social skills. It follows that they were good in technical abilities and STEM (science, technology, engineering, and mathematics) knowledge. It is a challenge as the STEM education becomes less popular and often not properly taught. It moreover can negatively influence soft knowledge needed in the project as it must take into account some aspects of STEM knowledge. The deteriation of STEM education is a threat for the quality of coding and for the education of coders. They moreover tend not to work together with users and to use user-oriented knowledge domain.

XI. Future research

The present curricula induce the fragmentation of education processes. It is then very difficult to organize long lasting student projects as well as scientific projects. There is a stronger challenge. Current principles of evaluation of universities and their professors based on impact factors prefer very strong specialization of research, narrow knowledge areas, and short term projects. It handicaps multidomain knowledge and skills needed in system analysis and requirements specification.

It is opened how to combine the training of technical skills needed for SME with the training of the skills for large software vendors. It main issue is the difference in enterprise culture, resources, and needs. It follows tthat many aspects of our projects must still be tuned. The idea is, however, crucial as otherwise there were be lack of good project managers having economic, social, as well as technical knowledge and skills. There is a danger that otherwise our alumni will become laborers (line workers) at Scrum-based duplicate production.

We intend to develop methods for development of quite complex systems using multiple student projects. We believe that it is possible if a specific SOA architecture [11], [19] is used. We intent to use open source and free software and combine it with commercial commodity software offered by large software vendors (e.g. Microsoft Excel, Microsoft PowerPoint, or OpenOffice Calc). We will attempt to apply the experience of small Czech software firms here.

Abstract—The present paper describes the strategies used to compile and teach an Informatics course developed during last years at Tallinn University of Technology. The strategy is based on the main principles of blended learning and the analysis of the results of experiments with students from different faculties. Various tests were carried out to identify students' levels of knowledge and preferences in their learning process based on their learning styles. Throughout the experiment, students were divided into groups according to the test outcomes. Separate groups were formed of students with different levels of knowledge and learning styles, determined using the Felder-Silverman model.

Adaptive learning tools were provided for the students considering the three main aspects: students' background, the level of their prior knowledge and their preferred learning style. The success of the strategy presented in this article is demonstrated by comparing the achievements of the test group with the reference group, who were not taught using the new strategies.

I. Introduction

E-learning is a rapidly developing world-wide system. Currently, it is not possible to imagine any educational process without e-components or a holistic e-learning system. The main aim of such systems is to provide knowledge in a convenient form for its consumer – the learner. Abundance of information does not guarantee perfect knowledge. Teaching materials should be carefully structured to cater for the needs and preferences of the students.

All present-day knowledge in engineering education is changing so fast that we cannot predict what the 21th century students will need to know tomorrow. Instead, we should be helping them to develop learning skills and strategies so that they will be able to learn whatever they need to. A combined set of knowledge, skills and attitudes is essential to strengthen productivity, entrepreneurship and excellence in an environment which is based on technologically complex and sustainable products, processes and systems. Similarly, we could improve the quality and nature of engineering education. Thus the objective of engineering education today is to educate students who are ready to engineer, and deeply knowledgeable about technical fundamentals.

Computer science is an integral part of the curriculum, which contents change fast. The general aim of this course is to develop logical, analytical and computational thinking by using the computer on the highest level.

Considering the target audience, several attempts were made to design the course material in the way that it would be easy to understand but would still achieve the goals. Nevertheless, the course seemed to be rather difficult for most of the students. It resulted in low examination grades and lack of motivation.

It became clear that more adaptive learning tools and taking into account individual properties of each student would motivate them and, as a result, would lead to better academic achievements. The question remained how to achieve as much individualization of teaching as possible, using the existing time and personnel resources.

II. A Brief Description Of The Course

The Informatics course belongs to the curriculum of the Institute of Informatics at Tallinn University of Technology. The aim of the course, designed for the first year non-IT students, is creation of applications by using standard PC equipment and developing object-oriented computational thinking. The learning process starts with processing information using Excel spreadsheets: formulas, diagrams, built-in functions and facilities. The set of practical assignments depends on the students' specialization: economics, social, chemistry and civil engineering.

Further, students learn the basics of programming in practice and the main principles of algorithmization. Python for technical disciplines and Visual Basic for Application (VBA) for humanitarians have been picked out as the programming languages for the second part of this course.

It should be noted that the programming part of the course was complicated for most of the students, especially for the humanitarians. This issue was solved by implementing Scratch in the course curriculum. This intuitive graphical

978-83-60810-58-3/$25.00

programming language helps students to take on board the main ideas such as brunching and cycle.

The Informatics course lasts for two semesters. During this period, we try to combine different styles of teaching and learning: classic face-to-face classroom methods, group work and learning in the Moodle e-environment [9]. The last one gives us a huge amount of different opportunities for individualizing the learning process, such as adjustment of the learning pace, for example, as well as increase and variety in the number of learning assignments. Furthermore, students get a diversity of ways to learn and possibilities for self-tests in the e-part of the course. During the study time, they can choose between different kinds of teaching materials and use what they prefer based on their knowledge and learning styles.

The course is taught in three languages: Estonian, English and Russian.

III. Research Methodology

A. Overview

It is generally known that it is not possible to provide all students with one-to-one tutoring at a university. However, this fact should not affect the main educational goal - to ensure high-quality competitive knowledge. In our experiments with course design and curriculum, we considered the differences in students' features, especially their learning styles and prior knowledge.

Since the 2010 fall semester, our group of lecturers has applied a new flexible and adaptive approach to designing computer science e-courses [8]. The basic idea of our methodology is to divide students into equal reference and test groups and to compare the results of these two groups. The reference group is taught using the same course materials and the same e-course but they were not helped with any additional system. The students of the test group, however, were directed in choosing their learning materials based on the data obtained through the tests.

The division into groups was random and was not linked to the students' specialization or knowledge. During the 4 years of the experiment, the group sizes varied depending on the number of students. An average number of participants in the experiment each year was about 100-150 students and they were not aware of the research.

To evaluate the students' progress we tested them at the beginning of the course and at the end of it. The test contents for both groups were similar and were based on the topics described in the European Computer Driving License (ECDL) [1]. The tasks focused on creating documents and presentations, processing spreadsheets, and elementary knowledge in programming.

The last category of the tasks was added recently. In this implementation, we proceeded from an elective course 'Basics of Application Development and Programming', which has been included in the curriculum of Estonian secondary schools.

The current situation of teaching computer science at schools is varied. Some schools do not have computer science lessons at all due to the lack of teachers. Unfortunately, most of those pupils who have obtained sufficient IT-knowledge at their schools are not non-IT students at university level, who our course is aimed at and designed.

B. Research stages

Theoretically, it is possible to name three main strategies in the process of improving the Informatics course and individualization of the learning process:

- e-course
- knowledge
- learning style.

The first stage, which was named 'e-course', includes the adaptation of the course materials for the e-environment. Theoretical materials and practical assignments were innovated and supported with videos [6] and self-tests. They made the Informatics course more attractive for students. Both groups, the test and the reference group got access to this renewed course. At the same time, face-to-face lessons were held, too. Here we preferred group work that gave the students an opportunity to try the obtained knowledge in practice and develop teamwork skills. In this case the role of the lecturer was slightly different – it became more of an advisor, motivator and supporter in the student's work with learning materials. During the contact lessons learners ask questions related to their homework and share their skills and experience with other. In addition, students have an opportunity to get the support not only from their teacher but from other students, too. This form of support is equally useful both for the students who get it and, especially, for the ones who give it. To find and correct a mistake is an important skill in computer science subjects.

It makes no sense now to enumerate all the advantages of e-learning – they have been known to all. At this stage, we got the first results of our work: positive feedback from students and increase in academic achievements. These results were extracted from the Studies Information System (ÕIS) – an e-environment, where students and teachers get information about courses and curricula, students declare courses, keep results and give anonymous feedback on their educational process [11].

The second stage, titled 'knowledge', is dedicated to the division of the test group students into three streams based on their subject knowledge at the beginning of the course. Those three groups receive different amounts of different level practical tasks in the Moodle e-environment (Fig. 1). So, we increased the number of practical tasks without increasing the subject hours.

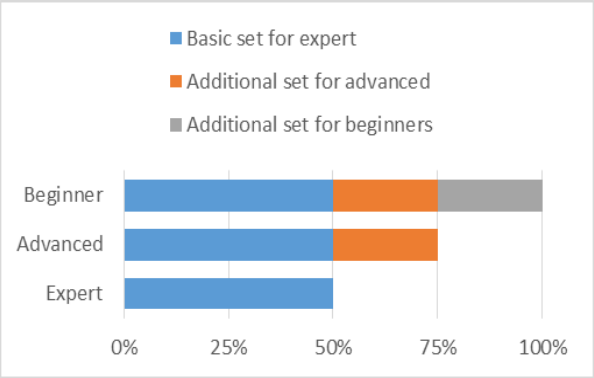

Fig. 1 The distribution of practical tasks

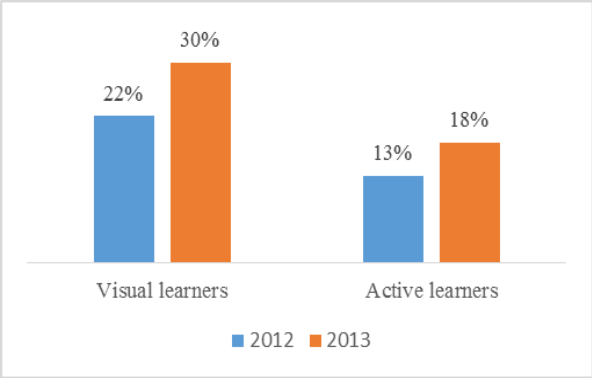

Fig. 2 Increase in the number of visual and active learners

The face-to-face lessons were held as before. The mentioned division provided us with important information about what the students knew before studying our course. Moreover, according to the data we were able to provide them with the necessary learning material.

The success of this stage of experiment was confirmed by positive results of the students' survey in the ÕIS and by the increase in academic results.

The 'learning style' phase of our experiment was the most laborious part. Learning styles are characteristic cognitive, affective, and psychological behaviours that serve as relatively stable indicators of how learners perceive, interact with, and respond to the learning environment. Students learn best when instruction and learning context match their learning style.

There are many studies about the individualization of learning depending on students' ability [7], [3]. Using one of these, the learning styles model of Felder-Silverman, we divided our test group students by their preferences and provided them with corresponding learning materials [3], [4].

Felder distinguishes the following groups of learners depending on their learning styles [2]:

- active and reflective
- sensing and intuitive
- visual and verbal
- sequential and global.

Through this division, we found that the majority of our students were active and visual learners and they had very strong preferences for their learning process. These preferences were detected according to the Felder test which was held at the beginning of the course [10]. Throughout the educational process, students were provided with the necessary learning materials and activities in accordance with Felder´s instructions [5]. For example, active learners received more group work and opportunities to help others; visual learners were provided with visual representation of the educational material.

It should be noted that each year the number of active and especially visual students increased (Fig.2).

The results of this stage of research showed us that the test group students managed with their practical tasks better than the students of the reference group. This has led to the better academic progress of the test group students.

Thus, we were able to create a model of our students´ learning preferences (Fig. 3), which considers their level of knowledge and preferences in the learning process. Using this model, we try to find an individual approach to each student in our course.

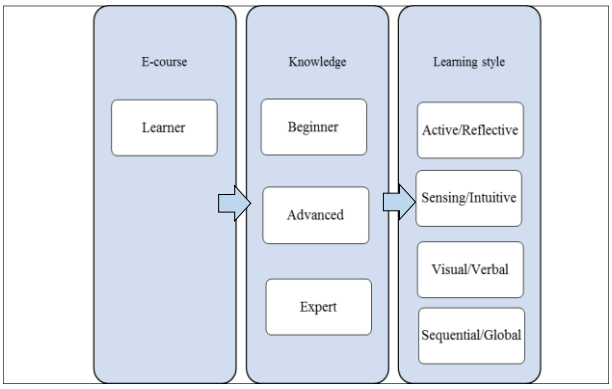

Fig. 3 The model of students' learning preferences

C. The Method of Research

Throughout the experiment, positive students feedback and good exam results showed the positive effect of the course and curriculum modifications. Finally, it was decided to examine the data with statistical methods. The aim of this examination is to check and prove the correctness of the chosen approach to an educational process.

As the method of the hypothesis testing, we chose the Student's t-test for the comparison of the two means. This test assumes a normal distribution of samples and not significant differences between the standard deviations of either samples. Our aim is to show that there were no significant differences between the test and reference group students in September, while in January the results are significantly different.

For calculations we use the equations for the averages $\bar{x}$ (1) and corresponding standard deviation S for both groups (2):

$$\bar{x} = \frac{\sum_{i=1}^{n} x_i}{n} \quad (1)$$

$$S = \sqrt{\frac{\sum_{i=1}^{n} \left(\bar{x} - x_i\right)^2}{n-1}} \quad (2)$$

After that, we calculated the standard error σ using the equation 3.

$$\sigma = \sqrt{\frac{\sum_{i=1}^{n} \left(\bar{x}_{Test} - x_{iTest}\right)^2 + \sum_{i=1}^{n} \left(\bar{x}_{Ref} - x_{iRef}\right)^2}{n \cdot (n-1)}} \quad (3)$$

Finally, using equation 4 we calculated the experimental value t_{exp}:

$$t_{exp} = \frac{\left|\bar{x}_{Test} - \bar{x}_{Ref}\right|}{\sigma} \quad (4)$$

In addition, to compare this value with theory we need to calculate the degree of freedom df using equation 5:

$$df = 2n - 2 \quad (5)$$

As initial data for calculations, we chose September 2013 students' test results of the test and reference groups, and the same groups' results in January 2014 (cf. Table I in the Appendix).

Both samples are in the equal size: n=89 and distributed normally (Fig. 4 and Fig. 5).

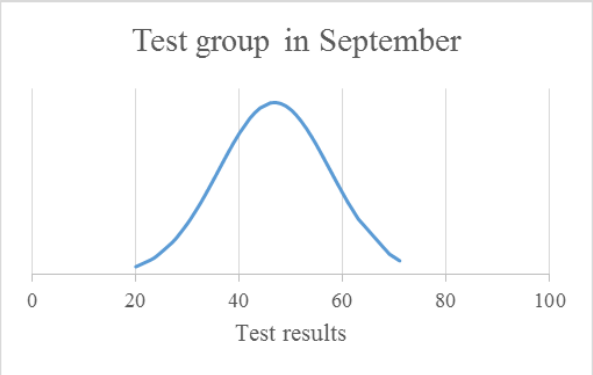

Fig. 4 The distribution of the test group results

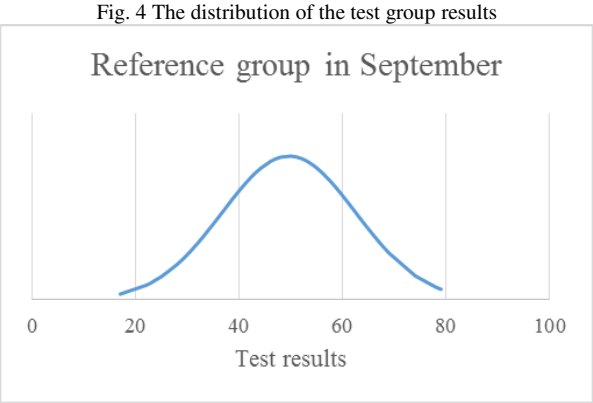

Fig. 5 The distribution of the reference group results

The two means and the corresponding standard deviations are calculated by using the equations 1 and 2:

$$\bar{x}_{Test} = \frac{4164}{89} \approx 46{,}787$$

$$\bar{x}_{Reference} = \frac{4413}{89} \approx 49{,}584$$

$$S_{Test} = \sqrt{\frac{10222{,}94}{89-1}} \approx 10{,}778$$

$$S_{Reference} = \sqrt{\frac{14721{,}62}{89-1}} \approx 12{,}934$$

Now we see that there is no significant difference between the standard deviations in either groups. It means that we can continue with Student tests.

The standard error of the difference between the two means is calculated by using equation 3:

$$\sigma = \sqrt{\frac{10222{,}94 + 14721{,}62}{89 \cdot (89-1)}} \approx 1{,}785$$

Experimental t value is calculated using equation 4:

$$t_{expSept} = \frac{\left|46{,}787 - 49{,}584\right|}{1{,}785} \approx 1{,}567$$

To compare this value with the theoretical t_{th} we need to calculate the degree of freedom using equation 5:

$$df = 2 \cdot 89 - 2 = 176$$

Using equations 1 to 4 we then calculated both groups´ results in January 2014:

$$\bar{x}_{Test} = \frac{8029}{89} \approx 90{,}213$$

$$\bar{x}_{Reference} = \frac{6896}{89} \approx 77{,}443$$

$$S_{Test} = \sqrt{\frac{5092{,}94}{89-1}} \approx 7{,}608$$

$$S_{Reference} = \sqrt{\frac{12518{,}22}{89-1}} \approx 11{,}927$$

$$\sigma = \sqrt{\frac{5092{,}94 + 12518{,}22}{89 \cdot (89-1)}} \approx 1{,}499$$

$$t_{expJan} = \frac{\left|90{,}213 - 77{,}443\right|}{1{,}499} \approx 8{,}489$$

D. Results of the experiment

Using the table of theoretical t_{th} values with the corresponding degree of freedom (cf. Table II in the Appendix) we found that the means of September results are not different at any critical level:

$$t_{expSept} < t_{th}$$

$$1{,}567 < 1{,}65$$

This means that at the beginning of the course both groups of students, the test and reference, had the same level of knowledge.

January results are the opposite – the means are different at critical levels.

$$t_{expJan} > t_{th}$$

$$8{,}489 > 3{,}29$$

It shows that the students who were taught using our system of the learning process individualization obtained knowledge much better then the others.

The progress of both groups is shown in the Figure 6 and Figure 7:

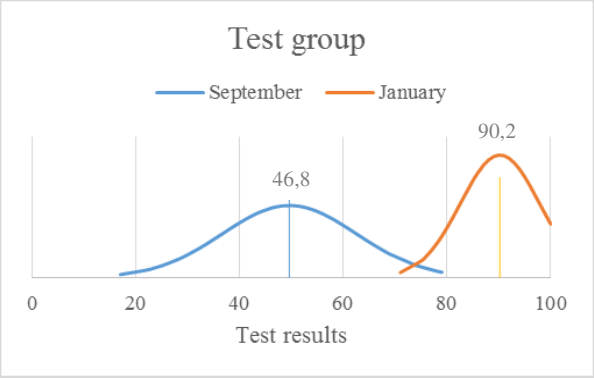

Fig. 6 The test group progress

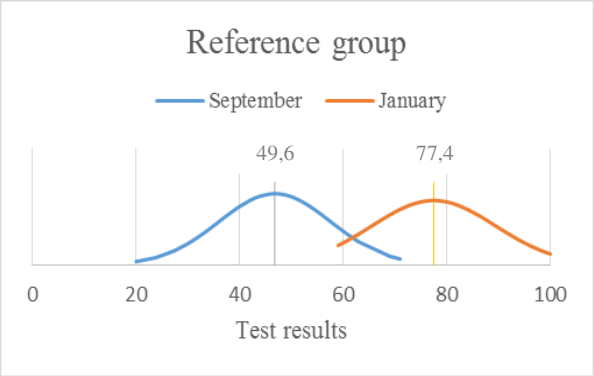

Fig. 7 The reference group progress

These results confirm the validity of our study and the chosen method of course individualization.

IV. Conclusions

The analysis presented in the paper shows positive outcomes of the strategy used. The calculations with two relevant groups, the test and reference, demonstrate significant differences in achievements at the end of the first part of the course.

The feedback, received from the groups, is also different. The test group shows higher motivation for further learning compared to the reference group. The main reason for it, picked out by students, was that there were no unreachable targets in the educational process.

Classroom activities of teachers and students took place in mutual communication. Therefore, the guidance and the formative role of the teacher was realized in the creation and review of the theoretical material and the material in practical classes.

The authors intend to continue developing the created model and Informatics course in the same style, trying to adapt it to individual students as much as possible.

Appendix

The results of each group are arranged in two columns under the name of the group in the Table I.

Table II shows only a part of the table of theoretical t values for Student's test. The whole table could be found in any book on statistical analysis.

Situational Software Engineering
Complex Adaptive Responses of Software Development Teams

***Abstract*— The Complex Adaptive Situational Model (CASM) promotes understanding of establishing conditions which enable software engineering success. Influenced by complexity science, CASM explains aspects of the state of dynamic equilibrium that is achieved under constraining influence of management and production governance. Four states of dynamic equilibrium are defined: Crafted Quality (Agile), Controlled Quality (waterfall), Managed Costs (WetAgile) and Self-Directed Quality. A band of software engineering feasibility is also described and it is suggested that successful software engineering initiatives require teams to operate in that band. The journey across the band of feasibility is explained by introducing SEMAT, with Crafted Quality amounting to applying SEMAT Essence, and Controlled Quality being achieved by introducing additional practices which satisfy the more stringent governance requirements. An enterprise is then described as a collection of CAS's, thereby setting the scene for further research into the complexities of human-driven complex adaptive systems.**

I. Introduction

FOR many practitioners, Agile software development seems the best way to develop software. But old-style management often presents the biggest obstacle to successful adoption of agile approaches. The model described in this paper promotes understanding of what it takes to establish conditions which enable software engineering success, not only with agile approaches, but also traditional, plan-driven software engineering.

Humans easily relate to causal determinism – a thesis based on experience that future events (combined with the laws of nature) are sometimes the result of past and present events. For example, causal determination enables us to catch a ball by predicting in which direction it is going. Causality also enables software developers to design, plan, and predict what software will do.

Immanuel Kant (1724-1804) promoted universal causal determinism. But causality is not enough. We can't accurately predict the weather. We can't predict the full combination of features, qualities, time and resources of a software project. As explained by Jurgen Appelo: *Predictability has a devious sister called complexity* [1].

II. Complexity

Our attempts at understanding complexity involve: Dynamical systems theory; Chaos theory; Network theory; Game theory and other branches of science that are collectively known as the Complexity Sciences. Causality ruled the sciences from the 17th century. Complexity is a product of the 20th century. Complexity theory offers a new way of understanding the problem of producing software and managing organizations - even though our minds prefer causality over complexity.

The human brain is wired to find purpose and causality in everything and we favor "linear thinking" to "nonlinear thinking". So we easily reason that the global financial crisis was caused by bankers. Bad atmosphere at work is caused by the manager. The team didn't make a deadline because of someone's mistake.

The mental addiction to causal determinism has led people to use control to ensure desired outcomes. Engineers and other people with technical minds are particularly susceptible to the concept of control. Engineers developed scientific management - the command-and-control style of management. Engineers devised the kind of control systems we still find today which work adequately with repetitive tasks that don't require serious thought and analysis. But these control systems don't work with creative product development.

Managers also look for causes that would produce the outcomes exactly as they need them: through careful up-front design, with meticulous top-down planning. Appelo explains that agile management derives when hierarchical management embraces complexity and non-linear thinking and is a logical companion to Agile software development [2].

III. Challenges of Software Engineering

The software development industry started in an ad hoc way with the term "software engineering" first appearing in the 1968 NATO Software Engineering Conference where

This work was not supported by any organization

attention was given to the perceived "software crisis" of the time which resulted from the impact of rapid increases in computer power and the complexity of the problems that could be tackled. In essence, it referred (and still refers) to the difficulty of writing correct, understandable, and verifiable computer programs. The roots of the software crisis have been recognized as being complexity, expectations, and change. All too often formal approaches introduced bureaucracy and delivered software much more slowly than the rate at which requirements were changing. At the same time, some teams of passionate and disciplined programmers, with ad hoc processes and flexible requirements, delivered products of higher quality at a fraction of the cost and in a fraction of the time.

The dilemma created by the constantly high rate of software project failure in the midst of a multitude of alternative ways of working, triggered the search for general theories of software engineering that could achieve recognition equivalent to that of, for example, Maxwell's equations in the electrical engineering community [3]. But where Maxwell's equations deal with translating natural phenomena into usable practice, software engineering is all about people applying process and technology to translate their ideas into operational solutions. This translation is enabled by design which, according to John Gero and quoted by Kruchten [4], is a goal-oriented, constrained, decision-making, exploration and learning activity which operates within a context that depends on the designer's perception of the context. In the same article Kruchten explains that he had to extend the boundary of "software design" to include much more than software practitioners' traditional activities as defined in the Software Engineering Body of Knowledge (SWEBOK). In SWEBOK, software design covers only a narrow set of processes and artifacts [5]. But if we accept that design is making choices that will shape the final product, we must include some requirements activities and all coding and testing activities. The significance of this statement is that, contrary to most other engineering disciplines, the design process remains active throughout – virtually up until the very moment that source software is translated into executable machine language. And people drive the design process. As is described later in this article, people are the active agents in a complex adaptive system (CAS) and CAS agents respond to governance forces while applying rules.

An early case study that deals with the tension between approaches is described in Dee Hock's fascinating book *"Birth of the Chaordic Age"* (1999). He describes how, in the 1960's, a management team responded to their concerns when the traditional approach to system delivery was failing. *The team took ownership of the challenge and we shut ourselves in a room and didn't come out until we had an approach to which we were totally committed*. He also confirms that: *out of initial failure grew a magnificent success* [6].

In 2001 a gathering held in Utah resulted in formulation of the "Agile Manifesto" [7] which was, on the one hand, a reaction against the bureaucracy of the formal approaches, while on the other hand, also taking a stand against the "chaotic" processes and low quality products of undisciplined programmers. It gave substance to the search for a middle road between structure and non-structure, between order and chaos.

Evidence demonstrates that Agile software development, when done well, shows a tremendous return on investment. But if Agile methods have such positive effects, why doesn't everyone use them? And why are so many software projects across the world still failing? Appelo refers to a "State of Agile Development Survey 2009" [8] which identified the following factors as contributing to failed Agile approaches:

- Management opposed to change
- Loss of management control
- Lack of engineering discipline
- Team opposed to change
- Quality of engineering talent
- Organizational need for planning, predictability and documentation

This seems to suggest that management preferences are the biggest obstacles to Agile software development. The CASM model described in this article sheds further light on this contention.

In 2009 a group of leading international software engineering personalities started collaborating on an initiative to "re-found" software engineering. Ivar Jacobson (Use Cases, UML, RUP), Bertrand Meyer (Design-by-Contract and the OO Language Eiffel) and Richard Soley (CEO of the Object Management Group (OMG)) established the SEMAT Initiative - Software Engineering Method and Theory. Supporters of the initiative signed a declaration somewhat reminiscent of the Agile Manifesto and since then a great deal of work has been carried out aimed at defining the "kernel of widely-agreed elements" and often referred to as "Essence", meaning the essence of software engineering.

Figure 1 highlights two important aspects of the SEMAT kernel:

- The Areas of Concern (Customer, Solution and Endeavor) and
- The Alphas (Opportunity, Stakeholder, Requirements, Software System, Team, Work and Way of Working)

Areas of concern are addressed in terms of Activity Spaces which involve the actions taken to achieve objectives.

Alphas represent essential aspects of software engineering and each progresses through a number of states (Alpha States) as the team conducts work.

As described in the submission to the OMG [9] and in the published book *"The Essence of Software Engineering: Applying the SEMAT Kernel"* (2013) [10], the SEMAT initiative promises to fundamentally affect the discipline of software engineering.

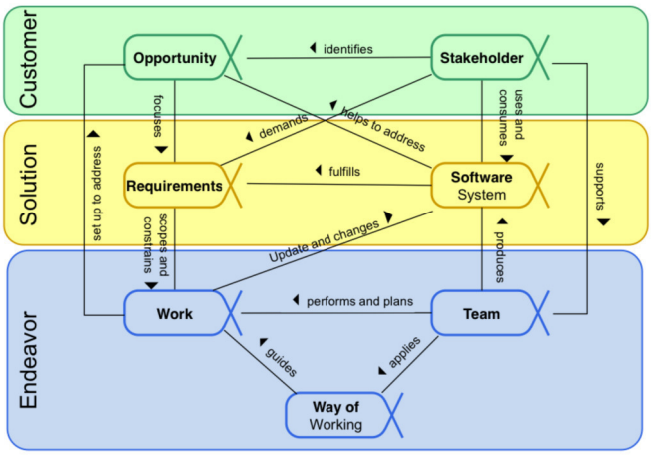

Figure 1: SEMAT Alphas in the Areas of Concern – Components of the Essence of Software Engineering

IV. Complex Adaptive Systems

A view shared by many software development experts and Agile/Lean evangelists is that software projects are complex adaptive systems (CAS's). CAS's are composed of agents - as described by M. Mitchell Waldrop in *"Complexity: the Emerging Science at the Edge of Order and Chaos"* (1992) [11]. CAS agents can be molecules, neurons, web servers, fish, starlings, and people - always forming new emergent structures with new emergent behaviors

Software projects involve people who are constantly organizing and reorganizing into larger structures: Project teams; Social groups; Task forces; Committees; etc.

CAS's are able to adapt to their environments: an infant learning to walk; car drivers evading a traffic jam; a software team adapting to what their customer really wants. Moving to the sweet spot between chaos and order, they learn and adapt and navigate their way with "chaordic" [12] processes that are neither fully ordered nor truly chaotic.

In Agile software development, we often hear reference to scientific terms such as self-organization and emergence. The concepts of emergence and the factors leading to emergent results lie at the heart of CAS theory's relevance to software development.

Examples of self-organizing systems include an ant colony, the brain, a Scrum team, a CMMI-Dev team, a team applying SEMAT Essence. Scrum, CMMI-Dev and Essence are not methodologies with defined processes or sets of procedures - they are development frameworks. And the frameworks provide rules and constraints on behavior that can cause a CAS to self-organize into an intelligent state of dynamic equilibrium.

When applying complex systems theory to software development and management, we are treating the organization as a system.

System dynamics - not to be confused with dynamical systems theory - is a technique from the 1950's to help managers understand and improve their industrial processes. System dynamics recognized that structure is often a more important contributor to an organization's behavior than individual parts themselves.

Systems Thinking was developed in the 1980's and popularized by Peter Senge's book *"The Fifth Discipline"* [13]. It's about understanding how things influence each other in the whole, a problem-solving mindset that views problems as parts of an overall system. In some ways similar to System Dynamics, but more subjective.

Social complexity is the study of complexity in social systems and to manage social complexity, we need to understand how things grow - not how they are built. This is an extension of ideas promoted by Fred Brooks in 1987 when he explained that the very essence of software engineering lies in complexity, conformity, changeability and invisibility [14].

Appelo's *"Management 3.0"* applies complexity thinking and assumes that managers cannot construct and steer a self-organizing team. The team must be grown and nurtured. Productive organizations are not managed with models and plans; they must emerge through the power of self-organization and evolution. Appelo suggests that complexity thinking is like the light that feeds all that grows and goes on to explain that at the project level, new emergent structures form and new emergent behaviors are displayed [15]. Like any other CAS with interconnected agents (people) interacting with each other to form an integrated whole. Even though software projects have many elements, only people are the real agents - the active elements. Teams themselves are agents on the next higher level.

Items that are not agents include: Requirements; Features; Artifacts; Deliverables; Tools; Technologies; Processes; Practices. They cannot actively organize and reorganize themselves. They cannot initiate interaction with any of the other elements in the project.

Appelo emphasizes that the primary focus of any manager should be to energize people - to make sure that they actually want to do what's required of them. Like a gardener looking after plants in a garden, a manager looks after the employees on the team/s [16].

For centuries mathematicians have preferred to work with linear (ordered) systems and considered nonlinear (complex) systems to be a special group. But nonlinear systems are the norm and abundant throughout the universe, whereas linear systems are a rare and special breed. From the beginning of the universe, everything in it was shaped by self-organization. Self-organization is the process where a structure or pattern appears in a system without any central authority or external element imposing it through planning. Self-organization is the norm. It is the default behavior of dynamic systems, whether these systems consist of atoms, molecules, species, businesses or software developers. Appelo emphasizes that self-organization is not a "best practice" - it is "default practice" [17]. No matter how a team

is managed, there will be self-organization. People will discuss and agree on lunch meetings, folder structures, workplace territories, birthday parties. Everything that management does not constrain - and much that it attempts to - will self-organize. Humans have behaved that way for 200 000 years.

But is what happens also happening in the "right direction"? Though every self-organizing system can have its own direction, the possible directions are limited by its environment. No self-organizing system exists without context. And the context constrains, governs and directs the organization of the system.

Environmental constraints affect the direction taken by a self-organizing system. This is illustrated by considering the Game of Life - a simple zero-player game invented in 1970 by the British mathematician John Conway. It is "played" on a grid of cells, where each cell has eight neighbors, one in each direction, including the diagonals. The cells can be born and stay alive or die as determined by the application of rules. The Game of Life is an example of a cellular automaton - a mathematical system in which cells are influenced by other cells according to some set of predefined rules. It is particularly interesting because it is a fine example of a system with a small set of simple rules, having complex behavior and ordering itself. The game also shows us that, whatever the initial situation is, the system will eventually always stabilize.

There is, however, one catch: the set of rules has to be chosen carefully. We therefore observe that rules must be tuned for a system to be both stabilizing and lively. A different set of rules leads to a different system with different behavior

As described by Waldrop [18] Stephen Wolfram proposed a classification scheme for cellular automata - named universality classes.

- Class I: These are the systems with “doomsday rules”. No matter what pattern of living and dead cells at the start, everything dies within a few generations.
- Class II: These systems are a bit livelier, but not much. Each initial pattern quickly collapses to a set of very boring, static configurations.
- Class III: These systems are at the opposite extreme: they are too lively. Each initial pattern in the system results in total chaos with no configuration stabilizing and nothing being predictable.
- Class IV: These are the systems with a set of rules not leading to dead, static, or chaotic configurations. Emerging patterns in this category are lively, creative, often surprising, but also stabilizing.

In dynamical systems, Classes I and II correspond to order. Class III corresponds to chaos. Class IV (of which the Game of Life is a famous example) corresponds to complexity. Given that complexity is usually explained as the region between order and chaos, this means that class IV finds itself between II and III.

Complex adaptive systems are systems that can find their own way toward that sweet spot of complexity, between order and chaos, where life blooms and creativity thrives. Scientists call it the edge of chaos, but they also could have called it the edge of order. This sweet spot represents a state of dynamic equilibrium between governance forces, parameters and rules that influence emergent behavior of the CAS.

Self-organization takes care of the edge of chaos when certain parameters fall within a critical range. The manager is not a game designer and is not concerned with the low-level rules of the game. Rather, the manager configures the high-level parameters, like diversity of team members, information flow between people, and connectivity between teams. When setting up governance in an organization, one responsibility of a manager is the development of a self-organizing system, defining the boundaries of the board but not the rules of the game. When a manager takes rule-making into own hands, self-organization will be significantly influenced and frustrated. And then creativity, innovation, and adaptability in the system will suffer.

Self-organization is fundamental for every complex system. But in a human social system, self-organization alone is not enough. Appelo explains how Glen Alleman described the need for management by pointing out that there is a difference between self-organizing and self-directing and this is the role of management [19]. This is not "directing" in the command and control sense. It is directing in the "required business value" sense. If self-organizing teams serve their customers, who "manages" the customer, when the customer is not prepared to behave in a "well-mannered" way? If there is more than one self-organizing team working on the same project, who coordinates the activities between these teams? When there are conflicts in resources, funding and requirements, who coordinates resolution of these conflicts? At least a little management is needed to steer self-organization in a direction that is of value to everyone in the system. Appelo points out that Sanjiv Augustine calls it "light-touch leadership". Appelo calls it alignment of constraints [20]. This author calls it balancing the governance forces.

Directed self-organization in software engineering is a matter of manipulating governance so that a group of people produces results valuable to the goals of the project.

V. The Complex Adaptive Situational Model

Humans, with the introduction of consciousness, invented morality, laws and authority. We defined preferred directions for self-organizing systems because some results are seen as valuable and others as harmful. We value human lives therefore consider malaria parasites and HIV viruses an undesirable result of self-organization. Appelo points out

that we value many irrational and unnatural things too, like non-discrimination, peace, monogamy [21]. Self-organization makes no distinction between good and bad, between virtues or vices, between valuable and harmful. Systems simply do whatever the environment allows them to do. Whatever they can get away with. And so, humans embraced the concept of command-and-control which enables attempts to steer self-organizing systems (businesses, teams, countries) in the direction that stakeholders considered to be valuable. That's how managers got their positions and how governments try to run countries. They care about results. They want to make sure that self-organizing systems either produce valuable things (products and services), or refrain from harming valuable things (human lives, economic growth, natural resources). Managers want software teams to create valuable software with which to make money or deliver good service.

Key constraints affecting the emergent behavior of a team of software engineers as a CAS are broadly identified by this author as:

- Management Governance and
- Production Governance.

Management Governance is a method or system of management practices that range from formal, high ceremony practices on the one hand, to informal, low ceremony practices on the other. The formal approach to management provides work products that could lead to high levels of visibility – producing project plan/s and progress reports, risk management plan/s and reports, quality management plan/s and reports, configuration management plan/s and status accounting reports, meeting agendas and minutes, etc. On the other hand, the informal, low ceremony approach depends less on detailed, written communication, hence leaving less visible evidence trails.

Production Governance is a method or system of production practices that range from engineering, "Waterfall" practices on the one hand, to organic, iterative or "Agile" practices on the other. A key engineering practice is to work according to the sequential stages of the life cycle, e.g.: Requirements Analysis; Design; Implementation and Unit Test; Integration and System Test; Qualification Test. Visible artifacts are then produced, including software requirement specifications, software architecture documents, software design documents, programming standard/s and test records. At the organic extreme we experience a situation where there is little emphasis on the life cycle stages and associated documentation, and high focus on the technical practices of software development.

As illustrated in Fig. 2, this author's hypothesis is that different combinations of governance constraints influence emergent behavior, resulting in four possible states of dynamic equilibrium:

- Crafted Quality (Agile)
- Controlled Quality (Waterfall or Plan-Driven)
- Managed Costs (WetAgile)
- Self-Directed Quality

While CASM identifies these four domains, it is important to realize that for a particular team and at a particular time, only one of the domains will be dynamically active to represent the emergent behavior of that team under particular circumstances.

Today's "Complex Adaptive Situational Model" (CASM) illustrated in Fig. 2 was first described as the model of "Situational Software Engineering" by Myburgh in 1992 [22]. Continuous application and research gave rise in 2005 to the second generation of the model, viz. the "Situational Process Model" (SPM), illustrating interaction between production processes and management & control processes [23]. CASM represents the third, published generation of the model and it identifies four behavioral domains that represent states of dynamic equilibrium as responses to the environmental governance constraints.

The terms "Plan-Driven" and "Agile" have been used by Boehm and Turner [24] to describe what are essentially the Controlled Quality and Crafted Quality approaches.

CASM in no way implies that the essence of software engineering is any different in Controlled Quality and Crafted Quality domains, but life cycle models will be different as later explained in this article.

A. Crafted Quality (The Curved Arrow)

This domain suits the information age organization where management formality is relaxed (low ceremony management governance) and production processes are accelerated by doing things in parallel (organic production governance). Crafted Quality is tantamount to taking an Agile approach. A key benefit of the Crafted Quality approach is faster delivery – exactly what is required in the

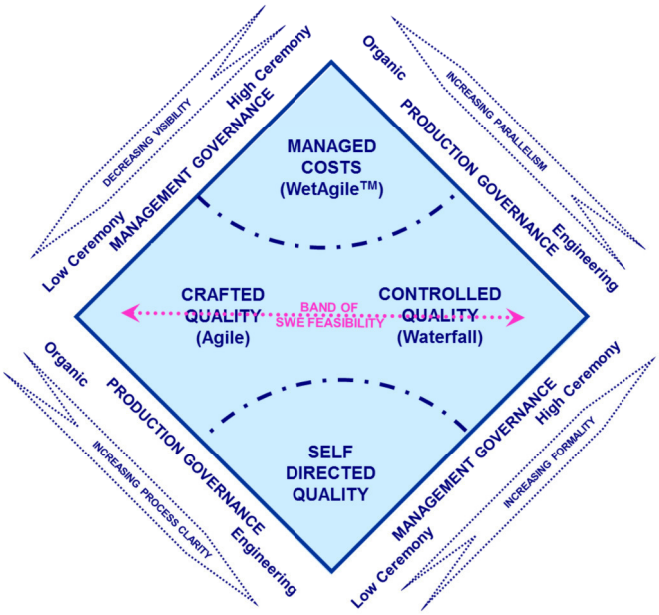

Figure 2: CASM – Insyte's Complex Adaptive Situational Model

competitive environment of the information age organization. Crafted Quality is the consequence of Agile Management meeting Agile Development.

The metaphor chosen for this domain is a curved arrow. It emphasizes the adaptive nature of an agile team that can rapidly respond to change.

But Crafted Quality does not only have benefits. Product rapidly brought to market is often not nearly defect-free, leading to potentially expensive re-work. This outcome is well demonstrated by software product with early releases that are plagued by defects that are only eradicated after a number of upgrades to the product have been implemented.

B. *Controlled Quality (The Cube)*

In this domain the emergent behavior derives from constraints of engineering-style production governance and formal, high ceremony management governance. A well-executed Waterfall approach to software engineering exemplifies Controlled Quality. Such an approach is described in the article *"They Write the Right Stuff"* by Fishman [25]. One of the key benefits of the Controlled Quality approach is that quality requirements are formally addressed at each stage of the life cycle – both in terms of initially specifying the requirements and subsequently verifying fulfillment thereof.

The metaphor chosen for this domain is the cube. It emphasizes the disciplined nature of a team operating under conditions of thorough governance.

But Controlled Quality does not only have benefits. A number of situational characteristics must apply for Controlled Quality to deliver value. These include the ability to drive out and specify requirements and having the time and other resources to analyze, specify and design the full-scope solution. And attempts to drive out full scope requirements, architecture and design can easily lead to a state of "analysis paralysis" which CASM calls "debilitating bureaucracy".

C. *The Band of Software Engineering Feasibility*

It is not by accident that CASM is represented as a diamond-shaped model. This layout places the emphasis on what is called "the band of software engineering feasibility" which stretches from Crafted Quality, Agile at the one end, to Controlled Quality, Waterfall at the other. Depending on circumstances, this implies that the state of dynamic equilibrium of a software engineering team can exist anywhere along the band and still produce value-adding results. An implied characteristic of the software engineering band of feasibility is that it is supported by a culture of "management-by-measurement", meaning that, no matter whether the way of working is Agile or Plan-Driven, management will be enabled by taking, analyzing and responding to relevant measurements.

The evolving, risk-driven approach described by Boehm in May 1988 in *"A Spiral Model of Software Development and Enhancement"* [26] could very well be understood to be a journey across the software engineering band of feasibility, with the first iteration being fully Agile, and the last solidly in Controlled Quality territory.

SEMAT Essence enables practices to define life-cycles, whether Agile or Plan-Driven, by sequencing a number of patterns, one for each phase and/or milestone in the life-cycle The life-cycles are illustrated using the template shown in Fig. 3.

Each Kernel Alpha and its states are shown in a vertical column with their creation at the top and their destruction at the bottom. Milestones are shown as a vertical bar across the grid starting with an inverted triangle to represent the milestone and continuing with a white line over which are shown the states to be achieved to successfully pass the milestone. Where achieving a state is either recommended or optional, the state is shown with a dashed outline and italicized text.

Using the template illustrated in Fig. 3, a sub-clause in the submission to the OMG provides illustrations of a few typical software engineering life-cycles, including an Exploratory Process life-cycle (Crafted Quality) and a Waterfall life-cycle (Controlled Quality). Readers who would like to review these models are urged to access the OMG submission [27].Another useful example is to be found in *"Agile and SEMAT – Perfect Partners"* [28].

This suggests that various instantiations of the SEMAT Life Cycle Model could be placed at various points across the software engineering band of feasibility.

Thus far we have considered Crafted Quality (Agile) and Controlled Quality (Plan-Driven). But what of the other two domains that are not in the band of feasibility?

D. *Managed Costs (The Explosion)*

This condition emerges when high ceremony management governance is applied to a situation that has been given the freedom of organic production governance. This means management expects Controlled Quality behavior while simultaneously giving developers the organic freedom of Agile production. A somewhat dysfunctional expectation as described in *"Corporate Information Systems Management"*

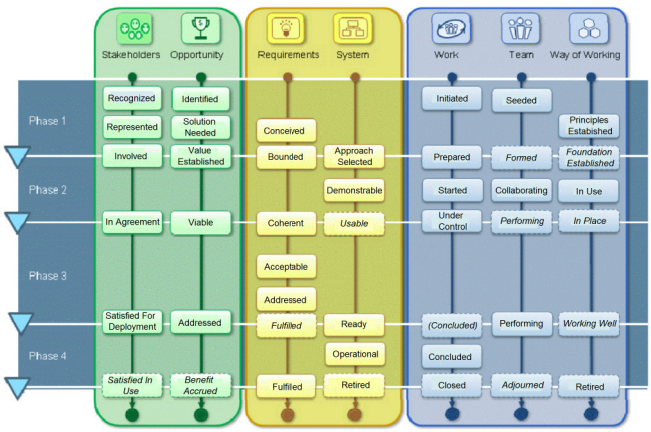

Figure 3: SEMAT Life-cycle Template

(1999) by Applegate, McFarlan and McKenney [29]. The Managed Costs name emphasizes that management will focus on cost and budget control while being quite disconnected from the day-to-day, technical activities of the team. Could this explain why Appelo's survey (referenced above) identified the following factors as contributing to failed agile approaches?

- Management opposed to change – hanging on to high ceremony management governance.
- Loss of management control – that is perceived to happen when moving to a low ceremony approach.
- Lack of engineering discipline – due to organic production approach.
- Organizational need for planning, predictability and documentation – associated with high ceremony management governance.

Steve Pieczko [30] suggests that Managed Costs might be a hybrid condition experienced by a team that is migrating from Controlled to Crafted Quality and, while still "dripping from the waterfall", they're trying to be agile. Hence the name "WetAgile", introduced in 2010 by Pieczko.

A possible explanation, but this author has experienced a number of situations where the somewhat dysfunctional, Managed Costs state seems to be permanent and a breeding ground for "management-by-politics".

The metaphor chosen for this domain is the explosion which emphasizes the often crisis-driven reality of the domain.

E. Self-Directed Quality (The Sphere)

When low ceremony management governance interacts with engineering production governance, the resulting state is Self-Directed Quality (SDQ) (The Sphere). A somewhat surprising situation. Why would practitioners elect to be constrained by engineering production governance when management governance expects no more than low ceremony? Followers of Controlled Quality would see this as an unexpected bonus, while Crafted Quality "agilista" might think of it as madness. This author suggests two possible explanations that need to be tested by means of further research.

The first might be because the tools being used enforce typical engineering production governance. It was for this reason that first generation CASM actually called this domain "Automatic Quality" [31].

A second explanation is that small, (one-person?) software development initiatives might be executed by individual/s who prefer to follow the defined stages of the engineering life-cycle. It might well be that some developers of open source software prefer to adopt this way of working.

The metaphor chosen for this domain is the sphere, emphasizing (from an engineer's point of view), the utopian situation where effective engineering is performed with few management constraints.

F. When Things Go Wrong

We earlier introduced Stephen Wolfram's proposed classification scheme where Class IV corresponds to complexity. Classes I and II correspond to order and Class III to chaos. As illustrated in Fig. 4, CASM's four domains are suggested to correspond to four types of Class IV - Complexity, with Classes I and II lying to the right of the band, and Class III to the left.

When the freedom of Crafted Quality is abused, the situation typically degenerates into a state of chaos (Class III).

Inappropriate responses to governance that desires a Controlled Quality outcome can easily result in creation of Class I or II situations with excessive order –experienced as debilitating bureaucracy.

G. CASM Characteristics

CASM has been introduced as a model of styles of team behavior and in broad terms, any software engineering team could, in response to the governance constraints imposed, be in any one of the four states of dynamic equilibrium. Each state has a set of defining characteristics. Table 1 describes characteristics of the domains. The table derives from published work (Myburgh [32], Boehm and Turner [33]) as well as from experience gained through practical application of the model.

VI. Bringing CASM To Life – Options for Management And Teams

CASM allows management to understand levels of governance that should be applied according to characteristics of the situation. The software engineering team then responds chaordically and achieves a state of dynamic equilibrium that is situationally appropriate. Table 2 identifies a number of these situational characteristics and suggests appropriate governance that should be applied. The table is based on the assumption that we are trying to pin-point the required point of dynamic equilibrium in the band

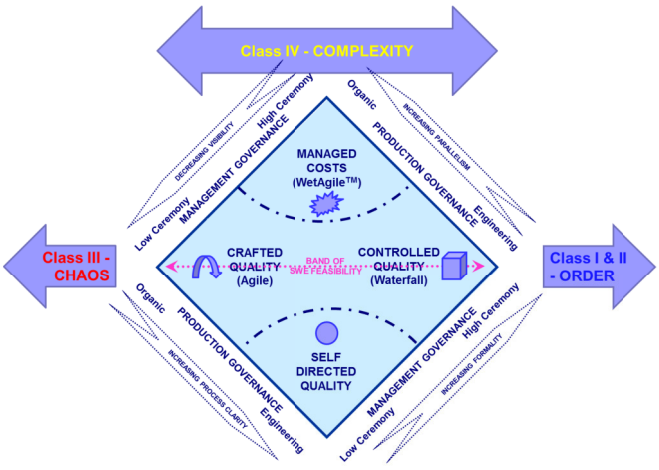

Figure 4: CASM – Modeling States of Complexity

Table 1 – CASM Domain Characteristics

	CRAFTED QUALITY (CrQ) (AGILE)	CONTROLLED QUALITY (CoQ) (WATERFALL)	MANAGED COSTS (MaC) (WETAGILE)	SELF-DIRECTED QUALITY (SDQ)
MANAGEMENT				
CUSTOMER RELATIONS	Dedicated on-site customers	As-needed, formal customer interaction	As-needed, formal customer interaction	As-needed, formal customer interaction
	Focused on prioritised increments	Focus on formal contract provisions	Focus on formal contract provisions	Focused on prioritised increments

Table 2 – Appropriate Software Engineering Responses to Situational Characteristics

SITUATIONAL CHARACTERISTIC	YES THIS DESCRIBES THE SITUATION	NO THIS DOES NOT APPLY
Are requirements readily definable?	A CoQ, Waterfall way of working could be adopted on condition that delivery time-scales permit.	The CrQ, Agile way of working is required.
Is there a comprehensive architectural description for the solution?	A CoQ, Waterfall way of working could be adopted. If the scope of delivery is large, an incremental approach will mitigate risk by delivering regular, pre-planned increments.	The CrQ, Agile way of working is required.
Is there pressure to rapidly produce results?	The CrQ, Agile way of working is required.	A CoQ, Waterfall way of working could be adopted on condition that requirements are definable.
Is there pressure to produce accurate schedules, budgets & estimates?	If the accuracy is to be based on schedules, budgets and estimates that are derived from a detailed action plan for the initiative, then a CoQ, Waterfall approach is required. If the accuracy is to be based on the cost per time-box, then a CrQ, Agile approach is indicated.	Schedules, budgets and estimates can be based on the cost per time-box and a CrQ, Agile way of working is suggested.
Does the size of the initiative introduce significant risk?	A CoQ, Waterfall approach is suitable for mitigating this risk – on condition that other characteristics required for CoQ also pertain.	The CrQ, Agile way of working is suggested so that the overhead associated with CoQ, Waterfall can be avoided.
Will implementation of the solution introduce significant change?	A CrQ, Agile way of working allows for resistance to change to be mitigated by limiting the extent of change associated with each iteration. An incremental, CoQ, Waterfall approach could also be used to limit the extent of change introduced during each increment.	Either CoQ, Waterfall or CrQ, Agile approaches could be viable. Other situational characteristics will influence the decision.
Is there significant risk due to technology? (This suggests that unproven, state of the art technology is to be implemented).	A CrQ, Agile approach should be followed by a team that is mandated to experiment with and get to know the new technology.	Either CoQ, Waterfall or CrQ, Agile approaches could be viable. Other situational characteristics will influence the decision.
Does cost-of-failure represent a source of significant risk?	A CoQ, Waterfall way of working should be adopted to allow for product assurance. If the scope of delivery is large, an incremental approach will further mitigate risk by delivering regular, pre-planned increments that could be separately assured.	Either CoQ, Waterfall or CrQ, Agile approaches could be viable. Other situational characteristics will influence the decision.
Does the software engineering team collectively have a high level of competence?	The team should be able to adapt to whatever way of working is situationally appropriate.	This situation represents a significant source of risk, and attempts to adopt a CoQ way of working could easily result in "debilitating bureaucracy", whereas CrQ approaches are likely to evolve into "freelance chaos".

of feasibility. Hence suggestions made refer only to options that lie in this band.

VII. Bringing CASM To Life – Options For The Enterprise

The above analysis of situational factors demonstrates that different ways of working apply to different situations. A small team of software engineers who are working on a focused initiative can be expected to adjust their way of working to be appropriate to the situation. However, in larger organizations where many teams are tackling many initiatives, one could expect different teams to be in different states of dynamic equilibrium at the same time.

To better understand this, we can consider the idea of a hierarchy of people-based complex adaptive systems – a system of complex adaptive systems. Working from the bottom up, we first find an individual person. (Remembering that a single person is already a CAS). If a few people collaborate towards achieving the same goal/s, we discover the next level CAS, viz. a team. Teams could also be contributing to achievement of common goal/s and hence a collection of teams could define the next higher level. For the purpose of this discussion, the highest level CAS will be the enterprise itself. Now, by employing the various metaphors associated with each state of dynamic equilibrium, the diagram in Fig. 5 represents an enterprise as a collection of complex adaptive systems and the metaphor for the Enterprise is suggested to be an amoeba.

VIII. Conclusion

The Complex Adaptive Situational Model described in this paper promotes understanding of what it takes to

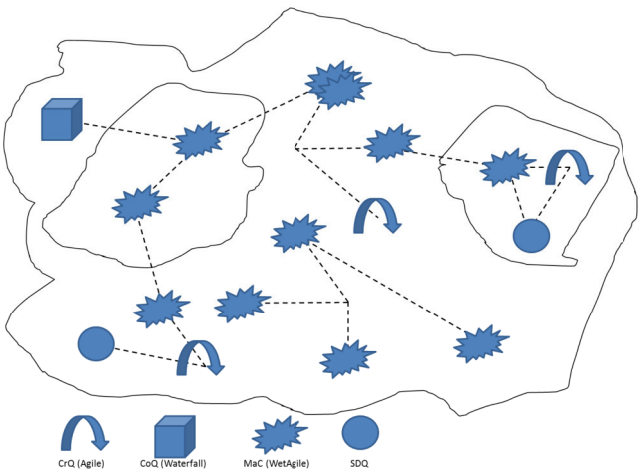

Figure 5: The Enterprise "amoeba" - represented as a System of Complex Adaptive Systems

establish conditions which enable software engineering success, not only with agile approaches, but also traditional, plan-driven software engineering.

Influenced by complexity science, CASM explains aspects of the state of dynamic equilibrium that is achieved by a software engineering team under the constraining influence of management and production governance.

Four states of dynamic equilibrium are defined: Crafted Quality (Agile), Controlled Quality (Waterfall), Managed Costs (WetAgile) and Self-Directed Quality. A band of software engineering feasibility is also described and successful software engineering initiatives require teams to operate in that band which stretches from Crafted Quality to Controlled Quality. Management's challenge is to apply appropriate governance to enable the required state of dynamic equilibrium.

The journey across the band of feasibility is further described by introducing SEMAT, with Crafted Quality amounting to applying SEMAT Essence, and Controlled Quality being achieved by introducing additional practices which satisfy the more stringent governance requirements.

CASM in its four states then allowed introduction of the idea of describing an enterprise as a collection of complex adaptive systems, thereby setting the scene for further research into the complexities of human-driven complex adaptive systems.

ACKNOWLEDGMENT

Many thanks to Dr. Alastair Walker for early support of the model and coining the name of the *Managed Costs* domain. Thanks also to Dr. Barry Dwolatzky for continued support and the opportunity to further develop the model. Dr. Whitey van der Linde is thanked for helping to find the links between the model and complexity science. The substance that SEMAT gives to Situational Software Engineering is primarily thanks to Dr. Ivar Jacobson, one of the founders of SEMAT.

Jurgen Appelo receives special thanks for the overview of complexity and complex adaptive systems that is at times paraphrased from: *"Management 3.0 – Leading Agile Developers and Developing Agile Leaders"* (2011). Readers of this article are encouraged to also read Appelo's publications [http://www.mgt30.com/].

Thanks also to other reviewers of the article including Adrian Schofield, Steve Piezcko, Paul MacMahon. Their feedback improved the final product.

Abstract—In spite of several efforts in the last decade by researchers and educators, expected potential from the use of mobile device technology (MDT) to effect learning transformation is largely unfulfilled. Quantifying benefits of MDTs in learning, either through achievement of learning objectives or enhancement of the process, remains problematic. Rapid changes in development and manufacture also continue to present additional challenges. Most trials typically employ use case approach of evidencing benefits through usage experience. In this paper, application of Requirement Engineering (RE) methodologies to specify goals and requirements for mobile learning (ML) is proposed. Alignment with teaching and learning strategies as well as other institutional goals and strategies will be essential for successful integration of MDTs in learning. RE techniques can be used to achieve this. Finally, a case study is presented to illustrate the use of some of the approaches proposed.

I. Introduction

In recent past, educational communities have appropriated available innovative technologies to enhance learning and transform the system. This has led into the coining of the discipline "educational technology", concerned with the effective facilitation of e-learning and technologies in learning. Technology appropriation has itself become a discipline of sorts, a way of exploring the impact of a given technology on a community or the society at large [1]. In spite of efforts with often mixed results, the community remain on the left foot forward; playing catch-up as advances in technology break moulds, making previously innovative ideas obsolete even before they have begun to take shape.

With increasingly powerful computing capabilities and affordance of convergence between multiple devices such as audio, video, camera etc., MDTs are transforming societal constructs and interactions. Businesses take advantage of advances to streamline their business operations; individuals, groups and communities use them to augment their life styles and coordinate relationships. The society as we know it in this generation is rapidly changing as a result [2], [3].

Within the modern UK educational sector, students admit to using devices to facilitate access to learning and for personal development but see no sustained use in most of their learning sessions and classrooms. Some educators confess they have no clue about precise benefits to learning or how this may be applicable to their teaching practice. Many schools and Further Education (FE) colleges impose an outright ban on the use of mobile devices by students within school premises, believing they are disruptive and problematic for classroom management. Many Higher Educational Institutions (HEIs) have implemented Bring Your Own Device (BYOD) schemes as part of their IT support provision strategies without fully exploring support, privacy and security issues [4], [5], [6].

The UK government is not left out in efforts to facilitate mobile device usage and information mobility in the society. Robust internet and WiFi connectivity is part of the policy strategies of the current government [7]. JANET, the body responsible for providing free public access to WiFi for FE and HE (Higher Education) establish a partnership with BskyB's The Cloud, "one of the UK's leading public WiFi providers" in November 2013, ensuring free and robust service for "over 18 million end-users in UK research and educational sector [8]. Interestingly, some of the staff respondents to a mobile learning research conducted in schools and FE colleges admit they either have zero or very little support to connect or are unsure of how to use them in teaching and learning practices in a mobile learning study conducted recently.

In some respects, BYOD schemes are sometimes little more than strategic ploys to minimise infrastructure costs while ensuring they are competitive in their provisions without really addressing underlying problems. And many support staffs admit they are struggling to support some of the less common or recently released devices. Many also feel they are unequipped or unsupported by the organisation; with no training and / or expert support knowledgebase [9].

The almost 'lightning-speed' pace of advances in MDTs continue to present both potentials and challenges. Previously innovative instructional designs become obsolete almost as soon as implemented. Yet, many remain in use for years well beyond use-by dates. Regardless, some would say mobile learning is here to stay. Others would add, perhaps cynically, that there is no evidence of actual learning involved in some efforts, the devices used primarily for access and delivery only for the most part [10], [11].

978-83-60810-58-3/$25.00

In this paper, it is proposed that application of domain neutral Requirement Engineering (RE) techniques may provide more insights into these problems, and perhaps help align business goals and requirements. Preliminary work relating to the use of RE techniques to explore current issues in mobile learning (ML) and the relationship between MDTs and education is first presented, followed by a case study illustrating some of the approaches proposed.

II. Engineering the current reality

Reference [12, pp. 7] defines Requirement Engineering (RE) as "a set of activities concerned with identifying and communicating the purpose of a software-intensive system". Software-intensive systems are described as systems comprising of some form of hardware or networked components, and involving human interactions and activities. Reference [12, pp. 3] added that RE "provides a framework for understanding the purpose of a system and the contexts in which it will be used", bridging "the gap between an initial vague recognition that there is some problem ... to building a system to address the problem".

Another definition for RE proposed in the year 2000 by [13] stated its suitability for specifying what the authors called "real-world goals" i.e. reflecting the tendency for change in the real world. More recently, [14, pp. 42] agrees, adding that "each RE process starts with an aim to change the current reality". The author stated all software systems are used within a context, adding that while system goals may be clearly defined, quite often variables within the context are not so clear. The latter may explain the rationale for a look to RE methodologies for ML systems. Although not strictly software-intensive applications but many interconnecting systems and technologies; the very nature of the system make it a likely domain for the application of RE.

Mobile devices have progressed from voice communication tools into computerised devices that not only enables easy collaborations between geographically dispersed individuals, but those also creating convergences between multiple media devices. Crucially, they are also providing means of connecting varieties of systems in ever increasingly complex contexts. For the sake of simplicity, these technologies will be referred to in this paper collectively as "mobile device technologies" or MDTs; encompassing mobile devices, convergence affordability, communication channels, remote, local and wireless network connectivity etc. Usage context is that relating to learning establishments, and HEIs in particular.

III. Requirements engineering techniques selection

According to [15], there is no one prescriptive way of applying RE techniques to a system but the authors caution on ensuring techniques are applied early in the system lifecycle. With so many to choose from, techniques will largely depend on the system goal and contexts. A major weakness found in many is their complexity and lack of clarity, making them unusable by anyone but experts in RE or software engineering techniques [16].

Regardless, many authors agree the following core stages are essential in RE [15], [17], [18]:

- Inception and elicitation
- Identification, analysis and negotiation
- System modelling and goal specification
- System validation, risk and change management

Some of the activities involved in each of these stages will be discussed next.

A. Elicitation of needs

The bulk of the fact finding process in RE is usually in the inception and elicitation phase. However, elicitation is also a task that will continue throughout the life of the project and beyond system implementation. For example, whenever changes are made to a system, requirements for those changes have to be re-evaluated [18], [19]. Reference [18] cautioned that not all the information obtained would become requirements. Some needs may not be feasible to implement in the final product.

There are several stakeholders with potential input into the ML system including device manufacturers, educators, students, policy makers and those in the role of learning support and governance. While device manufactures may not be particularly interested in prioritising the needs of the educational community at the exclusion of others, they are likely to be concerned if their product(s) are unusable by members within the community. If the device is overly complicated then consumers, who may also be students and / or educators will not want them. Device manufactures may also be concerned about policies preventing freedom of usage in learning establishments.

Educators are often keen to appropriate technology that would make their practice more effective and achieve learning objectives. They are however unlikely to want to give up too much of their time for pedagogic and instructional design. In the same way, students may have devices but unable to use them effectively for learning. Seamless usage may also be problematic because the necessary connections and support are not adequate or robust enough, or there may be policies prohibiting use [20].

For learning providers, as may be true also for educators and students, running cost is still an issue. Costs may also include provision of ongoing technical support by the institution. Interoperability with other applications on the local network systems will be essential and ensuring the environment is rich enough to support such levels of inter-connectivity may be beyond sustainable budgeting strategies. And while mobile devices include tablets / devices with wide screens, powerful media support features and educational affordances, there are many with less than satisfactory experience still. It is believed this will increasingly become less of an issue [10].

Personal preference and cultural perceptions will also play a key role in intentions to use. For instance, in the past majority of consumers are uncomfortable conducting financial transactions on mobile devices. Today, the number is growing despite persisting security concerns [21]. Possibilities of cyber bullying and abuse are other issues among others. In a research conducted recently, a group of staff and students in an HEI stated of mobile devices: "can cause epilepsy – when it does not work", "too dangerous" and "very dis-humanising". These statements may illustrate extreme opinions held by some stakeholders still. Thus, these and other concerns must be elicited carefully. It is also important to identify sub-groups within each stakeholder groups with potentially differing opinions. For example, educators group may include tutors or pre-service tutors who may also be students themselves in HE. Reference [22] called this purposive sampling; describing the conscious inclusion (and exclusion, as well as the contextual grouping) of certain groups of participants.

Techniques used in elicitation may typically be employed in other RE stages including those for eliciting and analysing goals for the system, which [18] suggest is sometimes overlooked but an important part of fact finding. Establishing goals may in fact aid requirement analysis and can be analysed using goal modelling. One of the more commonly known goal modelling techniques is referred to as KAOS (Keep All Objectives Satisfied) [18], [23] citing [24], [6]. KAOS specify the use of verbs as well as AND / OR operators to link goals to processes [25]. Goal modelling will be discussed and illustrated more in subsequent sections.

Other elicitation techniques include ethnographical research methods [15]. Ethnography is an exploration of the community concerned and the cultural contexts using quantitative methods such as surveys; and qualitative methods such as observations, interviews and focus group studies. In this manner, interests and the emotional appeal of components within the system or the product being developed can be measured [18]. Brainstorming and prototyping may also be employed during the elicitation stage.

B. Identification, analysis and negotiation

This is a logical stage following directly or conducted in parallel with the elicitation of requirements. Information obtained from stakeholders need to be analysed, categorised and ranked. What are the current and new requirements? Who are those involved and where are they located? What are priorities for the business or organisation, and what are the conflicts? Conflicting requirements or potential problems must be identified and resolution decided.

Stakeholder agreement on the goals and requirements could be difficult to obtain without negotiation. Alternative options and acceptable compromises must be presented to resolve complex dissensions and disagreements on requirements and / or goals. Identifying and phrasing the most important goals for the system in terms all stakeholders can agree with and understand, may also be useful [17].

Establishing agreement on root problems can be problematic as in the ML system. Many of the stakeholders may be steeped in blame culture, making buy-in from stakeholders difficult. Even when buy-in is assured, having input from several groups of stakeholders may present a problem for the study. Reference [26] suggest the use of trade-offs adding that it is impossible to satisfy all the requirements by one specification quite often; usually typical of non-functional requirements. An example of trade-off analysis for the ML system can be seen in Table 1. The table shows strengths in opinions and level of importance by doubling or tripling certain symbols.

Reference [18] propose negotiations and brainstorming in several scheduled Quality Attribute Workshops (QAWs). In QAWs, the facilitator creates a Quality Attribute Scenario (QAS) for each of the concerns expressed by a stakeholder. Each stakeholder can express two or more of their most important concerns. The QAS is presented to the group and a handful is selected and debated. Finally, the facilitator supports the group to identify important requirements to be included in the system.

Another potential problem could arise from volatility in functionalities and the increasingly convergence nature of MDTs. Establishing meaning and interpretations of requirements may be difficult, or worse impossible if device features keep changing [18]. Some level of stability may need to be assumed or achieved. Other techniques employed may include prototyping, global analysis, focus group, requirement analysis and release planning [27], [28].

C. System modelling and goal specification

Modelling is an essential RE technique often used to analyse requirements as well as goals at various stages throughout the process lifecycle. Some of the more commonly used modelling techniques are listed below [18]:

- **Artefact modelling:** Used to define the work products and interdependencies and to specify maintenance requirements for processes.
- **Goal-oriented modelling:** Concerning the needs and vision of the business organisation and not necessarily the customers or users of the service(s) or system products.
- **Model-driven RE (MDRE):** Model-driven requirement engineering is typically used for large complex systems and can span the project lifecycle, from inception through to maintenance.

Other modelling techniques used in RE include **feature** and **process** modelling, typically used during the elicitation phase. In Sections IV and V, modelling techniques applicable to the ML system are illustrated in more details.

D. System validation, risk and change management

During this stage system model(s) and specification are evaluated against requirements and agreed. Validation process can often be the most complicated part of RE, resulting in inability to reach a consensus agreement, especially where different stakeholders with conflicting opinions and goals are involved. Risks to the system are identified and measures established to minimise their effect on future optimum performance of the system and to manage changes.

Reference [13, pp. 6] warns, "If stakeholders do not agree with the choice of problem frame, it is unlikely that they will ever agree with any statement of the requirements". The authors suggest a resolution may be to promote an agreement "without necessarily making the goals explicit"; in other words, rephrasing goals and requirements using terms that may be more moderate than specific.

Several RE methods have been suggested for investigating ML and similar systems, and for aligning the goals of the system with learning / business strategies. In the next two sections, categorizing and modelling techniques are explored in more details. A case study using goal modelling to specify some goals for the system is next presented. Information used in the goal model will be extracted from corporate and operational strategies of a UK HEI, demonstrating how alignment may be more easily achieved.

IV. GOALS FOR MOBILE LEARNING (ML)

Information obtained during elicitation needs to be organised, ranked and / or categorised in order to identify them as either goals or requirements of the system. This can often be complicated by the many different classification techniques available in RE. Again, the technique chosen will depend on the objectives for the system and the type of information to be analysed.

Some authors suggest goal analysis and specification is one of the methods that should be used more carefully and prioritised [29], [25]. Both of these authors believe that while many appreciate its importance, it is often side-lined in literature and formal specifications for the system. Goals are well understood to be the objectives or targets to be satisfied by the system under development, and they may often be explicitly presented to system engineers by stakeholders at project inception. The assumption then, that a formal specification for achieving those goals is all that's required may account for the oversight. Reference [25] refer to this as the "top-down" approach [pp. 3].

For [18] and [25], the initial set of goals is just the beginning of goal development process; an important basis on which to continue further analysis and refinement. Reference [25] believes that will require asking the 'HOW' and 'WHY' questions [pp. 3]. Thus, goal elicitation continues alongside establishment and elicitation of needs. Conflicts and problems are identified and resolved. New features or changes in the system will require alterations or modifications. New goals may also arise from validation, risk and change management processes [25], [18].

Goal modelling is sometimes seen as a discipline of sorts and also referred to as Goal-Oriented Requirement Engineering (GORE). This section outlines some strategies used in GORE, which may be employed throughout a project lifecycle during RE stages explored in the previous sections.

A. Classification of goals & requirements

An explicit set of goals or strategies for ML and the integration of MDTs in learning are sometimes missing from teaching and learning strategies. Many institutions would often specify a goal for technology infrastructure provision and support, of which it is assumed technologies supporting ML may be a part. It is proposed in this paper that a specification is necessary to move the agenda forward. This may be explicit or inferred from other goals or strategies. Unfortunately, such considerations have so far been glaringly omitted in past and current ML implementations and literatures.

Goals and requirements for a system may sometimes be classified as **soft** or **hard**. Soft goals describe objectives that are more 'desirable', less precise and therefore subjective; while hard goals are usually specific. Consequently, hard

TABLE I.
A SUB-SET OF TRADE-OFF ANALYSIS TABLE FOR A MOBILE LEARNING SYSTEM

	Functional requirements / stakeholders						Non-functional requirements (NFRs)*		
Goals	Students	Educators	Learning support	Governance	Government / global educational policies / acts	Device manufacturers	Pedagogic	Learning enhancement	Usability

** Other non-functional requirements may include security, availability, etc. [14]*
Strengths or level of importance is signified by doubling or tripling of some symbols

Key
Ticks (✓): Prioritisation for stakeholder group
Dash (-): Neutral stand
Double dash (--): Disapproval, conflict or concerns
Plus (+): Relationship between goals and NFRs

goals are sometimes also referred to as functional specifications for the system. For example, specifying requirements for obtaining an educational qualification, 'passing the assessment examination' may be a "hard" goal / requirement but 'passing the assessment examination with distinctions' is not. 'Passing' is required but 'passing with distinction' can only be classified as a 'soft" goal [30], [31]. Therefore, at the top-level, most goals and requirements can be categorised into functional or non-functional. Functional requirements represent functions or actions that the system or part of the system must perform while non-functional requirements are those that measure how well those functions have been performed. While this categorisation is well suited to systems resulting in an end-product, it can be possible to miss other variances within some systems if they are not classified further and the ML system may be an example.

When the root problems in a system have not been established or agreed by stakeholder groups, goals are often unclear and subjective. RE techniques used must therefore be able to not only identify the root problems and specify requirements, but also specify goals for the system. Identifying the factors, issues and strategies within the system may be more relevant in this case. They are also particularly suited for classifying soft goals and requirements, especially those that are subject to many interpretations. It is also possible to develop use cases that can be used in testing the system from developed use case scenarios, which can be generated from the factors [32].

B. Factors, issues and strategies

Factors, issues and strategies are techniques used in global analysis; an RE methodology used to categorise "soft" goals and requirements that may not quite fit well into the functional / non-functional categorisation [30]. Reference [25] defines these as those whose "satisfaction cannot be established in a clear-cut sense"; as opposed to "hard" or requirements "goals whose satisfaction can be established through verification techniques" [pp. 3]. Global analysis is particularly suited to systems that need to be examined from several perspectives and involving many different groups of stakeholders.

Another advantage is that they can help in addressing concerns and barriers within the system when used early in the elicitation process. Classifying all the information gathered during global analysis into factors, issues and strategies may also simplify the ranking process, making it easier to prioritise goals and requirements for the system.

Factors are different from requirements, in that they do not exactly describe the system but may relate to the context or a component of the system. For example, a student stakeholder stated "I have a Blackberry but I can't use it properly and I can't sync it with my MacBook"; relating to the effective working of part of the system and achievement of the goals rather than a requirement of the system. The statement reveals a few factors:

- Synchronisation with a PC / laptop is a desired requirement.
- Some devices (e.g. Blackberry) may not sync properly with some PCs / laptops (e.g. MacBook) … OR … some students may be unaware of how to sync some devices (e.g. Blackberry) with some PCs / laptops (e.g. MacBook)

Factors are sometimes referred to as Quality Attribute Scenarios (QASs) in a general sense which will normally have related use case scenarios defined so that requirements can be linked to them and tested. When there are conflicts in factors, it is classified as an issue and where there are issues there will likely be factors to be identified and strategies to address the issues. These may be indefinite, later to be confirmed within the architectural model for the system. An example of an issue is in the following statement from another student stakeholder.

"I would use my smartphone if I was desperate as in location difficulty; internet access is limited in some places. However due to the small size of the screen I would prefer to use a tablet or a PC."

The above statement technically an issue for the goal of the system can reveal several factors:

- Internet access is limited in some places
- Small size of the screen
- There is a preference for tablet or a PC

The example has also shown how factors inherent within issues can be identified and categorised. The goals of a system can be represented by the factors. Issues can be derived goals that meet the requirement of the factors. Reference [18] refer to these as "issue-goals" and described the dynamic as that of developing a product (solution) that "satisfies a particular combination of factor-goals". Strategies can be decisions contributing the satisfaction of issue and factor goals [pp. 153]. Factors, issues and strategies need to be managed or they might grow into unmanageable levels in the global analysis [18].

C. Quality Attribute Scenarios (QASs)

QAS is another RE technique for categorising information obtained during the elicitation process. The importance of using QAS to further categorise information was mentioned briefly in previous sections. QAS is recommended in architectural requirement engineering in general for collating concerns from stakeholders and categorising them. They provide a "structured textual" way of managing stakeholder concerns and describing how it may respond to the introduction of certain stimulus. A QAS may have the following: stimulus, origin or source of the stimulus, artefact to be stimulated, stimulus context or environment, response to the stimulus and response measure i.e. satisfactory response to the stimulus as its properties [18, pp. 143].

For example, consider the following scenario in an ML system:

"In a BYOD (Bring Your Own Device) scheme in a university, a student requests support for a new type of device after staff training for known systems have been completed. An IT service support personnel was able to figure out how to resolve *the student's problem without any* need for likely costly support required from the device manufacturer nor was there any significant delay in supporting the student. The staff documented the process and trained other staff colleagues to support similar devices within one week."

The above example can be categorised into QAS parts as follows:

Stimulus: Support request for a new type of device.

Stimulus source: A student.

Artefact: The system and the IT service department.

Environment / context: After staff training for known systems has been completed.

Response: An IT service support personnel was able to figure out how to resolve the student's problem.

Response measure: No likely costly support was required from the device manufacturer nor was there any significant delay in supporting the student. The process was also replicable as part of operational strategies in the department within one week.

Not only has a QAS been defined for this scenario, it is also possible to now derive a requirement for the system, based on the QAS process:

- zero device manufacturer support
- no extra delay
- process re-engineering within one week

The following may also be inferred through the QAS process which could form part of the requirement specification:

- Since there is no device manufacturer support, there must be a limit to the types of devices that can be supported. If there is device manufacturer support in place, potentially any type of device may be supported.
- Delay in supporting the student's device may create a negative impression about the department's effectiveness.
- Process re-engineering will require a member of staff with adequate expertise to document the process and train other colleagues to carry on the process in future.
- The staff with the expertise is already a member of the university and part of the system i.e. a stakeholder within the system.

In considering the use of QAS, [18] cautions that it is important to remember there will likely be changes to stakeholders' priorities and to ensure use case scenarios are defined in addition to QAS.

D. Use case analysis and scenarios

Use case analysis is a process modelling technique used to analyse processes so that the relationship of the process within the system to external systems or components can be evaluated and understood fully. Like a QAS, use cases have several parts as follows [18]:

- Actors / users, interacting with the use case.
- Events depicted in the system causing the use case to occur.
- Pre-conditions that must be true for the use case to occur.
- Post-conditions that must be true after the use case has completed successfully.
- Activities within the use case.
- Included use cases for other processes, if any.
- Extended use cases for processes that may take place (optionally) while the use case is occurring.

Use cases are sometimes better defined using scenarios. An activity diagram can also be used to define all possible scenarios within use cases. In a QAS, scenarios involved may include those occurring during normal operations, system-as-objects i.e. passive objects and growth – dealing with changes and exploratory, as well as those dealing with scenarios that are unlikely to occur.

E. Using goal-oriented modeling techniques

Goal-oriented modelling is a useful technique for refining the goals of the business which can be associated with the requirements and needs of a system. They are particularly useful for revealing the relationship between the business goals of the system and functional as well as non-functional requirements of the system.

Review of literature has revealed that one of the problems for the sustenance of ML is the difficulty in quantifying precise benefits when used within a learning process. Defining requirements for the system from business or strategic goals of the learning establishment could be a useful way of establishing relevance to strategic decisions and processes. Goal modelling are often used with Quality Assessment Methods (QAMs), which is a measure of how the defined goals meet the desired quality expected of the system. QAMs can be used as checklist for guiding against the omission of important non-functional requirements. The goal modelling technique presented in this paper illustrates how requirements can be inferred from business goals and strategies.

There are many approaches to goal-oriented modelling, including KAOS, mentioned earlier in this paper, and Non-Functional Requirements (NFR) framework [23] citing [24], [33]. Reference [19] stated that KAOS is "the most formal application of the goal-oriented approach to deriving requirements for computer-based systems" [pp. 15].

V. DERIVING REQUIREMENTS FOR MOBILE LEARNING (ML) FROM GOALS: A CASE STUDY

There could be a disparity in what an organisation define as business goals and what is actually offered in practice. This can sometimes be very costly, leading to losses in revenue and / or goodwill branding as well as inefficiencies. Defining and implementing Quality Attribute Requirements (QARs) may guide against this or minimise the likelihood of devastating differences. Another way may be to develop requirements from the business goals of the organisation [19]. Extracts from the policies and strategies proposed in a white paper by a UK HEI will be used in this section to illustrate this. The HEI is located in London, with campuses in the East. Relevant policies in a strategy document include the following [34]:

- We will ensure that our campuses are an identifiably academic environment with innovative provision for digital mobile learning and spaces for both collaborative and reflective study.
- We will be recognised as a leading university for employability and enterprise, routinely exceeding benchmarks and providing transformational opportunities.
- In all of these areas we will seek to be at the forefront of removing barriers to progression to further study for first-generation undergraduates, supporting access to employment and postgraduate qualifications. In this way, and others, we will facilitate greater UEL student competitiveness in employment markets and subsequently through CPD for promotion and career enrichment.
- In developing a more flexible offer for a more distributed, more mobile and more time-conscious market, we will enhance our distance learning capacity, partnerships and support mechanisms.
- We do not intend to invest significant amounts of capital in these ventures, but will explore a range of collaborative models in partnership with established and new high-quality providers.
- Over the period of this Strategy, when core, full-time undergraduate numbers are likely to remain restricted, there is a greater need than ever for us to deliver our programmes at times and in places which suit the learner. Both teaching and support need to be flexible so that students can access them appropriately.

From the list above, we can identify the following goals:

- Provision for digital mobile learning and spaces for both collaborative and reflective study.
- Provision of transformational opportunities.
- Removal of barriers to progression & facilitation of competitiveness in employment.
- Development of more flexible offer for a more distributed, mobile & and time-conscious market.
- Exploration of a range of collaborative / high-quality partnerships.
- Delivery of programmes at times and in places which suit the learner.

In deriving requirements from goals, [19] suggests a successive decomposition of the goals at the high level. The author suggests using adapted notations to decompose each goal into sub-goals where either all or at least one of the sub-goals will need to be realised for the high-level goal to be satisfied. When all sub-goals must be satisfied, this may be indicated with an arc across the directional arrows. Some goal components may also become sub-goals / requirements for the system. This resulting model is sometimes referred to as goal hierarchy or goal lattice [19]. An illustration can be seen in Fig. 1.

There are several taxonomies in use for defining QARs including ISO 9126 containing 22 quality attributes, including for example the use of ambiguous terminology in definitions [18].

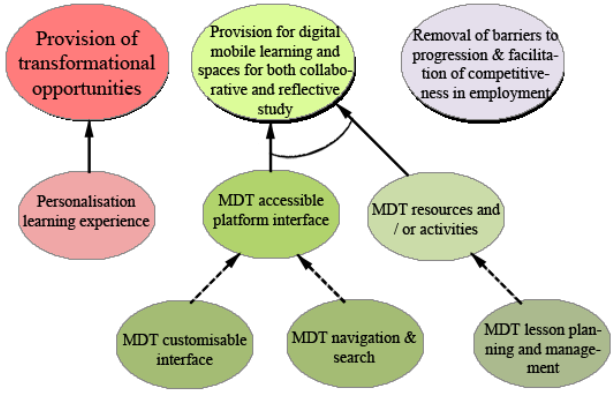

Fig. 1: Goal decomposition from business strategies

Some of the above statements / goals may fall into the category of those needing more clarity and less ambiguity which can be achieved by defining QARs. [18] suggests an integrated approach to defining QAR i.e. defining QAR from an integrated requirements model involving all the functional requirements and architecture of the organisation's operational system. For this, the authors recommend the use of an integrated artefact model (see Fig. 2) as well as goal models to show the artefacts within the system as well as the relationships linking the functional and architectural requirements.

A. Integrated artefact model for ML

Having derived requirements from the goals of the HEI (listed above) using goal-oriented modelling approach (see Fig. 1), an integrated artefact model architecture can also be created to show the relationship between the objects within the system and the attributes, as shown in Fig. 2. Defining the relationships between each of the artefacts within the system will make it possible to define QARs for the system. Relationship of the objects within the system to factors,

issues, strategies and also the placement of test cases are included; as well as how QARs may be applied to use cases, scenarios and functional requirements. An integrated artefact model architecture will also allow for "trace relationships" which are sometimes overlooked to be clearly defined and established (4).

Artefact models are particularly useful for aligning project goals within the broader goal(s) of an organisation. Symbolic notations are often used in some artefact modelling to illustrate relationships between the objects. Some may be defined using predicate logic language involving the use of symbols, quantifiers and logical operators. For example, the predicate equal(A, B) indicate A = B; plus(A, B) indicate A should be added to B and so on [35]. Using techniques such as predicate logic language notation for artefact modelling can however render the model too complex for those without expert knowledge on the subject [16].

Integrated artefact modelling can be simplified by using standardised object relationship notations commonly used in computer system modelling to reveal how the components of a system may be dependent on each other, guiding requirement specification for the system [18]. To illustrate, an integrated artefact model architecture showing how components within the problem statement for mobile learning is shown in Fig. 2. The model shows when QAWs, QASs and test cases may be required for the system. It also reveals when QAR may be needed to guide against extreme differences in opinion among stakeholders. Use cases will need to be established for testing how well the requirements achieve defined goals as well as the functional / non-functional specifications.

VI. Conclusion

In this paper, the use of RE is proposed to explore relationships between MDT and education. Work presented in this paper is part of an ongoing study involving the application of RE techniques in an HE setting, and this work is yet to be completed. Therefore, a full picture of the requirements and goals for the system are yet to be established. The paper has however shown how RE techniques can be of some considerable benefits when used in systems such as ML, in spite of the very challenging prospect of usage within the complex contexts characteristic of ML systems.

A peripheral question in the wider context not addressed in this paper is how a co-evolution relationship between MDT and education may impact these requirements and goals. Arguably, early promises of a technology are often overshadowed by the "hype" accompanying technological adoption in learning establishments. Some technological systems are eventually found to be either badly managed, unfit for purpose and / or mal-aligned with the broader learning and teaching strategies of the organisation; as noted by Gartner, describing this phenomenon as typical Hype Cycle behaviour. Hype Cycle is the graphical representation of the phases of technological adoption and integration into the marketplace. Early adoption often follows rapidly after a trigger period and Research & Development (R&D. This phase is characterised by scores "inflated expectations" and sometimes ill-judged experimentations. The process continues through periods of disillusionment, enlightenment and productivity in a graphical maturity curve. A likely phase at any time could of course be obsolescence, if the technological system implementation is impracticable or unfit for purpose [36].

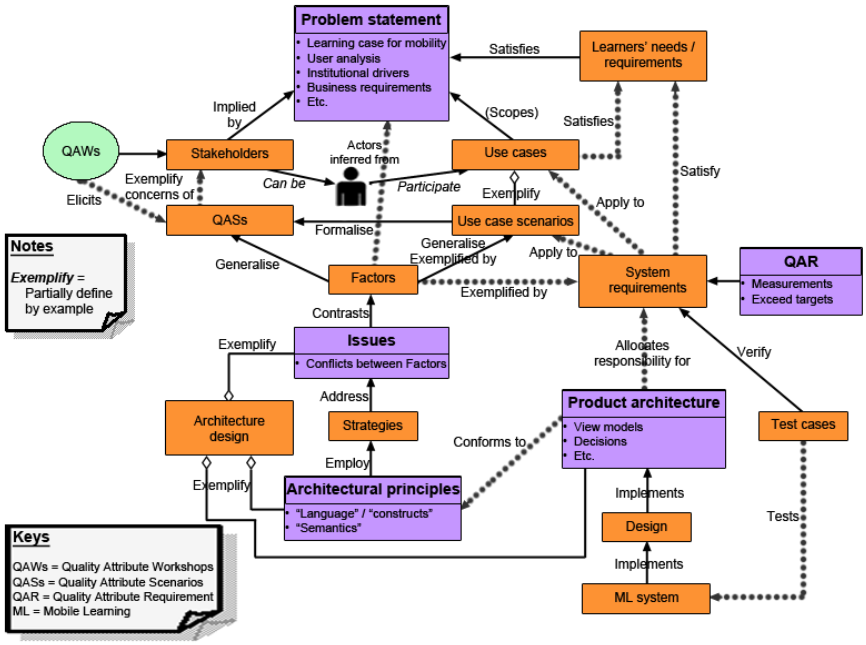

Fig. 2: Integrated artefacts model architecture for Mobile Learning (ML)

Modified from source [18, pp. 130]

Apart from educating a subset of its citizens, two other important functions of HEIs within a nation are "research and innovation", as noted by Professor Paul O'Prey (Vice-Chancellor, University of Roehampton and Chair, Universities UK Longer Term Strategy Network), writing a preface for the 2011/12 UK Higher Education Statistics Agency (HESA) report [37, pp. 2]. It may be a generalised view to state some have found injecting innovation into HE practices including those relating to technological adoption almost impossible. Regardless, and to move the agenda for ML forward, a likely area of further study may be to what extent (if any) HEIs are able to influence products emerging from the R&D phase of technological development and manufacture. Are there any attempts to determine the needs and requirements for learning and advancements and to what extent are these driving the direction and marketisation of advancements? Also related to this track is how quickly and effectively members of educational community innovate and review its learning and teaching strategies / practices to ensure educational technologies such as MDTs are fully integrated; progressing seamless and rapidly towards the productivity phase of the Hype Cycle soon after adoption. Ensuring this occurs will not only save time and effort, but prevent wastage, redundancies and / or inertia that is fast becoming commonplace in many technological adoptions, including MDTs, in learning and teaching.

Emerging Aspects in Information Security

ADMITTEDLY, information security works as a backbone for protecting both user data and electronic transactions. Protecting the communication and data infrastructure of an increasingly inter-connected world has become vital nowadays. Security has emerged as an important scientific discipline whose many multifaceted complexities deserve the attention and synergy of the computer science, engineering, and information systems communities. Information security has some well-founded technical research directions which encompass access level (user authentication and authorization), protocol security, software security, and data cryptography. Moreover, some other emerging topics related to organizational security aspects have appeared beyond the long-standing research directions.

The Emerging Aspects in Information Security (EAIS'14) workshop focuses on the diversity of the information security developments and deployments in order to highlight the most recent challenges and report the most recent researches. The workshop is an umbrella for all information security technical aspects. In addition, it goes beyond the technicalities and covers some emerging topics like social and organizational security research directions. EAIS'14 is intended to attract researchers and practitioners from academia and industry, and provides an international discussion forum in order to share their experiences and their ideas concerning emerging aspects in information security met in different application domains. This opens doors for highlighting unknown research directions and tackling modern research challenges. The objectives of the EAIS'14 workshop can be summarized as follows:

- To review and conclude researches in information security and other security domains, focused on the protection of different kinds of assets and processes, and to identify approaches that may be useful in the application domains of information security
- To find synergy between different approaches, allowing to elaborate integrated security solutions, e.g. integrate different risk-based management systems
- To exchange security-related knowledge and experience between experts to improve existing methods and tools and adopt them to new application areas
- To present latest security challenges, especially with respect to EC Horizon 2020

Topics

Topics of interest include but are not limited to:

- Biometric technologies
- Human factor in security
- Cryptography and cryptanalysis
- Critical infrastructure protection
- Hardware-oriented information security
- Social theories in information security
- Organization- related information security
- Pedagogical approaches for information security
- Individual identification and privacy protection
- Information security and business continuity management
- Decision support systems for information security
- Digital right management and data protection
- Cyber and physical security infrastructures
- Risk assessment and risk management in different application domains
- Tools supporting security management and development
- Emerging technologies and applications
- Digital forensics and crime science
- Misuse and intrusion detection
- Security knowledge management
- Data hide and watermarking
- Cloud and big data security
- Computer network security
- Security and safety
- Assurance methods
- Security statistics

***Abstract*—Information technology is widely used in processes vital to enterprises. Therefore, IT systems must meet at least the same level of security as required from the business processes supported by these systems. In this paper, we present a view on cybersecurity management as an enterprise-centered process, and we advocate the use of enterprise architecture in security management. Activities such as risk assessment, selection of security controls, as well as their deployment and monitoring should be carried out as a part of enterprise architecture activity. A set of useful frameworks and tools is presented and discussed.**

I. Introduction

CYBERSECURITY has been recognized as a business concern and declared an enterprise-wide activity. There is a growing understanding that cybersecurity requirements for the confidentiality, integrity and availability of services provided by the IT infrastructure in an enterprise must be elevated to the same, or higher, level, as the security requirements for the elements of the enterprise that deliver a business function. In consequence, cybersecurity should not be associated with IT technology alone and should no longer be regarded as purely an IT domain. In essence, IT departments are not able to conduct proper risk assessment and mitigation on their own. The information necessary to conduct risk analysis properly is available to business management. When decisions and actions are taken in a process in which IT and business management work together to assess risks and determine priorities in risk mitigation, we can speak about *enterprise-oriented cybersecurity management*. Current practice shows, however, that cybersecurity is still based on technical rules of thumb. The use of formalized methodologies like risk management is not common. The perception of business goals in the process is fragmentary; so many aspects are omitted in cybersecurity. In consequence, the process is incomplete. In this paper, we promote the usage of enterprise architecture-based tools and methodologies to deal with cybersecurity in enterprises which rely on IT infrastructures to deliver products and services.

The proposed approach calls for a paradigm shift in cybersecurity. It requires management personnel to share essential data with IT people to enable business impact analysis and to rely on outcomes that define security priorities. The knowledge of risks in IT departments (likelihood and impact of various threats) and countermeasures should complement the knowledge in business departments. A common workspace for business and IT is an enterprise architecture. It enables collaboration, owing to an improved awareness of the business processes that support the company's mission on one side, and their realization through operational activities, supported by IT, on the other side. The decisions pertaining to security are based on a proper assessment of vulnerabilities and threats and provide options for a response (e.g., continuity and recovery plans, security controls).

Enterprise-oriented cybersecurity management is not a state but a persistent process, with the ability to adapt continuously to a changing environment. Cybersecurity must not be considered an isolated activity—merely a domain-specific precaution against isolated hacking or sabotage activity. Attackers will tend to affect business by targeting general, enterprise-level goals by impairing applications and supporting infrastructure (e.g. platform systems). A vulnerability at one level impacts other levels. Consequently, loss expectancy tends to magnify through cross-layer dependencies. To understand vulnerabilities, risks need to be studied and evaluated top-down: from business principles, through business objectives, and business functions, down to security controls, and also bottom-up for traceability and evaluation. Such analysis is enabled by a thorough description of the enterprise architecture along with an aligned *risk assessment*. Afterwards, the main goal of the *risk response* is to select countermeasures dealing with the risks recognized. The effects of the deployed measures are *continuously monitored*. The enterprise architecture should also drive transition with change management, including major upgrades in security policies and their implementations. One of the critical methods for achieving the goal is risk management [1]–[3]. This should employ enterprise architecture as a valuable source of information about the enterprise. While this may seem engaging too much overhead and may seem counterproductive, even the first exercise will provide value in a reasonable time. In the course of the paper we discuss a collection of tools (e.g., frameworks and software applications) supporting change or risk management.

In our paper, we elaborate on the pillars fundamental to organizing cybersecurity management (enterprise architecture, threat meta-models, risk assessment and response, risk moni-

TABLE I
SELECTED ENTERPRISE ARCHITECTURE FRAMEWORKS

Framework	Context	Description	Advantages	Drawbacks
TOGAF 9.1 (2012)	Open, universal	Provides a process lifecycle to build and manage architecture transitions within an enterprise—Architecture Development Method (ADM) and a set of models.	• ADM is the central point • Ensures a controlled environment for change • Substantially aimed at transitional architectures	Lack of precise model guidance (Archimate 2.0 fills that gap)
DoDAF 2.0 (2009)	Military	Defines a set of views and models for visualizing the complexities in an architecture description and reasoning for various stakeholders. The architecture data gathered becomes central, and the data schemes provided define its structure. There is no obligatory method of development	• Provides data schemes and a precise meta-model • Aimed at transitional architectures • Supports SOA • Tailored for large and complex systems	• No single obligatory method of development • Military-oriented • Limited support for non-functional requirements (like cybersecurity)
The Zachman Framework (2008)	Business	Is best described as a scheme or taxonomy of EA. It classifies views based on six interrogative questions (why, how, what, who, where, when) and five abstraction layers (contextual, conceptual, logical, physical, detailed). No methodology is defined for developing an architecture	• Compact and easy to follow • Well defined viewpoints	• No methodology for building EA • No transitional architectures • Limited support for non-functional requirements (like cybersecurity)

toring) and then summarize how they are integrated. Section II introduces enterprise architectures. Section III deals with the main processes in cybersecurity provisioning, that is, risk management. Section IV summarizes the ideas presented in a unified view. Afterwards, we shortly conclude.

II. ENTERPRISE ARCHITECTURE

Enterprise architecture (EA) is used for the description of complex enterprises. The description includes business processes and their mapping to operational activities for the key processes. It serves as a blueprint for the enterprise structure and operations. Enterprise architecture is a set of models that depict how various business and technical elements work together [4]. Along with ontologies or meta-models, it describes the terminology, the composition of enterprise components, and their relationships with the surrounding environment, as well as the guiding principles for eliciting requirements, design and evolution. The enterprise architecture frameworks (see examples in Table I) are templates for development of instances of EA. A set of languages used to describe the enterprise architectures has been developed and a few of the popular options are sketched in Table II.

A. Role of EA in Security Management

Technically speaking, cybersecurity activity is about establishing a linkage between secured objects and vulnerabilities, threats and countermeasures, as well as monitoring them. Risk is the perception of a relation between these and business objectives. A balance is required between these elements for three essential, interdependent objectives: confidentiality, integrity, and availability. The enterprise approach to cybersecurity requires that risk management should be carried out simultaneously at the business, application, data and technology layers, and combined. Business impact analysis, as a basic step in risk assessment, and business continuity planning, the main concern of risk response, requires precise data about the enterprise. Such knowledge should embrace at least simplified principles defining the enterprise's mission and the manner in which this is accomplished.

Security management should be organized as a process of continuous improvement. Activities such as, for example, risk monitoring, risk assessment, selection of security controls and their deployment need to be carried out repeatedly. Short iterations lend themselves to rapid response to risks that require prompt response.

The security management process causes modifications to the enterprise. These changes can be considerable. As such, they should be staged in transitions describing the change of enterprise architecture.

B. Sample Case Study of EA

To illustrate various EA-related aspects, we have developed a sample view of EA presented in Fig. 1. It shows an architecture for an IT infrastructure supporting a gas transportation process using a networked SCADA control system. As can be seen on the right, EA describes the structure of enterprise organization, business processes, applications and technology that allow the enterprise's goals to be achieved. The notation uses the Archimate 2.0 language, which allows for linking the elements of the architecture together and tracing the relationships among elements. Here, the main business process is gas transportation. This is supported by four subprocesses at the application layer (agreement management, etc.). Those subprocesses are supported by software applications

TABLE II
SELECTED ARCHITECTURE DESCRIPTION LANGUAGES

Framework	Context	Description	Advantages	Drawbacks
Archimate 2.0 (2012)	Enterprise-oriented	Archimate is an architecture description language. The main part covers business, application, and technology layers. There are two extensions: motivation and implementation which makes it compatible with the TOGAF framework. Archimate defines multiple views, but it is possible to define other views, too	• Allows for modeling dependencies • In line with the newest version of TOGAF	• Suitable only for modeling on the enterprise level, lower levels need another notation (like BPMN) • Thus far, a limited set of the supporting software tools
UML 2.1.4 (2013)	Software	UML is a universal language, but is usually perceived as software-oriented and is used for the solution architecture description	Wide modeling software support	Seldom used for business purposes
BPMN 2.0 (2011)	Business	Standard for business process modeling. Provides a graphical notation and model elements focused on business processes and roles. Flow diagrams are similar to UML activity diagrams	Widely used in business analytics	Not possible to map business processes to applications or technologies
UPDM 2.1 (2013)	Military	UML profiles and graphic notation supporting the models and views taken from DoDAF framework	Full enterprise architecture support	Military-oriented
SysML1.2 (2010)	System engineering	Extension of a subset of UML	• Compact set of diagrams • System-of-systems support	No relationships modeled to business

(like CRM system) and cyberinfrastructure (file management system, databases, etc.). After adding security knowledge, it becomes possible, for instance, to trace the impact of a file server fault (induced by DDoS attacks) on two systems: CRM and capacity planning, which as a consequence influence (via the information service) the SCADA control system and impair business processes. A real EA will contain much more information for use by stakeholders (like clients, owner, or governmental administration) and formulated with multiple views. The data can be stored in a repository, where a formal representation of the structure along with the related threat models enables reasoning and reporting on the likelihood or impact of various incidents, thus supporting risk assessment.

C. Vulnerability and Threat Meta-Model

Cybersecurity management requires deep knowledge of vulnerabilities and threats. This knowledge is maintained in respective databases and needs to be incorporated intothe enterprise architecture. To make this possible, efficient meta-model of cybersecurity-related data is necessary. This introduces a vocabulary, syntax, and constraints as well as enables cybersecurity modeling. The enterprise architecture description is enriched by risk assessment with contextual information on cybersecurity issues.

A fragment of an example cybersecurity meta-model is shown in Fig. 2 (see for instance [7] for an alternative model). *Secured objects* span many categories: humans, physical resources, and immaterial assets. All in all, these fall into two classes, being an *asset* or a *process*. They have their own *security attributes* (like a predefined value of availability, for instance). *Vulnerabilities* are attached to security objects during risk assessment. Vulnerabilities will manifest as incidents in the event of a *threat* materialization, which will exploit them. *Risk* is a measure of *likelihood* and *impact* of threat realizations. After the vulnerabilities and threats are identified, it is possible to produce countermeasures using *security controls*, which are a technique for risk response. A control can be accomplished with an organizational procedure (like authentication enforcement) or with an asset protecting other assets (e.g. IPS/IDS systems) or a combination of the two.

III. RISK MANAGEMENT

As a formalized process, risk management aims at dealing with all the threats and related countermeasures in a cyclic manner as shown in Fig. 3. Risk serves as an explicit interface between the business and IT. The following three aspects are taken into account during risk assessment: *exposure* of a secured object to selected threats; and two quantifiable aspects—the *likelihood* of those events, and the *impact* on the enterprise, if they occur. While threat analysis and likelihood evaluation are evaluated by IT experts, the evaluation of impact on business processes is of a non-technical character only, related to financial measures (for instance, penalties for outages), or public safety and liability issues. The business impact is assessed either in qualitative terms (high-medium-low), or preferably in quantitative ways, as this allows for finding a risk response based on optimization methods. Risk assessment has been studied for a long time and commercial frameworks to perform it are also present [8], see Table III. Typically, frameworks suggest what should be done, but not exactly how to carry it out.

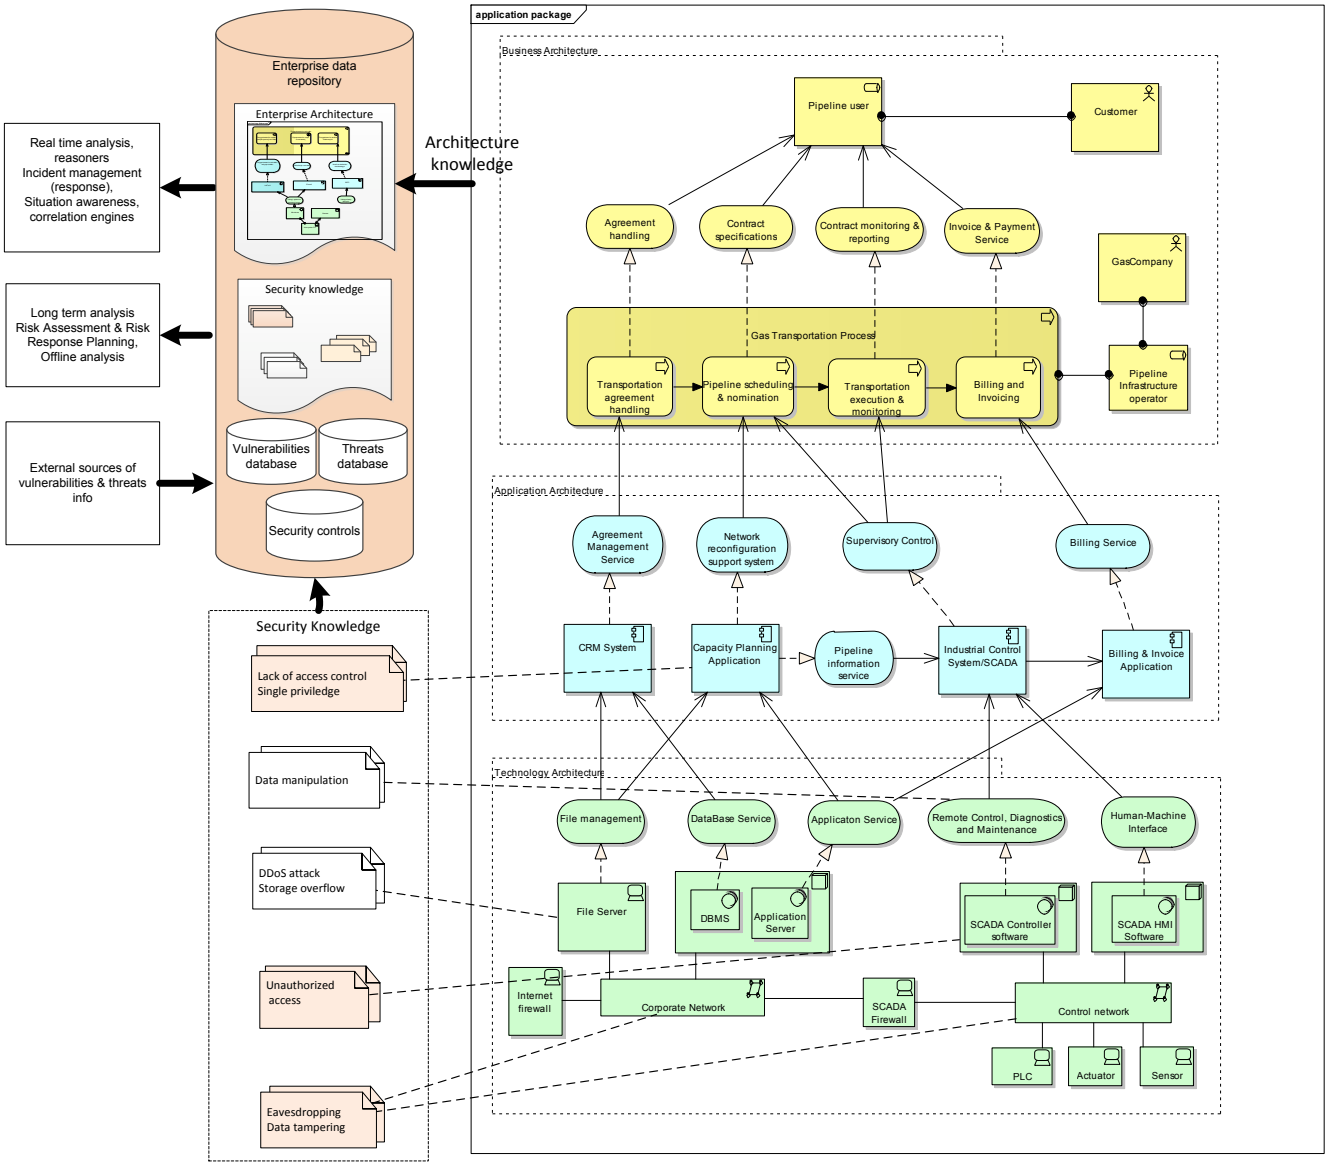

Fig. 1. Role of an example instance of an enterprise architecture in cybersecurity management [5], [6].

Risk management has become overwhelming in information technology as it covers a broad range of issues, as shown in Fig. 4. Its usage in the context of network resilience against attacks is covered in [10] and against random failures in [2]. Sometimes, it is even postulated to engage the end user in this [11], despite some concerns: no clear goals from customers, a low level of considering their actions, a lack of interest in security, a pure lack of technical expertise, or even a slowdown in the adoption of new technologies. Enterprises have better knowledge of their goals, actions and technology to be able to effectively combine the data provided by the enterprise architecture and use it with risk management techniques to improve its operations.

A. *Risk Assessment*

Risk assessment analyzes the enterprise operation from various domain viewpoints: public safety (against threats of massive human injuries); business logic (like checking for process deadlocks); IT cybersecurity in relation to a specific industry field (e.g. SCADA concerns in oil transportation systems); The system-of-systems analysis encompasses methodologies for analyzing multi-scale, interconnected and interdependent systems with emergent behaviors [12]. The following three types of failures are characteristic of interdependent infrastructures [13], but can also be observed in Fig. 1.

- Cascading: when a failure in one infrastructure causes the failure of other infrastructures (note the propagation of technology failures all the way up to business process

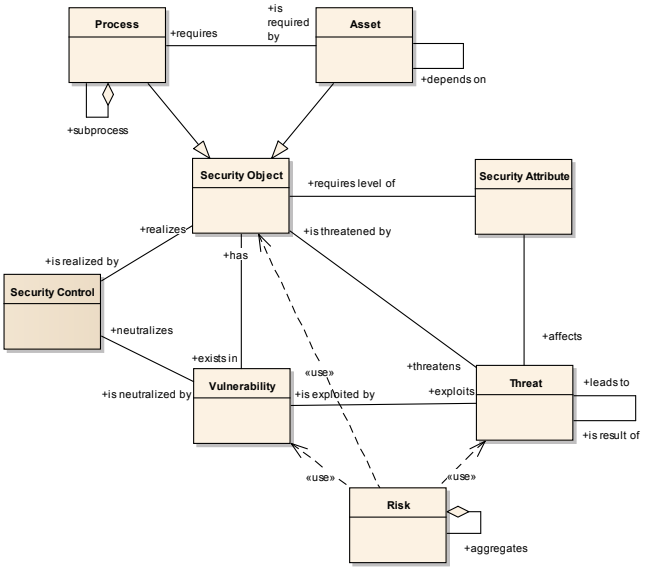

Fig. 2. Cybersecurity meta-model [5], [6].

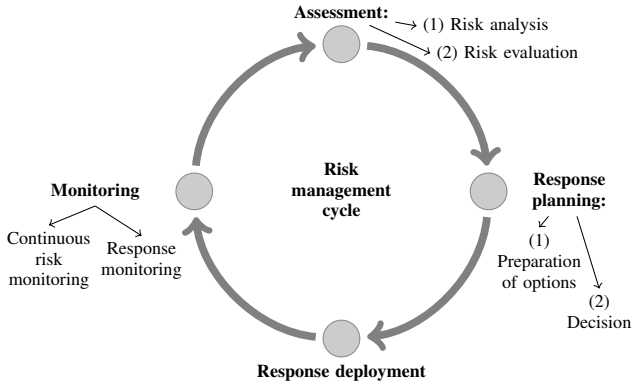

Fig. 3. Simplified risk management cycle [9].

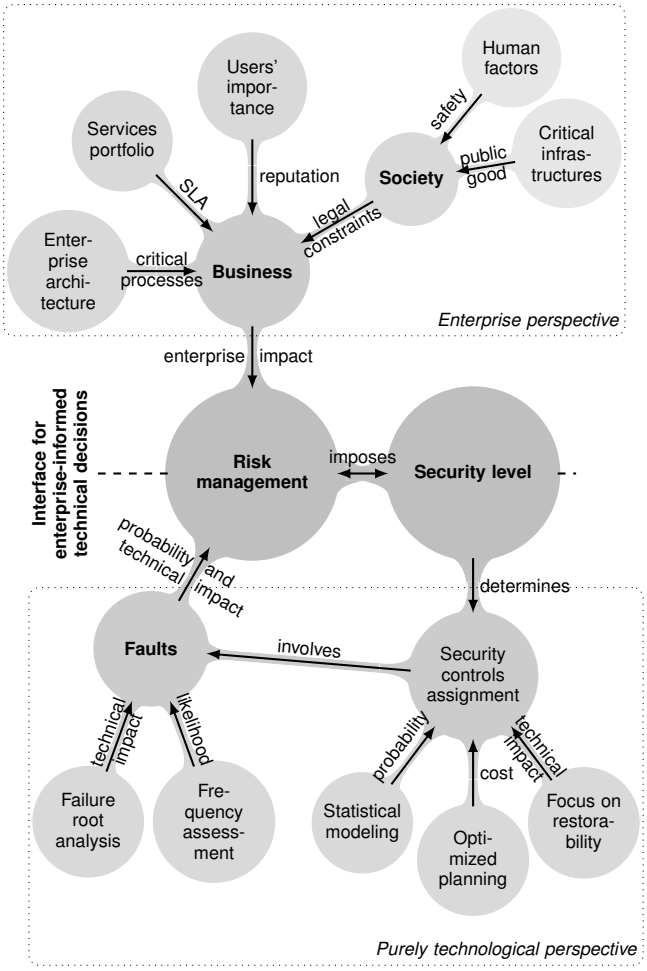

Fig. 4. Different aspects of risk management.

discontinuity).

- Escalating: when an existing failure in one infrastructure exacerbates an independent failure in another infrastructure, increasing its impact (see the earlier example of a file system failure in combination with SCADA control faults).
- Common cause: when two or more infrastructures are affected simultaneously because of a common event (see the destructive impact of corporate network outages on all subprocesses).

Basically, risk assessment consists of risk analysis (identifying vulnerabilities, threats, and related risks) and risk evaluation, determining their probability and impact on the business goals. Although risk can be assessed qualitatively, where probability and impact are assessed using ordinal scales (e.g. small-medium-high) and their combinations, a more sophisticated approach, known as probabilistic risk assessment (PRA), is more meaningful. It is a strictly quantitative approach during which both impact and probability are assessed and expressed mathematically [14]. In the best case scenario, the full probability distribution function (PDF) of the impact expressed in monetary units can be found. In this case, business-related measures like Value-at-Risk (VaR) can be applied. These are easily understood in the investing sector, and therefore can be useful in communicating risk to management. Although such measures were invented for the banking sector to assess the obligatory level of savings, it is suggested that they be used in the telecommunications sector to assess the level of cybersecurity-related investments in network design [2], [10], [15], [16]. The usage of such metrics is especially useful as there is a large toolbox of optimization methods elaborated in the modern portfolio theory, for which VaR is the basic quantitative risk measure and can be used during risk response planning.

B. Risk Response

After analyzing threats and evaluating the related risks, it is necessary to prepare a risk response proposal to be decided and accepted by business management. One of the

TABLE III
SELECTED FRAMEWORKS SUPPORTING RISK MANAGEMENT FOR IT CYBERSECURITY

Framework	Scope	Advantages	Drawbacks
COBIT 5.0, **Risk IT**, **Val IT** (2012)	IT governance (COBIT) combines a business perspective and IT control model approach. Risk IT focuses on IT-enabled risk management and Val IT covers financial IT governance	• Emphasizes relationships between business and IT processes • Includes aspects of control, risk, cost efficiency and maturity • Compatible with audit procedures • Uses RACI (Responsible-Accountable-Consulted-Informed) charts presenting a detailed allocation of responsibilities	• Lack of technical details and low level practices • No description of methods to transition
SABSA (2009)	Framework for the development of a security architecture in an enterprise	• Intuitive and understandable distribution of layers • Well planned and described risk management processes and their succession, interfaces and attributes	• Lack of coverage of all aspects of IT cybersecurity at an equal detail level • The concepts covered without the required explanation, which makes it difficult to properly implement
ITIL 3.0, **M_o_R** (2011)	A set of practices for IT service management, combining IT services with a business perspective	• Popular and widely used description language • Recommendations based on best practices • IT service management considered in a systematic and consistent manner	• Expensive to implement • Long time to implement correctly • Neither generic nor self-sufficient, should be combined with another risk management framework
CC-ISO 15408 ver. 3.1 (2009)	International technical standard for IT cybersecurity certification of products related to IT	• Facilitates risk assessment in relation to particular assets (systems, applications, devices) • Defines different levels of cybersecurity and quality requirements	• Expensive to implement • Used mainly at the development stage • Does not support a holistic approach to the organization, but focuses only on the evaluation of a particular resource or product

most important parts of the risk response is to ensure continuity in the business process operation. This is performed by *business continuity planning* and *disaster recovery* [17], where continuity may be defined as a state in which a system is operational again after disruption at a well-defined level after a certain time, bounded by the maximum tolerable downtime parameter. While it is possible that this goal can be realized by various methods, scenarios are prepared. Each scenario should contain a set of countermeasures (*security controls*), their manner of implementation, the resulting risk change and the cost involved. The first decision is how to deal with recognized risks. Typical decisions that are relevant in the technical context are as follows: *acceptance* when nothing is done about the recognized risks (no changes in comparison to the actual state are necessary); *avoidance* of situations where threats take place (elimination of a problematic information system with many vulnerabilities); *reduction* of the likelihood (addition of a firewall decreasing the number of successful attacks); *mitigation* of the impact, the most popular decision (encryption of data so that it cannot be used even if stolen). Three most common strategies apply to mitigation [18], [19], see Fig. 5:

- *Risk minimization*: choice of the minimum impact possible; can be very costly but might be the first choice especially in critical infrastructures, where the public good is most important.
- *Total (benefit) coverage*: a strategy where the cost of scenario implementation is balanced with the reduction in impact; the strategy is imposed by NIST series of recommendations [20] for US federal institutions.
- *Profit maximization*: a choice of scenario where the marginal impact reduction is balanced by the marginal cost of this reduction, ensuring minimization of the total cost of incidents and risk mitigation.

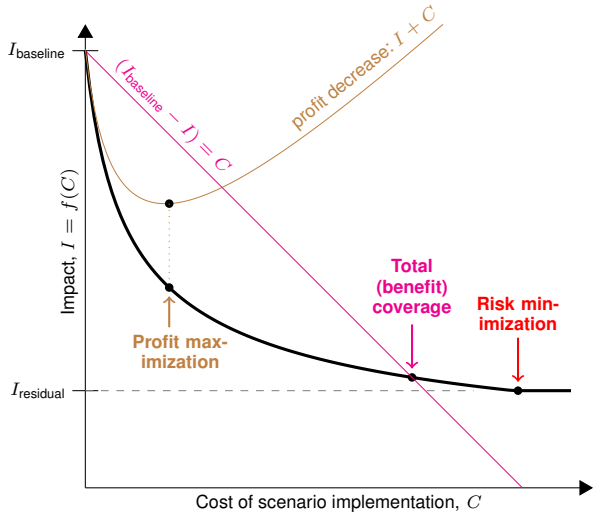

Fig. 5. Illustration of the three basic risk mitigation strategies.

C. Examples of Security Controls

Security controls are countermeasures aimed at avoiding, reducing, or mitigating risk. Two popular catalogues of security controls are ISO 27002 [21] and NIST 800-53 [22] (see Fig. 6). ISO 27002 provides 176 cybersecurity controls organized into twelve sections. The controls contain well defined objectives as well as implementation guidance. Its broad scope makes it applicable to any industry and business of arbitrary size. NIST SP 800-53 groups 317 controls into 18 families organized under three classes:

- *Technical* (e.g. AC-11: session locks).
- *Organizational*: for managing information cybersecurity programs (e.g. MP: media marking).
- *Management*: pertaining to business governance (e.g. PM-10: cybersecurity authorization process).

D. Continuous Monitoring

The main goal of the continuous monitoring process is to maintain up-to-date knowledge about the effectiveness of the risk response scenarios implemented in the enterprise. The monitoring has the following goals:

- to deliver the information about the state of the processes and assets to appropriately assess the current risk;
- to discover changes in processes and assets state that may influence the level of security and effectiveness of the implemented security controls, resulting in new threats;
- to recognize cybersecurity incidents.

Continuous monitoring is responsible for ensuring consistency between the implemented security controls and standards, recommendations and regulations. Collection of cybersecurity related data is a discrete process triggered by incidents, changes, etc. Some of the monitoring tasks can be called repeatedly or on schedule. However, monitoring is a continuous process.

IV. Consolidated View on Enterprise-oriented Cybersecurity Development

So far, we have defined various elements of an enterprise-oriented approach to security deployment. Here, we show how they are integrated. The cybersecurity management process will consist of at least four repetitive steps: risk assessment (adjust), risk response (plan), implementation of security controls (do), and continuous monitoring (check).

Each of the four phases of the cybersecurity management process consists of several tasks. The scope, granularity and time frame depend on the enterprise. The activities of the process are carried out with a focus on various aspects pertaining to different layers of the EA: business, application, or technology. Security principles, requirements, goals and constraints are thus formulated at various levels of enterprise description. The implementation process should be coordinated at various levels, in accordance with the four steps. The scope is tailored to the enterprise's needs, priority and the available level of funding. The activities may have different durations, but they complement each other. For example, an implementation of a security control protecting a server against a specific attack at the technology level supports a security implementation process at the application level dealing with the classification of confidential information which, in turn, protects a well defined business goal (e.g. compliance with the regulations on personal data security).

The processes organizing the cybersecurity management cycle operate on various time scales. The incidents require a rapid response. Also, new vulnerabilities should be addressed without delay. In such cases, primarily risk assessment, response and implementation of security controls must be performed rapidly. Then, these are based on common IT cybersecurity practices, not always optimal from the cost viewpoint. Immediate solutions are called 'quick wins.' On the other hand, a security implementation related to a new project run in the enterprise, the deployment of new assets, or the creation of novel operational processes result in triggering a long-term process. Each phase will then require very careful analyses and involve much more time.

The EA transition process should be closely related to the security implementation process. While defining current state and intermediate state (transitional) enterprise architectures, all recognized assets and processes will require risk assessment and the preparation of a risk response. The security controls should be employed together with the implementation of the new enterprise architecture.

A new instance of security implementation process may be triggered in various cases:

- Continuous monitoring recognizes that an implemented security control has become ineffective or inadequate (e.g. due to a change in the surrounding environment).
- A new vulnerability in an asset or a new threat exploiting a recognized vulnerability has been announced.
- New assets have been deployed in the enterprise: all dependent systems must at least be assessed from the risk viewpoint.
- The process of enterprise architecture transition has started (e.g. due to a business management decision).

V. Conclusions

Cybersecurity is crucial to the contemporary enterprise. We describe a business view of cybersecurity by showing recognized frameworks known thus far in enterprise governance. Enterprise architecture frameworks allow the development of an EA, which is crucial to properly address risk, but differ in the extent to which they guide through the cybersecurity aspects. Given the vast number of incidents, machine-assisted decision support becomes a decisive factor and this is the main issue to be solved in the future.

***Abstract*—Arbiter-based Physically Unclonable Function (PUF) is one kind of the delay-based PUFs that use the time difference of two delay-line signals. One of the previous work suggests that Arbiter PUFs implemented on Xilinx Virtex-5 FPGAs generate responses with almost no difference, *i.e.* with low uniqueness. In order to overcome this problem, *Double Arbiter PUF* was proposed, which is based on a novel technique for generating responses with high uniqueness from duplicated Arbiter PUFs on FPGAs. It needs the same costs as 2-XOR Arbiter PUF that XORs outputs of two Arbiter PUFs. Double Arbiter PUF is different from 2-XOR Arbiter PUF in terms of *mode of operation for Arbiter PUF*: the wire assignment between an arbiter and output signals from the final selectors located just before the arbiter. In this paper, we evaluate these PUFs as for uniqueness, randomness, and steadiness. We consider finding a new mode of operation for Arbiter PUF that can be realized on FPGA. In order to improve the uniqueness of responses, we propose *3-1 Double Arbiter PUF* that has another duplicated Arbiter PUF, *i.e.* having 3 Arbiter PUFs and output 1-bit response. We compare 3-1 Double Arbiter PUF to 3-XOR Arbiter PUF according to the uniqueness, randomness, and steadiness, and show the difference between these PUFs by considering the mode of operation for Arbiter PUF. From our experimental results, the uniqueness of responses from 3-1 Double Arbiter PUF is approximately 50%, which is better than that from 3-XOR Arbiter PUF. We show that we can improve the uniqueness by using a new mode of operation for Arbiter PUF.**

I. Introduction

RECENTLY, counterfeit products have been a problem in commercial market. The security for existing anti-counterfeit technologies relies on the technical difficulty to create a duplicate. However, future developments in counterfeit technologies might affect the technical difficulty. Physically Unclonable Function (PUF) [1] is being focused as a future solution [2].

PUF is a function in which an input (challenge) is related to one unique output (response) based on physical units such as semiconductor circuits. It is difficult to duplicate PUFs because the response values of PUFs depend on a physical variation. This difficulty to duplicate PUFs can be used device authentication against counterfeiting [3][4]. For example, a server as a verifier stores challenge–response pairs for a device as a prover. The verifier can authenticate the device by using the challenge–response pairs since they are unique for the PUF implemented in the device. PUFs are also used for a more secure method of storing secret keys than non-volatile memories. A secret key stored on internal memories will be revealed if an attacker can open the package of a device. In contrast, the secret key on PUFs cannot be read out accurately because physical variation and the values of responses have been changed once the package of the device is opened. Therefore, it is expected that PUFs are used for secure key generation [5][6].

PUFs are implemented not only on ASIC (Application Specific Integrated Circuit) [7] but also on FPGA (Field Programmable Gate Array) [8][9]. FPGA implementations have an advantage that their design and implementations are easy to change. Therefore, FPGAs are widely used in commercial products in the real world [10].

Some evaluation results on FPGAs of Arbiter PUF (APUF) [11], one of the delay-based PUFs, have been reported [12][13]. Previous work of [12][13] suggests that the APUFs implemented on Xilinx Virtex-5/Kintex-7 FPGAs generate responses with quite low uniqueness. The authors of [14] claim that one of the reasons for the low-unique responses obtained from APUFs on Virtex-5 FPGAs is based on the problem of SLICEs on the FPGAs. The problem is mentioned in general FPGAs. In a conventional APUF, a response is generated by comparing signals through two wires. The length of the two wires for any challenges in APUFs is expected to be equal. However, the layout of logic elements (*i.e.* SLICE) on FPGAs is completely fixed, so the length of wires among the logic elements cannot be controlled by designers. Because the difference between delay times arisen from physical variation is much smaller than that from the wire length, the responses obtained from different APUFs on different devices have small difference against a lot of challenges, *i.e.* low uniqueness.

In order to generate responses with high uniqueness on FPGAs, a novel technique that is called *Double Arbiter PUF* (DAPUF) [14] is proposed. The authors of [14] duplicate another APUF on neighboring SLICEs where the original APUF is implemented. They assume that a wire of duplicated APUF has almost the same length as the wire of the original APUF. 2-XOR APUF whose response is obtained by XORing 2-bit responses from two APUFs on the same FPGA are proposed in [3]. It has the same circuit costs as DAPUF, *i.e.*

978-83-60810-58-3/$25.00

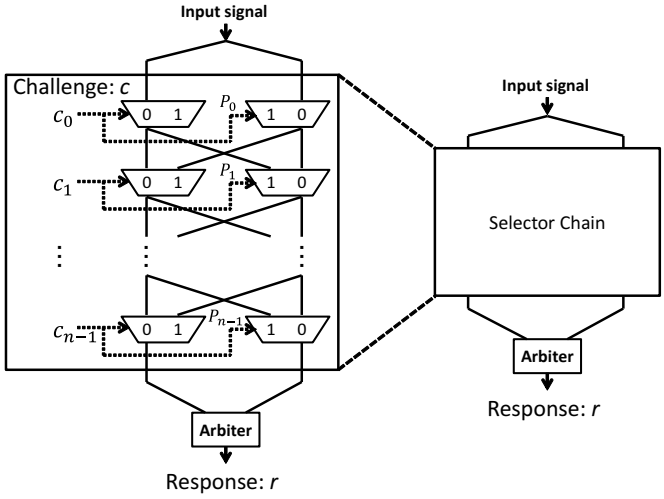

Fig. 1. Structure of conventional APUF

having two selector chains. In this paper, we call m-n APUF or DAPUF which has m selector chains and generates n-bit responses. For example, 2-XOR APUF is called *2-1 APUF*, and 2-bit output DAPUF is called *2-2 DAPUF*.

A. Our Contributions

In order to compare the structure of PUFs, we define a selector chain of conventional APUF as a building block as shown in Fig. 1. 2-2 DAPUF is different from 2-1 APUF in the wire assignment between the arbiter and output signals from the final selectors as shown in Figs. 2(a) and 3(b). Our two contributions in this paper are as follows:

- We introduce a new concept: *mode of operation for APUF* that is determined by a choice of the wire assignment. We compare PUFs that have two selector chains such as 2-2 DAPUF and 2-1 APUF and evaluate these PUFs on Virtex-5 FPGA regarding the uniqueness, randomness, and steadiness.
- We propose 3-1 DAPUF by using three selector chains, which is an improved version of 2-2 DAPUF. We compare it to conventional 3-XOR APUF, which have three selector chain. The evaluation results of these PUFs on Virtex-5 FPGA regarding the uniqueness show that 3-1 DAPUF generates responses with high uniqueness.

First, we evaluate four PUFs that have two selector chains. For a fair comparison, each PUF with the same-length response is compared. Therefore, 2-2 DAPUF is compared to *2-2 APUF*: two conventional APUFs as shown in Fig. 2(b). From our experimental results, we show that the uniqueness of responses from 2-2 DAPUF is higher than that from 2-2 APUF. We propose *2-1 DAPUF* by XORing 2-bit responses of 2-2 DAPUF as shown in Fig. 3(a), and compare it to 2-1 APUF. Our experimental results show that the uniqueness of responses from 2-1 DAPUF is approximately 41%, which is superior to 2-1 APUF.

One pair of the 2-2 DAPUFs has comparatively low uniqueness of responses because the proportion of 0s and 1s in responses (randomness) is still biased [14]. In order to eliminate the influence of the biased responses, we use another duplicated APUF, *i.e.* having three selector chains. In this paper, we propose *3-1 DAPUF* whose response is generated by XORing 6-bit responses of DAPUFs as shown in Fig. 4(a), for details to Sect. VI. Then, we compare 3-1 DAPUF to 3-XOR APUF that have three selector chains and generate 1-bit response. In this paper, we denote 3-XOR APUF as *3-1 APUF* as shown in Fig.4(b). Our experimental results show that the uniqueness of responses from 3-1 APUF is approximately 6%, which is still low. In contrast, the uniqueness of responses from 3-1 DAPUF is approximately 50%, which is much superior to that from 3-1 APUF.

We show that we can improve the uniqueness by using the new mode of operation for APUF and using responses obtained by XORing responses from more duplicated arbiter on Virtex-5 FPGAs.

B. Organization of This Paper

Organization of this paper is following. Section II gives previous work. Section III mentions the motivation of this work. Section IV shows experimental setup such as environment, and evaluation indicators. Moreover, we introduce the experimental results of conventional APUF evaluated by these indicators. Section V compares DAPUF to other APUFs which have two selector chains by using the indicators. Section VI proposes 3-1 DAPUF and compares it to 3-1 APUF, which have three selector chains by using the indicators. Finally, Sect. VII concludes this work.

II. ARBTIER PUF

Arbiter PUF (APUF) is one of the delay-based PUFs that use the difference between delay times of two signals. APUF has left and right selector pairs connected in series as shown in Fig. 1. Each bit of n-bit challenge c corresponds to a selection input c_i to the selector pair P_i ($0 \leq i < n$). After the challenge is determined, an input signal is supplied to the first selector pair P_0 at the same timing. For the case of $c_i = 1$, the left (right) selector in P_i is cross-connected to the right (left) selector in P_{i+1}, respectively. For the case of $c_i = 0$, the left (right) selector in P_i is straightly connected to the left (right) selector in P_{i+1}. This means that an input signal reaches through various paths depending on the value of the challenge. A 1-bit response is determined by which signal reaches an arbiter faster than the other. The response is strongly affected by the propagation path of the input signal, *i.e.* the challenge.

In APUFs, it is possible to increase the number of challenge bits easily by using more selector pairs [3]. APUF with n selector pairs has 2^n challenges. It is known that APUF can be modeled and simulated by building software models and programs based on the relation between challenges and responses [11]. This modeling against APUFs makes it possible for an attacker to predict responses for almost all challenges [15].

In order to prevent this modeling prediction, N-XOR APUFs have been proposed, where N-bit responses obtained from N APUFs are XORed into 1-bit response [3].

III. MOTIVATION

Previous work of [12][13] reports that APUFs implemented on Xilinx Virtex-5 FPGAs generate responses with low uniqueness. DAPUF has been proposed in order to generate responses with high uniqueness even on such FPGAs [14]. Although almost all of DAPUFs improve the uniqueness of responses, the authors of [14] clarify that one pair of the DAPUFs has comparatively low-unique responses, which should be solved.

In this paper, we divide APUF into three components as shown in Fig. 1.

- An input signal part

- A selector chain part (building block)
- An arbiter part

Two wires are input to the top of the building block, and two wires are output from the bottom of it as shown in Fig. 1. The two wires from the top connect the input wires to 1-bit selector pair P_0, and that from the bottom connect output wires from n-bit selector pair P_{n-1} to the arbiter. The input signal is provided into the selector pair P_0 at the same time through the two wires from the top. Depending on the challenge value, the right input signal reaches the arbiter as the left or right signals.

To divide APUF into three parts enables us to clarify the difference between 2-2 DAPUF and 2-2 APUF: assignment of the input signal part and the arbiter part to the selector chain part, *i.e.* the mode of operation for APUF. We evaluate both PUFs with the same circuit costs as for the uniqueness, randomness, and steadiness of the PUFs and make comparison of these.

IV. Preliminary for Our Experiment

A. Experimental Environment

In this paper, APUF was implemented on a Xilinx Virtex-5 FPGA (XC5VLX30) [16] on SASEBO-GII (Side-channel Attack Standard Evaluation Board) [17]. Xilinx ISE 13.2 and Xilinx PlanAhead 13.2 were used for logic synthesis and floorplanning, respectively. We designed the APUF with 64-bit challenges so that wire length difference between two paths could be minimized by using Static Timing Analysis (STA), according to [9]. The selector pair (P_i) is located on the SLICE pair (X14Y(76-i), X15Y(76-i)). An input signal is supplied from the register with the equal distances from 1-bit selector pair P_0. A response is generated from another register (*i.e.* the arbiter in Fig. 1) with the equal distance from selector pair P_{n-1}.

B. Evaluation Indicators

Several performance indicators of PUFs are introduced in [18].

1) Uniqueness: When the same challenge is given to different PUFs, the responses should be completely different from one another. We use the value of SC Inter-HD (Same-Challenge Inter-Hamming Distance) [13] divided by the response bit length as the indicator of uniqueness. SC Inter-HD is calculated as the average of the Hamming distances between two responses obtained from different two PUFs for the same challenge. If the value of the uniqueness is close to 50%, we regard the uniqueness of the responses to be high in this paper.

2) Randomness: The proportion of 0s and 1s in responses should be equal. In this paper, we define the randomness of responses as the average number of 1s in responses (for randomly chosen challenges) divided by the responses bit length. The randomness of responses is 50% ideally.

3) Steadiness: When the same challenges are given to a PUF for repeated measurements, all of the responses should be the same. We use the value of SC Intra-HD (Same-Challenge Intra-Hamming Distance) [13] divided by the response bit length as the indicator of steadiness. SC Intra-HD is calculated as the average of the Hamming distances between arbitrary two responses for the same challenge. If the steadiness is close to 0%, we regard the steadiness of responses to be ideal.

C. Results of Conventional Arbiter PUFs on FPGAs

Previous work [12][13] shows that APUFs implemented on Xilinx Virtex-5 and Kintex-7 FPGAs generate responses with low uniqueness, experimentally. In this section, we implement APUFs on Virtex-5 FPGAs and evaluate these PUFs for preliminary experiments.

First, we evaluate the uniqueness of 5000-bit responses obtained from APUFs on FPGA-A, FPGA-B, and FPGA-C. Table I shows the uniqueness of responses obtained from conventional APUFs on Virtex-5 FPGAs. The uniqueness is less than 5%, while 50% ideally. This means that physical variation of each PUF cannot be extracted as the uniqueness of responses.

Second, we evaluate the randomness of 2^{16} responses. The results are shown in the left part of Table II. The randomness is around 50%, which is the ideal. However, the authors in [19] report that the most of responses from APUFs on Virtex-5 FPGAs become either 1 or 0 with particular challenges. They evaluated 2^{16} responses from 64-bit APUFs for the challenges where $c_0 = c_1 = \cdots = c_7 = 1$ are fixed and $c_8, c_9, \ldots, c_{63}$ are randomly chosen. Under the condition that the Hamming weight is odd, the proportion of 1s in responses is approximately 80%, and under the condition that the Hamming weight is even, the proportion of 1s in responses is approximately 30% [19]. If the difference between the delay times of the two signals in selector chains is critically large, the responses are determined by whether the signal having larger delay than the other reaches right or left wire input to the arbiter. The two signals of conventional APUFs are crossed when $c_i = 1$ $(0 < i < 64)$. Therefore, whether Hamming weight of c_i is odd or even determines whether the signal having larger delay is supplied to the right or left wire. Under the condition of randomly chosen challenge, the proportion of 1s and 0s in responses become approximately 50%. In the result, the randomness of the responses from conventional APUFs on FPGAs comes to 50% regardless of the proportion of 1s and 0s in responses for particular challenges.

Finally, we evaluate the steadiness of 128-bit responses. The results are shown in the right part of Table II. The steadiness is calculated with 128-bit response for fixed challenges for 128 repeated measurements. The challenges are

randomly chosen. The steadiness is less than 1% among all pairs of FPGAs, which is nearly ideal as PUF. It shows that conventional APUFs generate the same responses for the same challenges. However, it is based on low uniqueness of the responses.

We reconfirm that the conventional APUFs on Virtex-5 FPGAs have low unique responses, which are not enough to perform as ideal PUFs.

V. DAPUFs *v.s.* APUFs OF $m = 2$

A. Modes of Arbiter Operation

1) Double Arbiter PUF: It is discussed that the length of the two wires in APUF are not equal at all [19]. In [14], it is suggested that the reason why conventional APUFs on Virtex-5 FPGAs generate low-unique responses is the unequal length of the two wires. Since the difference between delay times arisen from physical variations is much smaller than that from the signal propagation on the wire, the physical variations of each PUF cannot be found in responses, *i.e.* the uniqueness of responses become low. In order to generate responses with high uniqueness, it is proposed that a novel technique called *Double Arbiter PUF* (2-2 DAPUF) [14]. 2-2 DAPUF is designed for the purpose of equalizing the length of the two wires. Figure 5 shows the floorplanning for Xilinx PlanAhead. As illustrated in Fig. 5, the length of wires (1) and (2) seems equal but different precisely. Therefore, the authors duplicate another APUF on neighboring SLICEs where the original APUF is implemented. The authors expect that wire (1) has the almost the same length as wire (3) because both cell-pairs (1a,1b) and (3a,3b) are symmetrically located on the neighboring SLICEs.

Figure 2(a) shows the mode of operation for APUF of 2-2 DAPUF. Let $S_{i,L}$ and $S_{i,R}$ be the left and right wires which are inputs to the first selector pairs P_0 in Selector Chain i $(1 \leq i \leq 2)$, respectively, as shown in Fig. 2(a). The signals on $S_{1,L}$ and $S_{2,L}$ are supplied to Selector Chain 1 and 2 at the same time. Let $W_{i,L}$ and $W_{i,R}$ be the left and right wires, respectively. They are outputs from the n-th selector pairs P_{n-1} in Selector Chain i $(1 \leq i \leq 2)$, respectively. The signal on $S_{1,L}$ reaches $W_{1,*}$ $(* \in \{L, R\})$ and the signal on $S_{2,L}$ reaches $W_{2,*}$ regardless of the value of the challenge. Similarly, the signals on $S_{1,R}$ and $S_{2,R}$ are supplied to the Selector Chain 1 and 2 at the same time. Two 1-bit responses $r1$ and $r2$ are generated from two pairs of wires ($W_{1,L}$, $W_{2,L}$) and ($W_{1,R}$, $W_{2,R}$), respectively. Therefore, the signals on $S_{1,L}$ and $S_{2,L}$ are not crossed even if $c_i = 1$ $(0 < i < 64)$. The signals on $S_{1,R}$ and $S_{2,R}$ are also not crossed even if $c_i = 1$.

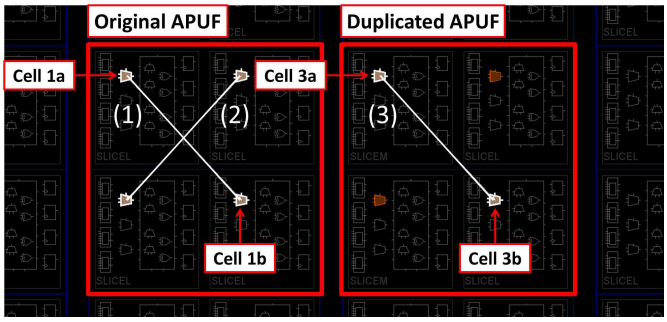

Fig. 5. Xilinx PlanAhead floorplanning

2-2 DAPUF generates 2-bit responses. We propose *2-1 DAPUF* that generates 1-bit responses obtained by XORing the 2-bit responses as shown in Fig. 3(a).

2) 2-XOR Arbiter PUF: We consider two PUFs that have the same circuit costs as DAPUFs of $m = 2$, *i.e.* having two selector chains. A straight forward example of APUFs of $m = 2$ is just two APUFs generating responses, *i.e. 2-2 APUF* as shown in Fig. 2(b). The signals on $S_{1,L}$ and $S_{1,R}$ are supplied to Selector Chain 1 at the same time. It depends on the value of challenges whether signal on $S_{1,L}$ or $S_{1,R}$ reaches $W_{1,L}$ or $W_{1,R}$. Similarly, the signals on $S_{2,L}$ and $S_{2,R}$ are supplied to the Selector Chain 2 at the same time. Two 1-bit responses $r1$ and $r2$ are generated from two pairs of wires ($W_{1,L}$, $W_{1,R}$) and ($W_{2,L}$, $W_{2,R}$), respectively. Therefore, the signals on $S_{1,L}$ and $S_{1,R}$ are crossed when $c_i = 1$ $(0 < i < 64)$. The signals on $S_{2,L}$ and $S_{2,R}$ are also crossed when $c_i = 1$. This is different from 2-2 DAPUFs in which the two signals are not crossed. We compare 2-2 APUF to 2-2 DAPUF and discuss the uniqueness, randomness, and steadiness. The difference of the wire connections has influence on its results, as mentioned in next section.

These 2-bit responses can be XORed into 1-bit responses: 2-1 APUF (2-XOR APUF) as shown in Fig. 3(b). We compare 2-1 APUF to 2-1 DAPUF according to the uniqueness, randomness, and steadiness.

B. Results

The results of the uniqueness and randomness of 2-2 DAPUF are from [14].

First, we evaluate the uniqueness of 5000-bit responses obtained from DAPUFs and APUFs of $m = 2$. The results are shown in Table III. The uniqueness of responses from 2-2 DAPUFs introduced in [14] is higher than that from 2-2 APUFs. However, the uniqueness of responses $r1$ between FPGA-A and FPGA-B is approximately 9%, which is comparatively lower than that of others. The reason for this is discussed along with the results of the randomness, as mentioned in the next paragraph. The uniqueness of responses from 2-1 DAPUFs is approximately 42%, which is much higher than that from 2-1 APUFs.

Second, we evaluate the randomness of 2^{16} responses. The results are shown in Table IV. In the following, we discuss the reason why 2-1 APUFs have low randomness although conventional APUFs have high randomness. From Table III, two conventional APUFs on Virtex-5 FPGAs generate low-unique responses: one PUF generates the same responses as the other PUF for many challenges. Therefore, 2-1 APUFs whose 1-bit response is obtained by XORing the responses of the two PUFs have low randomness obviously because the response becomes 0 when the same values are XORed. However, it is worth mentioning that the high randomness value is just superficial as mentioned in Sect. IV C. The reason why one pair of the 2-2 DAPUFs has comparatively low uniqueness of responses can be explained by low randomness of responses $r1$ on FPGA-A and FPGA-B. Here, we discuss one of the reasons of this low randomness.

A	0.76	0.67	0.67	7.11	1.43	7.79
B	0.83	0.73	4.70	6.52	1.36	11.22
C	0.45	0.08	2.96	7.24	0.52	10.05

2-2 APUFs
: Even if the deterministic difference between delay times of the two signals is produced, the randomness seems high. Because it depends on Hamming weight of challenge whether the signal having lager delay than the other is supplied to left or right wire input to the arbiter.

2-2 DAPUFs
: In contrast, if the deterministic difference between delay times of the two signals is produced, the randomness can become low. Because it does not depend on Hamming weight of challenge whether the signal having larger delay is supplied to left or right input to the arbiter. This is caused by the signals on $S_{1,L}$ and $S_{2,L}$ ($S_{1,R}$ and $S_{2,R}$) are not crossed, as mentioned above.

Finally, we evaluate the steadiness of 128-bit responses. The results are shown in Table V. Almost all of the implemented 2-1 DAPUFs generate responses with lower steadiness than 2-1 APUFs. We consider that the large difference of delay times arisen from the imbalance wire length, as mentioned in Sect. IV C, results in high steadiness, but in contrast, low uniqueness. There is a trade-off between steadiness and uniqueness.

VI. 3-1 DAPUF *v.s.* 3-1 APUF

A. Modes of Arbiter Operation

1) 3-1 Double Arbiter PUF: One pair of the 2-2 DAPUFs has comparatively low uniqueness of responses because they have still biased responses [14]. In order to eliminate the influence of the biased responses, we use the following technique. We duplicate another APUF, *i.e.* having three selector chains, and generates multiple responses. Even if each of these responses is biased, we can obtain a less-biased response by XORing these responses. Let $W_{i,L}$ and $W_{i,R}$ be the left and right wires which are outputs from the n-th selector pairs P_{n-1} in Selector Chain i $(1 \leq i \leq 3)$, respectively. We use two wires chosen from three left wires: $W_{1,L}$, $W_{2,L}$, $W_{3,L}$ to generate three 1-bit responses as shown in Fig. 4(a). Similarly, we use two out of three right wires: $W_{1,R}$, $W_{2,R}$, $W_{3,R}$. Therefore, the left and right wires can generate six 1-bit responses in total. In this paper, we consider *3-1 DAPUF*: having three selector chains and generating a 1-bit response by XORing the six 1-bit responses.

2) 3-XOR Arbiter PUF: 3-1 APUF (3-XOR APUF) generates 1-bit responses obtained by XORing 3-bit responses from three conventional APUFs as shown in Fig. 4(b). The circuit costs of a 3-1 APUF are the same as that of a 3-1 DAPUF. They have three selector chains and generate 1-bit responses. We compare 3-1 DAPUF to 3-1 APUF according to the uniqueness, randomness, and steadiness.

B. Results

First, we evaluate the uniqueness of 5000-bit responses obtained from APUFs and DAPUFs of $m = 3$. The results are shown in Table VI. The uniqueness of responses from 3-1 DAPUFs is $50\pm1\%$, which is very close to the ideal results. In contrast, the uniqueness of responses from 3-1 APUFs is approximately 6%, which is much inferior to that from 3-1 DAPUFs. Further, 3-1 DAPUFs generate responses with high uniqueness among all pairs of FPGAs although one pair of the 2-2 DAPUFs has comparatively low uniqueness of responses. This means that we can eliminate the influence of the biased responses from the DAPUFs. The uniqueness of responses from 3-1 APUFs does not improve similarly to 2-1 APUFs. We consider that this is caused by the low uniqueness of each response from three conventional APUFs.

Second, we evaluate the randomness of 2^{16} responses. The results are shown in Table VII. The randomness of responses generated from 3-1 DAPUFs is around 50%, which is almost ideal. Further, the randomness of responses from 3-1 DAPUFs is more improved than that from 2-1 DAPUFs. The randomness value of responses from 3-1 APUFs seems high since the number of XORing responses are three (odd number).

Finally, we evaluate the steadiness of 128-bit responses. The results are shown in Table VIII. The steadiness of responses from 3-1 DAPUFs is approximately 12%, which is

TABLE VI. UNIQUENESS [%] OF APUF AND DAPUF OF $m = 3$

inferior to that from 3-1 APUFs. We consider that one of the reasons is a trade-off between the steadiness and uniqueness.

We show the summary of the uniqueness, randomness, and steadiness for 1-1, 2-1, and 3-1 PUFs in Figs. 6, 7, and 8, respectively. The uniqueness of responses from APUFs and DAPUFs is improved with the increasing the number of selector chains. It is clear that the uniqueness of responses from DAPUFs using the new mode of operation is superior to APUFs. The randomness of responses from DAPUFs is also improved with that. That from only 2-1 APUFs having the even selector chains is lower than the other. However, the high randomness of 1-1 and 3-1 APUFs is just superficial as mentioned above section. In contrast, the steadiness of responses become low, *i.e.* the value of steadiness is high, with that.

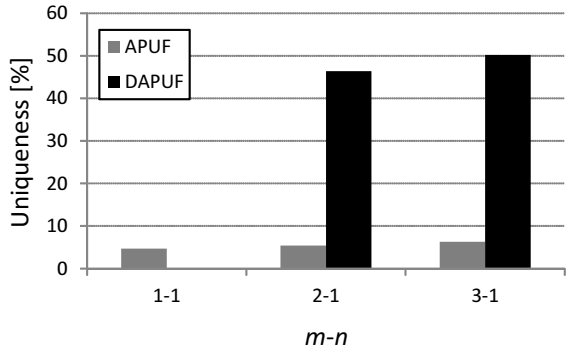

Fig. 6. Summary of uniqueness for m-n APUFs and DAPUFs

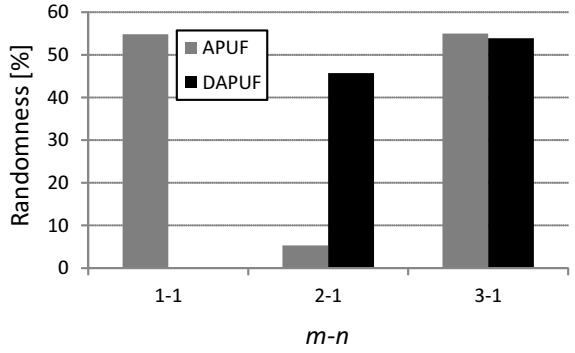

Fig. 7. Summary of randomness for m-n APUFs and DAPUFs

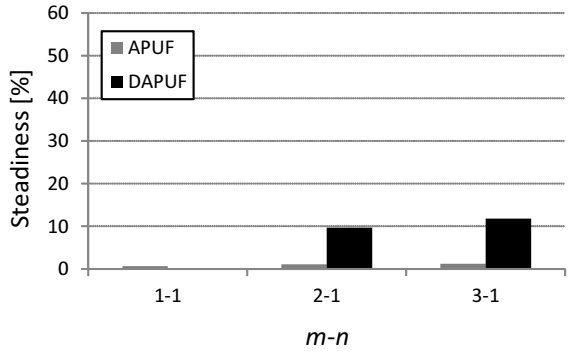

Fig. 8. Summary of steadiness for m-n APUFs and DAPUFs

We show that we can improve the uniqueness and randomness by using the new mode of operation for APUF and using responses obtained by XORing responses from more duplicated selector chains on Virtex-5 FPGAs.

VII. Conclusion and Future Work

2-2 DAPUF was proposed in order to generate responses with high uniqueness in previous work. In this paper, we introduced new concept: *mode of operation for APUF* that was determined by the connection method of the wires to arbiter. We compared DAPUFs and APUFs of $m = 2$ that have two selector chains such as 2-2 DAPUF and 2-1 APUF and evaluated these PUFs regarding the uniqueness, randomness, and steadiness. Further, we proposed 3-1 DAPUF by using three selector chains, which was improved version of DAPUF. We compare 3-1 DAPUF to 3-1 APUF, which have three selector chains, and evaluate these PUFs. From our experimental results, the uniqueness of responses from 3-1 DAPUFs was approximately 50%, which was much superior to that from 3-1 APUFs. On general FPGAs, we showed that we could improve the uniqueness and randomness by using the new mode of operation for APUF and using responses obtained by XORing responses from more duplicated selector chains.

The future work of this study is to implement *4-1* or *5-1 DAPUF* and to evaluate the responses from these PUFs according to the uniqueness, randomness, and steadiness. Further, we compare these PUFs to 2-1 and 3-1 DAPUFs by using the results.

***Abstract*—The paper presents a performance evaluation of message broker system, Rabbit MQ in high availability - enabling and redundant configurations. Rabbit MQ is a message queuing system realizing the middleware for distributed systems that implements the Advanced Message Queuing Protocol. The scalability and high availability design issues are discussed. Since HA and performance scalability requirements are in conflict, scenarios for using clustered RabbitMQ nodes and mirrored queues are presented. The results of performance measurements are reported.**

I. Introduction

MODERN distributed systems have modular architecture. The applications, devices or appliances which are distributed parts of the whole solution, need to connect and scale. The applications need to connect to one another as components of a larger application, or to user devices and data. Nowadays, messaging, understood as an information flow or a network rather than a stack, needs to be supported by the system. As Richardson writes in [21]: "Future applications (..) [will be] always on, cloud hosted, and accessible anywhere. Input and processing are continuous and automatic, and deliver a filtered stream of information that the user wants, as it happens."

The middleware layer, often referred to as a 'glue' between different system components, allows communication between them. The modern requirement is to overpower the limits of point-to-point communication, and, moreover, to do it in a non-synchronous fashion. This is also referred to as a time- , space- and synchronisation-decoupling [6], and is especially important, given the fact, that the distributed systems now involve thousands of entities, which may be distributed throughout vast geographical distances, and whose behaviour and even location may vary in time. Message queuing also called message-oriented middleware is an architectural pattern. It is based on a message broker, an intermediary program which realizes message validation, message transformation and message routing functions. Message broker provides common infrastructure for interactions between elements of the distributed systems, which interact by sending or receiving messages. It is a recent alternative for distributed interaction between components, entities of an information processing system. Message queuing is thoroughly described, for example, in [2], [3] and [6]. It is often based on a publish/subscribe-like interaction [6]. The message queuing is an alternative to Classifications, which are complementary to the publish/subscribe model of a distributed information system [9]. Classifications involve techniques such as message passing, shared spaces or remote invocations and constitute solutions to the middleware layer challenges. Middleware systems are also subject to numerous studies, concentrating on networking and concurrent design. There is a concept of using patterns in overall software architecture, with [5] as a main example, or for security related applications ([7], [8]).

This work was supported by Proximetry Poland

This paper describes design considerations of scalability and high availability (HA) improving solutions using RabbitMQ software, an open source message broker and queuing server that is becoming more and more popular as a middleware. The balance between HA and scalability is challenging because of contrary requirements, the scalability and performance-optimisation mechanisms are in principle hindered by high availability or fault tolerance solutions, which prefer stability and durability over performance.

This paper presents possible configuration scenarios for a RabbitMQ cluster of servers, which combine scalability with high availability / fault tolerance (HA/FT) requirements. For this purpose, RabbitMQ is described as middleware and clustering options are presented as well as HA possibilities. The scenarios were implemented for test-field studies, whose results are presented. Most of the available literature or reports such as [1], [19] or [13] concentrates on the scalability issues and performance results, or, from a different perspective, strictly on high availability / fault-tolerance solutions for queuing [21]. This paper aims to bring a novelty in discussing solutions that combine both requirements, as it is a probable industry scenario.

The paper is organized as follows: the design requirements for middleware system are presented and briefly explained—specifically, scalability and high availability concerns are discussed. The next part includes a short summary of RabbitMQ, the message broker used in research. The main part includes message broker configuration scenarios for scalability and high availability; the experimental results of constructed systems are presented for comparison. Finally, conclusions are revealed.

II. RABBITMQ AS A MIDDLEWARE

From designer's perspective, message-oriented middleware can be seen as a (1) queuing system, where messages are concurrently pulled by consumers, as well as (2) subscription-based exchange solution, allowing groups of consumers to subscribe to groups of publishers, resulting in a communication network or platform, or a message bus [6]. Such bus or queuing system has to be able to scale in terms of geographical distance as well as in terms of devices or applications served. Quoting Jones et al. [13], "the distribution of information sent from the publishers to the hub to be distributed to the necessary subscribers allows for applications to run while relying on data from other locations, wherever they may be."

RabbitMQ is an open source message broker and queuing server that can be used to let disparate applications share data via a common protocol or to simply queue jobs for processing by distributed workers. RabbitMQ middleware supports many messaging protocols [17], among which the most important are STOMP: Streaming Text Oriented Messaging Protocol [20] and AMQP: Advanced Messaging Queuing Protocol [11].

Within this paper the AMQP-defined messaging architecture is used. Within the core of the message broker architecture are queues; every message received by the RabbitMQ always is placed in a queue. Messages in queues can be stored in memory (memory-based) or on a disk (disk-based). Second important elements of the RabbitMQ are *exchanges* - the delivery service for messages. The exchange used by a publish operation determines if the delivery will be direct or publish-and-subscribe, for example. A client chooses the exchange used to deliver each message as it is published. The exchange looks at the information in the headers of a message and selects where they should be transferred to. This is how AMQP brings the various messaging idioms together - clients can select which exchange should route their messages [15].

A. Specific system design requirements for middleware

1) Scalability: Scalability is an architectural characteristic, which can be defined as a capability to cope and perform under an increased or expanding workload. A system that scales well will be able to maintain or even increase its level of performance or efficiency when tested by larger operational demands. In terms of message-queuing, or even publisher/-consumer exchange system, this would mean the possibility of increasing processing speed or message throughput, user capacity, etc.

2) Resiliency: In order to be resilient (which means to be able to deal with internal failures), the system needs to implement some forms of high availability (HA) or fault tolerance (FT). In general, HA and FT systems are designed with two different design principles in mind. Given the availability (A) formula (eq. 1),

$$A = \frac{MTBF}{MTBF + MTTR}$$

HA aims to minimize downtime and IT service disruption; so the common goal in HA is to increase Mean Time Between Failure (MTBF) and decrease Mean Time to Repair (MTTR). HA applications are designed to have a high level of service uptime. HA solutions may feature many elements, e.g: system management, live replacement (hot-swap), component redundancy and failover mechanisms. Common strategy is to avoid single points of failure in the system. This can be difficult, because demands on such systems include not only ensuring the availability of important data, but also efficient resource sharing of the relatively expensive components.

Typical HA solution involves clustering; symmetrical (all nodes have similar capabilities) or asymmetrical (nodes have different possibilities and inventory). Clustering in this context can be described as the use of two or more systems loosely coupled to provide system level redundancy. Because these systems are not directly coupled, they utilize standard network connections to communicate failovers. This can cause failover latencies to take several seconds to complete. Typically, there is a middleware software solution to provide a failover mechanism between the two systems. But this middleware has to be protected with HA in mind as well, possibly with the use of clustering.

Contrary to HA, which implies a service level in which both planned and unplanned outages do not exceed a small stated value [18], fault-tolerant (FT) systems tend to implement as much component redundancy and mirroring techniques as possible, in order to eliminate system failures completely (this is of course from client's perspective, in fact introducing redundant components will make component failures occur faster) [4].

But FT has its problems; performance degradation is another concern. As an example, let's discuss mirroring a single server. Besides handling all of the file transfer work for network users, the primary server may have to process additional I/O as it passes information along to the mirror server. This can also add substantial processor overhead if system usage is heavy. In effect, RAM, CPU and network performance is degraded.

B. Scalable and fault-tolerant middleware

Message broker, being one of the most crucial components of distributed system, is supposed to be fault-tolerant. That means, typical HA configuration (as described in II-A1) is not the best option; restarting message broker on another node in case of failure would introduce a timeout span, as the service is being restarted and prepared for operation, but, what is worse, the message queue of failed message broker would be lost entirely. For message broker, both HA and FT solutions were considered:

1) HA (Active/Passive solution): in which the downtime of message broker service is expected in case of planned or unplanned unavailability of primary server. Queues and messages have to be persistent (disk-based), and message broker can be restarted elsewhere in the system. It is possible to base such solution on virtualization, where MB running host can be virtualized and rely on hypervisor built-in HA mechanism. This would cause hypervisor to run another instance of VM in case of a failure of primary MB guest or

even virtualization host. Another active/passive solution is to deploy clustering HA solution like pacemaker [16] in order to manage message broker and restart it (or migrate) when necessary, using available resources.

2) FT (Active/Active solution): means that the planned or unplanned downtime of message broker doesn't have any effect on queuing system. Typically it is implemented by MB leveraging clustering mechanism built-in RabbitMQ, which is developed strictly for such situations, and replicates queues on every RabbitMQ node in the cluster. RabbitMQ nodes failure monitoring, and IP load-balancing techniques are explained further in detail. Active/active solution can also be based on virtualization, where MB running host can be virtualized and, for example, marked as FT-demanding in VMware vCenter virtualisation environment. This would create a VM mirror image called "replica", updated in real-time, ready to be run in case of a failure of primary MB host.

The second solution is a typical Active/Active topology and is recommended as more reliable and scalable at the same time. Additionally, virtualization was not considered, because it would introduce additional conditions and variables to the experiments and is a subject for another study. This paper's research is concentrated on RabbitMQ message broker clusters and its characteristics.

C. RabbitMQ cluster setup and operation

The clustering built into RabbitMQ was designed with two goals in mind: allowing consumers and producers to keep running in the event of node failure, and linearly scaling messaging throughput by adding more nodes [21]. With clustering, a client can connect as normal to any node within a cluster. If that node should fail, and the rest of the cluster survives, then the client should notice the closed connection, and should be able to reconnect to some surviving member of the cluster. [17]

The design decision that had to be made was an IP addressing of the cluster. As RabbitMQ documentation describes, it's not generally advisable to hardcode node hostnames or IP addresses into client applications: this introduces inflexibility and will require client applications to be edited, recompiled and redeployed should the configuration of the cluster change or the number of nodes in the cluster change. As in general, this aspect of managing the connection to nodes within a cluster is beyond the scope of RabbitMQ itself. RabbitMQ's authors recommend a more abstracted approach, including a dynamic DNS service which has a very short TTL configuration, or a plain TCP load balancer (for example HAproxy [12]), or some sort of mobile IP achieved with pacemaker or similar technologies [16]. For this study, HAproxy was chosen as a load balancer between clients and cluster nodes.

III. Clustering scenarios

The maximization of the systems performance suggests that content of the queues should not be replicated throughout the cluster. The queue owner node has full information about it; other nodes in the cluster only know the queue's metadata and a pointer to the node where the queue actually is stored.

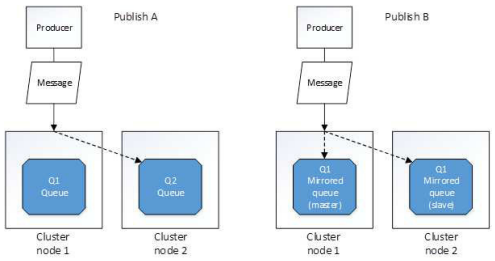

Fig. 1. Publishing to queues: a) on another node, b) to the mirrored queue.

This solution allows to limit storage space requirements and increase performance—replicating messages to every node would result in increase of network and disk load for every node, keeping the performance of the cluster the same (or worse) [21]. Regardless where publish is made, message will end up on the queue owner node. This leads to main performance optimization technique: to increase performance for every added node by spreading queues across nodes. On the contrary to performance-driven requirements for queues, there is a need for queue to be redundant when the main goal is to achieve high availability and fault tolerance. If a queue owner node fails, all of the messages within a queue are gone. An active-active redundancy option is possible; any queue can be mirrored. The mirrored queue is achieved by creating slave copies of the queue on other nodes in the cluster. It can be copied on every node, but the designer is able to specify a subset of nodes in the cluster for a queue to live on. Both situations are presented on Fig. 1.

The design of the cluster and its queues can support the following:

1) Creating fully mirrored queues on every node in order to achieve HA; create very efficient connection between nodes and create RAM nodes for quick distribution of messages,
2) Creating spread queues, but configure mirrored queues for at least one master and one slave (allowing for one node failure),
3) Creating fully spread queues and do not mirror them, but make them durable instead—all of the nodes are disk based, and in the event of failure, message broker is restarted elsewhere.

Within above listed possibilities, 1) is a scenario for maximum fault-tolerance, 3) is a scenario allowing some downtime for maximum performance (which is HA scenario) and 2) is a compromise between those two.

A. Cluster and queues configuration

Considering a three-node cluster, one can come up for specific testing scenarios that can provide comparable results for performance assessment [14]. Those results may provide an answer, whether given configuration is useful for a specific real-world scenario [10]. For testing purposes, there were following implications made: a) cluster may include up to three nodes, b) queues are created in the cluster as a single

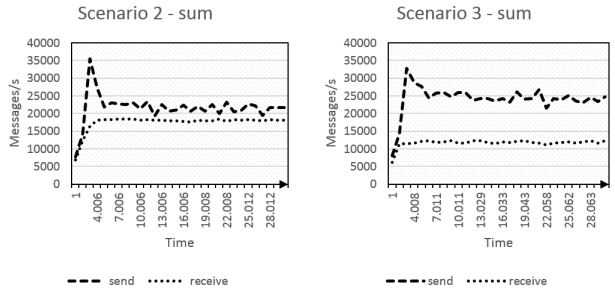

Fig. 3. The comparison of two-queue, one-client-per-queue publishes and consumes using scenario 2 and scenario 3.

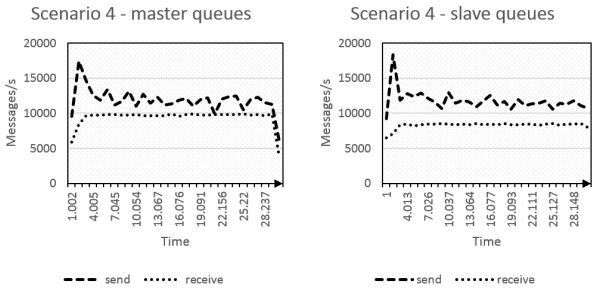

Fig. 4. Mirrored queues performance results example.

(non-mirrored), fully mirrored, and spread (mirrored to one node) queue, c) all of configuration scenarios are put to the three tests:

1) single publishes and consumes: there are single publishers and consumers for both queues,
2) balanced conversations: there are three publishers and three consumers for every queue (as many as cluster nodes),
3) many conversations: there are six publishers and six consumers.

Possible configuration possibilities for two queues are presented on Fig. 2. On the left, there is no fault-tolerance; queues are not mirrored and the cluster is configured for performance scalability; on the right, queues are mirrored for resiliency—this is possible only using two nodes minimum; adding the third node creates two possibilities—mirroring queues and adding one node for scalability (scenario 5) or spreading mirrored queues on available nodes (scenario 6).

B. Initial testing and results

All of scenarios were tested with commodity-equipped virtual machines (single core, 4GB RAM, 8GB HDD) which eliminated any possible networking issues. The hypervisor host was equipped with Intel i7 CPU and 32GB RAM. There was no resource overload. The most interesting observations were as follows. In conclusion A, there is practically no difference between the performance of publishing to single or multiple queues on one node. Scenario 1 is viable and does not introduce any performance problems. This question doesn't need any more evaluation.

The results of scenario 2 and scenario 3 (more than one node in the cluster) show significant improvement of performance over scenario 1. Fig. 3 presents exemplary results of single publisher and consumer for both queues, summarized for comparison. These results are expected, however designer has to keep in mind such configuration is not fault-tolerant—if a node fails, the queue is no longer available for publishing or consuming. The difference between scenario 2 and scenario 3 is interesting and should be a subject for another study—adding supplementary node allowed faster publishing, but the consuming rate dropped, as the cluster nodes communication introduced an overhead. In effect, whole system performance was kept on the same level. This design could be more appropriate with large number of publishers and consumers, but such study is out of scope for this paper.

The performance of sending and receiving to mirrored queues, as in scenarios 5 and 6, is significantly worse. Fig. 4 shows typical results (scenario 4 is shown). The difference between publishing and consuming to the master (owner) node compared to publishing and consuming from the slave node is as expected - publishers are unaffected, but the consumers suffer from intra-cluster traffic (master-to-slave) overhead.

C. Detailed evaluation

The initial tests results show the importance of load balancing the traffic between the clients and cluster nodes. The message publishing or consuming rate depends whether the client was redirected to the:

1) "master" node (the node which is the master for the specific queue being used),
2) "slave" node (the node which specific queue is being replicated onto),
3) "empty" node (the node which is part of the cluster but the queue resides on other nodes).

If the client is redirected onto "master" or "slave" nodes, the published messages do not need to be communicated to every node in the cluster, which has good effect on performance. Otherwise, message sending/receiving rates drop.

For detailed information on this impact, the cluster was set up with three nodes - two disk-based and one RAM-based. Such configuration assures that if queue is mirrored, it always resides on at least one disk-based node, and messages are written to disk and can be retrieved even after power failure. For such cluster, a single queue was tested for performance when configured as:

1) "single" queue (not mirrored at all, for performance comparison and load balancing issues evaluation described before),
2) "spread" queue (mirrored to one other node in the cluster, as suggested in scenario 6),
3) "mirrored" queue (mirrored to every other node in the cluster).

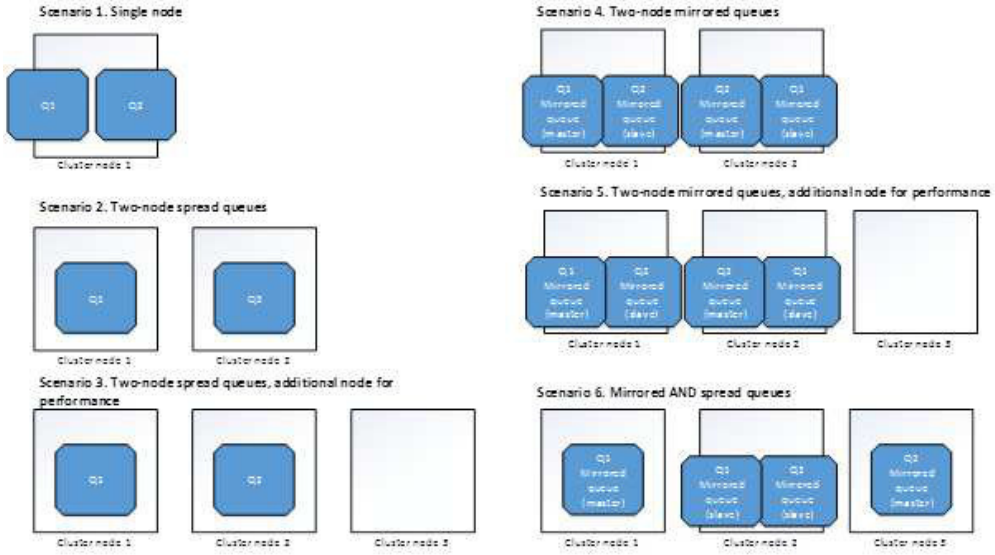

Fig. 2. Performance-driven vs. Fault-Tolerant-driven testing scenarios.

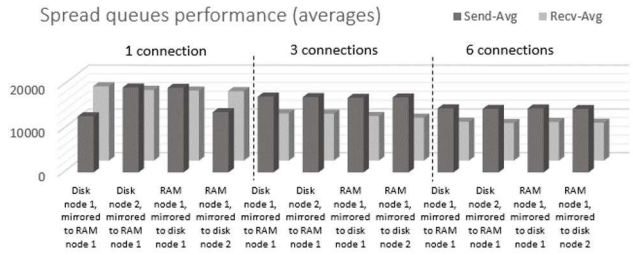

Fig. 5. Spread queues performance extensive testing results comparison

The results are presented in Table 1. For every queue configuration average message publication/consummation rates (for 9 consecutive tests) are shown, as well as standard deviation. The effect of load-balancing is visible mostly for single client consuming from mirrored queues—if the client's request is redirected to an empty node, the average message receive rate is significantly lower. Also, the effect is visible when sending to single-hosted queue, as the two other nodes are empty, therefore they need to redirect a request.

Fig. 5 presents exemplary detailed extensive testing run results in quantitative form, but gathered for comparison and conclusions. Every queue configuration was created on master disk or RAM node, then tested for a minute-long run ten consecutive times. Such tests were conducted for one, three and six simultaneous connections.

Most important observations are, as indicated by mutliple tests (ca. 50 re-runs), the performance of single queue drops significantly when this queue is mirrored throughout entire cluster for fault-tolerance. Full mirrored queue is therefore not as good architectural choice as it would seem, especially if there are frequent moments of only one producer active. The performance of spread queues is about 10%-20% minimum better than fullmirrored queues on a three-node cluster. There is no significant difference in RAM / disk node effect on mirroring. Spread queues are stable; performance degradation is however visible when receiving by many clients at once.

IV. Conclusions

This paper shows there are many considerations for building clustered middleware and implementing scalable yet fault-tolerant system. Queues need to be distributed evenly, or internal transfers within the cluster will cause performance to drop, especially for receiving clients. There is, however a way to mirror queues asymmetrically, which is shown by experimental results in this paper.

Relevant studies show many more aspects have to be taken under consideration—for example, the disk-based nodes compared to RAM-based nodes performance, or the expected distribution of the clients (publishers and consumers) but results show there is a possibility to create a design principles for specific clients count and message rates requirements, which can be a subject of next authors' study. This is authors' contribution in discussing solutions that combine both requirements, as it is a real industry scenario.

To summarize results, study shows that while typical single queues on clustered nodes are key to performance, if the requirements include fault-tolerance, performance can still be improved by "spreading" queues to be mirrored only by one more node, as N+1 rule dictates.
