***Abstract*—Cloud computing and, more particularly, cloud databases, is a great technology for remote centralized data managing. However, there are some drawbacks including privacy issues, insider threats and potential database thefts. Full encryption of remote database does solve the problem, but disables many operations that can be held on DBMS side; therefore problem requires much more complex solution and specific encryptions. In this paper, we propose a solution for secure private data storage that protects confidentiality of user's data, stored in cloud. Solution uses order preserving and homomorphic proprietary developed encryptions. Proposed approach includes analysis of user's SQL queries, encryption of vulnerable data and decryption of data selection, returned from DBMS. We have validated our approach through the implementation of SQL queries and DBMS replies processor, which will be discussed in this paper. Secure cloud database architecture and used encryptions also will be covered.**

I. Introduction

RAPID growth and development of cloud technologies has leaded them to popularity and widespread usage. Although customers are excited by cloud features and benefits, they are very concerned about confidentiality of data stored and processed in a cloud. Insider threats combined with a general lack of transparency into provider process and procedure has dropped confidence in security of cloud data storage [1].

Data confidentiality is highly important for Cloud Databases (Database as a Service, DbaaS), and there are threats of disclosure of vulnerable user's data to unauthorized parties. First of all, curious and malicious database administrators may capture or leak data [3]. Also a theft of database may possibly occur, leaving data in hands of malefactor [4].

Listed problems are still actual [2], and as a result multiple solutions to problem of trusting clouds have been developed. Encryption of all data in remote database was offered as a method of providing provable confidentiality [5, 6]. But such an approach demands all operations will be held on a client side after decryption of database content. Other solutions, such as MIT CryptDB [7], lack fully homomorphic encryptions and use third-party encryptions with relatively low cryptostrength and known vulnerabilities [8].

To address listed cloud security issues we designed secure cloud database architecture, several encryption algorithms and a SQL data encoding component. Proposed solution addresses mentioned challenges using following key ideas:

- The first is to parse SQL queries and encrypt selected user data on client side. None of encryption keys are passed to server or to any proxy; all confidential data passed to DBMS are secure.
- The second idea is usage of wide variety of order preserving and fully homomorphic encryptions. All encryptions that are used in proposed solution are proprietary developed encryptions with relatively high speed and provable cryptostrength.
- The third technique is a combination of various encryptions in single table. Encrypting different columns with different encryptions within one table greatly reduce chances of successful cryptanalysis.

In this paper we present designed architecture, description of main components and overview of used encryptions.

The next section of paper features a brief explanation of basic principles giving the main idea of a handling of SQL queries used in proposed solution. After it, in Section 3, we describe the general architecture of proposed secure cloud database and client's component. Section 4 gives some insight into encryptions, which are used in secure SQL queries processing. Finally, the last section of this paper summarizes our achievements, also exposing some possible future development and additional security features improving protection of cloud database.

II. Basic Principles

In this Section basic principles are discussed illustrating main idea of secure cloud database. Core component of proposed secure cloud database is SQL queries processor. All user's SQL queries are analyzed and transformed by program components on client's side before sending to DBMS (see Fig. 1). Similarly, all replies from database are processed.

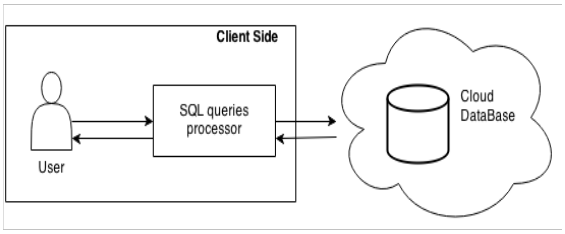

Fig. 1 Overview

Also, encryption of data, extracted from user's queries, is a responsibility of SQL query processing component. Proposed solution doesn't require any modifications on DBMS side.

User's SQL query handling is shown on Fig. 2. Information about encrypted columns such as encryption keys and encrypted column name(s) is needed in order to parse, decrypt and reconstruct user queries.

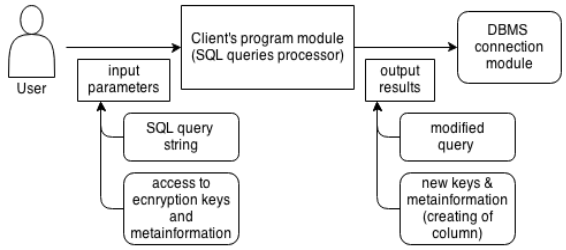

Fig. 2 Query processing

When user retrieves data from cloud database, selection of column comes as a reply from DBMS. Information about encrypted columns is needed to decrypt and present selected data to user in suitable form (see Fig. 3)

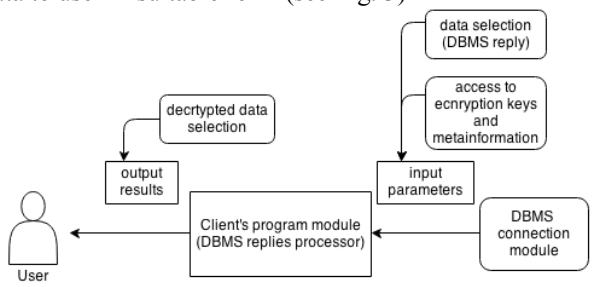

Fig. 3 Data selection processing

Basic idea of SQL queries processing is explained on different types of SQL expressions below.

"CREATE" statement is the only statement in terms of proposed secure cloud database, which may contain additional keywords, which are not included in SQL language. These keywords are markers of different encryptions applied to table columns. To indicate that column in currently created table should be encrypted, user should add a constraint corresponding to encryption's marker (identification string).

If SQL queries processing component encounters encryption marker, following steps will be performed. First, there encryption's keys are generated or chosen. Next, based on encryption information, number (can be more than one, in case when the result of encryption is a vector of multiple values), names, types and constraints of output columns are determined. Correct SQL string is created according to determined information.

After that modified statement is sent to DBMS. Output names of encrypted columns are anonymized, while anonymization of table name is optional (anonymization means changing real names of column to generated ones).

Processing of SQL statements such as "INSERT", "SELECT", "DELETE" uses common principles. All data from query are extracted and data from encrypted columns are encrypted. Also names of columns, which values are encrypted and used in processed statement, are modified according to their anonymized names. In some cases (for example, homomorphic encryption) changes in mathematical operation can be made. Responses for "SELECT" queries from database are decrypted if needed.

Correctness of performing "JOIN" operation inside DBMS depends on encryption properties. If encryption is deterministic, output column is single and both columns from each joining tables, have same key, no additional mechanisms are needed to perform "JOIN" operation.

It is very important to understand that some restrictions may apply to using full functionality of SQL language and different DBMS specific structures due to fact that proposed solution targets multi DBMS support, also various constraints can be caused by using order preserving or fully homomorphic encryption.

One of the restrictions is limited usage of "ALTER TABLE" construction is. As long as table altering doesn't affect encrypted columns, it can be performed, but adding or removing encryption from already existing table is unsupported. Another restriction is incompatibility of encryptions with several column constraints (e.g. "FOREIGN KEY").

This concludes basics principles and mechanisms of SQL queries processing in discussed approach. Main idea is to perform query analysis and modification, which include encryption of vulnerable user's data on client side, without affecting DBMS or adding any intermediate components.

III. ARCHITECTURE

Section 3 gives insight into secure cloud database architecture. As it was declared in previous sections, proposed solution does not use any DBMS components or any proxies in process of processing user's SQL queries and encrypting or decrypting data. All description of architecture applies to client's program module.

Client's program module consists of 4 basic components:

- Encryptions interfaces and encryption modules.
- Cryptographic metadata storage
- SQL queries processing component
- Database response's processor

Encryptions interfaces module provides two interfaces – "Key" and "Encoder". These interfaces define set of properties required for encryptions' correct work and interaction with other components. Due to "Encoder" and "Key" interfaces architecture and realization of entire solution does not depends on specific encryptions and is open to integration with other crypto algorithms.

Cryptographic metadata storage is responsible for storing information supporting SQL queries and DBMS replies processors. Among service information, the following values are kept in this storage:

- crypto keys for encryption of data in column
- map of real name of the column to anonymized names
- types of encryption used for column
- names of tables, where encrypted columns are located

Cryptographic metadata storage is an interface for retrieving and adding information about encrypted columns. Current realization means that all data are stored in file. File handling is a subject of future development. Expected solution is to store file encrypted on user's removable drives.

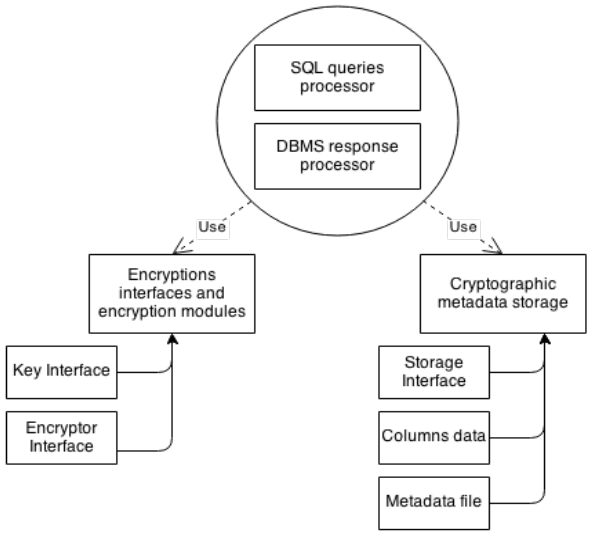

Fig. 4 Architectural overview

Core component of proposed solution is SQL queries processor; other components one way or another support its main function – analyze SQL queries and encrypt/decrypt data. SQL queries processing module consists of sub modules, each responsible for parsing exact SQL statement: "CREATE", "SELECT", "INSERT" and so on. These sub modules follow statements grammar to extract data, intended to be encrypted by user.

Last observed basic component is Database response's processor. Its main purpose is to detect encrypted columns in response, combine them (when multiple output columns correspond to single initial column), and to decrypt data to display them in suitable form to user. This module actively interacts with Cryptographic metadata storage, in order to correctly decrypt and modify response.

Architectural overview is summarized in Fig. 4. Two service components, Encryption and Crypto Storage modules, support SQL queries and database response processors in their main purpose – to manage all encryption and arithmetical transformations, while leaving secure cloud database's user with illusion of work with ordinary database.

IV. Encryptions

This section features description of encryptions that secure cloud database uses. We use three types of encryption: deterministic, order preserving and homomorphic encryptions.

Deterministic. Deterministic encryption provides strong security, it leaks only which encrypted values correspond to the same data value. In secure cloud database it can be used for storing password hashes, when no operations are conduct over data, but confidentiality is very important.

In proposed solution, we use proprietary developed deterministic block encryption [10].

Order Preserving. Order preserving (OP) encryption allows order relations between encrypted data items to be established, without revealing data itself. Such encryption can be used to protect salaries or other economical information inside secure database with possibility of performing order operations.

There are various OP encryptions, used in solution. For different types of data we can use different OP encryptions in single table; this provides extra resistance to crypto attacks. Only two encryption schemes will be discussed in this paper.

A. Arithmetic coding encryption

The first scheme, *based on arithmetic coding*, builds a representation of integer in an appropriate form. Assuming that integers are non-negative and do not require more than n bits, Then each number c is mapped to bit string $b=(a_1,a_2,\dots a_n)$ with first most significant bit. Let us define f as order-preserving mapping which maps string to some real number from interval $[0,1)$.

The simplest way to represent number s:

$$s=a_1\frac{1}{2}+a_2\frac{1}{2^2}+\dots+a_n\frac{1}{2^n}$$

$$s=\frac{c}{2^n}$$

One more way of representation:

We will seek for another representation for the number s.

We will use the arithmetic coding for representation f. Note, that s satisfies the equation:

$$2^n s=c$$

We will solve equation:

$$G(x)=2^n x-c=0 \quad (1)$$

Equation (1) has only one solution on the interval $[0,1)$. In case of bisection method for seeking solution, the source number s will be found in n steps. The main idea of arithmetic coding is that intervals can be split at random. In this case, the approximate solution of (1) can be found in fewer steps which allow arithmetic coding to compress data.

Let us describe splitting process. Let define

$$k=\frac{p}{p+q},l=\frac{q}{p+q},k+l=1,$$

where p and q are random natural numbers. Next, let us split interval $(0,1)$, in two pieces:

$$\left[0,\frac{p}{p+q}\right],\ \left[\frac{p}{p+q},1\right]$$

and calculate $G\left(\frac{p}{p+q}\right)$. If $G\left(\frac{p}{p+q}\right)>0$, we choose interval $\left[0,\frac{p}{p+q}\right]$ and return 0. Else if $G\left(\frac{p}{p+q}\right)<0$ then

interval $\left[\frac{p}{p+q},1\right]$ is chosen and *l* is returned. Chosen interval will be marked with $\left[a_1,b_1\right]$.

New interval is split into two pieces at ratio $\frac{k}{l}$. After that following steps are performed: calculating value of *G(x)* in new point and choosing one of new intervals according to sign of *G(x)*; marking new interval with $\left[a_2,b_{12}\right]$. Proceeding by induction, we compute the interval $\left[a_n,b_n\right]$. Its length is $k^r l^{n-r}$, where *r* is the number of zeros in *b*. b_n is rational, so it can be expanded in powers of up to m degree, where m is the smallest number satisfying the equation:

$$\frac{1}{2^m} < k^r l^{n-r}$$

This equation can be rewritten in

$$-m < r\log_2 k + (n-r)\log_2 l$$

form, or

$$m > -r\log_2\frac{p}{p+q} - (n-r)\log_2\frac{q}{p+q} =$$
$$= r\log_2\frac{p+q}{q} + (n-r)\log_2\frac{p+q}{q} =$$
$$n\log_2 p+q - r\log_2 p - (n-r)\log_2 q$$

Therefore *m* can be calculated if *b*, *k* and *l* are known. Estimation of *m* does not have depended on *r* for the general case. There is very rough approximation:

$$m > n\log_2(p+q)$$

If for b_n there is an appropriate estimate which takes *m* bits, then bit string $f(b)=(b_1,b_2,\ldots,b_m)$. Designed mapping preserves the order by construction.

So, $f(b)$ is a value, that is sent to DBMS, the key is set of intervals (p_i,q_i) where value i is in interval $[1;n]$. Value *n* depends on size of input data.

B. Radix encryption

The second scheme's, *based on different number systems*, basic idea is conversion of numbers from notation with one radix to another.

For the first step is necessary to obtain the vector of coefficients from number in first-radix representation. Next step is replacing in the current representation first radix with second chosen radix. At the last step performed when a subsidiary vector of nonnegative numbers is added to the vector of coefficients from the current number representation. Note that values of the sum of these vectors must be less than second radix and second radix is greater than first.

Having final representation with new radix and modified coefficients the result can be calculated as second-radix – decimal conversion. The secret key is consist of first, second radixes and subsidiary vector of nonnegative numbers.

To illustrate this idea, let us consider one iteration of encryption. There can be made several iterations.

Original number is $s \in N$.

Secret key is $p,q \in N$, $\langle b_0, b_1, \ldots b_{n-1}\rangle$, $b_i < q, b_i \in N$.

Steps of encryption:

1. Obtaining S's p-radix representation:
$$s=\alpha_0+\alpha_1*p+\alpha_2*p^2+\ldots+\alpha_{n-1}*p^{n-1}$$
2. Replacing p-radix with q-radix:
$$s'=\alpha_0+\alpha_1*q+\alpha_2*q^2+\ldots+\alpha_{n-1}*q^{n-1}$$
3. Adding subsidiary vector $\langle b_0, b_1, \ldots b_{n-1}\rangle$ to the vector of coefficients $\langle \alpha_0,\alpha_1,\alpha_2,\ldots,\alpha_{n-1}\rangle$.
$$s''=(\alpha_0+b_0)+(\alpha_1+b_1)*q+(\alpha_2+b_2)*q^2+\ldots$$
$$+(\alpha_{n-1}+b_{n-1})*q^{n-1}$$

where $\forall i: \alpha_i + b_i < q$.

The result of encryption is $w=s''$.

Process of decryption consists of following steps:

1. Obtaining w 's p-radix representation:
$$w=y_0+y_1*q+y_2*q^2+\ldots+y_{n-1}*q^{n-1}$$
2. Replacing q-radix with p-radix:
$$w'=y_0+y_1*p+y_2*p^2+\ldots+y_{n-1}*p^{n-1}$$
3. Subtracting vector $\langle b_0, b_1, \ldots b_{n-1}\rangle$ from the vector of coefficients $\langle y_0, y_1, \cdots y_{n-1}\rangle$:
$$w''=(y_0-b_0)+(y_1-b_1)*q+$$
$$+(y_2-b_2)*q^2+\ldots+(y_{n-1}-b_{n-1})*q^{n-1}$$

The result of decryption is w'', which is equal to s

The algorithm of encryption is correct and order preserving.

Modification of the considered scheme was used in the implementation. There are several iterations; also number of bits for values in the key can be specified in encryption module configuration.

This encryption has passed multiple tests and following results were measured:

Speed of encryption 125 Mbit / s

Speed of decryption 111 Mbit / s

(PC's configuration: Mobile Dual Core Intel Atom N570, 1666 MHz, 4 GB RAM, OS Windows 7).

Homomorphic. An encryption scheme is called fully homomorphic if it's able to evaluate an arbitrary function over ciphertexts. In this case decrypted value must match to a calculation result of the same function over plaintexts. The main feature of scheme [11] that is used in proposed secure cloud database is ability to define a strict upper bound of ci-

phertext size when performing calculations on it for both addition and multiplication.

V. Achievements and future Work

Proposed solution is not theoretical work only. We have implemented described crypto algorithms, measured encryption and decryption speed, optimized realization. Furthermore, prototype of client's program module has been successfully coded and tested. We used C++ and Boost's regular expressions to perform all described operations on SQL strings and databases' data selection. During tests on simple data scheme, with different "SELECT", "UPDATE", "DELETE" queries, slight (around 10-15%) overhead was detected, because of time elapsed for encryption/decryption.

Future development of proposed solution aims three main targets. First, is to develop and improve existing encryptions. Speed optimization is one of the most significant goals. Second target is to further develop of client's program module. This target includes functionality expansion, support of different DBMS, development of supporting modules (metafile encryption, authorization module).

The third aim is security improvement. Interest in analysis of encryption weaknesses and vulnerabilities [8, 9] is escalating, thus several measures can be taken to minimize risk of successful security breach. For example, to complicate frequency analysis, subsystem of phantom "SELECT" queries can be made in order to average number of queries to each column. Another idea for improving system's resistance to attacks is to add to columns garbage data that will be detected and ignored during decryption on client side. This method can change distribution of encrypted data massive inside DBMS, and as a result can make more difficult crypto attack on OP encrypted columns.

Abstract—In this article we describe two alternative order-preserving encryption schemes. First scheme is based on arithmetic coding and the second scheme uses sequence of matrices for data encrypting. In the beginning of this paper we briefly describe previous related work published in recent time. Then we propose alternative variants of OPE and consider them in details. We examine drawbacks of these schemes and suggest possible ways of their improvement. Finally we present statistical results of implemented prototypes and discuss further work.

I. Introduction

Security is a fundamental issue solved by DBMS and cloud service designers. Using cryptographic algorithms to store confidential data in encrypted from isn't always the best solution. In case of relational (SQL) database it is impossible to process encrypted data on DBMS side. Generally two options are possible. The first one is to decrypt and process data on client side, which leads to significant traffic increase between DBMS and application due to general inability to single out the necessary data. Second option is to decrypt data on DBMS side, which is unsafe in case DBMS or cloud service isn't reliable.

The research speculates on ability to use special types of encrypting, which allow not only to safely store data, but also to perform a set of operations on it. Particularly, the research concerns order-preserving cryptosystems.

Definition (order-preserving function). Let A, B be sets with given order relation on each set. Function

$$F : A \to B$$

is said to preserve order if

$$x < y\,(x, y \in A) \Leftrightarrow F(x) < F(y).$$

Encryption based on using such functions is called order-preserving encryption (OPE). Assume there is a set of unique plaintexts $P = p_1, p_2, \dots p_{|p|}, p_i < p_{i+1}$. The corresponding encrypted values are represented as $C = c_1, c_2, \dots c_{|c|}, c_i < c_{i+1}$. Such encryption enables subset of SQL operations on encrypted data including, e.g. selection of encrypted values intervals.

II. Related work

In the last 10 years several scientific papers has published, which introduced different schemes of order-preserving encryption.

A. OPE based on pseudo-random number generator

One of the first approaches, represented in the research [1], suggests that integer number p is encrypted as follows:

$$c = \sum_{j=0}^{p} R_j,$$

where R_j is jth number generated by reliable pseudo-random generator. The drawbacks of this scheme are the memory footprint of encrypted values and possible overflow, resulting from calculation of ciphertexts for large plaintexts while working with built-in types. There is also the complexity of adding new plaintexts: for adding p_i where $p_i < p < p_{i+1}$ we need to re-encrypt values $p_j, j > i$.

That's why this method is ineffective for big numbers and, in some cases, the encryption result can be predicted. For instance, suppose μ average distribution of numbers, generated by the pseudo-random number generator. For uniform distribution on the interval $[1 \dots Max]$, $\mu = \frac{Max + 1}{2}$, then $f(x) = \mu x$ will approximate encryption function.

B. OPE based on polynomial functions

In research [2] a sequence of strictly increasing polynomial functions is used for encrypting integer values. These polynomials may be of first or second order. The secret key is polynomial coefficients. Sequence of polynomials is applied to initial number in a way that one function's output value is another function's input value. Decryption is done by applying inverse functions in reverse order. Sometimes it might be impossible to find the inverse function for a specific polynomial. Authors suggest using simple polynomials $f(x) = ax^b + c$ as they all have inverse

This research was performed in Novosibirsk State University under support of Ministry of education and science of Russia (contract no. 02.G25.31.0054).

functions $f(x)=\sqrt[b]{\frac{x-c}{a}}$. Besides, maximum degree of such polynomials, according to the authors, does not exceed 2, and a set of possible coefficients – $\{1\ldots32\}$. In this case decryption is a lot more complicated than encryption due to square root operation. As built-in integer types are implemented with fixed length, inevitable overflow errors appear. In this work authors suggest using logarithmic functions $f(x)=\log_2 x+c$. This implies working with non-integer types, therefore accuracy errors should be considered. To avoid accuracy and overflow errors this scheme requires rather complex selection of parameters.

C. Research by R. Agrawal, J. Kiernan, R. Srikant, and Y. Xu

Research [3] speculates on encryption of data from subset of integers, authors also think it possible to use non-integer types represented as integers of the same size. This method encrypts data so that ciphertexts follow a certain distribution selected by the user. In order to generate encryption function they use all data that needs to be encrypted (if the database doesn't contain records, administrator has to add several possible records) and the list of possible sample distributions. Key is generated from all these samples. Besides, in order to simulate distribution data has to be split into buckets, in which linear interpolation is used. One of the main drawbacks is that the time of key generation time is linear in the size of database. And if the key has already been generated with adding of new records it might need to be regenerated along with re-encryption of data.

D. Research by A. Boldyreva N. Chenette, Y. Lee and A. O'Neill

A. Boldyreva in [5], [6] shows the connection between OPE schemes and hypergeometric (HG) и and negative hypergeometric (NHG) distributions. The connection allows to simulate OPE scheme through HG or NHG generator. There are effective algorithms of accurate random value generation of these distributions. One of order-preserving encryption features is that range of encryption function is always larger than input argument set (two different numbers can't be encrypted to the same numbers). Suppose encryption function maps a set $[1\ldots M]$ to a set $[1\ldots N]$, $N>M$. In order to encrypt the set of numbers $[1\ldots M]$ we need M random numbers from the set $[1\ldots N]$. Let us denote the set of these numbers by N_M. They have to be ordered and associated correspondingly with initial numbers. I.e. function $f:[1\ldots M]\to N_M$ maps the ith element of the set $[1\ldots M]$ to the ith element of the set N_M. Since we don't know, how many plaintexts have to be encrypted, we cannot determine the size of the set $[1\ldots N]$. Authors offer to generate the next element of the ordered set N_M only when it is necessary for ciphertext generation. This approach is called lazily sampling the function.

Let m be a plaintext from the set $[1\ldots M]$, g – a function, generating the set $[1\ldots N]$, x – number of elements selected into the set N_M after y steps. The number x is characterized by the hypergeometric distribution. Encryption starts with entire domain $[1\ldots M]$ and range $[1\ldots N]$. Let $y=\frac{\max(N)}{2}$ be a range gap. With a certain key and initial parameters the number x can be calculated. If $x<m$, we need to consider the points of the domain greater x and y, and less than or equal to x and less than or equal to y in case of $x\geq m$. As a result we get admissible set of ciphertexts.

E. Alternative OPE schemes

In our research we consider other ideas, which OPE can be based on. We propose two alternative OPE schemes, research problems of overflow and computational accuracy and try to increase cryptographic strength of schemes.

III. OPE SCHEME BASED ON ARITHMETIC CODING

This scheme builds a representation of integer in a suitable form. Representation preserves the order, so we can talk about order-preserving mapping. Suppose we consider positive integers requiring for their representation not more than n bits. Each number c is mapped to a bit string $b=(a_1,a_2,\ldots a_n)$, where a_1 is MSB. Let us define the order-preserving mapping f. We assume that the string defines certain real number $s\in[0,1)$. The simplest way to define it:

$$s=a_1\frac{1}{2}+a_2\frac{1}{2^2}+\cdots+a_n\frac{1}{2^n}.$$

In other words $s=\frac{c}{2^n}$.

Let us seek a different representation of the number s. To do it let us use ideas associated with arithmetic coding. The equation:

$$G(x)=2^n x-c=0 \qquad (1)$$

has only one solution on the interval $[0,1)$. In case of bisection method of solving the equation (1) we get the number s after n steps. The main idea of arithmetic coding is that segments can be split into parts arbitrarily. In this case approximate solution of equation (1) can be found in fewer steps. That allows us to achieve compression of data while using arithmetic coding.

Let us describe the process of segments splitting. Suppose, $\gamma=\frac{p}{p+q}, \mu=\frac{q}{p+q}$, where p, q are random natural numbers. Obviously, $\gamma+\mu=1$. Let us split segment $[0;1)$ into two parts $\left[0,\frac{p}{p+q}\right),\left[\frac{p}{p+q},1\right)$. After that, if $G\left(\frac{p}{p+q}\right)>0$, we choose $\left[0,\frac{p}{p+q}\right)$ and produce 0. In

case of $G\left(\frac{p}{p+q}\right)<0$, we choose $\left[\frac{p}{p+q},1\right)$ and produce 1. Let us denote the segment we chose by $[a_1,b_1)$.

New segment splits into parts in the ratio $\gamma:\mu$. According to the sign of $G(x)$ in the point, one of the segments is selected. Let us denote it by $[a_2,b_2)$. Proceeding by induction, we compute the interval $[a_n,b_n)$. Its length is $\gamma^r\mu^{n-r}$, where r is number of zeros in b. By construction of $b_n, b_n \in Q$, so it can be expanded in powers of $\frac{1}{2}$ up to m degree, where m is the smallest integer satisfying

$$\frac{1}{2^m}<\gamma^r\mu^{n-r}.$$

That condition may also be written as

$$-m<r\log_2\gamma+(n-r)\log_2\mu$$

or

$$m>-r\log_2\frac{p}{p+q}-(n-r)\log_2\frac{q}{p+q}=r\log_2\frac{p+q}{p}+$$
$$+(n-r)\log_2\frac{p+q}{q}=n\log_2(p+q)-r\log_2 p-$$
$$-(n-r)\log_2 q$$

Therefore, we can calculate m, if we know b,γ,μ. For universality we need m estimation not to depend on r value. E.g, we can require condition $m>n\log_2(p+q)$. Let us approximate b_n with bit string $f(b)=(\beta_1,\beta_2,\ldots,\beta_n)$. Obviously, this transformation preserves order.

General conclusion, which is using adaptive arithmetic coding, is to use different ratio on each step, when approximating the solution of equation (1). It allows making cryptosystem cryptographically stronger.

VI. Key generation

Key is set of ratios, which segments are divided in. Suppose current segment is split in a ratio $p_i:q_i$ on ith step. To be able to decrypt the cipher for n-bit number, the length of the segment obtained after decryption should be less than $\frac{1}{2^n}$. Maximum segment length, which can be obtained as a result of decrypting is $\prod_i\frac{\max(p_i,q_i)}{p_i+q_i}$. Consequently, the key generation algorithm has the following form:

1. Choose random ratio $p_i:q_i$.
2. Check the condition

$$\prod_i\frac{\max(p_i,q_i)}{p_i+q_i}<\frac{1}{2^n}.$$

If condition is satisfied, go to step 3, otherwise – to 1.

3. Complete key generation.

V. Encryption

Suppose we need to encrypt $Num\in\mathbb{N}$. On each algorithm iteration the interval $[a_i,b_i)$ is considered, where $a_0=0, b_0=1$. Let us examine the ith iteration of the algorithm.

Current segment $[a_{i-1},b_{i-1})$ is divided in a ratio $p_i:q_i$. Let point $s\in[a_{i-1},b_{i-1})$ separate it, i.e. $s=a_{i-1}+\frac{(b_{i-1}-a_{i-1})p_i}{p_i+q_i}$. If $s>\frac{Num}{2^n}$, then the output is 0, $a_i=a_{i-1}, b_i=s$. Otherwise the output is 1, $a_i=s, b_i=b_{i-1}$. It can be seen, that $\forall i\ \frac{Num}{2^n}\in[a_i,b_i)$ (by a_i and b_i selection).

After performing k iterations (where k is key size, i.e. the number of ratios) we obtain a bit sequence $\sigma=(\sigma_1,\ldots\sigma_k),\ \sigma_i\in\{0,1\}$, which is ciphertext for Num.

VI. Decryption

Suppose there is a bit sequence $\sigma=(\sigma_1,\ldots\sigma_k),\ \sigma_i\in\{0,1\}$, which is a ciphertext for unknown number Num. Just as in the encryption algorithm, at each iteration is considered the interval $[a_i,b_i), a_0=0, b_0=1$. Consider the ith iteration of the algorithm.

Current segment $[a_{i-1},b_{i-1})$ is divided in a ratio $p_i:q_i$. Let point $s\in[a_{i-1},b_{i-1})$ separates it, i.e. $s=a_{i-1}+\frac{(b_{i-1}-a_{i-1})p_i}{p_i+q_i}$. If $\sigma_i=0$, then $a_i=a_{i-1}, b_i=s$. Otherwise, $a_i=s, b_i=b_{i-1}$.

After performing k iterations (where k is key size) we obtain a segment $[a_k,b_k)$, and $(b_k-a_k)<\frac{1}{2^n}$ because of key selection. As $\frac{Num}{2^n}\in[a_k,b_k)$ number Num is uniquely decoded as follows:

$$Num=\lfloor 2^n a_k\rfloor+1,$$

where $\lfloor x\rfloor$ is the largest integer, which comes before x.

VII. Increasing cryptographic strength of the algorithm

If attacker does not know a secret key, all he knows is that encrypted value belongs to the interval $[a_0,b_0)$. But to make algorithm more secure, this segment can be hidden.

Let us choose an arbitrary strictly increasing function $f(x)$ so that $\lim_{x\to-\infty}f(x)<0$, $f(x)=+\infty$. Suppose $f(a)=0$, $f(b)=2^n$. Let us use function $f(x)$ to encrypt n-bit number $s: 0\le s<2^n$. Using modified arithmetic

encryption algorithm, we encrypt number x from interval $[a,b)$, where $f(x)=s$ (fig.1).

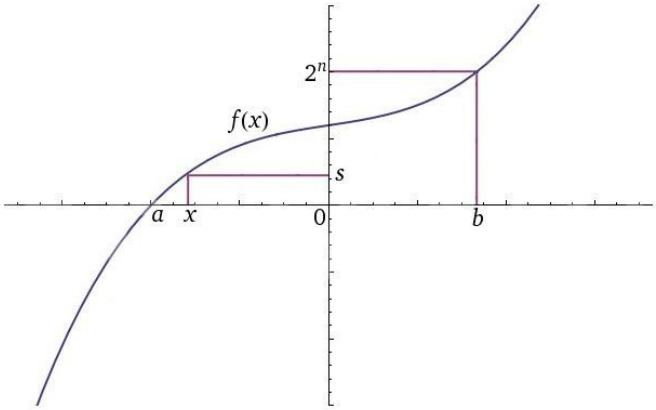

Fig.1 Increasing cryptographic strength of algorithm

In this case secret key is set of ratios p_i, q_i (key for modified arithmetic algorithm we already described earlier) and function $f(x)$, that was used in encryption.

To decode a cipher h we should find a and b such that $f(a)=0$ and $f(b)=2^n$ (they are unique, because $f(x)$ is strictly increasing function), decode x from interval $[a,b)$ and calculate $s=f(x)$. Now if attacker doesn't know a secret key, he doesn't have any information about s.

VIII. Implementation features

The algorithm described above can be implemented using only integers, which allows the implementation to eliminate rounding or computation errors. Nevertheless, the size of the numerator and denominator of fractions a_i, b_i and $x=\frac{Num}{2^n}$ can't be limited in general case, and therefore arbitrary-precision integer arithmetic should be used. As a result algorithm speed is not high enough.

The algorithm can be modified in order to accelerate implementation. On each iteration of the encryption transformation matrix $[a_i,b_i)\to[0,1)$ can be applied to segment $[a_i,b_i)$. Then it is obvious that $a_i\to 0, b_i\to 1$. Point x transforms by the following rule:

$$\text{if } \sigma_i=0, \text{ then } \frac{Num}{2^n}\to\frac{Num}{2^n}\frac{p_i+q_i}{p_i}, \quad (2)$$

$$\text{else } \frac{Num}{2^n}\to\frac{Num}{2^n}\frac{p_i+q_i}{q_i}. \quad (3)$$

It saves time for the calculation of the segment, and long arithmetic is only required for the storage of a fractional number x.

As a result the encoding iteration includes comparing points x and $\frac{p_i}{p_i+q_i}$ and following x recalculation according to the rules (2) and (3). In case of decrypting we need to know final segment $[a_k,b_k)$, so decoding iteration is implemented directly with a_i and b_i recalculation.

In order to remove one of the slowest parts of the implementation - arbitrary-precision integer arithmetic, we can apply rounding to the largest previous integer, which is used in many implementations of standard arithmetic coding[1].

The idea of this approach is that all fractional numbers such as a_i, b_i and x, which belong to the interval $[0,1)$ are multiplied by 2^r, where r is some power of two. Thus, arithmetic operations can be quickly performed. E.g. in case of 32-bit architecture, it is convenient to choose $r=32$. After multiplying the resulting fraction shall be rounded down to the nearest integer. The more is r, the smaller is rounding error, so it is advisable to choose large values for r.

On each iteration of the encoding (or decoding) algorithm initial segment $[a_0,b_0)=[0,2^r)$ decreases, because $[a_i,b_i)\subset[a_{i-1},b_{i-1})$, so rounding error increases and at some point it is impossible to determine if $x=\left\lfloor\frac{Num}{2^n}2^r\right\rfloor$ belongs to segment $[a_{i-1},s)$ or $[s,b_{i-1})$. To avoid it, the length of interval $[a_{i-1},s)$ and $[s,b_{i-1})$ after the process of rounding should be not less than 1. In other words,

$$s-a_{i-1}\ge 1,$$

$$\frac{(b_{i-1}-a_{i-1})p_i}{p_i+q_i}\ge 1,$$

$$b_{i-1}-a_{i-1}\ge\frac{p_i+q_i}{p_i}.$$

Similarly for the interval $[s,b_{i-1})$:

$$b_{i-1}-a_{i-1}\ge\frac{p_i+q_i}{p_i}.$$

Thus, in order to be able to perform the ith iteration, the current length of the segment $[a_{i-1},b_{i-1})$ should not be less than

$$\max\left(\frac{p_i+q_i}{p_i},\frac{p_i+q_i}{q_i}\right)\le p_i+q_i\le\max_i(p_i)+\max_i(q_i) \quad (4)$$

There is a special renormalization operation, which allows to increase the length of the current segment. It can be used in one of three cases:

1. Segment $[a_{i-1},b_{i-1})$, lies in the left half of the interval $[0,2^r)$, i.e. $[a_{i-1},b_{i-1})\subseteq[0,2^{r-1})$. In this case interval $[2^{r-1},2^r)$ is not involved in the encryption process anymore, so we can "bring closer" $[0,2^{r-1})$ segment twice, i.e. use transformation $[0,2^{r-1})\to[0,2^r)$. Then

[1]Moffat, Alistair. ACM Transactions on Information Systems / Alistair Moffat, Radford M. Neal, Ian H. Witten // – 1998. – Vol. 16, No. 3, July 1998.

$$a_{i-1} \to 2a_{i-1},$$
$$b_{i-1} \to 2b_{i-1},$$
$$x \to 2x.$$

2. Interval $[a_{i-1}, b_{i-1})$ lies in the right half of the interval $[0, 2^r)$, i.e. $[a_{i-1}, b_{i-1}) \subseteq [2^{r-1}, 2^r)$. Similarly to the previous case, we can use transformation $[2^{r-1}, 2^r) \to [0, 2^r)$. Then

$$a_{i-1} \to 2(a_{i-1} - 2^{r-1}),$$
$$b_{i-1} \to 2(b_{i-1} - 2^{r-1}),$$
$$x \to 2(x - 2^{r-1}).$$

3. Interval $[a_{i-1}, b_{i-1})$ lies in the central part of the interval $[0, 2^r)$, i.e. $[a_{i-1}, b_{i-1}) \subseteq [2^{r-2}, 3 \cdot 2^{r-2})$. Then let's "bring closer" twice the interval $[2^{r-2}, 3 \cdot 2^{r-2})$, i.e. use transformation $[2^{r-2}, 3 \cdot 2^{r-2}) \to [0, 2^r)$. Then

$$a_{i-1} \to 2^{r-1} - 2(2^{r-1} - a_{i-1}),$$
$$b_{i-1} \to 2^{r-1} - 2(2^{r-1} - b_{i-1}),$$
$$x \to 2^{r-1} - 2(2^{r-1} - x).$$

It is easy to notice that each case of the renormalization increases the length of the segment twice. If none of the renormalization conditions is satisfied, then the length of this interval is strictly greater than 2^{r-2}. According to this we can find the maximum size of p_i and q_i. If they are m-bit numbers, then (by (4)) current segment length after renormalization should be greater than

$$\max_i(p_i) + \max_i(q_i) \le 2^m + 2^m = 2^{m+1}.$$

Then $m_{max} + 1 = r - 2$, and $m_{max} = r - 3$. Larger size makes no sense to choose, because rounding leads to (r-3)-bit p and q numbers.

As a result we turn from calculations with fractional numbers with unlimited numerator and denominator to calculations of the fixed integers. This fact significantly increases the speed of algorithm. The price of this acceleration is a rounding error, which may reduce the strength of cryptographic algorithm.

IX. Statistics

Any order-preserving encryption can be represented as transformation from domain $[0, 2^{b_1})$ to some range $[0, 2^{b_2})$, where b_1, b_2 are the sizes of input and output data respectively, so it is possible to attack a cipher using linear approximation cryptograms on extreme values (fig 2).

In other words, cryptogram for a certain $x \in [0, 2^{b_1})$ is approximated with value $2^{b_2 - b_1} \cdot x$, and plaintext for cryptogram $m \in [0, 2^{b_2})$ – with value $\left\lfloor \frac{m}{2^{b_2 - b_1}} \right\rfloor$. Knowledge of the secret key is not required to calculate the approximate value, only sizes of the input and output data are needed. To defend against such attack we should increase an approximation error.

Therefore, in order to study the cryptographic strength of the algorithm statistics of "segment" lengths was examined. The end points of such "segment" a_i equals successive encrypting function values, i.e. $a_i = [f(i), f(i+1)]$. Obviously, the closer "segment" lengths distribution to uniform distribution, the smaller the error of approximation.

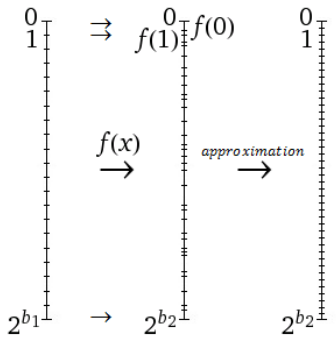

Fig.2 Linear approximation of cryptograms on extreme values

As a result, it was found that the "segment" lengths distribution is close to exponential (fig. 3, the abscissa indicates the segments lengths and the ordinate indicates the number of such segments). As too big error appears, this attack cannot be applied.

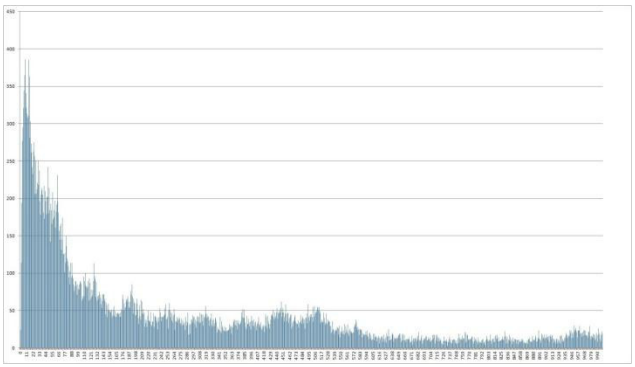

Fig.3 "Segment" lengths distribution of two-byte numbers

X. Matrix based OPE scheme

The suggested scheme allows to avoid overflow accuracy errors as it uses only integers. The scheme does not disclose any information about initial values of encrypted variables, except their order.

Tuple of three numbers (r, k, t) serves as a ciphertext. Suppose we need to encrypt positive integer x. In contradistinction to pseudo-random number generator method the first element of cryptogram is not the sum of numbers of random ascending sequence on the step x, but a number i of a step, such that sum of random numbers exceeds the initial number x on this step. The second element of the cipher is the difference between x and the sum of random sequence on (i-1)th step. It can also be

encrypted in a similar way, using the sum of random elements of a different sequence

$$g_1 < g_2 < \ldots < g_{r-1} \le x < g_r .$$

Obviously, $x - g_{r-1} < g_r - g_{r-1}$. Therefore, to encrypt residual $x - g_{r-1}$ we need to calculate the sum of the sequence elements, which will be limited by $g_r - g_{r-1}$. Instead of pseudo-random sequence elements sum we can use strictly increasing function with special features. The sum of the sum sequence of matrix elements is suggested to be used as strictly increasing function:

$$\sum_{i=0}^{n}\sum_{j=0}^{n} a_i ,$$

where a_i is an elements of matrix A_i of size $n \times n$. We use a certain sequence of matrices

$$A_1, A_2, \ldots, A_r, \ldots$$

First, a certain matrix A_1 is chosen. Each successive matrix can be calculated using some transformation of the previous one. As such transformation we research power function.

$$A_1, A_1^2, \ldots, A_1^r, \ldots$$

In order to prevent the increasing of matrix elements after multiplication operation, we consider matrix elements are from finite field $\mathbb{Z}_m$. Residual $x - g_{r-1}$ is hidden with the help of elements of the matrix, calculated on the rth step. Elements are summed up randomly, and the number k of step, where the sum s_k exceeds $x - g_{r-1}$, is the second element of the tuple. The residual obtained at this stage is the third element of the tuple. Let's look at the scheme in greater detail.

Encryption scheme under consideration is symmetrical, i.e. it uses private key for encryption and decryption of data. In the research the input data of cryptographic algorithm are integer non-negative numbers from 0 to 2^n, where $n = 16, 32, 64$, which corresponds to the size of built-in types unsigned short int, unsigned int, unsigned long int, unsigned long long int of C++ language, which the scheme is implemented on. The result of cryptographic algorithm is a tuple of three numbers (r, k, t), where $r, k, t \in \mathbb{Z}_{\ge 0}$.

XI. KEY GENERATION

The private key in the scheme is non-degenerate matrix $A(\det A \neq 0)$ over the finite field $\mathbb{Z}_m$, $m \ge 2$, with $n \times n$ size, where $n \in N, n \ge 2$ and a certain permutation of σ elements of matrix with such size, called matrix traversal.

A. Non-degenerate matrix generations

Standard way of non-degenerate matrix generation is to generate matrix with random elements and check its non-degeneracy. If the determinant of obtained matrix is equal to zero, generation shall be repeated until this condition is violated.

For small-size matrices this method is quite effective. However with increase of matrix size, multiplication operation takes more and more time, which reduce speed of private key generation.

Direct methods of determinant calculation can be based on permutations sum, or Laplace expansion of smaller degree determinants. However such methods are rather ineffective, because they require time complexity $O(n!)$ for n degree determinant calculation. There are other methods with fewer operations, e.g. Gauss method modification, where matrix is transformed to the form of echelon and determinant is calculated as product of multiplication of diagonal elements. Complexity of this method constitutes $O(n^3)$. If there is available multiplication algorithm of two square matrices of size n in time $M(n)$, where $M(n) \ge n^a$, for certain $a > 2$, then matrix determinant can be calculated in time $O(M(n))$. However if random matrix is degenerate, calculations shall be repeated until we get non-degenerate matrix.

This research suggests using knowingly non-degenerate matrix generation approach, based on the following linear algebra theorem.

Theorem. Square matrix A with non-zero principal minors can be presented in the form of LU lower triangular matrix L, whose main diagonal consists of non-zero elements, times upper triangular matrix U with units on the main diagonal.

Since lower triangular matrix L contains a single diagonal, its determinant equals one. Upper triangular matrix U determinant equals multiplication of elements on main diagonal. Using the property of determinant, we obtain $\det(A) = \det(LU) = \det(L)\det(U) = \det(U)$.

Thus, in order to generate non-degenerate matrix A, it is enough to generate matrices L and U, compliant with the above properties and find their multiplication result. Computational complexity of matrix product by definition is $O(n^3)$, however there are more effective algorithms, for instance, Coppersmith–Winograd algorithm, performing multiplication in $O(n^{2.3727})$.

B. Generation of matrix elements permutation

Algorithm uses permutation of matrix elements, imitating its traversal, a specific order in which to trace the elements of a matrix. Cryptographic robustness cannot be achieved through simple row traversal of matrix elements or row traversal with a shift. The traversal should be generated randomly. Traversing function shall go over all matrix elements (through each element only once), i.e. the function has to be bijective. For instance, we can use affine transformation.

It shall be presented through randomly generated non-degenerate in $\mathbb{Z}_m$ matrix B of size 2×2 (B shouldn't be identity matrix, or else the function implements row traversal with a shift) and vector $c = (c_1, c_2)$, where $c_1, c_2 \in \mathbb{Z}_m$. Matrix non-degeneracy provides inverse mapping, used in decryption. New element coordinates are calculated as follows:

$$\begin{pmatrix} u \\ v \end{pmatrix} = B\begin{pmatrix} i \\ j \end{pmatrix} + \begin{pmatrix} c_1 \\ c_2 \end{pmatrix},$$

where coordinates (i, j) mean initial row traversal $(1,1), (1,2), \ldots (2,1), (2,2), \ldots (n, n)$ and $(u(i, j), v(i, j))$ is traversal, used in algorithm.

Generally, to determine matrix traversal we can use any effective algorithm for random permutation of set of elements generation, e.g. Fisher–Yates shuffle algorithm (Knuth shuffle), with time complexity reduced to $O(n)$, along with its updated versions – Durstenfeld and Sattolo algorithms, using less memory space. When using high quality unbiased random numbers generator, algorithm guarantees equiprobability of permutations.

XII. Encryption

Let's consider data encryption procedure. Suppose we need to encrypt $x \in \mathbb{Z}_{\geq 0}$. At first private key (A, σ) is generated. The first element r of ciphertext is calculated as follows:

$$\sum_{i=1}^{r-1} d(A^i) \leq x < \sum_{i=1}^{r} d(A^i),$$

where

$$d(A) = \sum_{i=0}^{n^2} a_i$$

is the sum of elements a_i of matrix A. Power operation A^i is performed in $\mathbb{Z}_m$.

In order to determine the second element k of the cipher, we need to calculate the sum

$$S = \sum_{i=0}^{k} a_i',$$

where a_i' are elements of matrix σA^r, such that

$$S \leq x - \sum_{i=1}^{r-1} d(A^i).$$

Difference

$$t = x - \sum_{i=1}^{r-1} d(A^i) - S$$

is the third element of the cipher.

XIII. Decryption

Suppose the input of decryption algorithm is a tuple (r, k, t) and the key is (A, σ). First, we shall calculate matrix A^r. Using known permutation σ of matrix elements, we calculate

$$S = \sum_{i=0}^{k} a_i',$$

where a_i' are elements of matrix σA^r. Adding to the sum S the third element of ciphertext t, we obtain a certain number h, which, according to encryption procedure, equals

$$h = t + S = x - \sum_{i=1}^{r-1} d(A^i).$$

Using the first element r of ciphertext we calculate the sum

$$\sum_{i=1}^{r-1} d(A^i)$$

and obtain the number x, that was encrypted

$$x = h + \sum_{i=1}^{r-1} d(A^i).$$

XIV. Constructinon correctness

First of all we have to verify cipher uniqueness. Thus, the encrypted number should be the same number as decrypted. We also shall prove that such encryption is order-preserving.

Theorem 1. If with encrypted N there is cipher Enc(N), then with decryption Dec(Enc(N)) there is number N.

Proof. We need to prove that mapping, determining encryption algorithm, is bijective. In bijective mapping every element of one set corresponds to only one element of another set, along with inverse mapping with the same property.

Bijective mapping properties:

1. A function $f : A \to B$ is bijective if and only if it is invertible, that is, there is a function $g : B \to A$ such that $g \circ f$ is identity function on A and $f \circ g$ is identity function on B.
2. The composition $g \circ f$ of two bijections is again a bijection.

Function $f_1(x, A)$ calculates the parameter r. Since $\det A \neq 0$, then function

$$\sum_{i=1}^{j} d(A^i)$$

is strictly increasing, i.e.

$$\sum_{i=1}^{j} d(A^i) < \sum_{i=1}^{j+1} d(A^i).$$

Obviously, for any x from $\mathbb{Z}_{\geq 0}$ number r is found uniquely. Function $f_2(x, A, \sigma)$ calculates the parameter k. Since

$$x < \sum_{i=1}^{r} d(A^i),$$

hence we get

$$x - \sum_{i=1}^{r} d(A^i) < d(A^r).$$

Therefore, there is the only k, such that

$$S = \sum_{i=0}^{k} a_i', \quad S \leq x - \sum_{i=1}^{r-1} d(A^i),$$

where a_i' are elements of matrix σA^r. It is obvious that permutation of matrix A^r elements does not violate this condition. If functions

$$\sum_{i=1}^{r-1} d(A^i)$$

and S are bijective, then function $f_3(x, A, \sigma)$, calculating t, is also bijective.

Theorem 2. If with encryption of N_1 with the key K we obtained cipher Enc_1, and with encryption N_2 with the same key we obtained cipher Enc_2, and $N_1 > N_2$, then $Enc_1 > Enc_2$.

Proof. Let us say that tuple $\overline{A}_1 = (a_{11}, \ldots, a_{1m+1})$ is greater than vector $\overline{A}_2 = (a_{21}, \ldots, a_{2m+1})$, if $a_{1j} > a_{2j}$, where j is first position number, such that $a_{1j} \neq a_{2j}$, for all j, from m+1 to 0.

We shall consider $x_1, x_2 \in \mathbb{Z}_{\geq 0}$, such that $x_1 < x_2$. According to encryption procedure

$$\sum_{i=1}^{r_1-1} d(A^i) \leq x_1 < \sum_{i=1}^{r_1} d(A^i),$$

$$\sum_{i=1}^{r_2-1} d(A^i) \leq x_2 < \sum_{i=1}^{r_2} d(A^i).$$

Consequently,

$$\sum_{i=1}^{r_1-1} d(A^i) \leq \sum_{i=1}^{r_2-1} d(A^i), \quad \sum_{i=1}^{r_1} d(A^i) \leq \sum_{i=1}^{r_2} d(A^i).$$

These functions are strictly increasing, so $r_1 \leq r_2$. As

$$S_1 \leq x_1 - \sum_{i=1}^{r_1-1} d(A^i),$$

$$S_2 \leq x_2 - \sum_{i=1}^{r_2-1} d(A^i),$$

therefore, $S_1 \leq S_2$. By definition of S function, since all the matrix elements are non-negative, then $k_1 \leq k_2$.

$$t_1 = x_1 - \sum_{i=1}^{r_1-1} d(A^i) - S_1,$$

$$t_2 \leq x_2 - \sum_{i=1}^{r_2-1} d(A^i) - S_2.$$

If $\sum_{i=1}^{r_1-1} d(A^i) = \sum_{i=1}^{r_2-1} d(A^i)$ and $S_1 \leq S_2$, i.e. $r_1 = r_2$ and $k_1 = k_2$, then $t_1 = t_2$.

XV. Cryptographic strength

A. Ciphertext-only attack

Provided that the attacker doesn't have key parameter, i.e. matrix size n and modulus m, then ciphertext-only attack does not seem possible. Matrix size of $n \times n$ modulus m can be presented with m^{n^2} variants.

Suppose we extract a certain ciphertext (r, k, t). Suppose the size of secret matrix is $n \times n$, and operations are performed modulus m. As the matrix is non-degenerate and non-identity, minimum sum of its elements equals $(n+1)$ and maximum $n^2(m-1)$. Thus, initial number lies within the range from $(r-1)(n+1)$ to $rn^2(m-1)$. The sum S lies within the range from 0 to $k(m-1)$ and may be presented with m^k variants.

B. Chosen-plaintext attack

All order-preserving encryptions are vulnerable to such kind of attack. Let us encrypt a sequence of numbers $x_1, x_2, \ldots$. We shall consider ciphertexts of form $(r_i, 0, 0)$. With these values of encryption function, the sum is

$$\sum_{i=1}^{l} d(A^j) = x_i,$$

Hence for subsequent plaintexts $i+1, i+2, \ldots$. We can find residuals

$$\sum_{i=1}^{l} d(A^j) - x_i$$

encrypted with the last two elements of the tuple.

Next we shall consider ciphertexts of form $(r_i, k_t, 0)$. Since the last tuple element equals zero, corresponding residual equals

$$\sum_{j=1}^{k_t} a_j,$$

where a_j are elements of matrix A^{r_1} in accordance with secret traversal. Thus, examining successively $k_1 = 1, k_2 = 2, \ldots$, we can determine the elements of matrix A^r. During security enhancement, matrix elements are summed up randomly, with $n^2!$ possible variants. Besides, if $r > 1$, matrix root is an expensive operation.

Another way to enhance security is applying strictly increasing function value f(x) to initial number x before encryption procedure. For instance, f(x) can be Ax+B, where $A, B \in \mathbb{Z}$, $A > 1$, $0 < B < A$, and instead of x there is initial number. The procedure of encryption substitution is as follows. Suppose, $Num \in \mathbb{Z}_{\geq 0}$ a number, that needs to be encrypted. Let us randomly choose number A, which is the part of the key. Allowed value range for B is limited by A, therefore, the bigger number A, the more possible variants there are for B. Number B is also randomly chosen, and adding number B enables two neighbor numbers to grade into numbers, whose difference is a random number, i.e $Num_2 - Num_1 = A(x+1) + B_2 - (Ax + B_1) = A + B_2 - B_1$.

Thus, in order to find the number, following number Num_2, we need to sort out at worst $A + B_3 - B_2 = 3A - 2$ numbers, which enhances the construct security.

Next we substitute x for Num, calculate Ax+B and encrypt the deduced number. After decryption, we need to perform integer division of decrypted number by A in order to get initial number. This scheme doesn't require storing of coefficient B within the key and, therefore gives opportunity to use different B values for any numbers, including equal numbers.

XV. Statistics

The plots depicting dependence of r, k, t parameters on size of initial unencrypted values are provided below. We used secret matrix of size 10 × 10 with elements from $\mathbb{Z}_{10}$ and parameter $A = 2^8$ for encrypting 1000 subsequent 8-bit numbers.

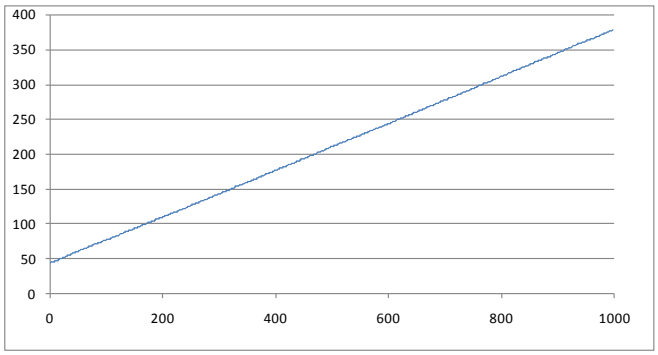

Fig.4 Dependence of r parameter on plaintext size

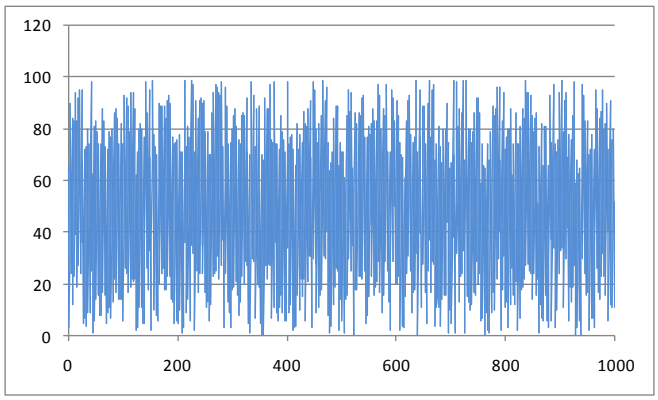

Fig.5 Dependence of k parameter on plaintext size

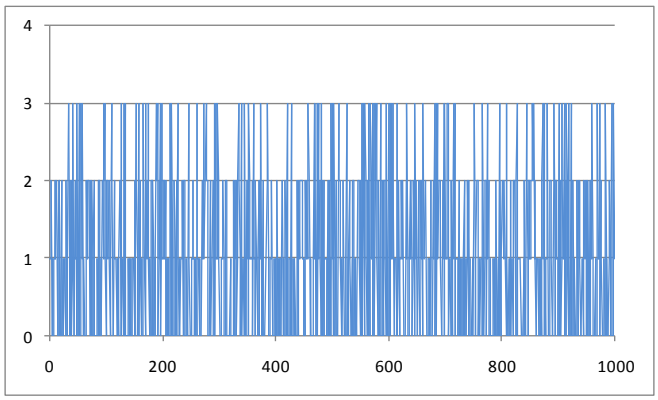

Fig.6 Dependence of t parameter on plaintext size

XVI. Further work

Currently we are examining other ways of attacking given OPE schemes and increasing cryptographic strength of them. We are also looking for optimal parameters of schemes, which provide an acceptable balance of speed and security.

There are several possible approaches to accelerate implementation such as using GPU for calculations, using specified matrix implementation, using faster standard algorithms required in schemes, etc.

After appropriate results are achieved, these schemes will be embedded as third-party libraries in security database service implemented in our laboratory.

***Abstract*—Information Security Standards such as NIST SP 800-39 and ISO/IEC 27005:2011 are turning their scope towards business process security. And rightly so, as introducing an information security control into a business-processing environment is likely to affect business process flow, while redesigning a business process will most certainly have security implications. Hence, in this paper, we investigate the similarities and differences between Business Process Management (BPM) and Information Security Management (ISM), and explore the obstacles and opportunities for integrating the two concepts. We compare three levels of abstraction common for both approaches; top-level implementation strategies, organizational risk views & associated tasks, and domains. With some minor differences, the comparisons shows that there is a strong similarity in the implementation strategies, organizational views and tasks of both methods. The domain comparison shows that ISM maps to the BPM domains; however, some of the BPM domains have only limited support in ISM.**

Keywords: Information Security, Information Security Risk Management, Business Process Management, BPM Methodology Framework, ISO/IEC 27001, ISO/IEC 27002, ISO/IEC 27005, NIST SP 800-39

I. Introduction

INFORMATION technology and systems play a crucial role by supporting the organization in achieving its goals and objectives. The main goal of information security (IS) is to secure the business against threats and ensure success in daily operations, and aid the businesses in reaching the desired level of reliability and productivity through ensuring integrity, availability and confidentiality [1]. We define the main profit of IS risk management (ISRM) as maximizing long term profit in the prescence of faults, conflicting incentives and active adversaries.

Business Process management (BPM) is a discipline that combines knowledge from information technology and management sciences and centers on business processes [2]. It is used to represent business processes (BP) for analysis and improvement purposes [3], [4]. The main goals of BPM is to align the organization's business processes to the organization's mission, goals and objectives and improve efficiency to create a competitive advantage [3], [5].

Some of the existing information security frameworks mention risk management (RM) of business processes in some form, e.g. ISO/IEC 27005:2011 defines BPs as a primary asset [6], and NIST SP 800-39 suggests RM of Mission/Business Process as tier 2 in the multi tier organization-wide risk management model [7]. While the purpose of both IS management (ISM) and BPM is similar, to map and improve organizational performance in their own way, they remain two different disciplines that require two different sets of skill.

In this paper, we investigate the similarities and differences between BPM and ISM, and explore the obstacles and opportunities for integrating the concepts of ISM and BPM. The BPM methodology framework [8] by BPTrends as described by Harmon [5] and Mahal [3] represents the main sources used to describe BPM, and we use the ISO/IEC 27000-series [6], [9], [10] and NIST SP 800-39 [7] to describe ISM.

A. Problem Description

While it can be said that the scope of ISM is turning towards BPs security, BPM and ISM remain two different disciplines and are most of the time regarded as separate activities [11]. However, the disciplines mutually affect each other's objectives, e.g. re-engineering a BP will often have security implications, and introducing an information security control is likely to affect the BP flow. In addition, the impact of a materialized security risk will usually affect the business. A different set of skills is required to risk manage a BP than an IT-system; one requires knowledge of BPM methods, and the other technical insight in information security. In addition, there exists several types of BPs, ranging in abstraction level, from value chain at the very top of the organization, to work instruction & procedures [3], [5], see Fig. 1. People employed at different levels of the organization, perceive and worry about different risks [12], and focus on a variety of different goals in their work efforts [5]. The difference in abstraction makes it likely that one ISRM approach designed for a low level BP is not likely to be applicable for risk managing the higher abstractions, such as value chain or core processes. Hence, there is a need to make sure that IS and BPM activities are aligned. Very little has been published in terms of investigations regarding to what extent IS and BPM guidelines and methods are well aligned, overlapping or in conflict. The aim of this paper is to contribute towards the filling this gap.

The remainder of this paper is structured as follows; In Sect. II, we present related work. In Sections III & IV we

978-83-60810-58-3/$25.00

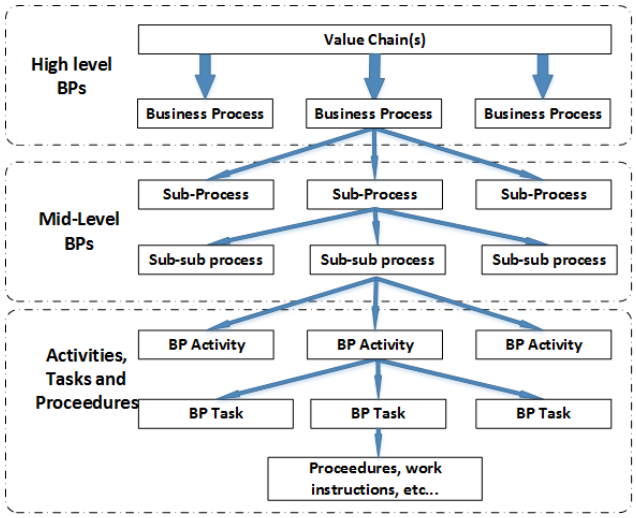

Fig. 1. Example of a Business Process Hierarchy.

introduce relevant IS and BPM concepts used in this article. Sect. V introduces the research method. Sections VI, VII & VIII presents comparisons of ISM and BPM and discussions of findings. The three areas of comparisons are Lifecycles, Organizational Views & corresponding tasks, and Domains. Conclusion and Future Work are given in Sect. IX.

II. Related Work

Much of the published research within combination of BPM and ISM focus on risk analysis of BPs; Milanovic et. al. [13] presents a framework for modeling BP availability. The framework takes into account services, the underlying ICT-infrastructure and people, and has a special focus on dependencies between these layers. Jallow et.al. [14] present a framework for risk analyzing BPs, using modeling activities and Monte Carlo analysis for calculating risks and forecasts. Asnar and Massacci [15] takes the GRC management approach to information security, and presents a method for analyzing and designing security controls in an organizational setting using BPs. Zoet et.al. [16] introduces the different kinds of risk that affect a BP and establishes the relationship between operational risk, compliance risk, internal controls and business processes. Zoet et.al. also present an integrated framework for dealing with RM and compliance from a BP perspective. Taubenberger and Jurens [17] suggest to improve security processes by using BP models to move away from probabilities.

There also exists approaches for risk managing BPs; In 2000, Kokolakis et.al. [18] presented a paper discussing the use of BPM for IS. The authors argue that the asset-based approach of ISRM treats IS as an add-on feature aiming to minimize the overhead cost. The authors suggests that the combination of BPM and IS-SAD (information security analysis and design) techniques can be used for security re-engineering of a BP, and integration of IS. The authors presents an overview of existing BPM approaches and requirements they should support to be used in ISRM.

Jakoubi and Tjoa [11] introduce a reference model for considering information within the BPM and RM domains. The authors argue for a stronger interweaving between RM and BPM, and present an approach for reengineering business processes as risk-aware. Herrmann and Herrmann [19] introduces the MoSS BP (Modeling Security Semantics of Business Processes) frame, based on object-oriented process models. The authors introduce several security properties and correlations between security requirements and BP elements, together with the following general approach to risk managing business processes, the three first steps focus on identificaiton of: (i) Business Processes and their actors. (ii) And valuation of assets and their security levels. (iii) Security requirements - and responding vulnerabilities and threats. While the two last steps address risk analysis and treatment: (iv) Assessment of risk. (v) Proposal, design and implementation of countermeasures.

AURUM [20] supports the NIST SP 800-30 standard [21], and is a framework for addressing IT risks which utilizes business processes for RM. AURUM prioritizes BPs based on importance, and derives the important assets from the BP. The method then continues to determine asset importance and conducts risk analysis based on Bayesian threat networks.

Ozkan and Karabacak [22] suggests that process modeling can be used to ease the use of risk analysis methods and move the IS focus from hardware and software over to IT processes. The authors suggests using process modeling to model the activities of the information processing and to determine the scope of the risk analysis. The CERT Resilience Management Model v 1.0 [23] (CERT RMM) is an approach for handling the challenge of operational resilience in day to day operations. The notion is that organizations deliver services that are supported by BPs' which are further supported by assets.

III. IT Governance, Information Security Risk & Management

Gregory [24] state that *"The purpose of IT governance is to align the IT-organization with the needs of the business"*. IT governance involves a series of activities to achieve this goal such as creating IT-policy, internal prioritizing between e.g. mission, objectives and goals, program and project management [24]. It also includes the responsibility for managing risks appropriately, and verifying that resources are used responsibly [7].

A. Information Security Management (ISM)

Generally, the main goal of information security is to secure the business against threats and ensure success in daily operations by ensuring confidentiality, integrity, availability (CIA) and non-repudiation [1]. Information can be present in many forms within the organization, it may be stored on a physical medium, be in the form of paper, or it can be an employee's knowledge and experience. Common for all these is that they are all valuable assets to an organization and

their security needs assurance. One of the main components of ISM is to establish a security program, often referred to as an information security management system (ISMS). The ISMS is a collection of security related documents often with the company wide security policy as the main document. The purpose of the ISMS is to ensure CIA through management of the organization; by choosing and implementing the appropriate security measures and controls. These measures can be chosen from e.g. the ISO/IEC 27002 [10], which is a standard consisting of security measures and how to implement them. The ISMS can be implemented following a Plan-Do-Check-Act (PDCA) cycle of continuous improvement [1], [6], see Fig. 2.

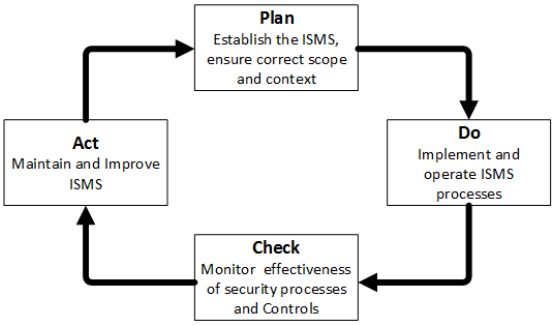

Fig. 2. Plan Do Check Act-phases of ISMS implementation as described in ISO/IEC 27000:2009 [1].

The security documentation of the ISMS is represented by a top-level security policy, generally founded in the organization's mission, vision, goals, values and objectives. Further represented by topic/issue-specific policies, standards, procedures and routines.

B. Information Security Risk Management (ISRM)

There exists several definitions of risk, ISO/IEC 31000:2009 [25] standard explains risk as *the effect of uncertainty on objectives*, and *Risk management* as a set of activities and methods applied in an organization to manage and control the many risks that can affect achievement of business goals. Hence, the main goal of ISRM is to maximize the long term profit, and optimally manage risks presented by potential failures, conflicting incentives and active adversaries.

A risk assessment is the *overall process of risk analysis and risk evaluation* [1], and risk analysis (RA) is the *systematic use of information to identify sources to estimate the risk* [1]. Risk evaluation is the *"process of comparing the estimated risk against given risk criteria to determine the significance of the risk"* [1].

ISO/IEC 27005:2011 [6] is a standard specialized for ISRM and defines the formal process of managing risks as an iterative process of reviewing and monitoring risks, including: context establishment, risk assessment, communication and treatment to obtain risk acceptance [6]. Risks for information systems are generally analyzed by using a probabilistic risk analysis (PRA) [6], [21], where impact to the organization (e.g. loss if a risk occurred) and the probability of the risk occurring is calculated. Probability calculation in ISRM has previously recieved critisism for relying too much on subjective estimates, and being too much like guesswork [24], [26], [27]. Risk evaluation uses the results from the analysis, and if the risk is found unacceptable, risk treatments are implemented, which consists of choosing a strategy and measures for controlling undesirable events.

C. Context Establishment for ISRM

The term "Context Establishment" is from the ISO/IEC Risk Management standard 27005 [6], and defines both the external and the internal parameters that must be considered when managing risks. The internal context for ISRM will usually be a product of different factors, such as IT systems, stakeholders, governance, contractual relationships, culture, capabilities, business objectives, and others. Examples of relevant external factors for establishing context are external stakeholders, external environment, laws and regulations, and other factors that can affect the organizations objectives.

Many established ISRM methods center around assets, the *NIST Specification for Asset identification* [28] uses three main classes of information system related assets; (i) Persons, (ii) Organization, and (iii) Information Technology. In addition, it provides nine sub-classes of assets of Information technology. In contrast to this, ISO/IEC 27005:2011 uses two primary asset classes; (i)Business processes & activities" and (ii)Information, with supporting assets: (i) Hardware, (ii) Software, (iii) Network, (iv) Personell, (v) site, and (vi) organization's structure.

A control can exist as automatic or manual, an automatic control performs its function with little or no human interaction, and a manual control requires a human to operate it, and generally fall within three major categories [24]: (i) Physical - represents controls that are found in the physical world, such as fences, doors with locks, and laptop wires. (ii) Technical - represents controls that are implemented in the form of information systems, they are usually in a logical form, such as a firewall, antimalware, and computer access control. (iii) Administrative - represents controls in form of e.g. policies and procedures that forbid certain activities, such as the IS policy.

The 14 Control Clauses and security domains from ISO/IEC 27002:2011 [10] and ISO/IEC 27001:2013 [9] are:

1) Information Security Policy - Top level documented security objectives for the whole organization, determined by management.
2) Organization of Information Security - IS Roles and Responsibilities, and IS management in general.
3) Human Resources Security - IS requirements and controls for recruitment of staff, terms of employment, security awareness training and process for termination.
4) Asset Management - The management and application of hardware and software assets, and classifying and handling of information.

5) Access Control - Effective password, privilege and user management on operating systems, applications and within networks.
6) Cryptography - Controls for securing CIA of information using encryption.
7) Physical and Environmental Security - Securing the human and system environment, including entry controls, power and cabling security.
8) Operations Security - Ensure CIA of operations and facilities.
9) Communications Security - Key security aspects of managing systems securely, such as backups, antivirus, media and laptop security
10) System Acquisition, Development and Maintenance - Secure development of software and maintenance of systems to maintain ongoing security
11) Supplier Relationships - Protect the organization from security breaches caused by third parties.
12) Information Security Incident Management - The reporting, recording, management and review of security incidents.
13) Information security Aspects of Business Continuity Management - Determine requirements, plan and training for response in the event of disasters.
14) Compliance - Ensuring compliance with legal requirements, including IPR, computer misuse and privacy legislation.

IV. Business Process Modelling and Management

A business process (BP) is a set of activities within an organization whose objective is to produce a desired result [29]. A process is, in short, "How work gets done" [3], and work is the *"exertion of effort directed to produce or accomplish something"* [4]. The purpose of modeling a BP is to describe the logical order and dependence, such that the practitioners can achieve a comprehensive understanding of the process [29]. A process generally has some sort input and transforms this into an output, e.g. a manufacturing process will take raw material as input, process this material, and output a product. We borrow the explanation from Mahal [3]:"a process is triggered by an event, governed by some rules using relevant knowledge, and executed through people using enabling technology and supporting infrastructure, such as facilities". A common abbreviation used to describe the components of a BP is IGOE - Inputs, guides, outputs and enablers [3], [5].

Besides from documenting processes, BPM can be used to facilitate large scale software developments to support BPs, BP analysis and improvement re-engineering [29]. The top-level representation of the BPM approach seen in Fig. 3.

A. The BPM Lifecycle

The BPM lifecycle represent the key activities in BPM. There is no uniform view of the number of BPM-LC phases [30]. Ko [31] state that there are many views of what steps the BPM life cycle actually consists of, and presents van der Aalst et.al.'s (2003) [32] view due to succinctness and relevance. Van der Aalst (2013) [2] has also published a newer review of the key activities in BPM after [31] was published. Wetzstein et.al. [30] present a general version of the BPM-LC. An analysis of the different lifecycle steps from [2], [30], [32], [33] show that they have the following steps in common:

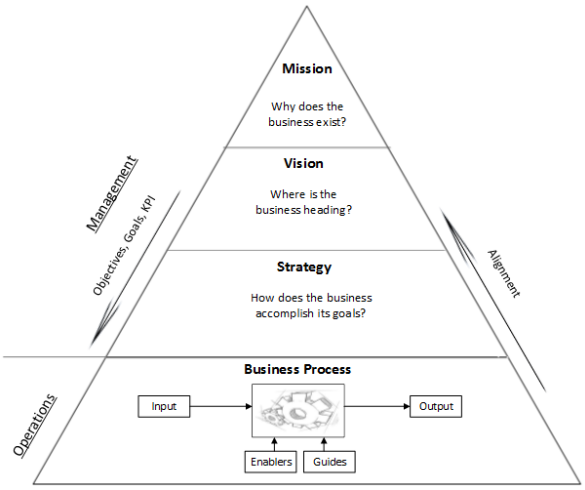

Fig. 3. Connection between Mission, Vision, Strategy and Business Processes. *Based on Mahal [3]*

1) Modeling and Design - Map/re-design or create a process model for analysis and/or enactment.
2) System Configuration & Implementation - Configure the system and implement the process model for enactment.
3) Enact/Execution - Deploy and execute the BP model using set configuration control and support concrete cases.
4) Monitor/Analyze - Analyze a process model studying the BP and/or event logs.
5) Manage/Diagnosis - Adjust/improve process, reallocate resources, manage large collections of BP models.

B. BPTrends Associates' BPM Methodology

The BPM Methodology Framework [8] is a best practices framework that provides a view of BPM sorted into three levels with associated steps. The framework recognizes the variety of goals at the different levels of the organization. The framework sorts the different levels into enterprise, process and implementation levels. The *Enterprise* level centers on corporate strategy, and focus on understanding and modeling BP architecture, definig performance measures, governance systems, aligning enterprise capabilities and prioritizing efforts. The main ongoing task consist of managing enterprise processes.

The *Process* level runs process improvement projects, where modeling, redesign and improvement of existing processes is in focus, taking processes from AS-IS to TO-BE. The main day-to-day tasks are BP execution and management.

The *Implementation* level focuses on designing human, software and information systems to implement BPs. It consists of

various IT and HR methodologies that are used for maintaining resources and continuous improvement.

C. BP Domains

Fig. 4 illustrates the BP domains, and shows how the different aspects of business support the BP, which ultimately determines enterprise performance. The general purpose of a BP is to transform an input to a desired output. The enterprise delivers value to its stakeholders and customers, and enterprise performance can be described using a set of measurable goals and objectives. KPIs provide the mechanisms for measuring performance. Information, knowledge and insight is what fuels the BP. The BP execution transforms the information into knowledge which is applied to create solutions. The "Guides" manages and controls the input/output transformation [3]. Put in the information security language; Guides are generally about governance and controls. The "Enablers" are the reusable resources of an organization that support the BP in transformation of input to output [3]. We leave inputs and outputs out of scope in this comparison. An explanation of the BP domains in the hexagon is as follows [3]: *Guides* provide

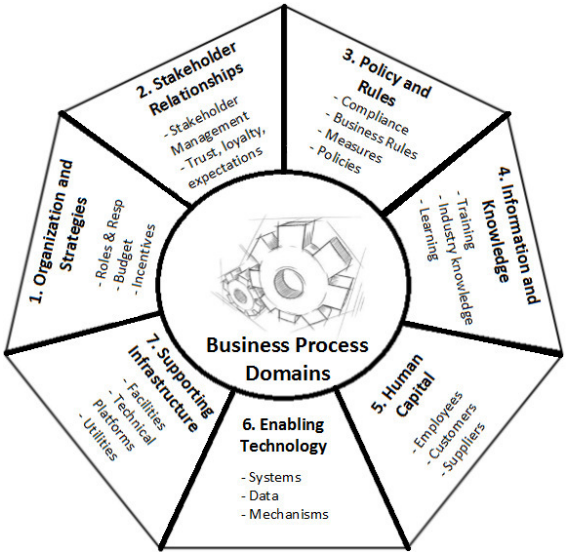

Fig. 4. Illustration of Guides and Enablers that contribute to the BP. *Based on [3], [34]*

governance, stakeholder expectations, direction, funding, rules and compliance restraints to the business process.

1) Organization and Strategies - Constitutes the organization's governance and its support structure. This domain covers consistent management, cohesive policies, processes, roles and responsibilities. It also includes organizational alignment and strategy development to achieve vision and deliver results.
2) Stakeholder Relationships - This domain constitutes both the external and internal stakeholders of the organization. It covers stakeholder management of expectations, trust and loyalty. The stakeholders are people who have vested in the success of the organization and can benefit from its performance.
3) Policy & Rules - Constitutes the business policies and rules of the organization, and are established to ensure compliance and mitigate risks through appropriate controls. The policies provide a decision-making framework at all levels of the organization.
4) Information and Knowledge - Encompasses training, learning and industry knowledge.*Defined as a guide in [3], [5].*
   Enabler are the reusable resources of an organization that support the BP in transformation of input to output. Enablers provide execution capabilities for the BP.
5) Human Capital - Constitutes of the people who enables the process, namely employees, customers, and suppliers. For the employee it is about their competence, which encompasses of a combination of knowledge, skills and behavior. Capable people are essential to optimally executing a process.
6) Enabling Technology - Constitutes of the technology that enables the BP. Includes information technologies such as business applications, data stores, and mechanisms such as production lines, robots, and engineering equipment.
7) Supporting Infrastructure - Constitutes of production facilities, technical platforms, communications, utilities and energy, and other infrastructure. Can also be considered as the capital asset of the organization.

V. Method

The primary research method adopted in this work is analytical. This article uses theoretical comparisons and mapping of BPM and ISM, for each BP activity we look for a corresponding IS activitiy. Similarly, for each IS activity, we look for a corresponding BP activity. This process will identify the intersection of BP and IS as well as what activities that are missing if BP and IS "compliance" is desired.

Following Ko et.al. [33] we start at the very top of the abstraction levels, comparing the generic lifecycles of BPM and ISM. Staying at a high level of abstraction, we compare organization/risk views and corresponding tasks. Lastly, we do a domain comparison of the BPM and ISM.

VI. A Comparison of ISM and BPM Lifecycles

The purpose of this section is to look for similarities and possibilities of integration between the top-level implementation strategies of the ISMS and BPM. We compare the high level steps of the plan-do-check-act (PDCA) lifecycle of the ISMS [9] and BPM lifecycle (BPM-LC) and look for common ground. Both cycles represent high-level views of the general activities of each approach. As there is no uniform view on the BPM-LC, we use the steps summarized in this article. We make the assumption that the ISMS lifecycle is compliant with the original PDCA-cycle, and compare the BPM-LC with the PDCA cycle as described by Moen and Norman [35].

TABLE I
A COMPARISON OF THE GENERIC PDCA STEPS AND THE BPM LIFECYCLE

PDCA steps/ BPM Lifecycle	**Plan**	**Do**	**Check**	**Act**
1. Modeling	X			
2. Implement/ Sys Config		X		
3. Enact/ Execution		X		
4. Analyze/ Monitor			X	
5. Manage/ Diagnosis				X

Table I shows that the generic BPM-lifecycle is loosely related to a PDCA notion of continuous improvement. A further comparison of the ISMS and BPM lifecycle approaches shows:

1) *Plan - Modelling:* The Plan-phase in ISMS is applied to establish context and scope the ISMS, together with planning for ISRM. In BPM, the steps in the modelling-phase maps existing BPs and plan/re-design BPs for enactment and analysis. Similar for both approaches is that they both establish the context and scope in this phase, the BPM uses BPs while IS uses e.g. an asset-based approach to establish organizational context. ISO/IEC 27005:2011 [6] names BPs as one of two primary assets, which may open for a combined approach of BPM context establishment.
2) *Do - "System Configuration" & "Implementation and Enact/Execution":* The steps in the Do-phase of the ISMS-lifecycle consists of implementing the processes associated with the ISMS. Usually in form of implementing risk treatment plans as a result of the ISRM program.
   The system configuration and implementation-phase in BPM implements designs by configuring process aware information systems and the underlying infrastructure. While the Enact/Execution phase executes and enacts the BP model. Both these BPM-phases correspond to the Do-phase in the PDCA cycle. Similar for both the ISMS and BPM lifecycles is that they both *implement* plans.
3) *Check - Analyze/Monitor:* This ISMS-phase monitors and reviews the effectiveness of implemented security process and residual risks. While the BPM-phase monitors and analyzes BPs for optimization. Both the IS and BPM lifecycles utilizes this phase for *monitoring and analysis* of the implemented processes.
4) *Act - Manage/Diagnosis:* The ISMS act-phase is mainly used to improve existing security processes based on analysis. The Manage and Diagnosis phase is utilized to adjust and improve BPs based on results from the previous lifecycle phase. This phase is also used to reallocate resources between BPs and manage large collections of BPs. Common for both lifecycles is implementing improvements based on analysis results from the previous phase.

We see from this comparison that the approaches are closely related; they are both founded on the PDCA principle, and the main tasks of each step is also similar.

VII. A COMPARISON OF ORGANIZATIONAL VIEWS

People employed at different levels of the organization both perceive and worry about different risks [12], which is also similar for the different concerns in the BPM hierarchy [5]. There is therefore a difference in what kind of information is needed to conduct tasks for both BPM and ISM at different levels of the organization. The purpose of this section is therefore to compare and map the organizational views and associated tasks presented in BPM and ISRM literature.

The BPM Methodology Framework represents a view of BPM sorted into levels including enterprise, process and implementation level, with recommended BPM steps per level (see [3], [5], [8]). NIST SP 800-39 [7] presents three different tiers for ISRM views, the comparison between the organizational views can be seen in table II.

TABLE II
A COMPARISON OF ORGANIZATIONAL VIEWS FROM THE NIST SP 800-39 [7] AND BPM METHODOLOGY FRAMEWORK [3], [5], [8]

Abstraction level	**Category**	**Multitier Org -Wide RM**	**BPM Methodology Framework**
Level 1	**Perspective**	Organizational	Enterprise
	Management	Top management	Organizational Management
	Main Tasks	Strategic risk management	Corporate Strategy in BPM, Supply chain
Level 2	**Perspective**	Mission/ Business Processes	Processes
	Management	Middle management	Process Management
	Main Tasks	RM of M/BP	Process Improvement
Level 3	**Perspective**	Information Systems	Implementation Level
	Management	Operations	Activity Management
	Main Tasks	Tactical Risk	Implementation of Information systems

The top-level comparison of the organizational views reveal a strong similarity. This is not surprising as one of NIST SP 800-39's main focus areas is securing BPs. Looking closer at the comparison we see a strong similarity in perspectives, tasks and responsibilities at each level:

- *Level 1* - We consider top management and organizational management to represent the same point of view. Both have a top-level management focus and are concerned

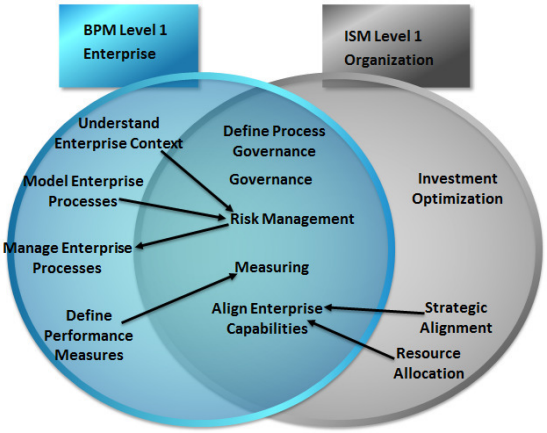

Fig. 5. Illustration of common BPM & ISM Level 1 tasks. Arrows indicate that a task is part of an activity, and that conducting the individual task will not complete the activity.

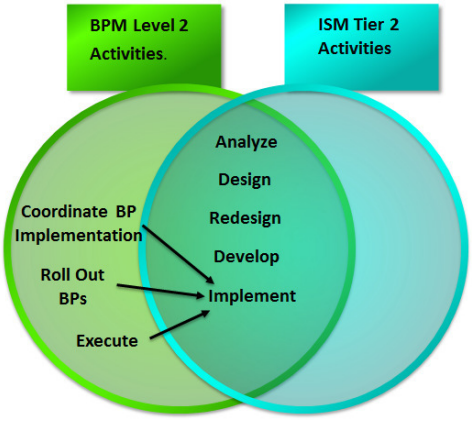

Fig. 6. Illustration of common BPM & ISM Level 2 tasks. Arrows indicate that a task is part of an activity, and that conducting the individual task will not complete the activity.

with governance and strategy tasks. We use the BPM tasks as described by [3], [8] to compare the subtasks from ISRM. Since there is no standardized steps per level from NIST SP 800-39, we analyzed and summarized the following steps for level 1 [7]: (i) Governance - assign roles and responsibilities to provide strategic direction, mission and objective achievement, risk management and resource usage, (ii) Strategic Alignment - of mission and business functions, (iii) Execution of Risk Management - frame, assess, respond to, and monitor risk (iv) Resource Allocation - of RM resources, (v) Measuring - monitoring and reporting RM metrics to ensure aligment, and (vi) Investment optimization - based on RM in support of organizational objectives.

The results from the comparison between ISRM and BPM level 1 sub-tasks can be seen in Fig. 5. The comparison show that the NIST RM function cover both *understanding the enterprise context* and *modelling enterprise processes* under Risk Framing, both activities necessary to conduct ISRM. However, the RM function only contributes to *Managing enterprise processes* which also includes activities such as establishing a BP services charter [3]. The same can be said for *Strategic aligment* of risk decisions, which is a part of completing *Aligning enterprise capabilities*, but does not complete the task. Our comparison show that there is no support for *Investment optimization* based on risk management at this level in BPM. Conducting resource allocation of RM resources will not complete any BPM tasks, but is a part of the *aligning enterprise capabilities* activity.

Comparing the other way, we see that there is no single ISRM Level 1 subtask to understand enterprise context and model enterprise context, but both are necessary steps in *executiion of RM* task. While *defining performance measures* is a part of the ISRM activity *measuring*, we cannot say that completing the BPM activity also completes the ISRM task. However, managing enterprise processes also measures processes and allocates resources.

- *Level 2* - Middle management and Process management are descriptions of the same responsibilities and points of view, only differentiated by organizational structure (e.g. matrix based for process management, or traditional department-based organization for middle management) [5]. Both have a BP perspective, and are concerned with modeling, prioritizing and re-designing processes. Further comparison of level 2 subtasks is seen in Fig. 6, where we see that the Level 2 BPM activities resemble the BPM lifecycle. As there are no standard steps in NIST SP 800-39, we have summarized the following level 2 steps from [7] for developing Risk-aware BPs: (i) Design - Existing BP (AS-IS), (ii) Develop - secure BP (TO-BE), (iii) Implement - secure BP. The standard also suggests to develop Secure Enterprise Architecture (EA) as a Level 2 task, which comprises maximizing effectiveness of BPs and information resources. We regard this task as present in all the BP-ISRM steps, and therefore do not count it as a standalone task.

  Our understanding of the NIST SP 800-39 tier two steps is that implementing a secure BP includes the BPM tasks "Coordination" (preparing for implementation), "Rolling out" and "Executing". Which means that all the BPM activities are supported in the ISRM approach. Comparing the other way shows that the "Analyze" and "Redesign" activities are covered by the ISRM steps, and that three remaining tasks together complete the ISRM "Implement" activity.
- *Level 3* - The information systems and implementation level perspective represents the operations and activity management point of view. The processes are found at the lower levels in the BPM hierarchy (see section 1), and represents where "the rubber meets the road" [3]. We consider this to represent the same management and perspective. Although both BPM and ISRM share the

operations view, they have slightly different concerns; IS is focused on securing information systems from tactical risks and managing controls, while BP is concerned with designing systems to implement with BPs.
As BPM employs several methodologies at this level, and the BPTrends associates' BPM Methodology framework does not extend to software and HR development [8], we have no standard tasks to compare to the ISRM. Mahal [3] mentions that one commonly used BPM method at this level is the software development lifecycle (SDLC). Risk managing the SDLC is also the main approach in NIST SP 800-39. Althought concrete HR-strategies are not present in the NIST standard, it does discuss organizational culture and it does also discuss the topic of trust, which we can not see mentioned in the BPM literature.

VIII. A COMPARISON OF ISM AND BPM DOMAINS

The main objective of this section is to compare the ISM and BPM domains to investigate if all control objectives can be integrated using BPM, and that all relevant aspects of BPM are covered in the control objectives. IS encompasses many fields related to information technology and systems, the ISO/IEC-standards in the 27000-series are industry standards and we use them as representatives of what must be covered to achieve IS (Notably ISO/IEC 27001 & 27002 [9], [10]). Therefore, to compare BPM and ISM approaches we use the 14 security domains and controls from ISO/IEC 27002 [10]. We mutually compare the IS domains to the domains of BPM defined by Burlton [34] and refined by Mahal [3] and Harmon [5].

A. Summary of Comparison, ISM and BPM

This section contains a summary of the integration results of IS into BPM. Table III shows a high level comparison of how the control clauses are supported by the BPM-domains.

The comparison of the ISM and BPM domains shows that we can integrate the security clauses and controls into the BPM domains of enablers and guides, and model them as BPs. An example is the implementation of the controls from the Information security incident management-security categories, illustrated in Fig. 7, which shows how the guides and enablers support the process.

One significant finding was that the domains of BPM does not directly consider internal or external attackers. This can in some cases be considered as a weakness of BPM as it concerns itself availability and integrity of BPs. RM is suggested as a supporting practice in development of the guides "Policy & Rules" [3]. The attacker might be considered as a part of general RM, but RM is such a wide discipline that it is likely to mean different things to different people [27].

BPM also presents a bit different view of assets; as the context, represented by BPs, is established before identifying the assets. In traditional ISRM, the situation is the other way around; first the asset that needs protection is identified, and then the context is modeled around the asset. Besides from

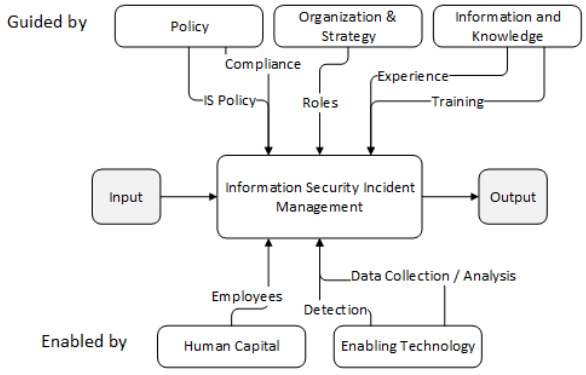

Fig. 7. The illustration shows how the IS Incident Management control can be modelled within the BP domain.

knowledge, intangible assets are not reflected in the BPM domains.

Another result that can be seen from the comparison is that the enabler "Human Capital", which generally represents employees, are needed to implement and operate every ISM control domain. However, the comparison show that out of fourteen control domains, only four are related to the security of human capital.

B. Summary of Comparison, BPM and ISRM

This section contains a summary of the integration results of BPM into ISM. Our comparison shows that the controls in ISO/IEC 27002:2013 are properly scoped to address four of the seven BPM domains. The enabler-domains were all addressed, but there were issues when addressing three of the Guide-domains:

1) Organization and Strategies: ISO/IEC 27001, section 5.1 a) emphasizes IS policy's compatibility with the organizations strategic direction, however, it is not mentioned in one of ISO/IEC 27002's 114 controls that the IS policy should be aligned with business. We can make the assumption of alignment from clause control objective 5.1, which is to provide management direction and support for IS in accordance with business requirements and compliance. The control itself state that the policy should be defined and approved by management. This points to a difference in perspective between the two disciplines, where BPM hammers organizational alignment of BPs as one of its main mantras.

2) Stakeholder Relationships: Nurturing both internal and external stakeholder relationships is an essential component of BPM; stakeholder identification, steering expectation, ensuring trust and loyalty are essential to BPM success [3], [5], [36]. Section "6.1 Internal organization" [10] covers some stakeholder groups (without using that term), as authorities and "special interest groups" are both types of stakeholders. The suggested controls put emphasis on maintaining contact with these stakeholders. However, these external groups are per BPM definition not important stakeholders, ISO/IEC 27001:2013 address the stakeholder needs in section 4.2 *Understanding the needs and expectations of interested parties*, but we can not see this reflected in the control objectives. The ISMS-program risk failing if key stakeholders lose interest, several instances of failure due to not having sufficiently powerful allies is highlighted in [22]. Although not completely neglected by IS, there is a clear gap between how much emphasis BPM and ISRM put on stakeholder management.

3) Information and Knowledge: It is a given that information is covered by all of the security domains. In BPM, information is utilized as knowledge by employees to fuel BPs [3], and knowledge is generally possessed by employees. The "Return of Assets"- security control (8.1.4) briefly mentions knowledge; *In cases where an employee, contractor or third party user has knowledge that is important to ongoing operations, that information should be documented and transferred to the organization.* This reflects a preventive control at the *end* of an employment. Capturing knowledge presents difficulties, as the interviewer must know exactly what questions to ask and the subject must be cooperative and willing to communicate the information in a comprehensive way.

This brings up the question if an ISRM process can identify and protect critical knowledge. Knowledge is viewed as an intangible asset [37], but e.g. is not included in the asset overviews in [28] or [6]. However, loss of availability due to lack of knowledge is a plausible IS risk (e.g. during incident handling), combined with the importance of knowledge in BPM, makes it an important business area to secure. Depending on the skill of the analyst, knowledge runs the possibility of being overlooked by ISO/IEC 27005:2011 and asset-based approaches.

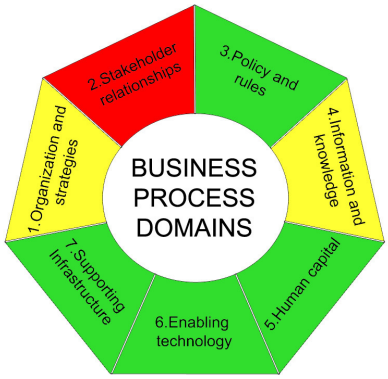

Fig. 8. Heatmap indicating how well ISM covers the BPM domains, green signals no issues, red signals significant issues.

IX. Conclusion

We have shown in this article that both the top-level BPM and ISM approaches are based on a Deming-cycle (PDCA) of continuous improvement, and that the main tasks of each step are similar.

We have shown that there is a strong similarity between the BPM Methodology framework and the ISRM standard NIST SP 800-39, as both approaches uses similar organizational views, only applying different names. We have also shown that the tasks and goals of each level are similar, with some key differences: the tier/level 1 ISRM approach does not include an activity for managing enterprise processes, and BPM does not include risk based investment optimization and trust-issues.

When comparing BPM and ISM domains we found that the ISM tasks can be supported by BPM, but that BPM does not include the concept of internal or external attackers. Further we found that ISO/IEC 27001/2 standards emphasized, but not controlled that the IS policy was aligned with business requirements. We also found a large gap between how much emphasis ISM and BPM put on stakeholders. Where BPM have fully adopted the principles of stakeholder management and recognized its importance, there is no real approach adopted in ISM to address stakeholders. We also found that the need for securing knowledge possibly is underestimated in ISM.

A. Future Work

As our findings are theoretical, we suggest further validation of the results from this article. This article has also shown that there is some common ground between BPM and ISM, and this warrants further investigation to determine if a joint approach is feasible. This work has revealed the potential for further research concerning stakeholder management in information security.

***Abstract*—Physically Unclonable Function (PUF) is expected to be an innovation for anti-counterfeiting devices for secure ID generation, authentication, etc. In this paper, we propose novel methods of evaluating the difficulty of predicting PUF responses (i.e. PUF outputs), inspired by well-known differential and linear cryptanalysis. According to the proposed methods, we perform a first third-party evaluation for Bistable Ring PUF (BR-PUF), proposed in 2011. The BR-PUFs have been claimed that they have a resistance against the response predictions. Through our experiments using FPGAs, we demonstrate, however, that BR-PUFs have two types of correlations between challenges and responses, which may cause the easy prediction of PUF responses. First, the same responses are frequently generated for two challenges (i.e. PUF inputs) with small Hamming distance. A number of randomly-generated challenges and their variants with Hamming distance of one generate the same responses with the probability of 0.88, much larger than 0.5 in ideal PUFs. Second, particular bits of challenges in BR-PUFs have a great impact on the responses. The value of responses becomes '1' with the high probability of 0.71 ($>$ 0.5) when just particular 5 bits of 64-bit random challenges are forced to be zero or one. In conclusion, the proposed evaluation methods reveal that BR-PUFs on FPGAs have some correlations of challenge-response pairs, which helps an attacker to predict the responses.**

I. Introduction

RECENTLY, the concept of Internet of things (IoT) has been widely spread. Various things such as vehicles, home appliances, medical devices and sensing devices are connected to the Internet. It is expected that this provides us a lot of new services and products in the field of industry, education, healthcare, agriculture, etc. First of all, the secure IoT requires us to realize an authentication system for things. This is because counterfeiting the things causes serious security problems for the services and products based on the IoT concept. Generally, hardware-based approaches are often used for the authentication of things. For example, cryptographic hardware using integrated circuits (ICs) stores a secret key in its internal memory. A secure cryptographic protocol using the cryptographic hardware enables us to authenticate the things, making the secret key invisible from the outside. This approach prevents a leakage of the key outside, and makes it impossible to counterfeit things. However, recent research has found that the secret key could be revealed by de-packaging the IC and analyzing the IC mask design [2]. Therefore, further techniques are necessary to protect the cryptographic hardware storing the secret keys.

Recently, Physically Unclonable Functions (PUFs) have been focused as a solution to the secure authentication for things [3]. PUFs are realized in individual IC chips, and have a completely identical circuit structure. In spite of the identical circuit, PUFs generate the unique output values (responses) to the same input value (challenge) for each individual IC. This uniqueness is provided by process variations in memory characteristics or wire/gate delay occurring in the manufacturing process of each IC chip [4] [5]. Even if an attacker de-packages and analyzes ICs of PUFs, she cannot analyze the process variations due to the identical PUF structure. As a result, she cannot reveal the challenge-response pairs of PUFs. Therefore, PUFs can be utilized for a secure authentication system for things.

There are two categories in the PUFs on ICs: *memory-based* PUFs utilizing the memory characteristics and *delay-based* PUFs utilizing wire/gate delay variations [6]. One of the most feasible and secure memory-based PUFs is latch-based PUFs (LPUFs) [7] [8]. The LPUF generates an N-bit response based on N outputs from N RS latches. The RS latch is composed of cross-coupled logic gates, and is similar to a memory cell. Each bit of the response is generated from each latch output in a stable state after a metastable state. The metastable state is affected by the memory characteristics, thus the latch outputs (i.e. response bits) are also unique for each individual IC. One of the most famous delay-based PUFs is Ring Oscillator PUFs (RO-PUFs) [9]. The RO-PUF has M number of ROs, one of which is composed of odd number of cascaded inverters as a ring. The RO-PUF derives 1-bit responses from the difference of oscillator frequencies between two arbitrary ROs. Consequently, 1-bit response becomes zero or one, depending on which RO has a larger frequency. The number of responses is ${}_M\mathrm{C}_2$, which corresponds to the number of combinations of M ROs taken 2 at a time. The oscillator frequencies are affected by the wire/gate delays, which makes the responses unique for each individual IC.

Bistable Ring PUFs (BR-PUFs), having both properties of memory-based and delay-based PUFs, were proposed and self-evaluated by Chen et al. (hereinafter called "developers") [10] [11]. There are two major differences between BR-PUFs and

The preliminary version of this paper was presented in a Japanese domestic symposium without peer review [1].

978-83-60810-58-3/$25.00

RO-PUFs: (1) the structure of a ring, (2) response generation. (1) A BR-PUF is composed of cascaded inverters as a ring (hereinafter called "primitive BR-PUF"). A primitive BR-PUF is similar to an RO-PUF in terms of the ring of cascaded inverters. The difference is that the number of the inverters is not odd but even. Hence the primitive BR-PUF does not keep oscillation, but make the transition from metastable to stable state like memory-based PUFs. The primitive BR-PUF derives a 1-bit response from which stable state the ring is, e.g. '10101010' or '01010101' in a ring of 8 inverters. (2) A primitive BR-PUF generates just one 1-bit response because it consists of one ring, while an RO-PUF includes multiple rings. To generate multiple 1-bit responses, the BR-PUF has a *basic component* instead of the inverters in the ring. The basic component consists of two logic gates, either of which is selected by 1 bit of challenge [10]. The BR-PUF with 64 basic components, for example, has 64-bit challenge to select the logic gates. The BR-PUF is organized by 2^{64} different types of rings, the logic gates of which are differently selected depending on the values of challenges. Therefore, the BR-PUF can generate multiple challenge-response pairs without having multiple rings like the RO-PUF.

In this paper, we evaluate security aspects of BR-PUFs implemented on FPGAs. The reason why we focus on this PUF is that BR-PUFs have the following advantages with both memory-based and delay-based PUFs, as claimed by the developers:

- BR-PUFs are similar to delay-based PUFs in that the number of challenge-response pairs is exponential to the bit length of challenges, which makes difficult the predictions of responses.
- BR-PUFs also have the resistance against a machine learning attack and a modeling attack like memory-based PUFs.

BR-PUFs are evaluated by developers themselves. These self-evaluation results are very useful for users to understand the effectiveness of the proposed PUFs. However, the evaluation results may be different depending on PUF implementations since PUFs are based on physical characteristics in ICs. Hence it is quite important to evaluate and analyze newly proposed PUFs by third-party researchers as attackers. These BR-PUFs with excellent characteristics have not been evaluated by other researchers yet.

A. Our Contributions

In order to evaluate the security of PUFs, we focus on the difficulty of predicting responses. This difficulty is one of requirements for PUFs. Consequently, responses for unknown challenges should be unpredictable and non-biased even when some challenge-response pairs are known. In this paper, we propose novel two methods of evaluating this difficulty:

Our Evaluation Method (i):

> What is the probability that PUFs generate the same responses for two challenges with small Hamming distance?

Our Evaluation Method (ii):

> What is the probability that PUFs generate the same responses for multiple challenges whose particular bits are forced to be zero or one?

These methods are inspired by well-known cryptanalysis methods: differential cryptanalysis [12] and linear cryptanalysis [13]. The Evaluation Method (i) focuses on how differences in the challenge (plaintext) lead to differences in the response (ciphertext). The Evaluation Method (ii) is based on the idea that the response (ciphertext) is linearly approximated by particular bits of the challenge (plaintext). If the probabilities in these methods are close to 0.5, the evaluated PUFs are highly secure because they can generate non-biased responses independently of the values of challenges.

In this paper, we evaluate the security of BR-PUFs on Xilinx FPGAs (Spartan-6) according to our two evaluation methods. We analyze a number of challenge-response pairs obtained from BR-PUFs consisting of 64 inverters implemented on FPGAs. As a result, our case study supports that BR-PUFs on FPGAs have undesirable performance in the differential and linear evaluations; the probability is far from ideal 0.5. The differential evalaution shows that two types of rings for the challenges with small Hamming distance have many common logic gates (i.e. similar circuit characteristics), which are likely to generate the same response. The linear evaluation implies that BR-PUFs have some special inverter gates which have a great impact on the responses.

This paper is the first time that BR-PUFs on FPGAs have some security issues of response predictions. More importantly, our two evaluation methods can be used as universal methods for evaluating the security of other types of PUFs.

B. Organization of the Paper

The rest of the paper is organized as follows. Section II gives an outline of the BR-PUF. Section III proposes two evaluation methods of the difficulty of predicting responses. Section IV evaluates the BR-PUFs implemented on an FPGA platform according to the evaluation methods. Finally, in Section V we summarize our work and comment on future directions.

II. Bistable Ring PUF

The BR-PUF was proposed by Chen et.al. in 2011 [10]. Figure 1 shows the basic mechanism of the BR-PUF. The BR-PUF consists of the even (e.g. eight in Fig. 1) number of inverters (INVs), which are connected as a ring. After voltage is supplied, the ring has two possible stable states, '10101010' ('A'-state) or '01010101' ('5'-state), enumerating inverter's outputs beginning from INV_1. The ring generates 1-bit response according to which state the ring falls into. The BR-PUF is similar to the delay-based RO-PUF in terms of having inverter rings. It also has the same characteristic with the memory-based Latch-PUF, having two possible states.

Figure 2 shows the circuit structure of the BR-PUF, presented in [10]. The inverter in Fig. 1 is implemented by a *BR-S*, which is a basic component of the BR-PUF. The l-th BR-S, i.e. BR-S_l ($1 \leq l \leq 64$), is composed of two NOR gates,

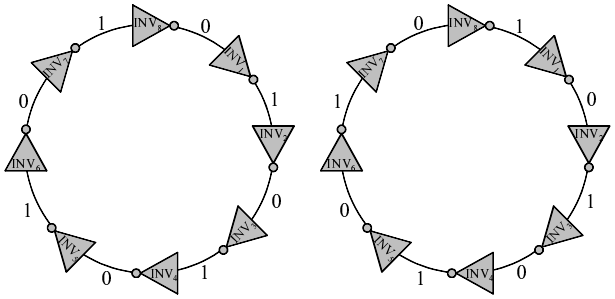

Fig. 1. Two possible stable states on a primitive BR-PUF with 8 inverters.

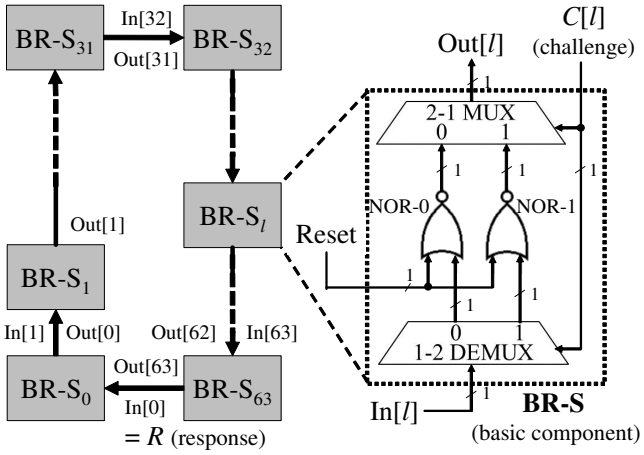

Fig. 2. Circuit structure of Bistable Ring PUF.

a 2-to-1 MUX and a 1-to-2 DEMUX. A 1-bit challenge $C[l]$ is input to the BR-S$_l$ to select either of the NOR gates. The BR-PUF with 64 BR-Ss has 64-bit challenges, which means 2^{64} different types of rings can be organized. Each NOR gate has different characteristics, i.e. drive capability or gate/wire delay. Hence the value of challenges has a great impact on the decision of stable states, either A-state or 5-state, as claimed by the developers. A 1-bit response is extracted from an arbitrary signal between two BR-Ss, e.g. the output from BR-S$_{63}$, i.e. Out[63] (=In[0]) in Fig. 2. The BR-S$_l$ works as an inverter when reset signal equals to 0. In contrast, the input and output of BR-S$_l$, In[l] and Out[l], can be forced to zero when the reset signal is 1 (i.e. neither A-state nor 5-state). This enables us to generate responses at any time after power up. In conclusion, BR-PUF has multi-bit challenges and generates a number of challenge-response pairs at any time.

III. Proposed Evaluation Methods

It is well known that responses of some delay-based PUFs are predictable through a machine learning attack [14]. The developers of BR-PUFs claim that BR-PUFs have a resistance against such an attack [10]. This resistance is based on the complex and non-linear behavior of BR-PUFs, different from other delay-based PUFs. Hence they claim that an attacker cannot predict responses of BR-PUFs. For the verification of this resistance, we consider that the correlation among challenge-response pairs should be evaluated experimentally. This evaluation, unfortunately, has not been performed by other researchers yet.

In this paper, we propose novel two methods of evaluating PUFs in terms of the resistance against response predictions. In the proposed method (i), we evaluate whether or not challenges with small Hamming distance result in highly correlated responses. In the proposed method (ii), we evaluate whether or not we obtain the same responses with high probability if certain bits of challenges are forced to zero or one. In the following, we explain these methods, assuming the case of evaluating BR-PUFs.

A. Proposed Method (i): Differential PUF Analysis

A group of challenges with small Hamming distance may cause the problem that most of NOR gates are selected commonly, so the characteristics impacting on the responses are also similar one another. In detail, let R_j's be the responses obtained from 64-bit challenges C_j's. Here, let $\tilde{R}_j^{(1,i)}$ be the response obtained from $\tilde{C}_j^{(1,i)} (1 \leq i \leq 64)$ whose Hamming distance is one from C_j (i.e. the only i-th bit from least significant bit (LSB) is different). In ideal PUFs, $\tilde{R}_j^{(1,i)}$ and R_j have little correlation. If a correlation exists, $\tilde{R}_j^{(1,i)}$ has a possibility to be easily predicted by an attacker when challenge-response pairs (C_j, R_j) are known. This means that the implemented BR-PUFs have a serious security issue.

The proposed method (i) is inspired by the well-known cryptanalysis method: differential cryptanalysis [12]. The differential cryptanalysis evaluates the avalanche effect: the effects of the changes of plaintext bits on ciphertext bits. In the proposed method (i), we evaluate how differences in the challenge (plaintext) lead to differences in the response.

B. Proposed Method (ii): Linear PUF Analysis

We consider that some logic gates and wires may be quite different from many other ones. This is because of the process variations in the circuit characteristics such as drive capability or gate/wire delay. If such gates and wires exist in a ring of the BR-PUF, the stable state falls into either state with high probability. As a result, the number of independent challenge-response pairs is very small, which is a security problem for PUFs.

This method is inspired by linear cryptanalysis [13]. In this cryptanalysis, an attacker tries to find linear equations with plaintext bits and ciphertext bits which have a high bias. This provides us with the inspiration of the general method of evaluating PUFs in terms of response predictions.

From the view point of designers of PUFs, they must design a secure PUF whose responses cannot be predicted by an attacker. Of course, machine learning attacks can evaluate a tolerance against the response predictions. However, a concrete method of designing such a secure PUF has not been established yet. Therefore, in this paper, the proposed

evaluation methods provide fundamental principles to design secure PUFs, in terms of correlations between challenges and responses. Next section experimentally evaluates the BR-PUFs implemented on FPGAs according to our proposed methods.

IV. Experimental Evaluation

A. Experimental Setup

Figure 3 shows our experimental system, which consists of two boards: a custom-made board with a Xilinx Spartan-6 FPGA (XC6SLX16-2CSG324C) and a commercially-available Spartan-3E starter kit board with a Xilinx Spartan-3E FPGA (XC3S500E-4FG320C). We implemented the BR-PUF circuit with 64 BR-Ss on the Spartan-6 FPGA, and the peripheral circuits such as the block RAM and RS232C module on the Spartan-3E FPGA. An Spartan-6 FPGA chip was put on a socket of the custom-made board, being therefore easily replaceable by another chip. We evaluated 4 BR-PUFs implemented on 4 Spartan-6 FPGA chips: $\mathrm{FPGA}_x (1 \leq x \leq 4)$.

Our response acquisition process was as follows. When the RS232C module in the Spartan-3 FPGA received a start command from a user PC, the module sent a start signal to a CTRL module. The CTRL module got a 64-bit linear feedback shift register (LFSR) to generate 2,048 random challenges $C_j (1 \leq j \leq 2,048)$. According to [15], the tap sequence of the LFSR was set to [64, 63, 61, 60], and the initial value was set to '0x123456789ABCDEF0'. The 64-bit challenge was divided into four 16-bit values, which were sent and stored to the flip-flops (FFs) on Spartan-6 FPGA. The reset signal to the BR-PUF was changed from 1 to 0, then the response acquisition was started. Not only 1-bit output but also all of 64-bit output from BR-Ss was stored into the 64-bit flip-flop. This enables us to confirm whether or not the response is stable; if the 64-bit value has at least two consecutive 1's/0's, the response is regarded as unstable state, vice versa. In our experiment, the 64-bit value was stored after sufficient time (i.e. approximately 6 ms) from the reset signal changing to 0 in order to make the response as stable as possible. The 64-bit value was sent to a block RAM on the Spartan-3E bit-sequentially, and was transmitted to the user PC through an RS232C port.

Both design and implementation of the BR-PUF are very important because they have a large impact on the eventual response behavior of the PUF itself. Hence we take great care of the symmetric layout of the BR-PUF as follows. Figure 4 shows our custom layout of a BR-PUF with 64 BR-Ss on a Spartan-6 FPGA. The 64 BR-Ss were implemented on the ring-shaped neighboring CLBs (configurable logic blocks), expecting that the wire lengths between all BR-Ss are identical. This symmetric layout is expected to make a uniform ring and a bias of responses as small as possible.

Before we perform an experimental evaluation, we verify the implemented BR-PUFs according to the responses R_j's for the 2,048 random challenges C_j's. Average Hamming distance between two arbitrary 64-bit challenges among the 2,048 challenges is 32.00. This is extremely close to theoretical value $(= 64/2)$, so our using challenges are enough random. By

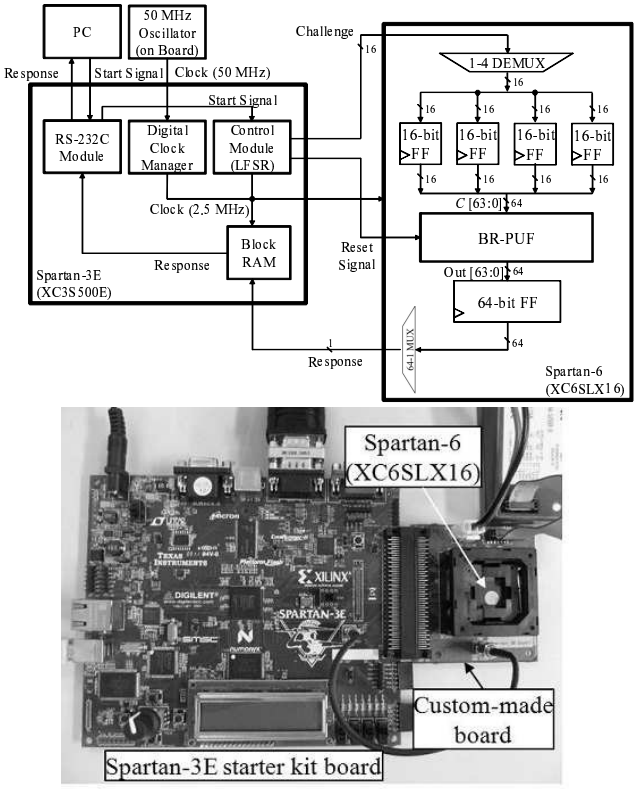

Fig. 3. Experimental system.

using these challenges, we evaluate average hamming distance between two arbitrary responses among the 2,048 responses (i.e. ${}_{2048}\mathrm{C}_2$ combinations). The results are 0.50, 0.49, 0.49 and 0.46 in four BR-PUFs, respectively. These are very close to the ideal value (= 0.5), so our implemented BR-PUFs are verified to generate almost non-biased responses for random challenges.

B. Experimental Results - using Proposed Method (i)

This section evaluates the correlation among the responses obtained from challenges with small Hamming distance. We generate a certain number of challenges $\tilde{C}_j^{(k,i)}$ satisfying the following condition: the Hamming distance between C_j and $\tilde{C}_j^{(k,i)}$ being equal to k, i.e. HD(C_j, $\tilde{C}_j^{(k,i)}$) $= k$. For example, in the case for $k = 1$, we generate 64 challenges $\tilde{C}_j^{(1,i)} (1 \leq i \leq 64)$, where i-th LSB is just different. In our experiment, we evaluate the responses in $k = 1, 2, 4, 8$ and 16. In the case where $k > 1$, however, the number of challenges $\tilde{C}_j^{(k,i)}$ is ${}_{64}\mathrm{C}_k$, which becomes quite large for the value of large k. Due to time constraints, we generate the following two types of challenges $\tilde{C}_j^{(k,i)}$:

Type A

Neighboring k bits are different between C_j and $\tilde{C}_j^{(k,i)}$ as shown in Fig. 5(I).

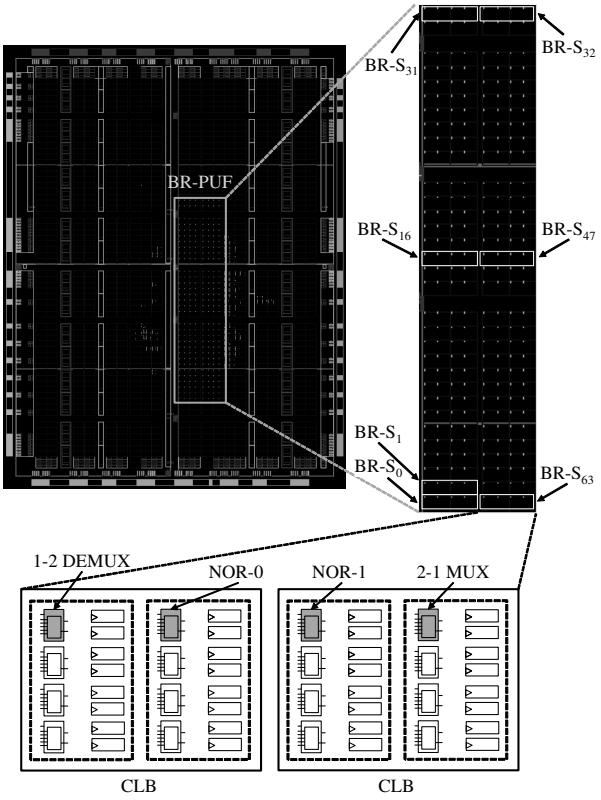

Fig. 4. Implementation of our BR-PUF with 64 BR-Ss on a Spartan-6 FPGA.

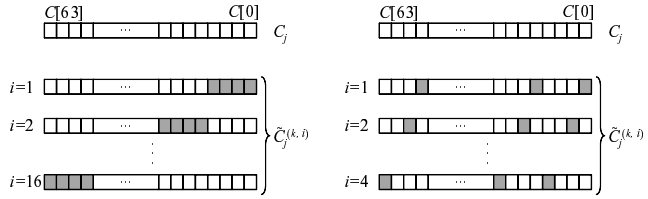
Type B
: Intervals of $64/k$ bits are different as shown in Fig. 5(Ⅱ).

Table I shows the number of $\tilde{C}_j^{(k,i)}$ in each k according to the aforementioned types. We generate 184 ($= 124 + 60$) challenges $\tilde{C}_j^{(k,i)}$ for each of 2,048 C_j's. Hence we obtain the total of 378,880 ($= 2,048 \times 185$) challenge-response pairs from each BR-PUF.

Figure 6 shows the ratios of the challenges $\tilde{C}_j^{(k,i)}$ which generate the same responses as each C_j. These results are the means of 4 implemented BR-PUFs. From the result of Type A in $k = 1$, 88.0% of challenges $\tilde{C}_j^{(1,i)}$ lead to the same responses as C_j. This ratio should be around 50% in secure PUFs. The larger the value of k is, the lower the ratios of such challenges are. However, even in the Type A of $\tilde{C}_j^{(16,i)}$ where HD(C_j, $\tilde{C}_j^{(16,i)}$)=16, the probability is approximately 0.665, which is larger than ideal 0.5. Additionally, there is almost no difference between both types in Fig. 6. This indicates that the similarity of responses depends not on the locations of the different bits, but just on the Hamming distance of the challenges. Consequently, if a challenge-response pair is known to an attacker, she has a high possibility to predict the responses for challenges with small Hamming distances by using the known challenge.



(I) Type A ($k = 4$) (Ⅱ) Type B ($k = 16$)

Fig. 5. Two types of challenges $\tilde{C}_j^{(k,i)}$ (Colored bits are different between C_j and $\tilde{C}_j^{(k,i)}$).

TABLE I
NUMBER OF CHALLENGES FOR k IN BOTH TYPES.

k	Type A	Type B
1	64	N/A
2	32	32
4	16	16
8	8	8
16	4	4
Sum	124	60

Different from other PUFs, the generation time of responses, i.e. the duration period for stable states, is quite different depending on values of challenges in BR-PUFs [10]. The generation time has a strong impact on the *reliability* and *uniqueness* of the responses, systematically defined as PUF performance metrics in [16]. Especially, the responses obtained in a short transient time have little uniqueness[1]: a small difference among BR-PUFs because circuit layout influences the responses strongly. Hence we should select and use the only responses with long transient time, as presented in [10]. In the above-mentioned evaluation we focus on all of challenge-response pairs without consideration of the transient time. We anticipate that highly-unique responses with the long transient time have a lower similarity, even if the challenges have a small Hamming distance. To confirm this we obtain the 64-bit outputs of BR-Ss, i.e. responses for 2,048 C_j's, in a short time of approximately 70μs after the reset signal to the BR-PUF is zero. 1,658 (approximately 80.96%) out of 2,048 C_j's lead to stable responses with alternate bits. Here, we focus only on the remaining of 390 C_j's and perform the same evaluation as above mentioned, whose results are shown in Fig. 7. The correlation between the value of responses and the Hamming distance of challenges becomes small, as we expected. However, the correlation still exists: 68.1% of challenges $\tilde{C}_j^{(1,i)}$ lead to the same responses as C_j's. This indicates that the responses of BR-PUFs are predictable even if we use the selection of challenge-response pairs, presented by developers. In conclusion, this dependency of the responses on the Hamming distance of challenges might facilitate an attacker to succeed in her modeling attack, and predict most of unknown responses.

[1]According to the BR-PUFs on ASICs self-evaluated by the developers through SPICE simulations in [11], the PUF performances such as reliability and uniqueness are not affected by the generation time of responses.

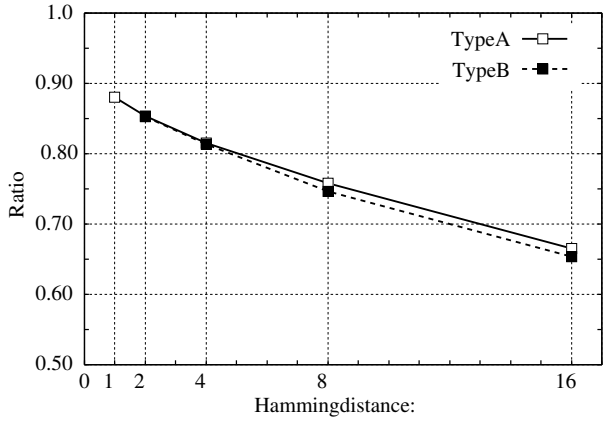


Fig. 6. Ratios of challenges $\tilde{C}_j^{(k,i)}$ generating the same responses as C_j for k in both types.

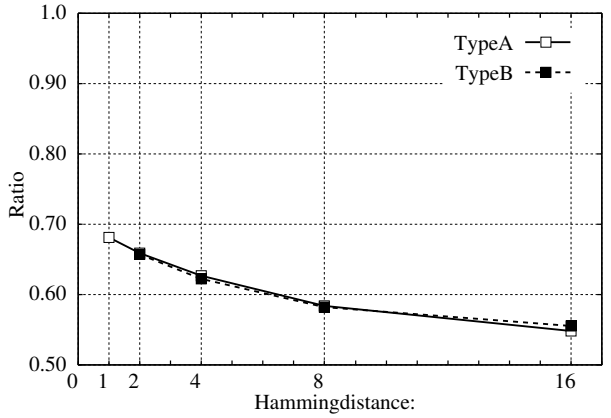

Fig. 7. Ratios of challenges $\tilde{C}_j^{(k,i)}$ generating the same responses as C_j whose transient time is longer than 70 μs.

C. Experimental Results - using Proposed Method (ii)

This section evaluates whether or not BR-PUFs have a BR-S with an *influential* NOR gate, which has a decisive impact on the value of responses. We anticipate that the influential NOR gate has quite different circuit characteristics from other NOR gates. The location of the influential NOR gate is defined by the following two parameters: *enforced bit* ($\leq$ 64) and *enforced value* (0/1). The enforced bit means the location of the BR-S including the influential NOR gate. The enforced value represents either NOR gate in the BR-S. For example, if the enforced bit is 33 and the enforced value is 1, the influential NOR gate is the NOR-1 gate in BR-S_{33}.

As a preliminary experiment to confirm the existence of influential NOR gates, we analyze the 2,048 challenge-response pairs (C_j, R_j) same as Section IV-B. 64-bit challenges of BR-PUFs correspond to the way of selecting NOR gates in BR-Ss. We extract part of C_j's from 2,048 ones whose certain m ($1 \leq m \leq 5$) bits are the same one another, i.e. common NOR gates are selected. Our software program searches all patterns of selecting m NOR gates (${}_{64}\mathrm{C}_m \cdot 2^m$ combinations). Due to time constraints, we set m to less than 6. Table II shows the number of responses (=‘1’s) for the part of C_j's. We explain how to read the table with the specific example of $m = 3$, as follows. Out of 2,048 there are 236 C_j's whose 58th, 13rd and 6th LSBs are 1, 0 and 1, respectively. The number of responses whose values are ‘1’s is 205, which is 86.9% of 236 R_j's. Hence these three NOR gates are predicted to be influential NOR gates, i.e. (enforced bit, enforced value)= $(58, 1), (13, 0), (6, 1)$. Table II also shows the 6 patterns of influential NOR gates for each m. From Table II, we see that more than 65% of responses become 1 in the BR-PUF with just one influential NOR gate (i.e. $m = 1$). The number of the influential NOR gates is around 10 in the 64 BR-Ss. The larger the number of influential NOR gates ($= m$) is, the larger the percentage of responses (=‘1’s) is, i.e. the larger impact on the responses. Especially, all responses become 1 when $m = 5$. In conclusion, according to the analysis of 2,048 C_j's, we demonstrate that our BR-PUF on FPGA has influential NOR gates with a decisive impact on the values of responses.

Above-mentioned results are obtained from a BR-PUF on FPGA_1. We also confirm that the other three BR-PUFs on FPGA_2, FPGA_3 and FPGA_4 have influential NOR gates. BR-PUFs on FPGA_1, FPGA_2 and FPGA_3 generate responses biased to one, while the BR-PUF on FPGA_4 outputs responses biased to zero. The locations of influential NOR gates are different from each FPGA. These are caused by the characteristics of BR-Ss.

As a further experiment, we evaluate the responses for much larger number of challenges than 2,048. First, additional 2^{15} C_j's ($1 \leq j \leq 2^{15}$) are obtained by using the LFSR on the Spartan-3E FPGA. Next, we generate $\hat{C}_j$'s whose enforced bits are changed to the enforced values according to Table II. This means that influential NOR gates are definitely included in the rings of our BR-PUF, and the other NOR gates are selected randomly. Figure 8 shows the ratio of responses equal to 1 for $\hat{C}_j$'s. The line graph represents the average result of six patterns of influential NOR gates as shown in Table II. The upper and lower bounds for error-bars mean the maximum and minimum results of the six patterns, respectively. From Fig. 8, we see that the responses are biased to one when our BR-PUF includes influential NOR gates. The probability of responses being one is 71.4% and 54.5% when the number of influential NOR gates is set to 5 and 1, respectively. The reason why the degree of the bias is smaller than in Table II is more likely that responses are affected by other influential NOR gates not shown in Table II. In conclusion, an attacker who knows some challenge-response pairs could reveal the properties (i.e. influential NOR gates) of her target BR-PUF like Table II. After that, she has a high possibility to predict unknown challenge-response pairs. To minimize the impact of the influential NOR gates, special layout and implementation custom-designed for each BR-PUF are required, however, increase the manufacturing costs dramatically.

TABLE II
INFLUENTIAL NOR GATES AND THEIR IMPACT ON A BIAS OF RESPONSES.

m	**Influential NOR gate(s)** Enforced bit (i-th LSB) : Enforced value (0/1)	# of responses (= 1) / # of responses for challenges with left-column's NORs
1	53:0	701 / 1046 (67.0%)
	25:0	716 / 1044 (68.6%)

D. Discussion

1) **Are the wire lengths between all BR-Ss identical?***:* There is no evidence that all of the wire lengths are completely identical. The reason is that it is difficult to exactly control the wire length because logic gates on FPGAs are fixed on grid-pattern layouts. As shown in Fig. 4, we implement BR-PUFs on FPGAs as carefully as possible. In spite of the careful implementations, our BR-PUFs have security issues: correlations of challenge-response pairs. This indicates that it is difficult for many designers to implement BR-PUFs on FPGAs securely. Therefore, this paper gives useful information for designers of BR-PUFs.

2) **Is the implementation of BR-PUFs in this paper the same as that in original paper?***:* We derive 64-bit outputs from all of the 64 BR-Ss, instead of just one in original. We consider that the original implementation is not the best option. This is because deriving only one output may lead to unbalance of capacitive loads on the output of each BR-S, which causes influential gates. We derive outputs from all of BR-Ss in order to prevent this unbalance.

3) **Is it appropriate to derive general results from a single implementation on a specific FPGA family (Xilinx Spartan 6)?***:* Xilinx Spartan 6 FPGAs are relatively newly-released, and have almost the same structure as other types of FPGAs such as Xilinx Virtex 6. We expect, therefore, that similar results are confirmed on the Xilinx FPGA family. In contrast, we need further evaluations on other FPGA families (e.g. developed by Altera) or ASICs because their structures are completely different from that of the Xilinx FPGA family.

4) **Why BR-PUFs are evaluated?***:* It is ture that BR-PUFs are not one of the most famous PUFs. However, we consider BR-PUFs to be excellent and promising PUFs bacause BR-PUFs have advantages of both memory-based and delay-based PUFs. That is why we focus on BR-PUFs in this paper. Our main contribution is to propose the evaluation methods for PUFs: differential and linear PUF analyses. The experimental evaluation of BR-PUFs is a case study of PUF evaluations based on the proposed methods. The proposed methods can be used to evaluate not only BR-PUFs but also other types of PUFs, e.g. arbiter-based PUFs [17].

V. CONCLUSION

In this paper, we proposed the evaluation methods for PUFs: differential and linear PUF analyses. Based on these methods, we experimentally analyzed responses obtained from BR-PUFs using 64 BR-Ss, composed of two NOR gates, implemented on Xilinx Spartan-6 FPGAs. We evaluated the probability of a prediction of the responses R_j for challenge C_j ($1 \leq j \leq 2,048$). According to differential analysis for BR-PUFs, we demonstrated that approximately 88.0% and 66.5% of responses become 1 for challenges with Hamming distance of 1 and 16, respectively. These results are much larger than about 50% in ideal BR-PUFs. Hence an attacker has a high possibility to predict the responses for challenges with small Hamming distances from her known challenge-response pairs. According to linear PUF analysis, we demonstrated that BR-PUFs have some *influential NOR gates*, which cause a strong bias of responses. The probability of responses being one is 71.4% and 54.5% when the number of influential NOR gates is 5 and 1, respectively. An attacker has a high possibility to predict unknown challenge-response pairs by specifying the location of influential NOR gates. Our experimental results are the first time that BR-PUFs present undesirable PUF behavior due to the response prediction, and

compromise the whole security of a system based on BR-PUFs. More importantly, our two evaluation methods can be used as universal framework for evaluating the security of other PUFs (e.g. Arbiter PUFs).

Other implementations of BR-PUFs would probably not behave likewise Spartan-6 FPGAs. For example, the bias of responses has a possibility to improve if BR-PUFs are implemented on other types of FPGAs or ASICs. Future work should include a discussion of security evaluation of BR-PUFs on various platforms.

Frontiers in Network Applications, Network Systems and Web Services

SYMPOSIUM SoFAST-WS focuses on modern challenges and solutions in network systems, applications and service computing. The Symposium builds upon the success of Frontiers in Network Applications and Network Systems (FINANS'2012) and 4th International Symposium on Web Services (WSS' 2012) held in 2012 in Wroclaw, Poland. These two events are now integrated into one event to fully exploit the synergy of topics and cooperation of research groups.

The topics discussed during the symposium include different aspects of network systems, applications and service computing. The primary objective of the symposium is to bring together researchers and practitioners analyzing, developing and administering network systems, with particular emphasis on Internet systems. Authors are invited to submit their papers in English, presenting the results of original research or innovative practical applications in the field.

Topics

Topics include (but are not limited to):

- Architecture, scalability and security of Open API solutions,
- Technical and social aspects of Open API and open data,
- Service delivery platforms - architecture and applications,
- Telecommunication operators API exposition in Telco 2.0 model,
- The applications of intelligent techniques in network systems,
- Mobile applications,
- Network-based computing systems,
- Network and mobile GIS platforms and applications,
- Computer forensic,
- Network security,
- Anomaly and intrusion detection,
- Traffic classification algorithms and techniques,
- Network traffic engineering,
- High-speed network traffic processing,
- Heterogeneous cellular networks,
- Wireless communications,
- Security issues in Cloud Computing,
- Network aspects of Cloud Computing,
- Control of networks,
- Standards for Web services,
- Semantic Web services,
- Context-aware Web services,
- Composition approaches for Web services,
- Security of Web services,
- Software agents for Web services composition,
- Supporting SWS Deployment,
- Architectures for SWS Deployment,
- Applications of SWS to E-business and E-government,
- Supporting Enterprise Application Integration with SWS,
- SWS Conversational Protocols and Choreography,
- Ontologies and Languages for Service Description,
- Ontologies and Languages for Process Modeling,
- Foundations of Reasoning about Services and/or Processes,
- Composition of Semantic Web Services,
- Innovative network applications, systems and services

***Abstract*—Service architecture of the Internet becomes more and more complex as it expands as a medium for large-scale distribution of diverse content. Dynamic growth of various content distribution systems, deployed by influential Internet companies, content distributors, aggregators and owners, has substantial impact on distribution of the network traffic and the scalability of various Internet services. The SNIFFER project, presented in this paper, aims to create a service for observing and tracking the long-term growth of various Internet Storage Networks (grids, clouds, Content Delivery Networks, Information-Centric Networks), using the OpenLab and PlanetLab environment. It can be useful to track and map the spreading of such Storage Networks on a global scale, providing more insight into the evolution of Internet towards a content-centric, distributed delivery model.**

I. Introduction

IN RECENT years we have observed an enormous increase in popularity of many Internet services, e.g., Facebook, DailyMotion, YouTube etc. It was possible due to an exponential growth of the number of broadband users and substantial increase in the availability of access bandwidth. During the last five years the Internet backbone traffic has been increasing at a compound aggregate rate of approximately 40% to 50% per year and for the countries of the European Union (EU) the cumulated monthly traffic ranges from 7,500 to 12,000 PB.

The increase of bandwidth usage is closely related to the growth of video traffic in the Internet, spurred by the undeniable trend towards active searching for the preferred content and watching it at the most convenient time. The success of catch-up services (iPlayer, Hulu), online movie rentals over the Internet (Netflix) and watching YouTube movies or podcasts on the TV only confirms this observation.

In order to serve the constantly increasing demand, Internet content service providers deploy content servers in multiple locations all over the world. To obtain high level of scalability and facilitate optimal distribution of popular content to geographically diverse population of end users, such content is usually distributed over multiple physical servers, for example by using the CDN (Content Distribution Networks) technology that utilizes storage located in the network. Such infrastructure, belonging to influential Internet companies, content owners, aggregators, distributors or CDN operators, consists of tenths of thousands of servers deployed throughout the world. Nowadays, it makes up a critical part of the Internet and has substantial impact on distribution of the network traffic and scalability of various Internet services beyond the first and middle mile.

Despite that, very little is known about the topologies, geographical spread, expansion and growth of systems that serve the most popular Internet content worldwide. The main objective of the SNIFFER experiment described in this paper is therefore to create a replicable base for long-running service using OpenLab and PlanetLab environment in order to better observe and track the long-term growth of Storage Networks distributing popular Internet content. The knowledge about location of the content servers and the possibility to monitor long term changes in the infrastructure deployed by popular content distributors, aggregators and owners, would allow better understanding of the nature, complexity and evolution trends of the Internet. It can be also used to improve planning of the Internet underlying transmission resources, which is important as the popular services are progressively more demanding, mainly because of the proliferation of multimedia rich content.

Similar attempts to Internet content server discovery were already undertaken, but lacked versatility (were limited to particular Internet services, such as YouTube [5] [6] [7] or CDNs [8]), sustainability and long-term observation capabilities. In the SNIFFER project we aim to achieve the above goals by developing the following elements that will constitute the final service running on the base of the PlanetLab infrastructure:

- The intercept mechanism, collecting web URLs for pattern discovery and matching to popular Internet services.
- The content server discovery mechanism, providing translation of the discovered web hostnames into IP addresses, clustering, and geo-location of discovered servers.
- The visualization service for easy access to discovered results.

The project uses common Internet protocols, PlanetLab infrastructure and capabilities of Orange Polska as the largest ISP in Central Europe to obtain a large sample of web-related customer activities. The general architecture of the SNIFFER system is presented in Fig. 1.

978-83-60810-58-3/$25.00

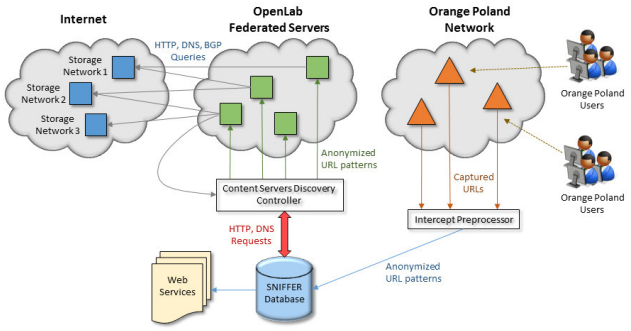

Fig. 1. General architecture of the SNIFFER system

The following sections provide an overview of the main modules of the SNIFFER system.

II. Intercept and Pattern Discovery

This module consists of two functional parts: the capture tool and the pattern discovery tool. The aim of the capture tool is to intercept user traffic and collect URLs of the visited web pages. For this task we use a server equipped with specialized DAG traffic intercept card and an adequate storage. The server is connected to the network with public IP address and 1 Gbps connection. The server also runs the TStat [12] software, functioning as a passive sniffer. It allows capturing the specified traffic at network and transport level. In case of the SNIFFER project, TStat has been prepared for logging TCP communication flows, particularly HTTP requests, as the HTTP GET method contains the URL address of the requested content and hostname of the content server.

The discovered unique URLs are stored on the project server for pattern discovery and further processing. The main function of this part is to analyze the collected URLs and generate URL patterns for selected services in a format that can be easily expanded to generate host names for web server discovery. This approach allows generating hostnames that were not actually intercepted, but for which it is probable that they will resolve to an IP address because of the similarity to some of the intercepted ones. Service selection exploits the fact that the domain names used by the internet service providers are usually equivalent to naming of the services provided to the end users.

III. Content Servers Discovery

To facilitate the conversion of discovered web host names to IP addresses, SNIFFER uses the DNS along with selected PlanetLab servers. The number of distinct IP addresses is used as an indirect measure of the quantity of content servers. A single IP address may however represent a number of physical machines that are indistinguishable for this tool without additional knowledge.

The discovery system takes hostname patterns obtained from previous task, expands them to create a larger set of hostnames, and searches for their IP addresses. The DNS servers are used to resolve the IP addresses, but for each hostname the returned IP address may depend on where the query was issued, as each local DNS can map the hostname to a different server. The goal is to discover as many IP addresses, to which a given URL is resolved in different network areas, as possible.

To obtain wide geographical distribution of queries, and a representative set of server addresses, we use the PlanetLab infrastructure. PlanetLab nodes are located in over 90 sites all over the world, therefore a huge set of local DNS servers can be queried. The system searches for both A and CNAME records. As each CNAME record is followed by complementary A record, at least one IP address is gathered for each hostname.

Popular services quite often have many A records (many IP addresses) assigned to one hostname. For example, a query for domain name *youtube.com* returns 16 A records pointing to 16 different IP addresses. Those 16 records do not exhaust the global list, as the same query executed from different host or after some time may return a different list of 16 IP addresses. Therefore, in case where multiple A records exists, all IP addresses are collected by the querying PlanetLab node.

The SNIFFER experiment does not require that all available PlanetLab nodes are used, as the data acquired by the algorithm are differentiated by geographical location, and so the responses from relatively close nodes are often similar and do not contribute much to the results. Therefore, from all available PlanetLab nodes about two from each top level domain were selected (95 total). As most of those top level domains suggest the country that the node is located in, the selection was driven towards obtaining a uniform distribution of nodes around the globe (to the extent limited by the fact that PlanetLab does not have nodes in every country). PlanetLab nodes availability varies daily, nodes go off-line for various reasons, and therefore at the algorithm initialization the list of on-line nodes is created. Usually around 80% of nodes is ready for use at the same time.

IV. Content Servers Clustering and Geo-tagging

The content server discovery tool collects thousands of IP addresses. Many of the servers behind these addresses are located in the same data centers. To get more insight into geographic distribution of the discovered servers, we employed a clustering algorithm that groups the servers together according to their approximate physical location at city level resolution. The IP address is converted to geographic coordinates using IP geo-location services. However, this approach is not sufficient to distinguish server clusters because of limited geo-location accuracy. Therefore, the algorithm also uses IP trace-route information collected from various locations around the world.

Each IP address from the set of IP addresses of the servers discovered for the particular service denotes a host. Actually, it can be a range of hosts behind NAT or a number of IP addresses located on the same machine. In case of NAT, the group can be treated as one powerful host without the loss of precision for the clustering algorithm. The second case leads to ineffective wasting of public IP addresses so this approach is most probably not used in content distribution systems.

A. Phase 1 - Collection of Gateways

For each IP address the algorithm checks the route through the Internet. The route to the host can be different if checked from different locations around the globe. The algorithm is not collecting the whole route but only the last routing device next to the host itself, called a gateway. If the last device is not discoverable, the second device closest to the target is collected, and so on. The gateway with network distance to the target IP address equal to N will be hereafter denoted by *gwN*.

The addresses of gateways leading to the same server can be different when the path is checked from different locations. The reason for this is that data centers rarely use a single edge router and may also utilize more than one ISP connection for efficiency and reliability. The algorithm collects *gwN*s for given IP addresses from more than 90 PlanetLab nodes and stores them on a dedicated server.

B. Phase 2 - Aggregation

In the second phase of the algorithm only the gateways with network distance one (*gw1*) are considered. Hosts are aggregated by the same gateways, creating clusters. In addition, the number h_N, denoting how often the host was accessible through the particular gateway, is stored.

C. Phase 3 - WHOIS Tagging

The IP address of each gateway is looked up in worldwide domain names register (known as the WHOIS database) to determine the single owner IP range (CIDR) it is in. This is necessary to group similar (belonging to the same organization) gateways later on. The names of clusters formed later are derived not from gateways but from CIDR's. Additionally, those CIDRs/ranges represent the network providers for the data centers. One issue in this process is that even if the WHOIS database is publicly available, the format of the answer is not standardized. It may return the CIDR notation (eg.201.218.32/19), but also the range (e.g., 195.182.218.0-195.182.219.255). Some WHOIS queries also fail, leading to dropping the data related to such query (however, the loss is marginal).

D. Phase 4 - Cluster Candidates

For each unique host IP, the data from previous phase is aggregated into the triple $\{$*cluster name*, *gateway list*, $h_N\}$. The cluster name is formed from all unique CIDRs from the set of triples with the same host IP. To make those names easily comparable, CIDR ranges were lexicographically sorted. The gateway list includes all gateways associated with the host IP and the h_N now represents a cumulative value for all of them.

E. Phase 5 - Cluster Geo-tagging

In this phase the location of the host part of all triples is acquired using geo-tagging tool, and the result is appended to the name of the cluster candidate, as the algorithm assumes that the physical location of the host determines the cluster position on the map. In this way some cluster candidates that have the same name will now have distinct names as they hold hosts at different locations. After geo-tagging, cluster candidates become final clusters.

F. Phase 6 - Aggregation of results

The results of cluster geo-tagging are aggregated by cluster names. The clustering process may omit some IP addresses from the input data due to trace-routing limitations. If a trace cannot find the gateway at distance one (*gw1*) it searches for more remote gateways (*gw2*, *gw3* etc.) but in phase 2 of the algorithm those gateways are filtered out. If a host is not reachable from any of the used PlanetLab nodes via *gw1* it is excluded from the clustering. To address this issue the list of left out IP numbers is processed by the algorithm once again with filtering in phase 2 changed to *gw2*. The resulting clusters are less reliable than the ones obtained in the first run, thus they are stored separately. After second run there may still be some IP addresses left, but at this stage there is no need for the third run of the algorithm with *gw3* filtering, as the number of them is usually minimal.

G. Remarks on Clustering and Geo-tagging Implementation

On each PlanetLab node the routes to tested hosts (IP addresses) are checked with the excellent *Paris traceroute* tool. The important advantage that this tool holds over the classic *traceroute* is the immunity to routers' load balancing. The whole process of checking all IP addresses for given service is rather time consuming so the cache for the queries is used and stored on SNIFFER server. A list of hosts sent to the PlanetLab node is filtered so that only the IP addresses not yet traced (from this node) are tested. The remaining traces are removed from the cache.

Clusters formed in this way should represent close estimation of real life data centers. However, as the algorithm is based on trace-routing data, it detects layer 3 network connections but cannot detect layer 2 links. Consider an example where many hosts are connected to the Internet through two gateways but the internal subnetwork (VLAN) is spanned over 3 switches, where one of them is located in a different data center and connected via a VLAN tunneling protocol (there are various technical methods to extend a single VLAN in such a way). This case can lead the algorithm to aggregation of data centers with the same gateways and different physical locations into one center.

At this point the clustering geo-tagging steps in. However, the geo-tagging accuracy varies a lot between various methods and IP databases. Not all owners of IP addresses want to reveal the exact location of the hosts, therefore the geo-tagging services and tools are imprecise by nature and evolve in time as the IP networks change. Currently, SNIFFER uses only a free of charge MaxMind GeoCity Lite database. It offers city level location service but in practice for a lot of IP addresses the tagging results are not accurate enough. Many tags can be resolved only down to a country or even a continent level. This deficiency is affecting the precision of the clustering algorithm.

V. SNIFFER VISUALIZATION SERVICE

SNIFFER web interface is available at *https://sniffer.mini.pw.edu.pl/*. The website was designed to present the most important results generated by the SNIFFER experiment in a graphical form, as the "snapshots" of worldwide content server infrastructure, taken at various points in time.

SNIFFER web pages use world maps rendered by the Google Maps V.3 engine and API (customized for the specific requirements of the project using JavaScript code). The GUI server is running on open source tools, such as Apache WWW server, MySQL database, Drupal Content Management System and other applications and libraries. It pulls the preprocessed experiment data from the data server in a daily routine, importing cluster lists, patterns, metadata related to specific run of the experiment, and special datasets prepared for comparing the results from various time points. The data is then rendered using the mechanism of Drupal views.

Data presentations accessible from SNIFFER website are created dynamically from database content which makes them very flexible. At present it is possible to visualize location of content servers of Akamai and YouTube discovered in a selected experiment, or in a form of differential maps showing changes in the discovered infrastructure between two different runs. In addition, a user can access various details and statistics of the experiment data, such as IP addresses, CNAMEs, and patterns found during the discovery process.

An example experiment executed in April 2014 took about 40h. The 315 URL patterns identified by intercepting end-user web requests were further used by the Content Servers Discovery module to search for Akamai servers using DNS queries from 76 geographically dispersed PlanetLab nodes. About 10,000 IP server addresses were discovered in result of this process, grouped into 585 clusters and geo-located to produce the map shown in Fig 2.

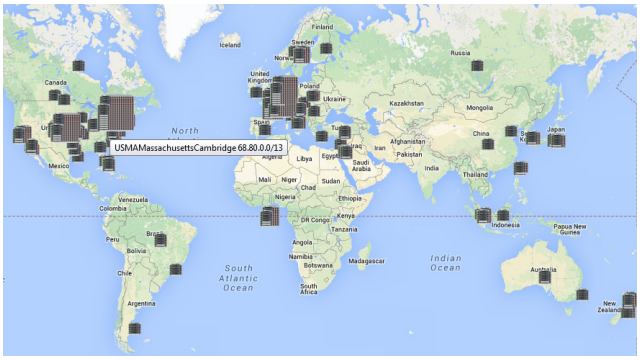

Fig. 2. Discovered locations of the Akamai servers

VI. CONCLUSION

In the paper we have described the SNIFFER project aiming to create a long-running measurement platform to monitor the location and evolution of the content distribution servers in the Internet.

The key difficulties encountered during the ongoing development of the platform were mostly related to precise clustering and geo-location of the discovered data centers. The clustering algorithm that uses *traceroute* and *whois* tools appeared more complex in practice than it was foreseen because of the difficulties in obtaining the proper gateway addresses and their actual locations. Some of the problems can be attributed to the deficiencies of the free IP geo-location database used in building the system.

During testing of the SNIFFER system in the development phase some variability in IP addresses found in consequent experiments was observed. This phenomena can be seen on differential maps and may arise in result of load balancing performed by service providers in conjunction with the scale on which they operate. Despite the fact that 95 PlanetLab servers deployed around the world were used to resolve and trace thousands of host names in each experiment, the architecture of investigated systems is so vast that each time some IP addresses fall outside the search. The providers purposeful approach to hide the actual architecture of their systems cannot be also excluded.

The experimental results from the SNIFFER project will be periodically published on the project web page *https://sniffer.mini.pw.edu.pl*. The discovery service in its current form is running from just March 2014, so the results should be still treated as preliminary. We hope however, that after SNIFFER platform is refined and its measurements database grows up, it will be useful in providing insight into evolution and growth of various Storage Networks related to popular Internet services or effective distribution of content.

***Abstract*—This paper presents an idea of new communication Application Programming Interfaces (APIs) based on graph oriented data stored in database. The use case described in paper allows the sending of traditional telecommunication messages (SMS or USSD) to dedicated people identified as best recipients based on their skills and location. A decision algorithm implemented in API, besides the organizational data takes into consideration geo-location of user' mobile phones.**

I. Introduction

NOWADAYS, with the Internet based on Web 2.0 we can observe a large expansion of social frameworks and services. Social portals such as an Facebook [1], Google+ [2], Twitter [3] and lately Instagram [4] have become very popular, especially among young people. The natural representation of connections between people linked by social networks or network of professionals (e.g. Linked In [5] or Viadeo [6]) is represented by data structures in a graphs form. This data structure in a very good way represents: people (e.g. as a graphs vertices), connection between them (graphs edges) and other parameters such as interests and hobbies (represented by attributes associated with its nodes or edges stored in graph). During the last 20 years in the Internet we can observe a large expansion of data generated by people and for people. This trend called "Big Data" in large part results generation of data sets which have the structure of a graph and can be stored as graphs attributes.

The paper is organized as follows: Section I presents a short introduction. Section II contains an overview of some related work. Section III describes the idea of a graph based messaging communication services. Section IV elaborates on our proof-of-concept prototype and system architecture. Section V presents future work, plans and intentions. The last section VI concludes this paper.

II. Existing Solutions

A. APIs exposed graph oriented data sets

Graph data sets and based on them services are used by many portals and application in the Internet. In this paper we concentrate on graph based data exposed in Application Programming Interfaces (API).

The most interesting API, based on a graph is offered by Facebook: (The Graph API [7]). This API allows: reading publishing, updating and deleting of records correlated with Facebook users activities: accounts, posts, groups, events, location and places.

Another information set (defined as a free, knowledge graph with millions of people, places, and things.) offers Google as an Freebase - Google's Knowledge Graph [8]. The Freebase APIs support a function responsible for searching and manipulating of this open database repository. Google also expose an additional data description language (Search Cookbook [9]), which allows including additional semantic information in text queries.

Another similar API based on Twitter data – GraphEdge API [10],[11] which allows for Twitter data manipulation has lately evolved to GraphEdge Pro service [12]. This solution helps PR marketing agencies track, report, and analyze the activity of their customers Twitter accounts.

The next service GraphMuse API [13] – is a solution dedicated for developers interested in the exploration of Facebook data. This easy RESTfull API returns: friends, groups, family or collective interests data sets in the JSON format.

CicerOOs Semantic Graph API [14] allows semantic searches of Points of Interest (POI) related to geographical objects (data correlated with tourism information in Italy). Apart from simple search, this API

978-83-60810-58-3/$25.00

can return the suggested possible topics of interest (e.g. restaurants, castles, galleries, parks) taken from the semantic graph.

A completely different, from above mentioned area of application is provided in the *RunKeeper's* Health Graph API [15] – which offers developers access to all of health oriented information such as: nutrition information, workouts, sleep and body measurements data, blood glucose levels etc.

The *Viadeo* [16], service which operates professional social networks provides the Graph API that allows developers to integrate professional social context with websites, applications and services. A social portal using this API offers developers access to public information on some objects: members, connections, jobs, articles, news, comments, etc.

Table 1. Exposed in the Internet graph oriented APIs

API	Functionality	Data Source
Facebook The Graph API	Data search and manipulation	Own data
Freebase Google API	Data search and manipulation	Own data
GraphEdge API	Data mining second level API	Twitter API
GraphMuse API	Data sets access simplification	Facebook API
CicerOOs Semantic Graph API	Simple and semantic data search	Own data
RunKeeper's Health Graph API	Data search and manipulation	Own data
Viadeo Graph API	Data search and manipulation	Own data

B. *Messaging applications and services based on graph data*

In the Internet some applications and services can be identified, which offer messaging functions based on information from graph oriented data sets. The *Meetbymaps.com* portal [17] offers the Instant Messaging (chat) communication service for Facebook users based on location and events (realtime geolocated chat) using the Facebook Graph API. Another portal, based on Facebook graph *WishMindr* [18] is the freely accessible virtual wish list. Using this application the end user can prepare wish lists from any site and add preferred gifts using the *WishMindr* search. *WishMindr* also offers an email communication channel used for reminders about wish lists for e.g. friends and family.

The next solution *oGoWoo* www.ogowoo.com [19] is a free advertising system. The *oGoWoo* service uses the Facebook API to post promotional and advertising messages on users Facebook walls on their behalf. As benefits, the application users get gifts and discounts. Another service *Decoda* [20] allows you to share favorite lyrics between Facebook users (e.g. marking favorite lines from a song and posting them to Facebook as a status or posting lyrics to Facebook wall). The service can also post information to a friend's Facebook wall thanks to the Facebook Graph API. Table 2 provides examples of communications applications using Facebook Graph API.

Table 2. Example communication driven applications based on Facebook Graph APIs

Application	Communication channel
Meetbymaps	IM (chat)
WishMindr	e-mail
oGoWoo	Facebook walls
Decoda	Facebook walls

C. *Telco Messaging based on API*

SMS, MMS and USSD based messaging is known in telecommunication for many years. Short Messaging Services and Multimedia Messaging Service can be originated (sent) and terminated (received) by network terminals (mainly phones). Unstructured Supplementary Service Data (USSD) can by initiated by phones (in the form of USSD codes e.g.*100#, *665*1#). Communication Service Providers (CSP) in the last decade of XX century, have started opening their networks to external developers by exposition of the Telco API in the Internet. This concept extends traditional device based messaging model to an API originated or terminated communication function. In the network architecture it appears as an additional exposed API element – Service Delivery Platform (SDP). SDP using API in Web Services form can provide external developers with a large set of communication functions from CSP networks such as send/receive: SMS, MMS or USSD, mobile terminal location, click to call, payment etc. for new innovative applications [21],[22],[23],[24]. Basic Telco APIs set is standardized by GSMA as OneAPI specification [25] based on RESTful architecture style Web Service [26]. Another specification ParlayX [27] uses Service Oriented Architecture and SOAP protocol [28].

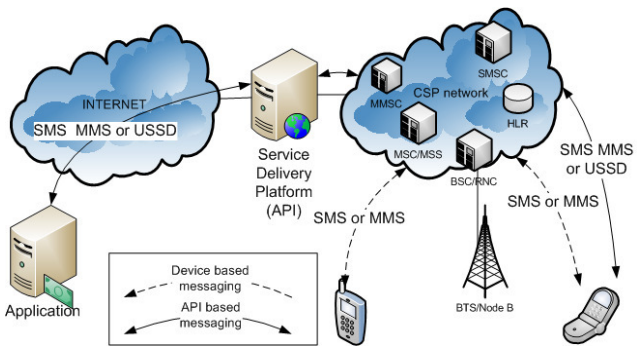

Fig 1.Telco messaging: based on devices and APIs

III. THE IDEA OF GRAPH BASED MESSAGING SERVICES

This chapter presents the idea of Graph Based Messaging (GBM) services exposed in APIs form. There are many solutions used in a single system that allow the communication of groups of people depending on their status, location or additional features e.g. the solutions based on the Unified Communications paradigm [29],[30], [31] or applications described in chapter II. The application based on the Unified Communication are dedicated to enterprise sector and mostly allow end users communicate using: voice calls, voice and web conferences, or chats. In UC, a system's subscribers are addressed using names, e-mails or phone numbers and applications are trusted and private from an enterprises point of view. Companies in the B2B sector have a lot of information which is graph oriented: organizational structures, information about calls and actions from private telecommunication or IT systems. This information can be very useful for the development of new applications and services but should be extracted from many ICT systems, structured and exposed in the form of dedicated Application Programming Interfaces. The second problem is related to the confidentiality of the exposed data. A dedicated API should also isolate sensitive private information which greatly simplifies the development of an external application from a legal point of view. The solution described in chapter 2 solutions use a graph API exposed in the public domain (in the Internet) and exposes a user's identifier (e.g e-mails or stored in Facebook data) based on permissions granted by users.

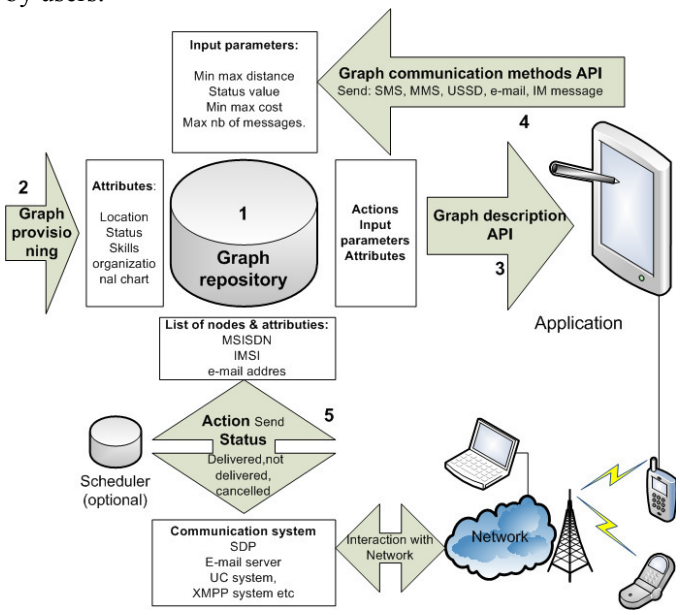

Fig 2. Idea of a Graph Based Messaging APIs

In the solution presented above the main element is **Data Repository** (1) – this is a database which contains the graph oriented data sets. Next, a very important is the **Graph provisioning** (2) – an interface for graph data sets maintenance (add/remove nodes, attributes), this element can be implemented in the form of: a web interface, an API or a batch file.

Graph description API (3) – is a high level API for external application defined as: a graph structure, graph attributes, and possible actions. By using this API an external application can automatically get graph meta data description.

Graph communication methods API (4) – a set of APIs dedicated to invoking some actions (e.g. send messages, display graph data sets etc.)

Actions (communication functions) (5) – executed by a graph messaging service, interacts with communication systems such as e.g.:

- Service Delivery Platform – sending SMS, MMS, USSD, Terminal Location,
- SMPT server – sending and receiving e-mails,
- UC system – read/set presence status , monitor office phone calls, invoke voice and web conferences etc.
- XMPP server – dedicated for sending Instant Messaging information (chats).

The idea of an API based on graph oriented communication services presented in this paper allows developers to think about communication more widely. The presented concept gives external developers a simple programming interface and provides following advantages:

- sensitive user data (e-mails, MSISDN etc.) is not exposed,
- developers do not need to implement graph specific algorithms on the application side (e.g. clustering, shortest path)
- developers are isolated from telecommunication specific protocols

Using the above presented concept allows developers to create applications in a simpler way. The majority of useful and needed (e.g. mobile) applications were invented by people from normal society. Graph oriented data exposed by social portals, communication providers or enterprises has a lot of potential. Developers, companies and people from societies are looking for a new ideas and applications. Graph based messaging API is the answer to computerized society needs.

IV. TEST DATA AND MEASUREMENT

As a test data set, in the presented in this paper proof of concept of a Graph Based Messaging APIs, the

organizational structure of the department of Open Communication Systems and Open Data Department in Orange Poland R&D Center was used. This structure is presented in Fig 3 and contains:

- graph vertices- represented by people (names)
- graph edges – based on ongoing projects and other activities virtual teams
- graph attributes - associated with vertices: employees: e-mails, phone numbers, terminal location and people skills. Skills are defined in following form:

DEV - developer
IN – IN network specialist
API – API expert
SDP – Service Delivery Platform expert
BD – Big Data expert
LOC – mobile terminal location specialist
DM – Data Mininig expert
STAT – Statistics
STD - Student

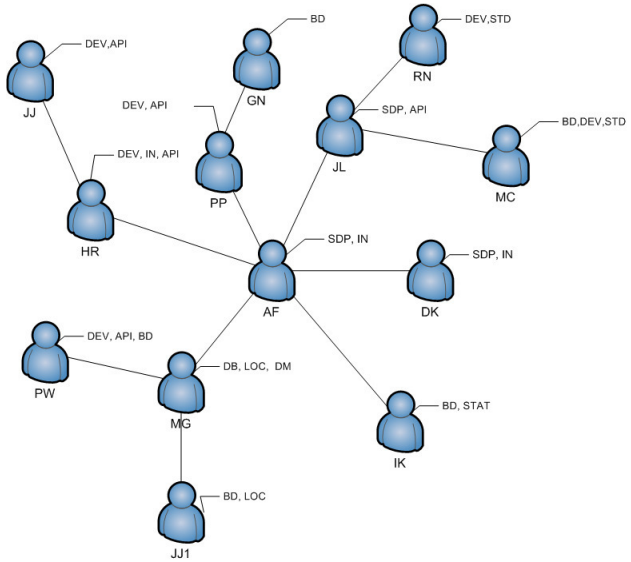

Fig 3. Test data set

Mathematically, a graph G is represented as G(V, E, A) where V are vertices (people), E a set of edges connecting some vertex in V (virtual teams), A set of attributes A={a1,a2, a3 , …an} is defined as list of skills, contacts (phone numbers, e-mails) and mobile terminals geolocation coordinates.

V. SYSTEM ARCHITECTURE

In this section a Graph Based Messaging API system architecture realizing messaging functions is described. The developed system, based on a graph database as a source of information, offers end users messaging functions such as SMS, USSD or e-mail in an Application Programming Interfaces form. The project integrates Gmail, Google Maps and Orange API services and creates a coherent communication system which it's high level architecture is presented in Fig.4.

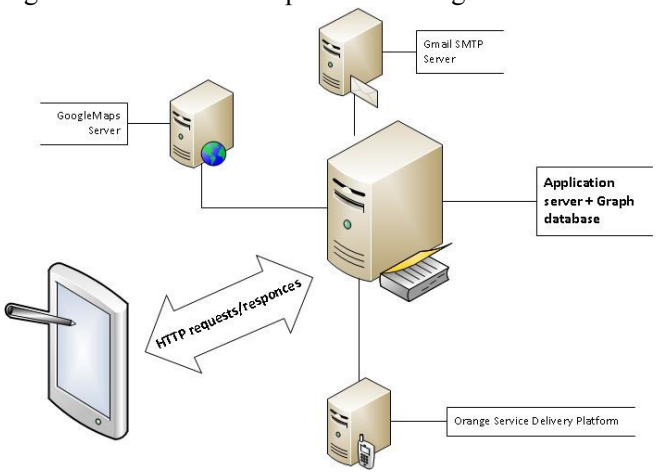

Fig 4. A high level architecture of the graph based messaging API

A. *Programing environment*

The Graph Based Messaging API system was developed in JRuby [33] – a Java implementation of the Ruby programming language and deployed on Linux Ubuntu server. The application server is exposed in the Internet using a public IP address. JRuby provides a set of classes and Standard Libraries for the Ruby language. The JRuby environment also offers a possibility of downloading many additional libraries (External Gems) created by independent developers and external companies. An example of an external gems, used during system implementation, are libraries that connect system with an open-source Neo4j graph database developed by Neo Technology. An embedded version of Neo4j database in High-availability Cluster mode was used in the graph based messaging API system as data repository.

B. *Database*

The system presented in this paper system was developed based on the Neo4j database in community open source version dedicated to the creation and testing of application prototypes. The Open Communication Systems and Open Data Department structure presented in Fig.3 was used as a test data set. A traditional, plain relational data model will not be efficient with these kinds of data sets because of a large number of relations between people which is characteristic for social networks. In comparison with relational databases, graph databases such as Neo4j [34] are faster and generate less processor load. Neo4j in the embedded mode offers an opportunity to store, on the local server, data consisting of users, places and competences entities with basic information like personal data or dynamic parameters defining unique terminal location or its actual status. Each of the users (vertices, nodes) is in relation with others by

assignment to a common workplace or some competencies shown in figure 5. All relationships are stored as graph attributes in both of the related entities, defined as incoming or outgoing. A graph oriented structure allows access to all nodes connected by a relationship with and additional set of parameters. From a data model point of view, operations like adding new relationships or attributes are easy to perform and do not demand a reorganization of data structure.

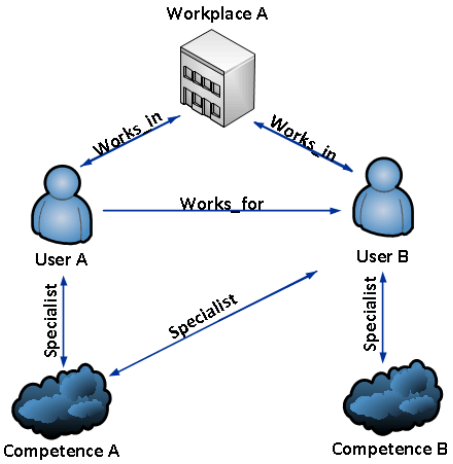

Fig. 5. Model of relationships

C. *Graph data provisioning - Web Application*

A dedicated web application was developed for end-user graph data provisioning and managing. This application allows for the creation of personalized accounts and edition and deleting of user data. Using web forms [Fig. 6] it is possible to set or modify data necessary to create or enlarge an user account. An interesting function is the definition of the location of workplaces/meeting places, which allows the implementation of messaging services based on user location. What is more, the system and proposed data model is extensible and its functionality can evolve depending on user needs.

Fig. 6. Web form interface

D. *Data Flow*

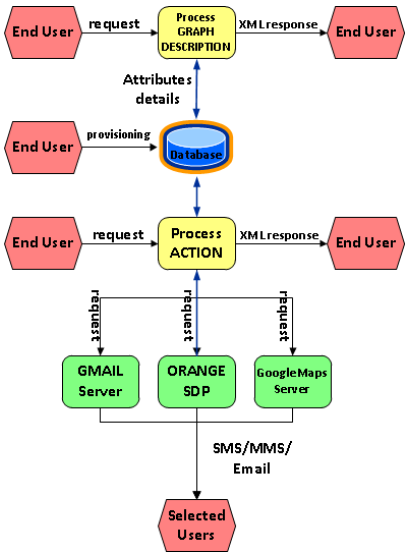

Fig. 7. Data flow in system

The model presented in fig. 7 shows the system data flow used to realize all implemented API messaging methods.

E. *Graph description API*

The Graph description API module exposes in RESTlike Web Service form, information about all the metadata (nodes attributes and communication functions) exposed by the system. The end GBM Application user (mainly the application used GBM API) can request, by using an URL, all actual graph attributes and methods that are possible to perform. The Graph description API return data in the presented below XML format.

```
<GraphDescriptionAPI>
<functions>
        <function>
                <functionname>SendSMS-
        competence</functionname>
                <link>
                http://80.48.104.236:8093/graph_api/SMS?
        competence=%&msg=
                </link>
                <description>
                Sending SMS messages to users with
        specified competencies
                </description>
        </function>
        . . .
        </function>
</functions>
<attributes>
        <competence>
                <value>DEV</value>
                <description>Developer</description>
        </competence>
        . . .
        <location>
                <value>BARBARY</value>
                <description>ul.Św.Barbary2</description>
        </location>
        . . .
</attributes>
</GraphDescriptionAPI>
```

In the presented above structure, the following functions and attributes described in Table 2 are defined as XML elements.

Table 2. Graph description API XML elements

XML element	Description
GraphDescription API	XML root element
functions	List of communication functions exposed by Graph
Function	communication function
functionname	Name of communication function e.g send SSMS or USSD
Link	URL for the server exposed communication function
description	Function description
attributes	List of graph attributes which can be used as parameters values in Graph communication functions
competence	Attribute name in this case – competence (skill)
Value	Attribute value (e.g. BD – Big Data)
description	Attribute value description (e.g. – Big Data)

The existing and exposed in graph database functions and attributes of the API presented in this chapter are similar to the concept of the Web Services Description Language (WSDL) for SOA or WADL (Web Application Description Language) proposed for RESTful Web services, but unlike them functions and attributes are dynamically changed with the change of contents of the database (for example, after adding new competences - employees skills) - they appear in the Graph description API as new attributes.

F. *The Graph communication API methods*

The Graph based messaging offer three communication functions: Send SMS, Send USSD and send e-mail as an easy RESTlike methods, which can be used in external applications for invoking communication between people which data contains an implemented graph database.

Sending SMS or USSD messages can be executed by calling an URL with the following syntax:
http://80.48.104.236:8093/graph_api/SMS?competence=value&msg=value
where:
competence - is the list of people skills (described in chapter 4)
message – is a text message sent to a group of people e.g:
http://80.48.104.236:8093/graph_api/SMS?competence=BD,SDP,LOC,STAT&location=OBRZEZNA&msg=Hello

An application server parses parameters and checks graph database content. A communication action (sending SMS or USSD messages) is processed by SDP (via Orange API) to the set of selected users. After a successful sending process, the API return a XML response with summary information about the number of informed people shown below:

```
<objects type=”array”>
   <object>
      <status>Success</status>
      <method>SMS</method>
      <ammout>5</ ammout>
      <message>Hello</ message >
   </object>
</objects>
```

The email sending process is similar to the SMS and USSD messages. The send email action has its own JRuby controller method which is accessible by the URL bellow.

http://80.48.104.236:8093/graph_api/Email?competence=value&location=value&message=value
where:
competence - is a list people skills (described in chapter 4)
message – is a text message sent to a group of people
location – a list of predefined location where An application will search for people who are located in a particular place
e.g:
http://80.48.104.236:8093/graph_api/Email?competence=ALL&location=OBRZEZNA&message

Calling this method allows the user application to send with the SMTP protocol an email messages to the list of selected people based on employees skills.

Successfully delivered messages are summarized in a XML response shown bellow.

```
<objects type=”array”>
   <object>
      <status>Success</status>
      <method>Email</method>
      <ammout>3</ ammout>
      <message>Hello</ message >
   </object>
</objects>
```

An additional special email API (DANGER e-mail type)

http://80.48.104.236:8093/graph_api/Email?type=DANGER

informs about a danger situation of the person which called the API function (all information about the person who invoked the API is collected from the username by using the HTTP Basic authentication method). In this special case, the graph application sends to the all the people in the nearest location a special e-mail containing a GoogleMap picture with a marker pointing to the location of the person who send requested as shown in Fig.8.

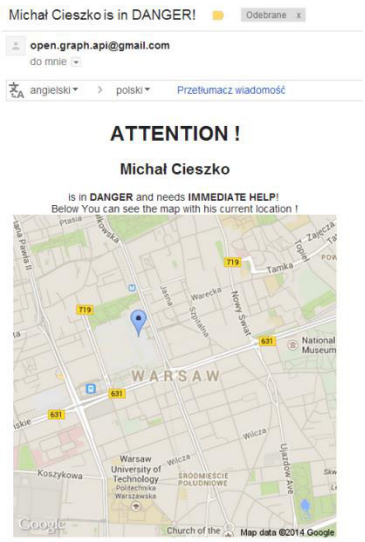

Fig. 8. An example DANGER type e-mail message

The presented above special type of GBM location API can be very useful e.g. in case a health problem with the person sending the request when immediate help is mandatory. In this case the API might be invoked by a mobile application using build in hardware like accelerometer, thermometer etc.

G. *End User applications*

The Graph Based Messaging concept includes functionality dedicated to wide range of applications and services. From the security point of view, API (using Base authentication method) invocations are processed only for correctly authenticated API users. The API was developed in a RESTlike architecture style. For an API exposed by the Graph Based Messaging system, the authors have developed a few example applications. The first one is a Windows application which offers the sending of SMS, USSD or e-mail messages to the users having defined skills or located in dedicated places.

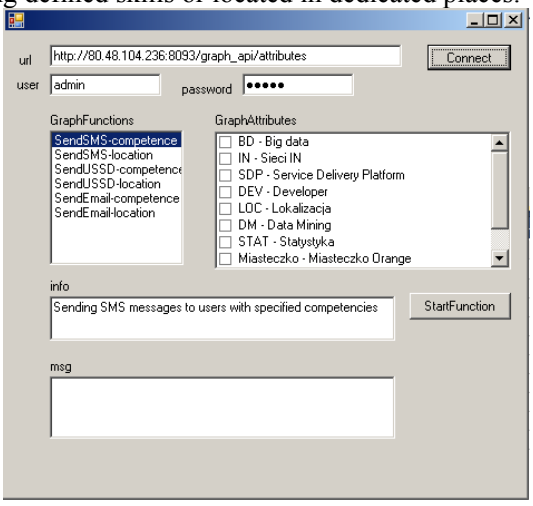

Fig. 9. Windows Client Application

After start, the application end user can choose any of the available *GraphFunctions* and then select some of the allowed *GraphAttributes*. The *GraphFunction* description appears inside the *info* section. Action (sending of messages) can be invoked using the *StartFunction* button which makes a HTTP request and invoke the selected Graph communication API method. A response received from the API is presented in the *info* field as is shown in Fig.11.

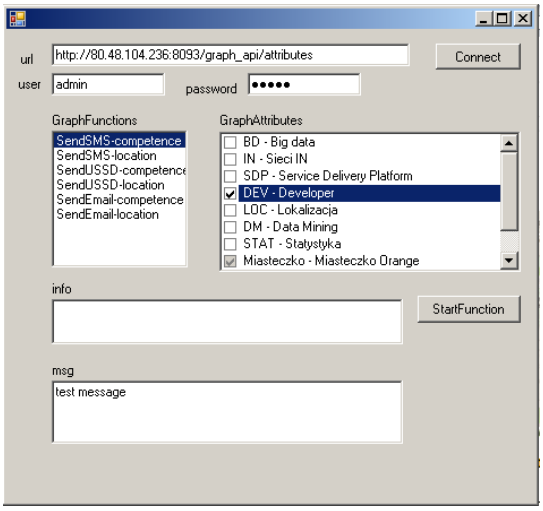

Fig. 10 Windows Client Application – an example function call

The second end user interface is dedicated web application. This subsystem is based on a web graphical user interface and offers additional features which makes it easier to invoke some actions (e.g. sending SMS/USSD/Email), check the system status or visualize a mobile terminal's (and themselves phone user) locating accuracy [Fig.11].

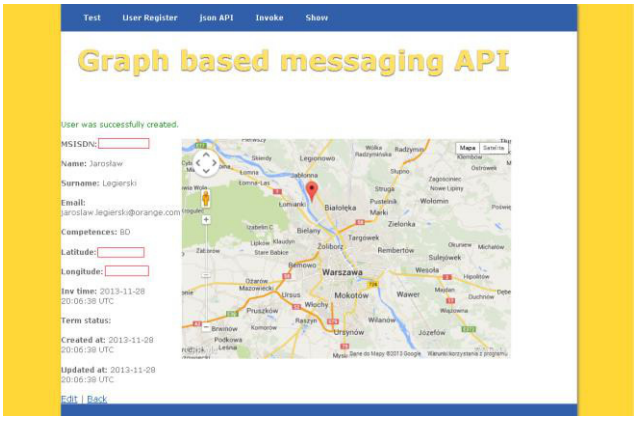

Fig. 11. End user Web GUI

Values of competence or predefined location parameters are store in database and represent the set of users which are related to requested skills and locations.

VI. FUTURE WORK

In the next system version the authors want to integrate

the Graph Based Messaging system with Facebook Graph API as a source of information about users, friends and other attributes, which can be very useful e.g. in e-mail messaging in case of emergency (DANGER e-mail API described in chapter IV F). The next functionality is a provisioning method, which can import and create a graph structure based on data from a text file provided by business clients. In future system versions there are also planned to be implement personal features (as stored in graph additional attributes e.g. users calendars), to extend the area of application usage.

VII. Summary

The Graph Based Messaging system is a prototype which presents the potential area of usage the traditional telecommunication channels connected with social networks technologies such as graph databases. The described communication oriented functionality in the API form allow to solving of many problems:

The system isolates user data (such as MSISDN number, e-mail) from the API requester and themselves thus addressing legal problems (sensitive data are not exposed). All data is processed on the server side, client applications are light and not generate client processor load from a computational point of view.

Client applications are not complicated from a mathematical point of view, graph oriented algorithms (clustering, shortest path) are implemented on the server side and the end result of them is available via the API.

The large advantage of the presented solution is the implementation of Neo4J – dedicated graph database. Relational databases generate many constraints. Programmers have found it difficult to append new objects and relationships to existing solutions while keeping system stability at the same time. The Graph based messaging system is a solution providing good performance while keeping all user data in full secret. What is more, the end user (API client) does not need to know the dataflow inside the system and details about implemented algorithms. The Author's aim was to provide the concept of the solution based on graph data structure with a wide range of functions and easy to implement in different business usage scenarios.

The prototype of the Graph Based Messaging System has been developed under the Orange Labs Open Middleware 2.0 Community program [35].

***Abstract*—The paper presents requirements related to a heterogeneous interoperable and transportable gateway called HitGW that is designated to connect different incompatible communication systems used by First-Responders (FRs) and to make them interoperable with IP-based networks. The HitGW allows IMS type of services and applications over a broadband network composed of ordinary Public Protection and Disaster Relief (PPDR) networks and Commercial Communication Networks (CCNs). Such a system solution for FRs becomes indispensable for interoperable, effective, secure, and safety communications especially in national and cross-border crisis scenarios. The innovativeness in the chosen approach to design and implement such a system gateway primary consists in the user needs and current trends of PPDR networks toward 4G LTE type of networks and services.**

I. Introduction

THE purpose of this document is to specify and describe some gathered user requirements in scope of the Hit-Gate (Heterogeneous Interoperable Transportable GATEway) project and to present a system concept how to use IP Multimedia Sub-System (IMS) as a component of the gateway for First-Responders. The main objective of the Hit-Gate project is to develop a generic gateway that allows communications across networks currently used by FRs in Europe especially during crisis events. Nowadays PSC (Public Safety Communication) systems use a large number of different and incompatible technologies therefore compromising or even disabling efficient coordination of combined operations (such as cross-border or crisis management when many services/utilities are involved) [1], [8], [13].

System solutions targeted by the Hit-Gate project are intended to be used by FRs and public safety entities, that is why they should be desirable and approved by the end-users and domain experts. To specify Hit-Gate user requirements, research in the area of general requirements for PSC systems have been performed first. Next, basing on identified and gathered requirements, they have been presented and consulted with end-users and domain experts in the form of questionnaire, brain storm discussion, and available references (state-of-the-art).

To prepare a list of end-user requirements we have applied VOLERE ([2], [3]) methodology that was however empowered by interactions and feedback from end-users. It allows the requirements to be more objective. The requirements have been defined based on consortium knowledge and experience, end-users/FRs and domain experts' opinions, available knowledge about general requirements for PSC systems, as well as literature survey. A collecting process included desktop research in the area of Public Protection and Disaster Relief (PPDR) systems, questionnaire for end-users and domain experts, and internal consortium discussions. It allowed grouping and prioritizing identified requirements.

For development of an interoperable gateway that meets end-users' and other system requirements the proposed solution is based on the 3GPP IMS architecture where Session Initiation Protocol (SIP) is used for control and signaling and Real-time Transport Protocol (RTP) for delivering voice, messages, and video over IP-based networks.

The paper is organized in the following manner. In Section II a short description of the Hit-Gate project and main features of HitGW are presented. The methodology of requirement collection and identification is described in Section III. Section IV includes general objectives of the Hit-Gate project which have great influence on requirements specification, while Section V comprises main requirements for the Hit-Gate system. The system architecture is demonstrated in Section VI. A trial implementation of the IMS platform for GSM network based on the proposed system architecture is presented in Section VII. In Section VIII conclusions are given.

This work is done within EU 7th Frame Programme - FP7 SECURITY, no. 284940

II. HIT-GATE PROJECT

The interoperability problem was perceived by EC a few years ago [19]. The main emphasis was put on spectrum interoperability across Europe ([20], [21], [24]) for broadband PPDR networks [22] that meet users' requirements [23]. These efforts have been also taken by many EU FP7 projects which aim at developing solutions that can deliver the interoperability among different PPDR systems. An objective of some projects is also to define a roadmap towards interoperability for PPDR agencies in Europe to support any cross-border events.

The Hit-Gate project is an EU FP7 SECURITY two-year small or medium-scale focused research project. Project Consortium is composed of eleven organizations from eight European countries ([18]). It includes large companies, Research and Technology Organizations (RTO), Small and Medium Enterprises (SME), and an external community of end-users. Consortium experience and knowledge in the area of development of PSC and security (mission critical) systems together with end-users support enables to develop solution, which is adequate to today's needs and covers lacks of interoperable technologies that offer interoperable IMS services. The main project goal is to develop a novel system solution for interoperability between access network elements (NE) (mobile terminals, base stations) of the First-Responder Networks (FRNs) and access network elements of the existing CCNs without modifications of handset devices or communication infrastructure of both network types. Because at both European and national/domestic levels, public-safety organizations have adopted a variety of systems, equipment, and incompatible technologies (different technologies, standards, and proprietary solutions of the system manufactures). To answer the FRs needs, HitGW is developed to support all those incompatible technologies ranging from legacy-PMR (Professional Mobile Radio), TETRA (TErrestrial Trunked RAdio) and TETRAPOL, to next-generation networks (e.g. LTE and LTE-Advanced). Other types of networks like GSM (2G), UMTS (3G), 4G LTE, WiFi and WiMAX can be used together with FRNs. Moreover, current security and emergency activities frequently involve multi-national FR teams (e.g., natural crisis response and cross-border operations) [10], [11], [12], thus the HitGW will enable efficient coordination of operations involving more than one nation. The main goal of this system gateway is to allow interoperability among NEs of the FRNs and CCNs used for PSC. It should:

- ensure mission critical requirements of PSC applications, i.e. high-availability, dependability, and security;
- be rapidly deployable over mobile, highly-dynamic, and unpredictable environments where existing infrastructures may be degraded and/or destroyed [4].

The Hit-Gate (HG) framework also includes system requirements and specifications, system architectures, development of the HitGW subsystems, system integration and validation, demonstration of the Hit-Gate Network (HGN), and standardization.

III. METHODOLOGY FOR GATHERING REQUIREMENTS

In order to gather the requirements from the consortium and end-users involved in Hit-Gate project, it has been considered necessary to use a suitable methodology. Thus, the VOLERE methodology has been chosen as a starting point for this work, adapting its requirements specification template to the particularities and needs of Hit-Gate.

Each of the partners involved in the project follows their own processes in the requirements definition phase performed within their activities. However it was important to propose a common way to formalize the requirements that is easy to use and adapt to the needs of the project by all partners. In this context, VOLERE is a straightforward methodology that does not require a complex analysis to be applied. Furthermore, it guarantees the participation of all relevant actors, who are further involved in the design and development that have to meet the requirements defined.

The adapted methodology allows for identification and formalization of unambiguous requirements, as well as assessment the correctness of the requirement in order to avoid of a lack of completeness and coherence.

The use of a common methodology to gather, classify, and assess the requirements a priori was important. The management of the requirements depends on this common methodology, providing the means to trace the identification, definition, assessment, formalization, and if necessary improvement of the requirements gathered.

On the other hand, the requirements should be the key to evaluate the entire project at the end of the development phase. A set of well-defined and unambiguous requirements is needed, not only as input for any further specifications and development, but also as part of the evaluation framework.

VOLERE defines the gathering process and the shell to register the requirements, classified in 27 categories in 5 main groups:

1. Project drivers, the business-related forces. For example, the purpose of the project is a project driver, as are all of the stakeholders — each for different reasons.
2. Project constraints, restrictions on how the product must be designed. For example, it might have to be implemented in the hand-held device being given to major customers, or it might have to use the existing servers and desktop computers, or any other hardware, software, or business practice.
3. Functional requirements, the fundamental or essential subject matter of the product. They describe what the product has to do or what processing actions it is to take.
4. Nonfunctional requirements, the properties that the functions must have, such as performance and usability. These requirements are as important as the functional requirements for the product's success.

5. Project issues, the conditions under which the project will be done. The reason for including them as part of the requirements is to present a coherent picture of all factors that contribute to the success or failure of the project and to illustrate how managers can use requirements as input when managing a project.

VOLERE methodology is an efficient way to describe requirements. In this document focus is on both the user requirements from the perspective of end-user needs and the system requirements that are assumed to be derivative of these former ones as well as other identified ones during the architectural framework. We assume that it is not possible to present only user view on the Hit-Gate project because users are not aware of many important system requirements, constraints, and other network requirements for developing a heterogeneous Hit-Gate Network of Networks (HG NoNs). Here, we will deliver an assemble of overall requirements collection consisting of end-user requirements and some high level functional and nonfunctional requirements in groups (chapters) more related to HitGW and its architecture. They can be divided into the following groups:

- Communication Requirements
- Data Requirements
- Usability Requirements
- Performance Requirements
- Operational Requirements
- Security Requirements
- Legal Requirements.

VOLERE specifies description of particular requirement with following characteristic:

A. Requirement Numbering — give each requirement a unique identifier to make it traceable throughout the development process. It is suggested that the numbering should include:
- Requirement number — the next unique requirement number;
- Requirement Type — the section number from the template for this type of requirement. This field serves as a reminder of what this requirement relates to and helps to compare requirements of the same type leading to detection of contradictions and duplications.

B. Event/use case number — the identifier of a business event or use case that contains this requirement. There might be several event/use case numbers for one requirement because the same requirement might relate to a number of events/use cases.

C. Customer Value — a measure of how much end-user cares about each requirement. It indicates the level of customer (end-user) satisfaction, if a given requirement will be implemented. It may help in prioritizing requirements and then system/solution's functions knowing which of them are the most important and desirable from customers (end-users) point of view. It helps looking at from different perspectives, and to uncover what they care about most deeply.

D. Priority — importance of the requirement.

E. Dependencies — keep track of other requirements that have an impact on this requirement.

F. Conflicts — keep track of other requirements that disagree with this one.

For this research we use simpler requirement cards with elements most suitable in this project. The fields in a questionnaire of the requirement template are:

- 'Id' is an identification of the requirement. It also includes a requirement type that precedes the requirement number. The requirement type is created as an abbreviation of <level 2> and <level 3> of sections (linked with a dash) that group requirements into types.
- 'Importance (priority)' (High/Medium/Low) tells how a requirement is important for end-users. "High priority" requirements are direct requirements of Hit-Gate, "Medium priority" ones are only desired requirements, and "Low priority" ones are optional.
- 'Source' indicates to references to a given requirement.
- 'Version' shows the evolution of the requirement.
- 'Speed' (Normal/Urgent) tells about a need of availability of the requirement in time during a mission.
- 'Reliability' (Normal/High) specifies the reliability of implementation of a given requirement. "High" means that there should be a confirmation of receipt of communication.
- 'Auditable' (Normal/High) denotes that the requirements should be tracked during operation.
- 'Security' (Standard/Enhanced) gives a level of security that the requirement should have.
- 'Quality' (Normal/High) tells about the quality of performing the requirement.
- 'Title' is a requirement name.
- In the 'Description' field the requirement is explained.

The process of defining end-users' requirements for the Hit-Gate project is split into four stages. Using existing different sources delivered by partners and found in available bibliography resources the preliminary list of requirements is collected in the stage I (from e.g. [1], [4], [5], [6], [7], [9]). These requirements are then updated by partners basing on their knowledge and experience in the stage II. In the stage III end-users are involved to review existing requirements and to define new ones. It is done during meetings at national level organized by consortium's partners. Then the collected information is merged in the stage IV.

IV. GENERAL OBJECTIVES

The Hit-Gate project defines the following general objectives for the HitGW that can be treated as baseline requirements [4]:

O1 it shall enable communications between First-Responders' heterogeneous networks used at European Level;

O2 it shall provide set of services required to meet First-Responders' needs across First-Responders' heterogeneous networks;

O3 it shall provide cross-network services to First-Responders in a seamless way;
O4 it shall be secure and shall comply with pre-established security policies;
O5 it shall be transportable, rapidly deployable, and autonomous;
O6 it shall comply with mission critical requirements;
O7 it shall automatically integrate new networks of known type;
O8 it shall require minimal or no changes to existing public safety communication (PSC) infrastructures;
O9 it shall provide a modular architecture allowing incorporation of future network types;
O10 it shall provide open-interfaces and will provide recommendations for standards;
O11 it shall address recommendations for interoperability dealing with operational, organizational, and legal aspects.
O12 it should ensure information exchange among First-Responders' networks.

The underlying requirements are [2]:

- Communications connectivity,
- Communications reliability,
- Communications deployability,
- Communications transparency: i.e. end-users are blind to the presence of communications, and only interact amongst each other at the information layer on the basis of "send information and forget how it gets there".

V. End-user requirements and needs

Identified functional requirements are shown in Table I.

Identified nonfunctional requirements (e.g. quality, efficiency, etc.) related to provided services are:

- for voice: Clarity of communications (no noise); High quality voice codecs;
- for data: Broadband data access; Enabling carry peak data rate.

The most important requirements identified in the process described in Section III are:

- PSC system in a typical operation should ensure connectivity Scene Command (tactical level) with Incident Command and with data centers (operational level) following the chain of command;
- There is a need to establish standard operating procedures;
- The interoperability gateway should not limit the coverage of communication provided by interoperating radio systems used on site during mission to an incident;
- The gateway should support from legacy to current to next-generation broadband networks used today by FRs;
- End-users of all wireless systems should have mobility as offered by a given system used on the scene;
- Interoperability gateway shall be developed in a way that allows adding new network (of known type) in a modular way, therefore ensuring an always up-to-date gateway;
- Interoperability gateway shall provide open-interfaces and a wide range of services across networks, based on widely adopted standards. These include IP (Internet Protocol) as basis protocol (for level 3 OSI interoperability), IPTV, VoIP, (Voice over IP), and SIP/SDP (Session Description Protocol) for signaling;
- PSC system in a typical operation should ensure inter communication between different entities, and these entities with Scene Command;
- Interoperability gateway should enable communications to FRs during operations across heterogeneous networks, using their current receiver equipment and with no impact on currently used PSC base-stations and infrastructures other than providing a connection-point to interoperability gateway;
- Interoperability gateway should automatically integrate new networks of known type using such functionalities like: (i) 'plug'n'play', being the ability for new networks (of known type) to be connected to interoperability gateway and become ready to use; and (ii) 'on-the-fly', being the interoperability gateway ability to automatically adapt and work with newly connected networks (of known type) without need to temporarily stop services;
- Interoperability gateway should be developed adopting methodologies defined for critical security systems, shall use secure technology and shall use proven security techniques for comprehensive end-to-end security across all networks;
- PSC system in a typical operation should ensure intra communication in particular entities — in Local Headquarters and between Local Headquarters and Remote Headquarters;
- There is a need for a set of standards for public safety services.

The most important requirements with their score are shown in Fig. 1.

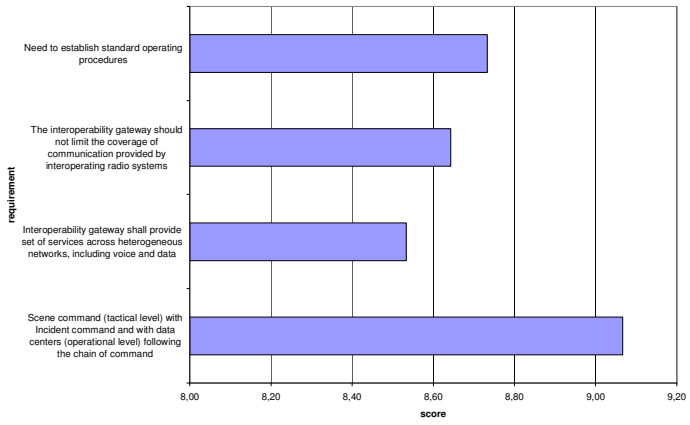

Fig. 1. Score for identified preliminary needs

Table I. Functional requirements

Domain	Functional requirements
Voice communication	Internal voice communications such as between closed user groups and end-to-end communications, etc.; External voice communications with other public safety forces or emergency services, at local level; Group communication: • ensures one to many communication to all registered in the group, regardless of the number of networks involved in the transmission, as well as the number of active users • must prevent the unauthorized access to a group • provides automatic answer of all calls within the group • prevents simultaneous voice transmission of many users within the same group • should notify the user about crossing the border of configured in the system group's activity area • ensures broadcasting capabilities to all registered users of the group • should provide a user ID presentation for all users of the group, regardless of the network used; Emergency calls to the number 112; Calls for end-user's PBX network; Call recording in dispatching communication system; Capability of assigning priorities to the individual users and type of connection; Capability of connection queuing
Data	Data access to radio channel; Data access for querying or others databases; Data transmission for decision making; Data exchange between different First-Responders; Image transmission if possible; Video transmission if possible; Metadata transmission for smart surveillance
Other	Roaming capabilities for cross-border operation if systems support this feature; Wide range of possible compatible communication technologies operating; Interoperable ad-hoc mesh network for several First-Responders operating in the same coverage area including other mesh networks deployed; Remote management of terminal by systems administrator (radio and telephone); Retransmission

VI. The Hit-Gate Architectural Concept

The Hit-Gate architecture (Fig. 2) is based on the basic concept of a Network of Networks ([15], [16]) to create a comprehensive system that supports Cross-Network Services (CNSrv) among FRNs. The Hit-Gate system is based on IP-based transmission, routing, signaling and communication. The system is compatible with any IMS type of network [17] that had been adapted in some key standards, e.g., 3GPP (3rd Generation Partnership Project), 3GPP2 and ETSI (European Telecommunications Standards Institute) TISPAN (Telecommunications and Internet converged Services and Protocols for Advanced Networking). IMS was selected to be implemented in the core of the Hit-Gate system because it performs all functions needed for call switching, user authorization and development of new services. Instead of development of an own switching and control node that manages calls and value-added services, it would be more efficient to use an existing and proved solution like IMS because it provides flexibility and ease for software developers.

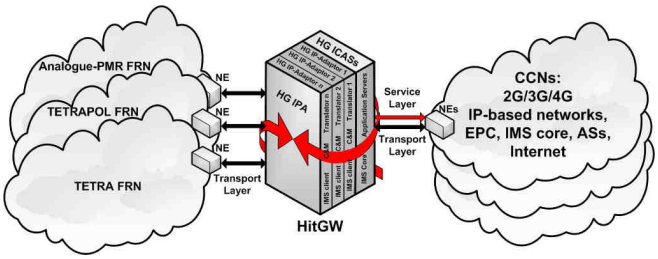

Fig. 2. The Hit-Gate architectural concept

One of the main components of the system gateway is HG IMS Core and Application Servers (HG ICASs) subsystem that is responsible for control, signaling and the CNSrv. The HG IMS Core functions are related to the generic communications services and standardized IMS interfaces, including IMS-based services. This component provides the basis for interoperability since it defines a common framework that ensures the interworking of all system nodes. The HG Application Servers (ASs) in the HG ICASs allow seamless access to CNSrv (e.g. presence function and conference connections) across whole HG NoNs even under high-dynamic conditions when additional NEs of the FRNs are attached using 'on-the-fly' and 'plug'n'play' features. The HG ICASs supports also transport network management (configuration, translation of data and protocol as well as discovery of network nodes) and transmission security.

The FRNs are connected to HG ICASs with HG IPA that consists of a set of n HG IP-adaptors ($i = 1, \ldots, n$). To have an access to a FRN over its access point, a FR Mobile Terminal (FR-MT) or Base Station (BS) and an HG IP-adaptor is required. A FR-MT is connected using manufacturer's specific interface by wire with HG IP-adaptor. FR BS can be also used instead of a FR-MT. The HG IPA can be done as one compact device that even allows connecting several incompatible technology types of mobile terminals or base stations, or it can be deployed as a distributed sub-system of n HG IP-adaptors and their attached FR-MTs or BSs. In this case the HG IPA and HG ICASs can be implemented on rugged PC tablets or laptops, respectively. An HG IP-adaptor consists of: an IMS Client representing unique user identification number; FR technology Translator that is responsible for translating the information from FR-MT into appropriate IMS messages as

well as from IMS messages into commands understood by FR-MTs; and Control and Management (C&M) component needed by an dispatcher who can handle CNSrvs among FRNs.

The "clouds" of incompatible FRNs and CCNs are interconnected with the HitGW. Thus a HG NoNs is created for CNSrv between FRs, its agencies, and other entities involved in a disaster scenario that used IP-based networks. The application components can be distributed and provided from HG ICASs or any CCN compatible with IMS, e.g. Evolved Packet Core (EPC).

The HG IPA constitutes a form of "bridge" between HG ICASs and specific radio access technologies that use manufacturer proprietary protocols which are accessible with an Application Programmable Interface (API) of the FR-MTs (Fig. 2). A HG IP-adaptor of HG IPA is used to adapt a NE of one FRN to an IMS type of network where services are controlled by HG ICASs. Due to this adaptation the IP connectivity is achieved between the FR-MTs and other IP NEs of the HG NoNs. Two types of interfaces are used to connect a HG IP-adaptor and HG ICASs:

i) SIP with extended header between HG IMS Client and HG ICASs (IMS interface); and
ii) HTTPS (Hyper Text Transfer Protocol Secured) for control and management commands (C&M interface).

The HG IP-adaptor has two additional interfaces:

i) External: to the mobile terminal; this interface has to meet radio manufacturer's specification (Translator specification).
ii) Internal: between HG IMS Client, C&M and Translator (Commands interface).

The HG IP-adaptor was designed to be compatible with several communication technologies listed in section II. It was developed comprising the common interfaces and functions used by the IMS type of network. For development of HG IP-adaptors for a FRN a software template in C++ for Visual Studio is available that can be extended to have a new HG IP-adaptor.

VII. Hit-Gate High Level Architecture

A. Development framework

In order to meet the basic requirements of creating an interoperable HG NoNs (see section IV), and all end-users requirements that are very diverse in application domains and configurable quantities, the HitGW should be based on a solution of significant flexibility. To achieve it several modern techniques have been selected to create a holistic development framework. The innovativeness of the gateway under the design makes use of the IP domain operating with SIP, IMS, and other open source solutions like On-Demand Intelligent Network Interface (ODINI) [14] that allow integrating e.g. trunking/dispatching analog/digital systems as well as data transmission ones. Such an approach accelerates a process of establishing the communication among different emergency services and other governmental organizations during crisis because the configuration procedures can be well-defined and versatile.

For the development framework of the Hit-Gate High Level Architecture (HG HLA) the Open IMS Core (www.openimscore.org) by Fraunhofer FOKUS and the application server Mobicents (www.mobicents.org) were selected. It is open source software that offers a flexibility to develop the IMS services and extensible solution and enables to make a proof of concept. The VoIP communicators were softphones OpenIC_lite for Ubuntu and X-Lite for Windows / Mac OS X. The Mobicents application server used JBoss server and SIP Servlets technology.

The HG HLA developed in Hit-Gate is shown in Fig. 3. This architecture has two layers: transport and service. The control/signaling sub-layer of the service layer consists of three Call Session Control Function (CSCF) modules and Home Subscriber Server (HSS) where subscribers' profiles are stored. The HG ASs lie on the application/service sub-layer of the service layer where the services are executed to provide them to the end-users.

The HG IP-adaptors (a distributed system solution of the HG IPA) connect access NEs of FRNs or CCNs to the HitGW, and jointly with HG ICASs they create a HG NoNs of incompatible NEs from FRNs and CCNs that are capable to exchange and use the information carried among them and thus offering the CNSrv for FRs. It ensures flexible and quick attachment of PSC systems.

Proxy CSCF (P-CSCF) component is a server that is the first point where a call is received. It also serves a function of firewall at the application level. Serving CSCF (S-CSCF) component is a central node responsible for handling the signaling. Interrogating CSCF (I-CSCF) deals with incoming SIP calls. Its address is published via DNS of the domain. It allows other servers to find this node and use it as a router for SIP packets. HSS is a main database about subscribers that supports call handling.

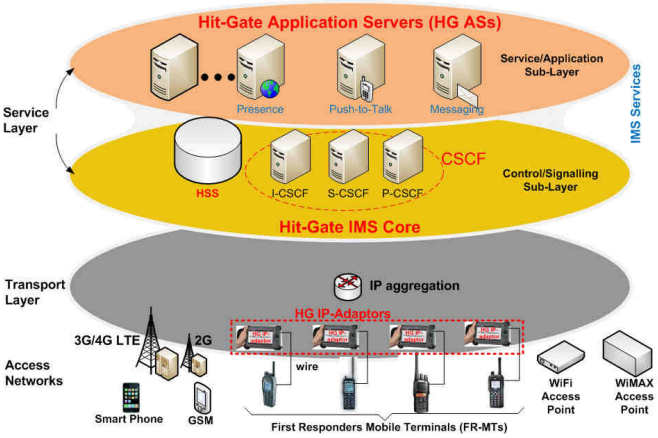

Fig. 3. The Hit-Gate High Level Architecture view

The architecture presented in Fig. 3 allows creating a wide scope of different services. FRs' services were primary targeted. The following services have been implemented: registration and authentication of NEs, presence, full-duplex and half-duplex private and group calls, emergency call, messaging, calling/talking party identification, broadcast call, retrieving a group list, group advertisement and session modification. Usage of other services (e.g., images, video streaming, IPTV) that are typical for 2G, 3G and 4G LTE type of networks can be performed as well between access NEs of FRNs and NEs of CCNs.

B. GSM Testbed

In a testbed developed we implemented the IMS platform to work with GSM (Global System for Mobile communication) network and to deliver voice communication and SMS (Short Message Service) between mobile terminals and a dispatcher. We used Nokia N900 mobile phone as a gateway terminal (access NE) to a GSM network. The analog voice signal from/to the terminal was processed in AD/DA converter and forwarded digitally with USB port to RTP driver and then to SIP softphone client. The mobile terminal was controlled using another USB port and by a software being an extension of the SIP client.

The testbed architecture is shown in Fig. 4. In such a testing environment we could set up voice calls between end-users' 2G/3G terminals and dispatcher's softphone client. Both call parties could also send SMS texts each other.

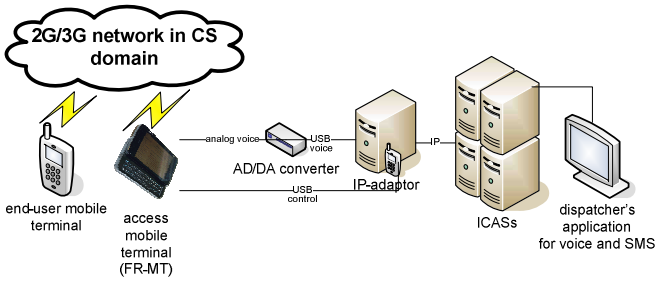

Fig. 4. Block diagram of the IMS testbed

VIII. Conclusions

In Fig. 5 one can see the coverage of end-user requirements with requirement types. The majority of requirements concerns communication aspects, and then performance ones.

Hit-Gate user requirements can be divided into five main categories of requirements:

C1 Communication services and performances requirements,
C2 Mobility and connectivity requirements,
C3 Interoperability requirements,
C4 Security and safety (i.e. confidentiality, availability, integrity) requirements,
C5 Management as well as monitoring needs requirements,

from which category C1 and C2 are described with the greatest number of requirements during the process of requirement collection.

Fig. 5. Coverage of end-user requirements with requirement types

The HitGW that offers interoperability between incompatible NEs of the HG NoNs has to meet end-user needs and expectations. Identified and defined requirements will be used for the future Hit-Gate product developments and as the guidelines for the Next Generation Networks (NGNs) and Future Mobile Convergence (FMC) as well as for ongoing standardization activities. They will be also helpful in defining overall and detailed system architecture, preparing system specification, as well as describing scenarios and use-cases, e.g., for the demonstration purposes.

The HG HLA is based on the NoNs concept. The system gateway HitGW is composed of two sub-systems: HG IPA and HG ICASs. Both sub-systems can be used remotely connected as network elements of HG NoNs or integrated as one compact system solution that interconnects incompatible NEs of the FRNs and IP-based networks. Within a HG IP-adaptor each FR technology (that is accessible via a FR-MT) should have a suitable technology translator that constitutes an interface between an access NE of the FRN and HitGW. The other HG IP-adaptor components — IMS Client and C&M — provide service as well as configuration and management solutions for FR-MT attached to it as well as for itself. Such an approach facilitates interoperability between heterogeneous systems because one just needs to develop a new translator in order to allow connectivity of a new FR-MT to its FRN.

The HG HLA was applied to elaborate a demonstrator that allowed developing a HitGW prototype as an interoperability gateway that offers FRs services and other services provided by 2G/3G/4G networks. The proposed system solution based on IMS occurred easy to install, run and configure. Development of new services to integrate other

communication systems needs Java programming and knowledge about API commands and hardware interface to control the communication via the terminal attached to the gateway. New services based on the IMS platform can extend the communication capabilities among PPDR entities offering them even ad-hoc integration and management.

***Abstract*—The W-LAN Ad Hoc network tends to cause problems called "Hidden Node" and "Exposed Node". RTS/CTS mechanism has been introduced to mitigate Hidden Node and most of existing researches assume that RTS and CTS are sent at the same transmission range. This paper describes a new method to improve the network throughput by adjusting the RTS transmission range. The simulation result showed that the proposed method achieved higher throughput in some degree.**

I. Introduction

THE W-LAN Ad Hoc network tends to cause problems called "Hidden Node" and "Exposed Node" [1]. Fig.1 shows an example of Hidden Node and Exposed Node. In Fig.1, transmission range and receive range are assumed to be equal. Assuming a sender node and a receiver node, a Hidden Node is located near to the receiver node and can hear the transmission from the receiver node while it cannot hear the transmission from the sender node as it is far enough from the sender node. The Hidden Node and the sender node can send a frame respectively at the same moment and can cause a collision at the receiver node. An Exposed Node is located near the sender node and its transmission reaches to the sender node but cannot reach to the receiver node as it is far enough from the receiver node. The Exposed Node doesn't cause a collision at the receiver node when it sends a frame at the same moment when the sender node sends a frame. But due to carrier sense mechanism of IEEE802.11, the Exposed Node detects a transmission of the sender node and has it suspend the transmission. This may cause unnecessary transmission suspensions and degrade network performance [2].

RTS/CTS mechanism as shown in Fig. 2 has been introduced to mitigate Hidden Node since the first version of IEEE802.11 [3].

First a sender node does carrier sense. If channel is idle, it further waits DIFS (DCF Inter Frame Space) period and random back off period. Then it sends RTS (Request To Send) and any nodes which hear the RTS reserves air time during

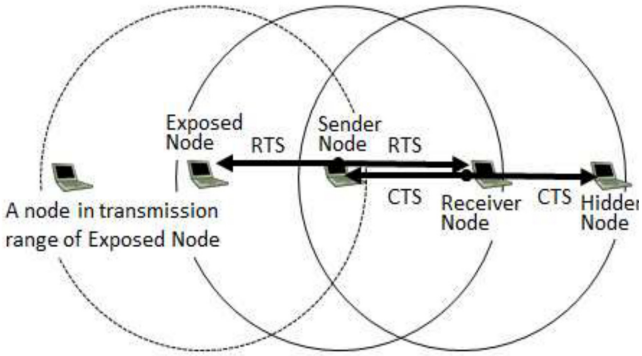

Fig.1 Example of Hidden Node and Exposed Node

NAV (Network Allocation Vector) period. The receiver node receives RTS and sends back CTS (Clear To Send) after SIFS (Short Inter frame Space) period.

CTS also have NAV and suspend transmission of nodes which hear the CTS until the receiver node sends ACK. Then the sender node sends a data frame after it receives CTS and the receiver node sends ACK after it receives the data frame. In this mechanism, Hidden Nodes around the receiver node can suspend transmissions by the CTS and the receiver node can avoid collisions to receive the data frame. But this mechanism creates Exposed Nodes around the sender node as they hear the RTS and suspend their transmission.

In this paper a new RTS/CTS method to reduce the number of Exposed Nodes has been proposed. This method assigns different transmission range to RTS and CTS respectively to reduce the number of Exposed Nodes. Simulation results shows that the proposed method improves the entire network throughput compared to the standard RTS/CTS mechanism, and also has effect to equalize variation of throughput among each node.

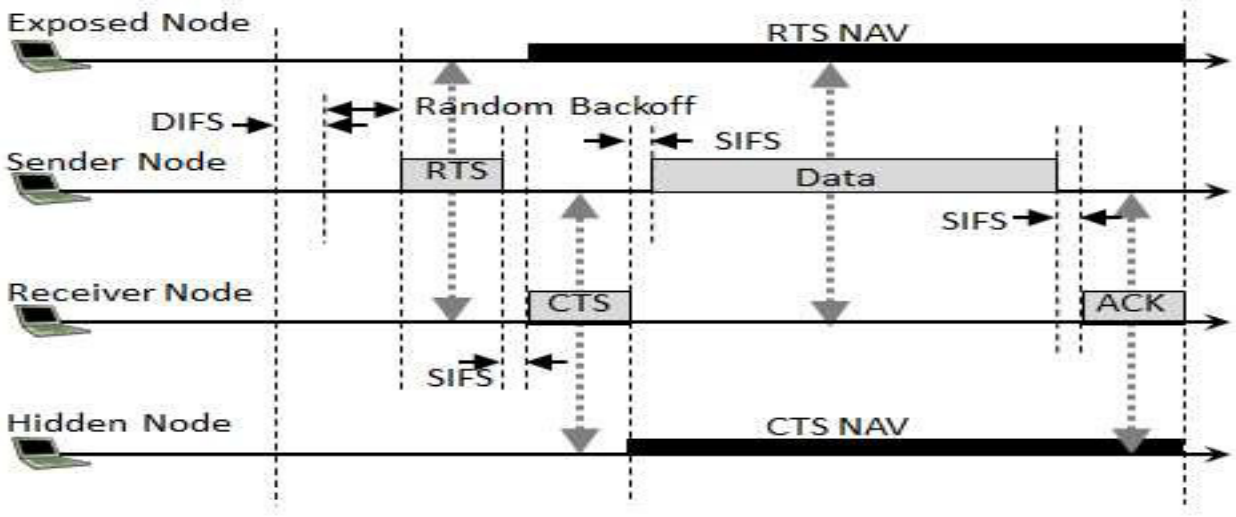

Fig. 2 Standard RTS/CTS Mechanism

II. Proposed Method

A. Related Work

Various researches have been conducted to mitigate Exposed Node and Hidden Node [4]. The most of existing researches assume that RTS, CTS and Data frame are sent at the same data transmission rate and have the same radio coverage. This was true with the first version of IEEE802.11, but now Data frame is sent at multi rates (54Mbps with 11a/g at maximum) while control frames such as RTS/CTS remain the lowest basic rate (1Mbps with 11g, 6Mbps with 11a). There are some researches to consider multi transmission rate, but no researches assume different transmission rate to RTS and CTS.

B. Basic Idea

In our research we intentionally allocate different transmission rate to RTS and CTS in order to proactively control the radio coverage and mitigate effect of Exposed Node. We have redefined the objective of RTS only to provoke CTS. RTS needs to reach to receiver node but it doesn't need to reach to any other nodes. So the RTS should be sent at the maximum data rate as data frame. This strategy introduces risk to lose CTS and ACK at the sender node by collisions from surrounding nodes (Exposed Nodes). But we assume this risk is minimal as CTS and ACK have short length in comparison to data frame.

Fig.3 shows the basic idea of our proposal. Here we define Sender Node as S, Receive Node as R, Hidden Node as H and Exposed nodes as Ei, Nj. Radius of RTS range and CTS range by standard method are defined as Rrts and Rcts. Radius of proposed higher transmission rate of RTS (i.e. RTS') is defined R'rts. As shown in Fig.3, higher transmission rate of RTS makes the RTS coverage range smaller than CTS and reduces Exposed Node. In order to avoid collision of data frame at the receiver node, CTS should be sent at lowest data rate to be heard by Hidden Node as many as possible. In case if RTS range is completely included in CTS range, there is no Exposed Node. The shaded area of Fig.3 contains the eliminated exposed nodes (i.e. Nj) by proposal.

The following steps show the procedure of the proposal;

Step1: S sends RTS' to R with possible highest transmission rate. This is to minimize the RTS' coverage range and to reduce the number of Ei.

Step2: R receives RTS' and sends back CTS with basic transmission rate. This is to ensure all potential hidden nodes to receive CTS and to suspend their transmission.

Step3: S receives CTS and sends data frame to R with maximum transmission rate. If the RTS' range is completely included in the CTS range, there is no exposed node.

Step4: R receives data frame and sends back ACK with highest transmission rate.

By the way above discussion, to reduce radio coverage is not applicable to CCA (Clear Channel Assessment). Any frames have PLCP preamble and header with 1Mbps, and the payload portion is in higher date rate (e.g. 54Mbps). The effect of CCA may need to be investigated further.

III. Simulation

A. Simulation Condition

We have assumed Wireless LAN standard of 5GHz band, IEEE802.11a. The system parameter for the simulation is shown in Table 1.

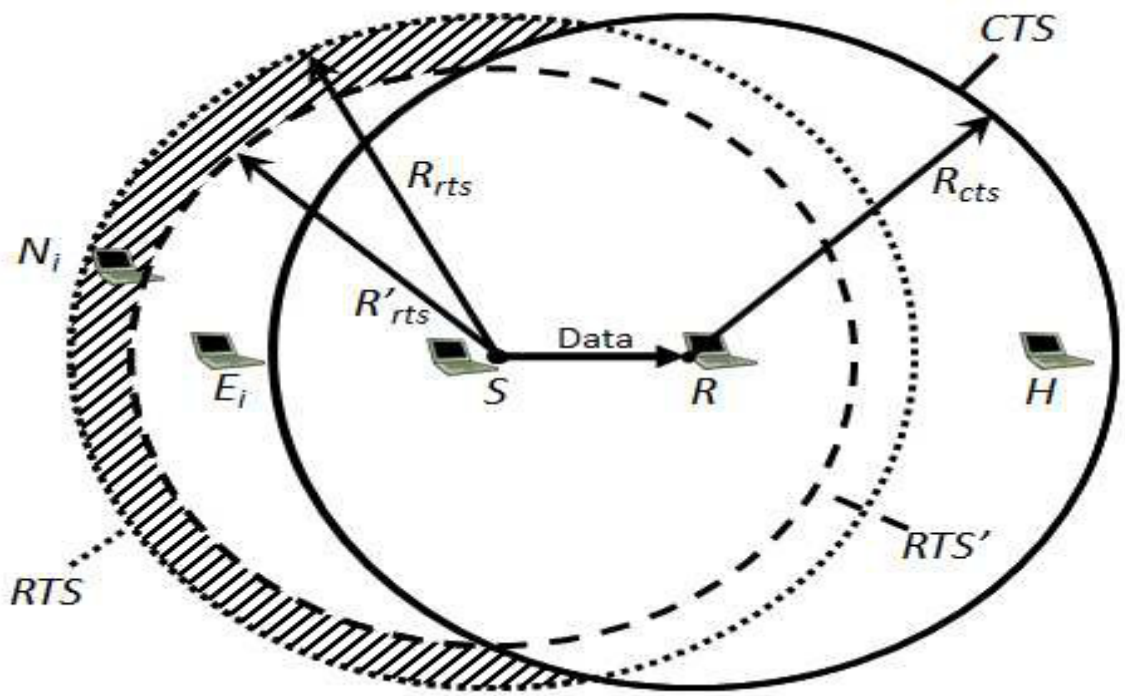

Fig. 3 Basic Idea of Proposal

In IEEE802.11a, 8 transmission rates are defined as 6Mbps, 9Mbps, 12Mbps, 18Mbps, 24Mbps, 36Mbps, 48Mbps and 54Mbps. For simplicity, in this simulation, RTS is sent at 18Mbps and CTS is sent at the minimum basic rate as 6Mbps. Data and ACK are sent at the same as RTS (i.e. 18Mbps).

As the simulated network topology all nodes are located in a grid with 70m interval. Seven cases are assumed for grid size from 3x3 with 9 nodes to 15x15 with 255 nodes. Nodes can be randomly distributed, but in practical deployment distribution of nodes is often governed by artificial objects such as walls, furniture, partitions and structures of building and it follows geometric arrangement. So we assumed the grid distribution as the initial research stage.

The 5x5 grid of nodes is shown in Fig.4. The node 13 is the sender node and receiver node is selected among node 8, 12, 14 and 18 at random. In Fig.4, node 14 is selected as the receiver node.

TABLE 1.

SYSTEM PARAMETERS FOR SIMULATION

Frame	Type	Transmission Rate	Range	
	RTS	18Mbps	88m	1 hop (70m)
	CTS	6Mbps	140m	2 hops (140m)
	Data	18Mbps	88m	1 hop (70m)
	ACK	18Mbps	88m	1 hop (70m)
Load	3Mbps per node with exponential distribution			
Data Size	1,000 bytes			
Distance	Nodes are located at 70m interval in a grid.			
Other	DIFS=34μs, SIFS=16μs and Slot time=9μs. Other parameters follow 802.11a standard.			

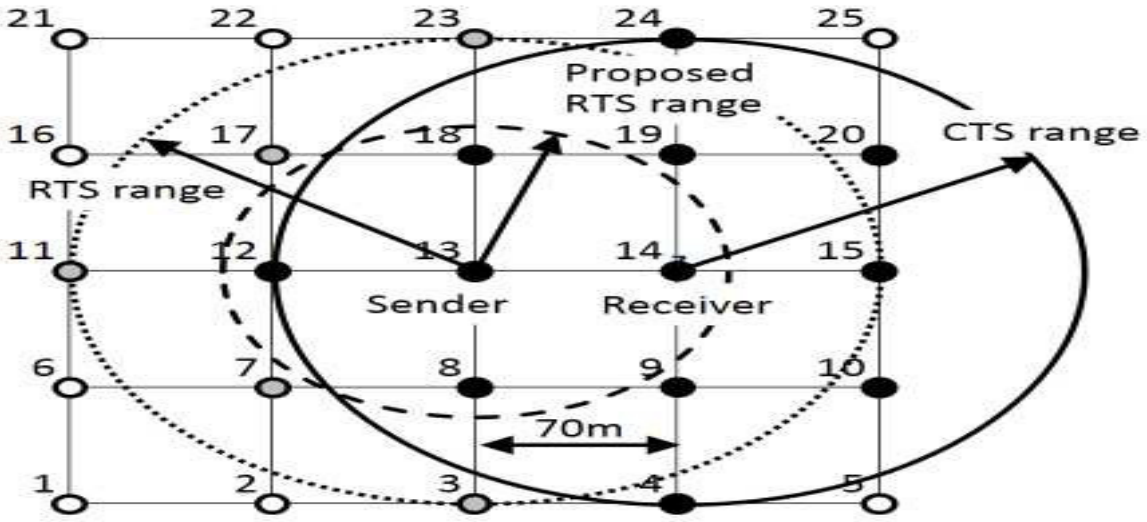

Fig. 4 25 Nodes (5 x 5) Example

An RTS with standard method reaches up to a node at two hop distance and totally 12 nodes excluding sender node are in transmission range. An RTS with proposed method reaches only to nodes at one hop distance and totally 4 nodes are in transmission range. As the CTS transmission range is two hops, RTS range of the proposed method is completely included in CTS range.

In Fig.4, black nodes are in the CTS transmission range and white nodes have no influences with the transmission from note 13 to node 14. Gray nodes would be Exposed Nodes if standard method is applied. As you see in Fig.4, in case of standard method with 5x5 grid, gray nodes (i.e. Exposed Nodes) are very often located at the boundary of the network. It is anticipated that boundary condition would affect throughput improvement ratio especially to small size grid. Therefore we have simulated up to 15x15 grid of 255 nodes.

B. Simulation Result

As shown in Fig.5, throughput per node goes lower as the size of grid goes bigger for both standard and proposed method. The simulation result showed that the proposed method achieved higher throughput per node in all grid sizes.

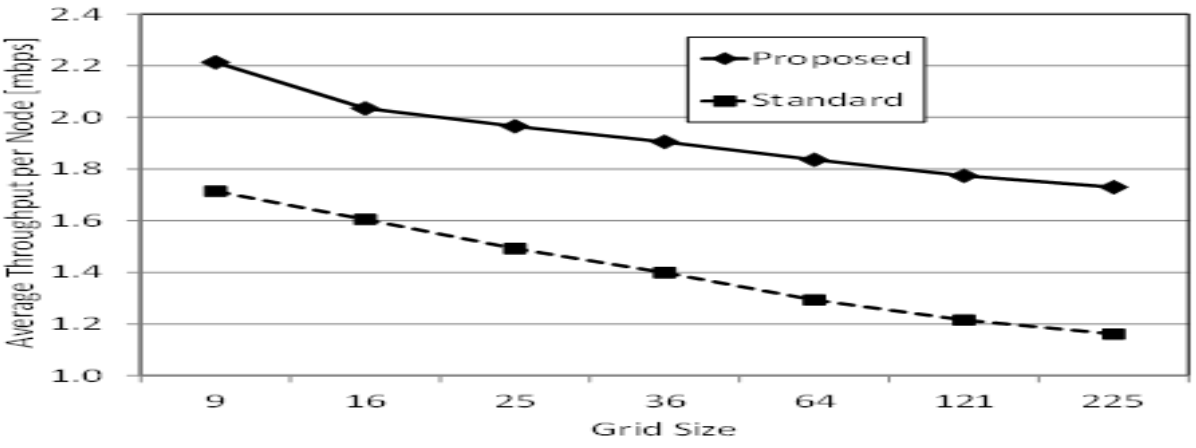

Fig.5 Average Throughput per Node

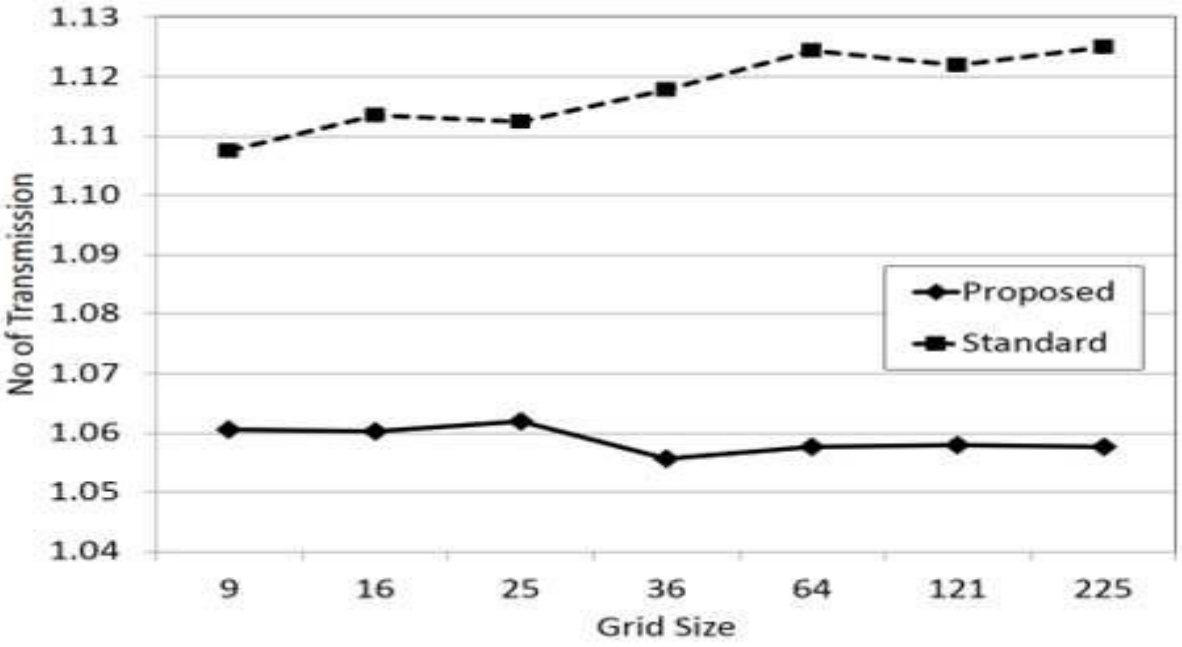

Fig.6 Average Number of RTS Transmission

Fig.6 shows average number of RTS transmission per data frame for each grid size. The number greater than 1.0 imply the occurrence of RTS retransmission. With standard method, 11% to 13% of RTS were retransmitted due to collisions. With the proposed method, only 5% to 6% of RTS were retransmitted.

Fig. 7 shows the average throughput dispersion. The proposed method has smaller dispersion than standard method, and this tendency is more ostensible with smaller grid size.

IV. Conclusion

In this paper we have proposed the new method to adjust the transmitting rate of RTS to the same as data frame in order to control its transmission range proactively.

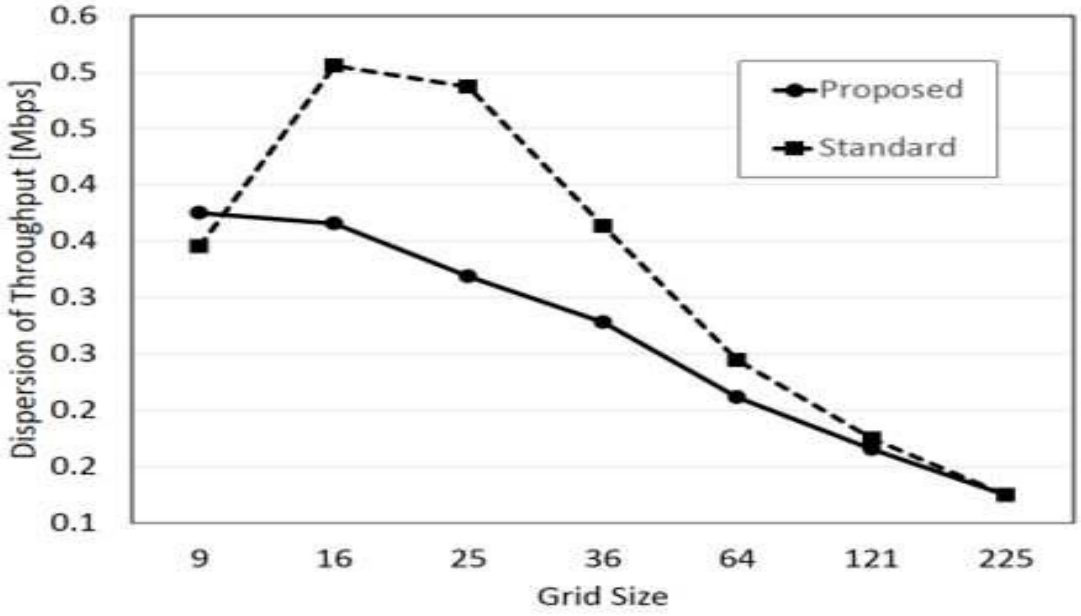

Fig.7 Dispersion of Throughput

We have showed by simulation that the proposed method can improve throughput. We need to investigate further to validate effect of proposed method and to find method of selecting appropriate parameters as well as theoretical explanation.

Abstract—**In this article, we propose an algorithm for the management of the structure of the tunnel connections in large, distributed nature, corporate network. Management is here understood as monitoring the availability and health of key elements and dynamic reconfiguring the system in situations of failure symptoms. It was assumed that the algorithm can be used in cases where the correct functioning of the network (providing the appropriate level of quality of service) means an access to distributed resources, usually redundant, which may be subject to reallocation. It was shown that developed algorithm may be used for maintenance of VPN network with dynamic tunnels (DMVPN).**

I. Introduction

In present-day's communication networks, which are networks of different services integration and networks giving access to a distributed resources, the efforts of the engineers, protocols and network hardware designers, and in particular, the information and communication systems administrators, focus on ensuring high-reliability of the system, continuous availability of network resources and the desired level of quality of services. Efficient and effective diagnosis of inappropriate states (incompatible with expected) of system functioning is unquestionably the most important challenge for administrators of complex ICT environments.

The algorithm used to oversee the operation and dynamic reconfiguration of the system of dynamic tunnels, raised between border routers of company's branches networks was proposed. It's not too hard to indicate many examples of systems, in which the continuous and reliable access to distributed network resources (for example resources within the cloud computing system, within distributed data centres, etc.) seems to be critical (especially important) and for which different optimizing algorithms of structure of connections and reallocating resources of servers and network nodes, with the requirement of achieving state of convergence as soon as possible are proposed [8], [9], [10].

The proposed algorithm for system of dynamic tunnels is based on some elements of system-level diagnostics and self-diagnosable systems [1] - [7], [13], [14].

Corporate network of dynamic tunnels (DMVPN - Dynamic Multipoint Virtual Private Network) [11] is seen by authors as a client-server system in which a significant problem is to provide reliable client-server communication, where server plays role of the tunnel broker, and reliable client-client communication through dynamically created tunnels.

The DMVPN network, from the point of view of the authors, contains certain number of clients, DMVP servers and, introduced by authors, the management station. Transmission links (tunnels) between clients and servers form a logical structure of connection links and the primary function of tunnel brokers (servers) is to provide communication between network clients by informing clients about tunnel parameters. Tunnels between clients are rise dynamically on transmission time only, so the logical structure is subject to continuous modification.

It is assumed that the client can forward the query about parameters of tunnel leading to another client to one of the many assigned (known) servers (it's system with tunnel broker redundancy).There are the primary server and backup servers in the group of servers. In the absence of the ability to provide client-server communication, or in case of communication parameters deterioration, the client should have the possibility to appeal (to send service order) to the other server from a server group. In addition, the client should send inaccessibility notification to the management stations (suspicion of primary or/and backup server failure notification). Quick server failure detection will be possible through periodic availability testing of the servers, that are assigned to the client.

Management station should have the possibility of reconfiguring logical network connections, which means the ability to assign clients to servers (primary and backup).It is assumed that the servers will have the opportunity to test the quality of the connections to clients (source to destination latency, packet loss, jitter, etc.), and the result of testing will have an impact on the allocation of clients to the server.

Quickly responding to the unavailability of tunnel brokers (detection of unfit brokers) will be carried out using IP SLA probes [12], available within operating systems of network devices, automating the login process (telnet/ssh) from the

978-83-60810-58-3/$25.00

management station to network nodes (clients and servers) and changing their configuration.

Authors propose the procedure of dynamic tunnels network management based on linking the utility functions of network devices with diagnostic functions. Methods of connecting utility functions with diagnostic functions belong to the system diagnostic methods (system-level diagnosis), and systems capable to indicate unsuitable items and reconfiguration (auto-repair) belong to class of self-diagnosable systems.

II. Characteristics and Structures of DMVPN Network

DMVPN is a technology that allows to build scalable VPN, combining the advantages of GRE (Multipoint GRE), IPSec and NHRP (Next Hop Resolution Protocol). DMVPN connects branch offices through the Internet (WAN) infrastructure based on tunneling and assuming that the tunnels will be "lifted" dynamically, as needed, and so will not be required to create persistent connections and, worse still, arranging them in a structure of type "full-mesh". The technology is based on a logical topology of a star, with the highlighted nodes called Hub and Spoke. In the basic configuration, DMVPN offers communication between branches through Central Branch (Spoke-Hub-Spoke connections) and in the enlarged configuration gives the ability to directly connect branch office networks with Spoke routers (Spoke-to-Spoke connections).

The general shape of the corporate network with dynamic tunnels was shown in figure 2.

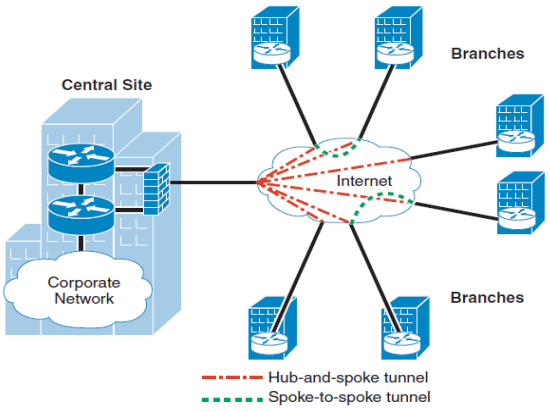

Fig. 2 Overall shape of DMVPN network[11]

Implementations of Dynamic Multipoint VPN networks

A particularly important feature of DMVPN is the ability to dynamic "lifting" tunnels, which encapsulate packets of any type (unicast, multicast, broadcast), IPv4, IPv6, and others. It follows directly from the application of GRE (Generic Routing Encapsulation) protocol. So, for example, DMVP can be seen as one of the transitional mechanisms for connecting IPv6-capable networks through IPv4-based network infrastructure. Importantly, packets transmission in dynamic GRE tunnels can be secured by IPSec, and one tunnel interface supports multiple IPSec sessions. It is also worth noting that due to the possibility of organizing tunnels between branch offices, although a little bit difficult, configuration of QoS policies, for example in system with VoIP calls, becomes more transparent.

DMVPN network in basic configuration was presented in figure 3.

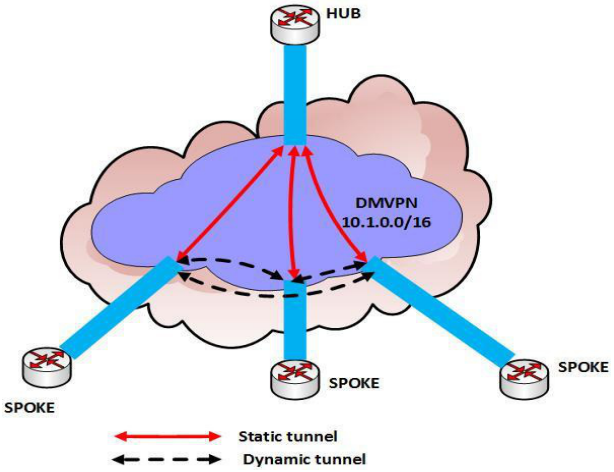

Fig. 3 DMVP Network with one Hub router

The router called Hub operates within the Central Branch network, while in remote branches act Spoke routers (Hub's clients). Remote branches have a persistent tunnel connection to Central Branch and access to Central Branch's network resources (static tunnel between a Spoke-Hub pair). In the case of realizing transmission between remote branch offices, transmission is preceded by sending an NHRP (Next Hop Resolution Protocol) initiator Spoke's request for tunnel address of Spoke router in a distant location. The Hub in a central location answers to NHRP query and is called NHS Server (Next-Hop Server), and NHRP protocol allows to get information about actual addresses of Spoke's interfaces. Tunnel connection between the branch offices can be implemented via the Hub, or it can be made a direct tunnel between Spokes. The main requirement of tunnel creation between the branches (direct or via the Hub) is Spoke's registration in NHS server and cyclic refreshing of registration. Hub's and Spoke's configuration details are discussed in the technical documentation [11] and will not be discussed here.

In the extended configuration (as in figures 4 and 5), to increase the degree of reliability of the network, additional Hub nodes are implemented or another DMVPN network is created.

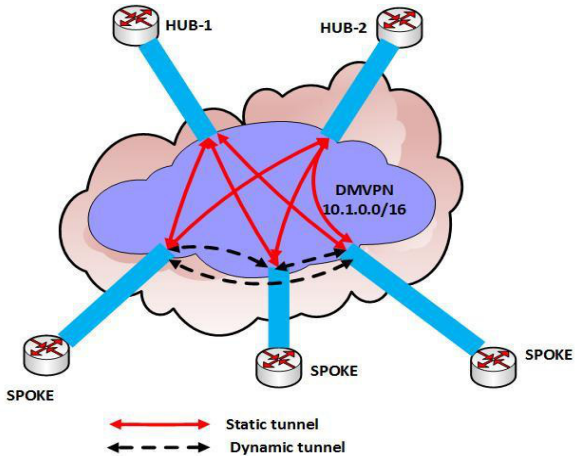

Fig. 4 DMVPN network with backup NHS server

In the case of single DMVPN cloud (figure 4), each Spoke uses a single mGRE tunnel leading to two or more Hubs, acting as the NHS servers.

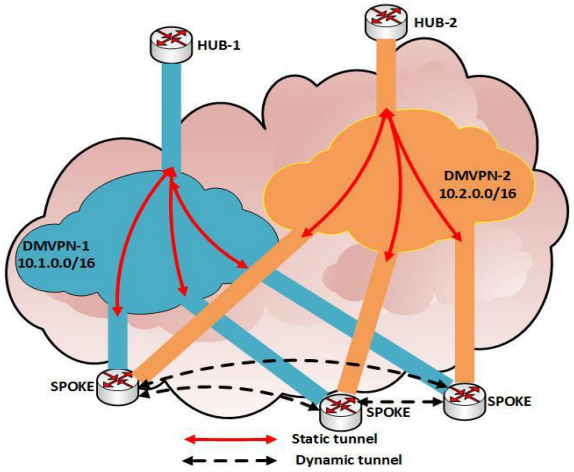

Fig. 5 Dual-cloud DMVPN

In dual-cloud DMVPN network (figure 5), each Spoke uses two tunnels, leading to two different Hubs.

Sample problems in DMVPN networks

As mentioned, the basic condition of successful tunneling between the different locations is proper functioning of the Spoke in Hub signing up mechanism, the polling mechanism about physical addresses of the final points of tunnels, but also disconnecting calls in case of failure (for example in case of demise Hub's network interface, its temporary loss, too much load of the Hub, too long a response time, etc.).

In some cases, such as realization of tunnel connections protected by IPSec, it is necessary to continuous monitoring Hub's availability and removing IPSec session after a period of temporary unavailability of the Hub (cleaning of IPSec Security Associations). In case of unavailability or even reduce the effectiveness of primary Hub, handling the entire NHRP process should be taken over by another (secondary) Hub.

DMVPN technology is refined through the years, but it's still possible to indicate some scenarios in which an administrator's intervention is necessary.

An illustration of problems appearing in the network DMVPN (besides the obvious problem of the physical unavailability of critical nodes) may be the following example with IPSec tunnels. In a simulation environment, DMVPN network with structure shown in Figure 6, has been configured.

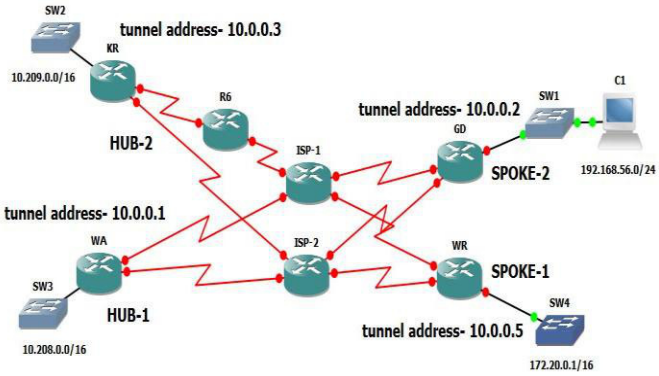

Fig. 6 Simulation environment of DMVPN network

In accordance with the assumption of DMVPN network, SPOKE-1 and SPOKE-2 maintain IPSec tunnels with theirs primary HUB-1. The sample configuration of Spoke's tunnel is as follows (for SPOKE-1):

```
interface Tunnel0
 bandwidth 1024
 ip address 10.0.0.5 255.255.255.0
 no ip redirects
 ip mtu 1400
 ip nhrp authentication dmvpn
 ip nhrp map 10.0.0.1 1.0.0.1
 ip nhrp map multicast 1.0.0.1
 ip nhrp network-id 99
 ip nhrp holdtime 300
 ip nhrp nhs 10.0.0.1
 ip tcp adjust-mss 1360
 delay 1000
 tunnel source Serial0/0
 tunnel mode gre multipoint
 tunnel key 232323
 tunnel protection ipsec profile dmvpn
```

Active IPSec connection can be listed after the commands: show dmvpn and show crypto session, as below (for SPOKE-1).

```
WR#show dmvpn
Legend: Attrb --> S - Static, D - Dynamic, I - Incompletea
      N - NATed, L - Local, X - No Socket
      # Ent --> Number of NHRP entries with same NBMA peer

Tunnel0, Type:Spoke, NHRP Peers:1,
 # Ent  Peer NBMA Addr Peer Tunnel Add State  UpDn Tm Attrb
 ----- --------------- --------------- ----- -------- -----
    1         1.0.0.1         10.0.0.1    UP 00:01:54 S
```

```
WR#show crypto session
Crypto session current status

Interface: Tunnel0
Session status: UP-ACTIVE
Peer: 1.0.0.1 port 500
  IKE SA: local 3.0.0.1/500 remote 1.0.0.1/500 Active
  IPSEC FLOW: permit 47 host 3.0.0.1 host 1.0.0.1
   Active SAs: 2, origin: crypto map
```

It's easy to demonstrate that a temporary loss of connection between Spoke and Hub, causes transmission rupture between two Spokes.

The following sequence of events is an illustration of this problem:

```
WR#ping 192.168.56.2 repeat 10000000

Type escape sequence to abort.
Sending 10000000, 100-byte ICMP Echos to 192.168.56.2, timeout is 2 seconds:
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!.....
```

In this moment, the temporary collapse of the HUB-*1's interface* occurs

```
*Mar 1 00:07:23.679: %DUAL-5-NBRCHANGE: IP-EIGRP(0) 100: Neighbor 10.0.0.1 (Tunnel0) is down: holding time expired.....................................................
.....................................................................
Success rate is 37 percent (79/209), round-trip min/avg/max = 156/365/844 ms
```

When we observe messages on HUB-1's console, just after lifting the interface, we see syslog messages, announcing incorrect SPI IPSec session ID.

```
WA#
*Mar 1 00:08:31.703: %CRYPTO-4-RECVD_PKT_INV_SPI: decaps: rec'd IPSEC packet has invalid spi for destaddr=1.0.0.1, prot=50, spi=0x741CDD33(1948048691), srcaddr =3.0.0.1

*Mar 1 00:09:32.139: %CRYPTO-4-RECVD_PKT_INV_SPI: decaps: rec'd IPSEC packet has invalid spi for destaddr=1.0.0.1, prot=50, spi=0x1085029(17322025), srcaddr=2.0.0.1
```

Unfortunately, the remedy in this case is "manual" breaking IPSec session, as illustrated below.

```
WR#clear crypto session
*Mar 1 00:11:59.223: %DUAL-5-NBRCHANGE: IP-EIGRP(0) 100: Neighbor 10.0.0.1 (Tunnel0) is up: new adjacency

WR#ping 192.168.56.2 repeat 10000

Type escape sequence to abort.
Sending 10000, 100-byte ICMP Echos to 192.168.56.2, timeout is 2 seconds:
!!!!!!!!!!!!!!!!!!.
Success rate is 94 percent (18/19), round-trip min/avg/max = 224/411/624 ms
```

The case discussed above helped the authors to test the procedure of monitoring and reconfiguration of the nodes (routers, Hubs and Spokes) and it should be noted that in multiple IPSec implementation, including Cisco device's implementation, a mechanism for detecting unreachability of nodes communicating by cryptographic tunnels and resolving the problem of "dead" IPSec session, known as the Dead Peer Detection, was introduced.

Beside the mentioned case, problems caused by the failure of nodes and network links were identified. Scenarios in which reconfiguring the nodes was necessary (because of the failure of the primary route leading to the HUB) were considered. The necessary reconfiguration included changes of static routing paths in the routing table and ensuring availability of one of two NHS servers by the Spoke node.

III. General Model of Self-Diagnosable Client-Server System

The procedure for oversee a network of dynamic tunnels, presented in chapter IV, allows to treat a managed DMVPN network as a client-server and a self-diagnosable system ([3], [4], [7]).

The self-diagnosable system determines the structure of mutual testing of elements, the method of using tests results, and the model of inference, based on the results of tests, about the reliability state of the system [3]. The structure of self-diagnosable system is described using a testing graph. Depending on the method for interpreting the results of tests, distributed systems and centralized systems can be distinguished. Inference about the state of the distributed system take place on the basis of results of parts of all the results of tests. Inference about the state of the centralized system take place on the basis of results of all the results of tests. In addition, stands out heterogeneous and homogeneous systems. Due to the reasoning model, which defines the relationship between results of tests and the reliability state of system, in centralized systems stands out PMC model [4] and BGM model [5], in distributed systems stands out MM and MM* models [1],[2].

In the self-diagnosable systems inference about the state of the system is implemented under certain conditions and on the basis of the results of tests obtained by fault-free and faulty elements. One of the specific conditions necessary for the reasoning about the reliability state of the system is the requirement for the maximum number of faulty elements of the system (called diagnosability) within a given number of all elements of the system. The diagnosability of the system is defined as the maximum number t, such that the system is t-diagnosable as long as the number of the faulty elements is not greater than t.

If a testing graph of a self-diagnosable system is a such edge induced subgraph of the system, which describes the t-diagnosable system, has minimal number of tests, then is called t-optimal testing graph of the t-diagnosable system. The t-diagnosable system has an irreducible testing graph if none of its edge induced subgraph does not describe a testing graph of t-diagnosable system. An irreducible testing graph that is not t-optimal is a t-quasi-optimal testing graph.

Sometimes, the system design must take into account that the costs of mutual testing of elements are not the same. If the arcs of the testing graph have assigned a generalized cost of testing, then such a graph can be called economic testing graph. The edge induced subgraph, that describes t-diagnosable system for which the generalized cost of testing shall give the minimum value, describes the cheapest t-diagnosable system. The t-diagnosable system, in the general case, may has several (many) t-optimal testing graphs. The cheapest testing graph is generally one of the t-optimal or t-quasi-optimal testing graphs.

General model of self-diagnosable client-server system

Assume that an organization has a computer network O, $O = \langle V, E\rangle$, of a certain logical structure, in which V denotes a set of computers ($v \in V$), E – a set of communication links ($v', v'') \in E \wedge v'' \in V(v') \wedge v' \in V(v'')$, where V(v) denotes set of nodes adjacent to node v. In the network O stands out computers of client type $k \in K$, computers of server type $s \in S$ and a computer of manager type z. It is assumed, for simplicity, that the manager is reliable. Also $(V = K \cup S \cup \{z\}) \wedge ((K \cup S) \cap \{z\} = \emptyset)$. A client k has assigned an ordered pair of servers $k(S) = (s', s'') \in S$, where s' is a primary server and s'' is a backup server. A client communicates with the server to invoke a given service on a server. A client also sends diagnostic messages (so-called traps) to the manager z. Similarly, each server sends traps to the manager z. The manager z stores information about logical structure of network O and about the status of clients and servers. Each server s stores information about adjacent clients: $s(K) = \{k \mid k \in S(s)\}$.

Set S of servers is a such subgraph of O, $\langle S\rangle_V$, that it is a testing graph of the PMC model.

It is known that if the system with |V| nodes is t-diagnosable for the PMC model, then [4]:

$$(|V| \geq 2t + 1) \wedge (\forall(v \in V) \mid \mu^-(v) \geq t), \qquad (1)$$

where $\mu^-(v)$ is indegree of node v.

A system with |V| nodes that satisfies the formula (1) is t-diagnosable if and only if [7]:

$$((\forall(0 \leq p \leq t-1) \wedge \forall(V' \subset V) \mid |V'| = |V| - 2t + p)) \Rightarrow |\Gamma(V')| > p, \qquad (2)$$

where $\Gamma(V') = \{v \mid \exists(v' \in V')\ v \in V'(v') \wedge v \notin V'$ means set of successors of elements of a set V', and $v \notin V'$.

Assume that subgraph $\langle S\rangle_V$ is described by a testing graph for 1-diagnosable system for the PMC model - it is assumed that the probability of damage of more than one server at the same time is low. From the formula (1) follows that $|S| \geq 3$. It is known that strongly connected graph, which has at least 3 nodes, is a testing graph for 1-diagnosable system of the PMC type.

The figure 1 shows an example of a testing graph (1b) for subnet of servers, which has a logical structure like in figure 1a. A such pattern of test d_{st} where server s is testing server t was shown in figure 1c. Symbols: n(e), $n_0(e)$ and N = [n(4), n(3), n(2), n(1)], n(i) = x, i = 1,...,4, $x \in \{0,1\}$ denote: a reliability state of node e, state where node e is fault-free and vector that describes a reliability states of system, wherein, if n(i) = 0, then the i-th node is fault-free. If N = [0001], then result of test [d_{12}, d_{23}, d_{34}, d_{41}] can be [0001] else [1001], which corresponds to the pattern [x001].

In PMC model all tests are performed between two adjacent nodes, and it was assumed that a test result is reliable (respectively, unreliable) if the node that initiates the test is fault-free (respectively, faulty).

IV. ALGORITHM FOR MONITORING AND MAINTAINING DMVPN NETWORKS

This chapter presents a general algorithm for oversee client-server networks, applied in the construction of self-diagnosable DMVPN network.

The fundamental objectives of proposed algorithm are as follows:

a) ensuring high reliability of the system on the basis of the continuous servers availability. We assume that the client should be able to communicate all the time with one/two servers. At the entrance, each client has assigned two servers, from a pool of servers (initial pool consists at least 3 servers to provide 1-diagnosability using the PMC model). In case of failure (unavailability) of one of the server, reconfiguration of the client is needed. Reconfiguration involves interfering in the configuration file and changes the settings of tunnel interfaces, which should indicate a new set of servers. So, also reconfiguration of the set of servers is needed.

b) shortening the convergence time of the system, which can be, in the opinion of the authors, achieved (in dynamic routing based and timers controlled DMVPN network) by forcing fast reconfiguration of nodes (servers and clients).

c) servers load balancing, which means that servers support nearly equal (comparable) number of clients.

We assume that the DMVPN network of an organization has a logical structure (figure 7) described by a graph O = ⟨V, E⟩ | (V = K ∪ S ∪ {z}) ∧ ((K ∪ S) ∩ {z} = ∅), where S denotes a set of servers (Hubs), K denotes a set of clients (Spokes) and z is reliable manager of the network. Servers s ∈ S form a testing graph for the PMC 1-diagnosable system, The testing graph has a logical structure which is the Hamiltonian cycle, which has a directed Hamiltonian cycle. As mentioned earlier, a client k communicates with its servers k(S) = (*s'*, *s''*), *s'*, *s''* ∈ S, where *s'* is a primary server and *s''* is a backup server. A client maintains constant tunnel with its servers and asks servers (primary at first turn) about tunnel parameters leading to other clients. Each client has the ability to send diagnostic messages about fault detection (inability to communicate with server) to the manager z. Similarly, each server can inform about problems within the set of servers by sending traps to the manager z. The manager z knows logical structure of network O and the role played by each network node (client or server). Each server s has a specific set of assigned clients s(K) = {k | k ∈ S(s)}.

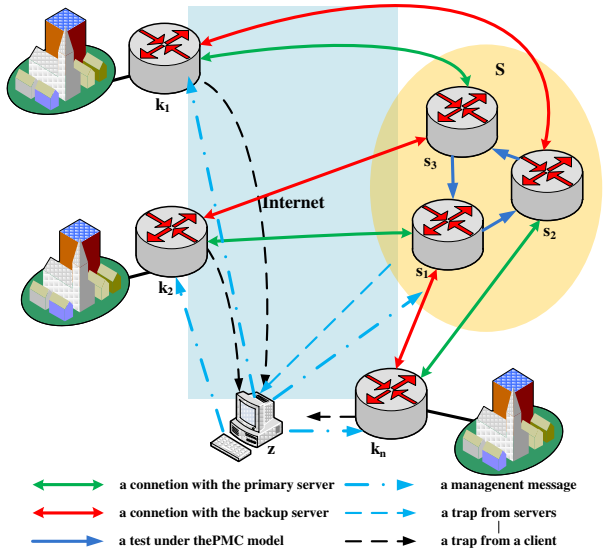

Fig. 7 Logical structure of connections and relations within DMVPN network

We assume that DMVPN system is running and has initial configuration, which means that each server supports some set of clients and the set of servers contains at least 3 servers. The set of potential servers (subset of all nodes) is also known.

The algorithm for monitoring and maintaining consists of the following steps:

1) The client k to perform a task (establish communication with the other client/server), invokes a service on a primary server s'. If the server s' can not do the job then:
   a) the client k invokes a service on a backup server *s''*,
   b) the client k generates the trap informing about server *s'* unavailability, which is sent to the management station (manager) z.
2) The manager z checks whether other traps, concerning server *s'*, from others clients k '| k' ≠ k were received, which would be a confirmation of the server's crash:
   a) if not, it is assumed that a failure of connections only between s' and k is occurred,
   b) otherwise, the manager z modifies a set of servers S, by removing the server s' and adding to this set a new server k * (from the pool of other network nodes) and by promoting it to the role of the server *s'*.
3) The manager z instructs the servers of S to execute functional tasks. Functional tasks are:
   a) the server s' instructs servers S(s') to perform the task of checking the connection parameters S(s')(K), where (S(s')(K) denotes set of clients adjacent to servers of S(*s'*)),
   b) servers S(*s'*), after checking of connections parameters with clients S(*s'*)(K), send these parameters to s'; sending responses to s' confirms the absence of failure of servers S(s'),
   c) if there is such s ∈ S(*s'*), which did not respond, the server s' sends to the manager z a trap, which inform about the not-responding server; a trap service is performed like in step 2b),
4) The manager z instructs servers s ∈ S to send back testing results, which are parameters values of connections between specific clients and servers.
5) After receipt of the test results from servers, the manager z allocate to clients k pairs of servers k(S). The method of allocation should result in an equal servers load and assuming that servers should support customers with the best connection parameter values.

In a DMVPN network, in relation to the general model of client-server, Hubs play a role of servers, Spokes play the role of clients and a manager manages a reconfiguration of Hubs and Spokes.

V. TEST ENVIRONMENT AND THE TECHNICAL FACILITIES USED IN THE COURSE OF EVALUATING THE FEASIBILITY OF THE ALGORITHM

Evaluating the feasibility of the algorithm was done in testing environment shown in Figure 8.

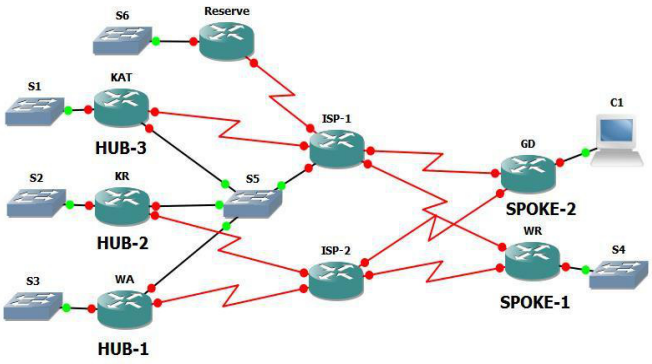

Fig. 8 Test environment of self-diagnosable DMVPN network

The set of potential Hub routers includes HUB-1, HUB-2, HUB-3 and Reserve. Routers called SPOKE-1 and SPOKE-2 register in the primary and backup server NHS (HUB-1 and HUB-2 routers). HUB-3 router is dynamically configured NHS server when the primary and/or backup server is unavailable.

Hub called Reserve was dynamically included to the set of hubs in case of failure of one of the hubs, which causes that testing in accordance with the PMC model assumptions was possible.

Simulated scenarios with symptoms of failure were as follows:

- loss of one NHS servers, caused by the failure of the primary link (leading to a primary NHS server) or simply by switching off NHS server,
- momentary loss of the primary server within IPSec connections.

Test environment has been built on the basis of Cisco equipment. Thus, offered by Cisco IOS system technical facilities for testing the quality of connections between nodes, with the possibility of sending a trap messages, generated by the device in the case of the unavailability of another tested device, were used. The logging from management station (C1 in Figure 8) on devices which require reconfiguration and the necessary changes in the configuration file was also used. At the moment, the procedure is not yet fully automated. Full automation of our system still requires writing shell scripts, woven into the configuration file of network devices (in the case of the Cisco, Tcl scripts).

The principal mechanisms of detecting the unavailability of network nodes and the state of the route's transmission parameters deterioration were IP SLA probes [12].

Sample configuration of two IP SLA probes is given below.

```
ip sla 1
 icmp-echo 10.0.0.1 source-interface Serial0/0
 timeout 1000
 threshold 1000
 frequency 30
ip sla schedule 1 life forever start-time now

ip sla 10
 udp-jitter 192.168.56.2 5000 codec g729a
 frequency 30
 ip sla schedule 10 life forever start-time now
```

The probe No. 1 was used to test reachability of a selected node (HUB router with the address 10.0.0.1), while probe No. 10 was used to verify the quality of the connection (transmission delay, packet loss, jitter).

In addition to the probes, the ability to track the status of the connection between nodes (up/down), with sending the syslog trap message to the management station, was used. A simple example of node's reachability monitoring, along with the illustration of sending messages to the management station when the Spoke loses connection with the Hub and the connection is restored, is given below.

```
track 1 rtr 1 reachability
 delay down 90 up 90

event manager applet track_SLA_1
 event track 1 state any
action 1.0 syslog msg "IPSLA collector 1 time out"

Dec 30 11:28:34.181: %TRACKING-5-STATE: 1 rtr 1 reachability Up->Down
Dec 30 11:28:34.217: %HA_EM-6-LOG: track_SLA_1: IPSLA collector 1 time
out

Dec 30 11:31:34.185: %TRACKING-5-STATE: 1 rtr 1 reachability Down->Up
Dec 30 11:31:34.245: %HA_EM-6-LOG: track_SLA_1: IPSLA collector 1 time
out
```

The result of the measurement of the quality of the connection between the network nodes is a series of statistics, as shown in the listing below. The most important are marked in bold.

```
WR#show ip sla statistics

```

The availability of NHS servers was supervised (in accordance with the proposed algorithm) by Spoke nodes with reachability testing probes. In the case of the unavailability of the NHS servers, the management station, on the basis of received messages-traps, decides to make Spokes and Hubs reconfiguration (firstly, resets the

connection between the Hub and Spoke—*clear dmvpn session*, secondly, indicates a new set of primary and secondary NHS server) or/and to start the procedure of mutual testing Hub nodes to the designation of a new set of NHS servers and the new allocation of clients to servers.

In the case of removing one of the Hub from the set of Hubs, Hub named Reserve was included to the set of Hubs. Test procedure, consistent with the PMC model, was initiated by the manager and the Reserve's job was to initiate testing of all Hubs. It was assumed that Reserve is a reliable node (reachable by all the other nodes).

Functional test performed by a single Hub relied on the use of probe like No. 10, although only the reachability test was taken into account. Hub was treated as capable of realize its function if it was able to communicate with all of its Spokes (Spoke-1 and Spoke-2).

Specifying a new allocation can be carried out on the basis of analysis of the results of testing the quality of the connection between potential NHS servers and Spoke nodes (probe like No. 10). It should be noted that the test results can be used to determine the new allocation taking into account the response times of nodes, packet loss, jitter, but also current load related to the number of supported Spokes, CPU utilization, memory consumption, etc.

Currently, the new allocation was implemented on the basis of assigning Spokes to the Hub that hosts the least Hubs.

In the case of temporary unavailability of the NHS server, with tunnels protected by IPSec, the management station, on the basis of received message-trap from the Spoke, has decided to log on the Spoke and to break active IPSec session (clear crypto session).

VI. Conclusion

The experiment had the hallmarks of a “manually” controlled experiment (supervised). The development work on fully automate the procedure of DMVPN network management is underway. The authors have a preconception about the effectiveness of the proposed solution. The tests (manual inspection and reconfiguration of the system) did not allow to assess the impact of the procedure on convergence time of large DMVPN network. It seems that a good means of verification and comparison proposed algorithm with system without modification or with other solution are simulation studies, which the authors intend to accomplish in the near future. Also, an interesting issue seems to be develop effective procedure for load balancing of Hubs, which will be based on the results of testing the communication parameters in the DMVPN network.

***Abstract*—The paper presents an anonymization of telecommunication data sets collected through Service Delivery Platforms (SDP), and describes an example tool SDPAnonymizer to make such operation. Information from SDP are processed in form of log files, consisting data sets, which show activity of users of APIs (Application Programming Interfaces). Data sets which should be anonymized contain sensitive data, for example: Names, MSISDN numbers (Mobile Station International Subscriber Directory Numbers) or IP addresses processed by Service Delivery Platforms..**

I. Introduction

IN ICT infrastructure of telecommunication operators, there is processed a large number of data related to subscribers activity and data from flow of information between different systems (call and messaging flows, billing, payment etc.). One of the systems taking part in processing of those information flow, is a Service Delivery Platform (SDP), which is e.g. used for exposure telecommunication services in Internet in form of API (ang. Application Programming Interface), for external programmers. In SDP, a large number of information is being processed, which is related to activity of users and used APIs. Among this data, there are both: information which can be public accessible (for example, the global number of API calls), and as well sensitive data, which publishing is impossible without the anonymization data sets for example the number of MSISDN, ID of localized people, content of SMS, MMS or USSD (Unstructured Supplementary Service Data) messages, Names etc.). This publication focuses on information processed by SDP and proposing a way of their anonymization, based on processing single data sets and presenting an example of application for processing them.

The article is organized as follows: Part I is a short introduction. Part II includes a review of some of the different works related to anonymization of telecommunication operator's data. Part III describes concept of Service Delivery Plaforms. Part IV concentrates on anonymization methods used in the application prototype. Part V presents examples of data sets undergoing the anonymization. Part VI describes the architecture of a solution and part VII shows plans of its further development. The last VIII part contains a short summary.

II. Telecommunication Data Anonymization

In literature, there can be found some examples of anonymization of information used in telecommunication systems. In position [1], the authors give examples of anonymization of IP addresses, made in real time, used during passive monitoring of networks based on TCP/IP protocol. Many works concentrates on issues of anonymization of information related to localization of mobile terminal (Location Based Services - LBS) [2], [3] made in order to provide privacy and security of information about subscriber's location (for example in case of unauthorized use of LBS). Many of data repositories on telecommunication operator's side has the information stored in form of records in databases. Due to that, the most safe way of anonymization is data processing on level of whole repositories, for both single records as well as their sets (data sets) according to k-anonymity methods [4], proposed in following literature positions [5], [6], and widely discussed in part IV of this paper.

III. Service Delivery Platforms

SDP (ang. Service Delivery Platform) is a system present in architecture of telecommunication operator systems, that manages network enablers and open API to allow third users to use these enablers. Such services can be for example:

978-83-60810-58-3/$25.00

functionality prepaid or exposing of functions of the operator in form of API e.g. in order to build services (in the sense of applicationsproviding specific functions) outside the operator - [7], [8], [9], [10]. The role of the SDP is creating and control of sessions and protocols for chosen service. Versatility of SDP usage makes, that it is present in almost every interaction of user with telecommunication service. This fact makes the service platform the source of large amount of data, which can be used in business, statistic or maintenance purposes, however they must undergo anonymization similarly often, before they can be provided.

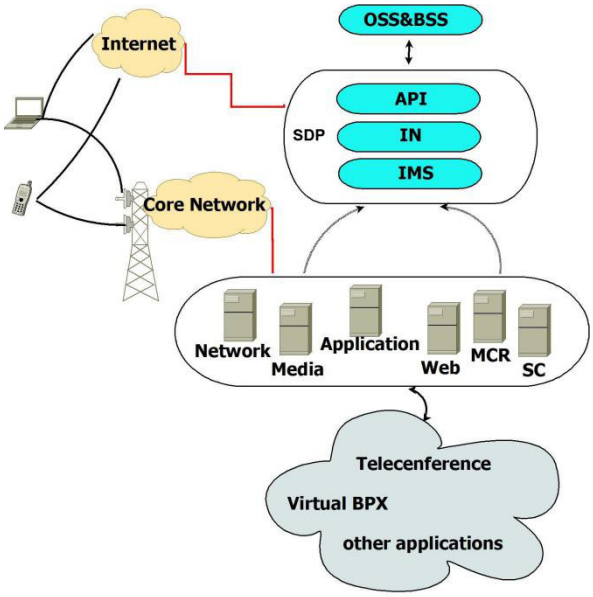

Fig. 1.Concept of Service Delivery Platform

IV. ANONIMIZATION METHODS

Anonymization of data is an operation of data processing, in way to disallow identification of individuals and sensitive data, existing in the processed data, in a way so that the data set remained as readable as possible, and so that it doesn't lose any of the content of general nature, and especially statistical data. Because in the information received from service platform, the basic unit of data is a single record, which represents - from the point of view of project-oriented programming - an event, in the following publication, the authors concentrated on processing of data in form of single records in data set, saved in logs of the SDP platform, provided in form of text files.

The operation of data processing focuses on methods based on data deletion and methods based on data disturbance [5], [6].

Among the most often used methods based on data deletion there are:

1) the deletion of variables - deletion of a record of direct identifiers, which allow identification (e.g. MSISDN number, name, surname, IP addresses etc.)

2) the deletion of records - deletion of individual records in data set. This method is advised only, when identification of sensitive data is possible despite the usage of different anonymization methods.

3) global recording - is based on aggregation of data in data set, according to predefined criteria (e.g. the number of terminals in given area defined by Local Area Code - LAC in various time intervals).

The methods based on data disturbance, in case of application presented in the following article, concentrate on methods from post-randomization group.In case of data from SDP, was implemented algorithms such as MD5 or SHA2 and replacement of sensitive data present in record, with character string generated by used hash function.

1) the method based on MD5 algorithm (Message-digest algorithm version 5). MD5 is an algorithm from cryptography field. It is a popular cryptographic shortcut function, which generates, from any data string its 128-bit hash .

2) the method based on SHA algorithm (Secure Hash Algorithm) - SHA is a family of connected with each other, cryptographic shortcut functions, designed by NSA (National Security Agency) and published by National Institute of Standards and Technology. It has several versions: SHA-1,SHA-256,SHA-384,SHA-512. In SDPAnonymizer application, was used the SHA algorithm, in SHA-256 version).

V. TEST DATA SET

As test data, was used a set of records from test Service Platforms exposing API to Orange network. Data sets were in form of text files in two versions:

Data partially aggregated - set of files with API users activities sorted on the basis of the MSISDN number in form of several files:

getlocation.csv - terminal location api function calls

getop.csv – which operator function calls

sendsms.csv –Send SMS function calls

sendussd.csv –Send USSD function calls

Every of presented above of files had following structure:

DATA HOUR|LOGIN=MSISDN

Where: DATA HOUR – date and time of the event, LOGIN number MSISDN of the API user e.g.:

2011.11.29 18:17:17|LOGIN=48500163047

The second type of data were raw data in txt format in form:
recordID Data Time Event GivenNameName MSISDN IP address deviceidhttpsessionID

2691 237633 2011-03-09 14:43:57 Authentication attempt (ussd pass sent) JaroslawLegierski48500163047192.168.20.124 null 1299678218892

2696 265971 2011-03-09 14:47:20 WebServ:http://10.255.240.50:2006/tp/orangelabs/jslee/oc/webservices/getRestTS?number=48500163047&webSerName=getRestTS JaroslawLegierski48500163047192.168.20.124 null 1299678218892

All of the example presented above records, included activity related to API usage, provided through SDP platform by the users (developers) in form of sending SMS, MMS, USSD message, logging in to the system or usage of mobile terminal location function.

VI. SYSTEM ARCHITECTURE

This section of the publication contains the architecture and functionality of the SDPAnonymizer application. The SDPAnonymizer is a simple application operating on SDP platform files in form introduced in chapter V. The application process the anonymization of data sets included in the files.

Input file containing database, which is the data set to anonymize, is loaded to application, and then modified by one of the user-chosen methods. The final result of the program activity is the output file containing anonymized data. The functionality of application is based among other things on algorithms already existing in Java libraries, such as MD5 [11], [12] or SHA2, and on mathematical operations (e.g. summation, deletion etc.).

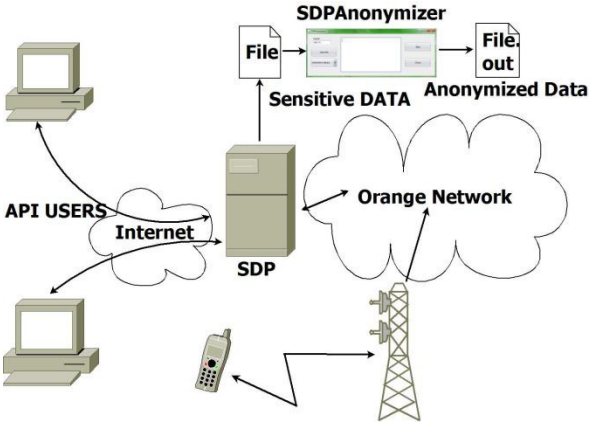

Fig.2. SDPAnonymizer– application concept

A) Programing environment

The application for data anonymization was developed and tested for Java environment JRE in 1.6 and 1.7version. In creation of the SDPAnonymizer application, was used Eclipse environment in "Juno Service Release 2" version. Application user's graphical interface was created with the usage of standard SWING libraries included in JDK.

B) Application

SDPAnonymizeris an application, dedicated for anonymization of data sets from operator service platforms.Tool was developed as easy to use and simple stand-alone solution not integrated with any ETL (Extract, Transform, and Toad)data management framework.

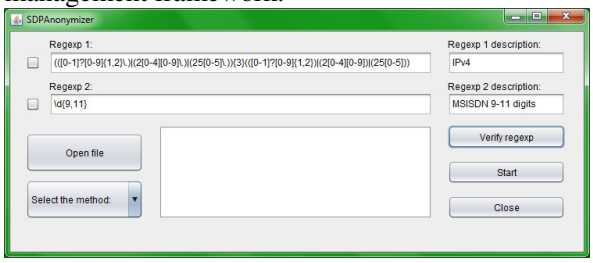

Fig.3. Application window.

In the program, there were implemented methods such as: SUM, DELETE RECORD, CATCH RECORD, DELETE NUMBER, MD5, SHA-256. Program identifies variables for anonymization using regular expressions defined in GUI in two textboxes.
The SUM method is a method from a group of methods based on deletion of data as a part of

global data set recording. In the version implemented in SDPAnonymizer, summation is based on summing of numbers of API usage by one user identified by MSISDN number.

Fig. 4. Application window –SUM method

DELELE NUMBER – is a method from group of methods based on deletion of variables. The MSISDN, IP address or Name is identified in the processed file using regular expressions, and it's deletion, through replacement by XXXX string.

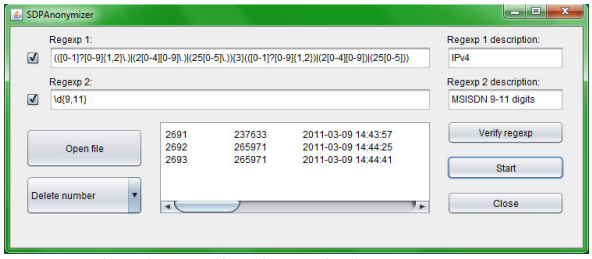

Fig. 5. Application window – DELETE NUMBER

DELETE RECORD method is based on deletion of records in data set. It works by deleting all records containing defined variables (MSISDN, IP address or Name etc.).

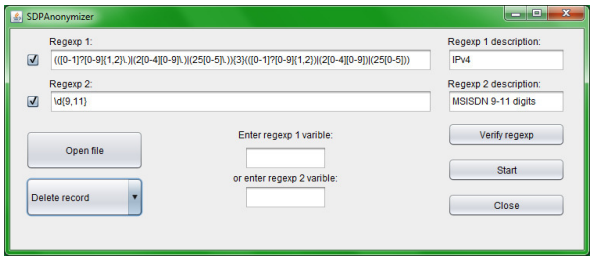

Fig. 6. Application window – DELETE RECORD

Complementary action to the method above is the CATCH RECORD method, which is based on deletion of all records in data set, which do not have defined variable.

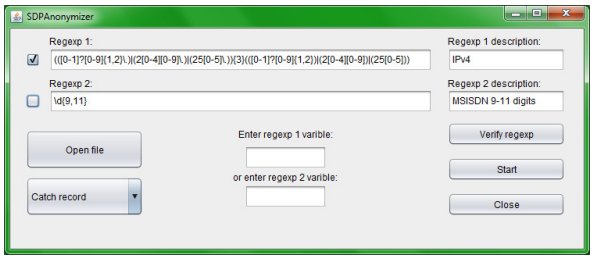

Fig. 7. Application window– CATCH RECORD

As it was already mentioned before, the application also implements two methods from Post-randomization group implemented. MD5 and SHA2 are shortcut functions, which transform a variable defined by regular expression in a hash string. Examples of records including data, for which hash functions were calculated are listed below (for MSISDN numbers anonymization):

Original record:
2691 237633 2011-03-09 14:43:57Authentication attempt (ussd pass sent)JaroslawLegierski485001630471192.168.20.124 null 1299678218892

MD5:
2691 237633 2011-03-09 14:43:57Authentication attempt (ussd pass sent)JaroslawLegierskiaf4f2db11d6a477aeed011a02aa9d549192.168.20.124 null 1299678218892

SHA2:
2691 237633 2011-03-09 14:43:57Authentication attempt (ussd pass sent)JaroslawLegierskid9e88a466dd7cc2527514581b2c73b0bffe34173ce60dd0ace42aa5751e79e19 192.168.20.124 null 1299678218892

Data marked in grey is the effect of encrypting, made with use of MD5 and SHA2 shortcut function.

The program also has the option to define another data than MSISDN, IP address or Name which can be anonymized, through the use of regular expressions(Table1) defined in SDPAnonimizer GUI, which gives us the possibility to anonymize data in different bases (e.g. consisting of telephone numbers of different length and stored in different formats, IPV6 addresses, or terminal location coordinates).

Table 1. Example regular expressionsused in SDPAnonymizer

Regular expressions	Identified variable
\d(9,11)	MSISDN (9-11 digits)
^(25[0-5]|2[0-4]\d|[0-	IPV4 Network Address

1]?\d?\d)(\.(25[0-5]|2[0-4]\d|[0-1]?\d?\d)){3}$	
^(?:[0-9a-fA-F]{1,4}:){7}[0-9a-fA-F]{1,4}$	IPV6 Network Address
[\s-]([A-Z][a-z]*)+[\s-]([A-Z][a-z]*)	GivenName Name

The handling of events and errors, from the application's end user point of view was implemented through display of a dialog windows (pop-ups).

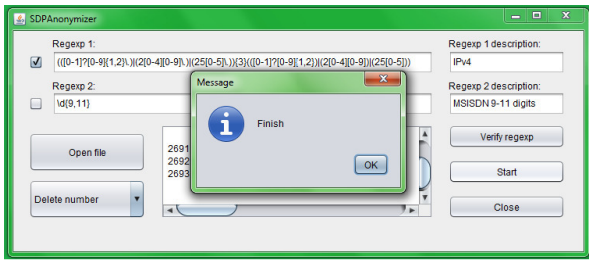

Fig. 8. Application window – dialog window, finish of file processing

VII. FUTURE WORK

In the future, the SDPAnonzmiyer program will be upgraded by functions, doing the process of microaggregation. The Micro-aggregation replaces the anonymized value - with medium value calculated for small group of records (micro-aggregate), which will for example allow to present the usage of communication functions, shown by API for example in hour intervals. Also additional method of encryption, which is the SHA3 method, will be added. In the next step the performance, and load test of application SDPAnonymizerare planned.

Target task is to transform the application into web service form, and exposure of anonymization methods in form of RESTlikeAPI, in order to increase the availability of anonymization methods for users - programmers.

V. SUMMARY

The SDPAnonymizer application is dedicated for Service Delivery Platform administrators, which, for example, share data from SDP system logs with external parties (e.g. the suppliers, which are responsible of the Level 3 maintenance of service platforms). Anonymization of information processed by service platforms in form of dedicated application, working on files solves following problems:

Legal (sensitive data such as MSISDN aren't shared) and data are anonymized as close as possible to the data source (anonymization is done by SDP administrator).

Computational - the SDP platform does not process data, so it's not overloaded with additional, computationally expensive tasks (data processing is done by additional component outside the SDP environment)

Mathematical - system administrator receives dedicated tool, with proper algorithms and mathematical functions already implemented (e.g. MD5, SHA).

Prototype of application SDPAnonymizer was made as part of the Open Middleware 2.0 Community by Orange Labs program[13]

MonSamp: A Distributed SDN Application for QoS Monitoring

Daniel Raumer, Lukas Schwaighofer, and Georg Carle
Technische Universität München, Department of Computer Science, Network Architectures and Services
{raumer|schwaigh|carle}@in.tum.de

***Abstract*—Software Defined Networks are intended to be less complex, more flexible, and free of vendor-lock-ins. Therefore the Software Defined Networking (SDN) instantiation OpenFlow has been designed according to these properties. The efforts are expected to result in lower expenditure and operational costs. To reach these objectives, mechanisms of classical networks that provide established functionalities have to be revalued and either transformed or redesigned from scratch to take advantage from SDNs. In this paper we describe our vision on flow sampling suitable for traffic monitoring in those networks. Without the loss of generality our approach was specifically created to monitor the quality of service for flows. We describe monitoring as one of possibly many applications that communicate with the SDN controller via the SDN Northbound API. We implemented a prototype SDN application called MonSamp and performed tests to demonstrate the feasibility of our concept.**

***Keywords*—SDN, QoS Monitoring, SDN Application, Flow Sampling, Northbound API**

I. Introduction

TRIGGERED by OpenFlow [1] (OF) the rise of SDN breaks one of the basic network design principles that was valid since the first days of the Internet [2]: the avoidance of central instances as these can be a single point of failure that compromise the robustness of the network. The main idea of SDN is the separation of control and data plane. The most prominent SDN instantiation, OpenFlow is managed by the Open Networking Foundation (ONF [3]). It provides access to the forwarding plane of network devices. Flexible controller software that performs the control plane tasks runs on commodity hardware while switches serve the data plane according to the rules received via the OpenFlow protocol. Uniform data plane hardware avoids vendor lock-ins and is expected to reduce capital expenditure as less functionality is required from it. The wide area network of Google, B4, demonstrated the feasibility [4] of SDN deployments in large and productive wide area networks. While the OpenFlow protocol itself is qute stable, real world SDN applications and their requirements for the SDN Northbound API (NB), allowing the combination of multiple, modular SDN applications into a single consistent controller, are still research in progress [5].

At the time of writing, SDN is still an active research topic. Only very few known SDN installations used for productive, non-research networks exist. One example is the B4 network [4]. With this paper we want to add techniques for sampling traffic suitable for quality of service analysis to the available SDN tools, as the OpenFlow protocol itself only provides little feedback (similar to SNMP) about the network traffic, which is unsuitable for an in-depth quality analysis. Thus, we introduce an SDN application for traffic sampling designed with the requirements for a later quality of service (QoS) analysis in mind. Our goal is to extract a subset of the packets handled by the switch, without limiting the selected traffic to a few ports or suffering from seemingly random drops because of an over-utilized monitoring link. We achieve this using the capabilities that are already present in SDN migrated networks, i.e. commodity servers and OpenFlow switches. We do not introduce a new technique for data analysis or traffic sampling. Our focus is on moving sampling away from dedicated hardware into cheap standard network hardware using SDN techniques.

The paper is structured as follows: In section II we give an overview to the state of the art in network monitoring. Section III describes the challenges of QoS monitoring and discusses ways of integrating these into SDNs. Based on these we infer properties for the sampling and present our architecture. In section IV the prototype, the setting in which we tested our prototype, and first measurement results that demonstrate the capabilities of our model are presented. Afterwards, in section V we discuss the state of the art and related publications. We conclude with by highlighting our contributions, giving a wrap up of open research questions and providing an outlook to our intended future work in section VI.

II. Excursus to Network Monitoring

Gaining information about the network performance is a worthwhile objective that is not unique to SDNs but has been addressed in classical networks since the first days. It is important to differentiate between the productive and the monitoring functionality. The latter could be omitted without having any direct effect for the information delivery. In this chapter we provide a short overview to the state of the art in QoS-monitoring and discuss what distinguishes QoS monitoring from other monitoring objectives.

A. State of the Art in QoS-Monitoring

Network monitoring techniques can be classified according to many criteria: They can be active or passive and require end host control or just access to the network. They may run on a single node or require aggregation of information gathered on different locations, require dedicated hardware and software or be part of existing network equipment. The techniques can be vendor specific, standardized or open solutions.

The value of the information provided by the different techniques for QoS monitoring is highly diverse. Active mea-

978-83-60810-58-3/$25.00

surement tools like SmokePing are used to monitor the latency and connectivity of a specific path but are impractical for monitoring each possible connection in a network. Passively collecting information about the network traffic is a service provided by most forwarding network devices. Information about flows can be pushed to a monitor using protocols like IPFIX (formerly NetFlow) or actively pulled from a monitor via device management protocols like SNMP, NETCONF, or OpenFlow. Theoretically almost any information can be exported via these protocols. However, each network device needs the capability to collect the required network information and to be able to export it to a collector or monitor where information of different networking devices can be combined or analysed. Although OpenFlow is intended to provide vendor independent access, the heterogeneity of the networking hardware available at the market leads to a situation where only selected devices are able to provide the desired information with an acceptable performance. Thus, specific requirements may limit the choice of vendors which again creates a dependency similar to vendor lock-ins. So, in practice, the usefulness of QoS information exported by the network devices is very limited. Additionally, pulling information too frequently causes high load to the network devices which may have a negative impact on the performance of the productive network (c.f. [6]).

The other widely used monitoring technique we will briefly introduce is the collection of local network information by so called sniffers. Sniffers may be hardware components or software tools; e.g. Wireshark (former Ethereal) or tcpdump. They are able to collect and log network traffic and usually require truncating, filtering, and aggregation of the collected packets to extract useful metrics. Software tool kits like VERMONT [7] contain a set of modules that allow configuring a sniffer with adequate post-processing functionality tailored to almost any problem. Other solutions like the intrusion detection system Snort [8] can also be described as sniffers with post-processing functionality focused on detection of network attacks. In state of the art approaches sniffers recognize packet drops by looking at higher level information like TCP retransmits and round trip times. Because the sniffers only have access to traffic of a certain network link or node, the information is necessarily incomplete: This approach is unable to determine where a drop occurred and is not applicable to UDP traffic used by most time-critical applications. To allow monitoring nevertheless, the analyser needs to understand each higher level protocol (e.g. SIP) that is to be monitored. The downside of this approach is that the monitoring has to be implemented for every protocol on top of UDP and may not be available for some protocols used in the network (especially proprietary protocols can pose problems). While it is theoretically possible to combine the information from multiple sniffers, the requirements to do so are quite high. The exactly same traffic has to be monitored on multiple locations (which may be a problem with sampling). Too much aggregation will diminish the usefulness but without aggregation the load on the analyser is very high as all the monitored packets from the whole network need to be correlated.

B. Sampling for QoS-Monitoring

In opposite to security monitoring where we need to find traffic patterns outlining an attack, QoS monitoring can be tackled by sampling. Whenever we detect bad performance of a single flow, we assume that other flows that are in some ways similar, e.g. they also traverse the same overloaded path, will suffer as well. Note that this assumption holds only to performance problems that are caused by the network and not necessarily to those caused by an application running on an end host. If monitoring is applied to all network nodes the performance degradation can be quantified per hop and thus per physical link or network device. Based on our assumption information about the performance gained from the sampled network traffic can be extrapolated to the whole network traffic using the sampling rate.

The IETF working group on Internet Protocol Performance Metrics (IPPM) focuses on developing and maintaining "standard metrics" that can be applied to the quality, performance, and reliability of Internet data delivery services and applications running over transport layer protocols [9]. The QoS metrics can be gathered on almost all layers of the ISO OSI model: e.g. connection establishment time, connectivity, (maximal/minimal) round trip time, delay, jitter, out of order delivery, (maximal/minimal) throughput/goodput, or packet/information loss.

For the quality perceived by the user the term quality of experience (QoE) is used. These metrics need to differentiate between different types of traffic, e.g. when using the network for telephony and the delay becomes greater than 150 ms the user experience will be bad (c.f. [10]) but same delay for a file transfer does not impact the user experience. Another property is the relation between metrics that may be gathered on different layers. Some indicators are highly dependent on the type of application and often difficult to quantify, but network problems detected on high levels are caused by lower levels. Higher level indicators are thus correlated to lower level metrics. For example layer 1 errors lead to retransmits on layer 2 which lead to more traffic causing a lower throughput. This may lead to congestion causing full buffers on layer 3 that cause higher delays or even drops of packets. The result are retransmits or missing packets on layer 4 impacting the performance of the application and thus the user experience. So it is desirable to gain information on a low protocol layer. For practical reasons the IP layer is used when a solution is intended to be applied to network traffic.

To allow detection of single lost packets, flow level sampling of network traffic is preferable to other sampling techniques as it allows the analysis of complete flows. For instance flow level sampling still allows determining performance metrics like the number of dropped packets and one way delays on the IP layer between two monitoring points. A drawback with state of the art monitoring approaches (c.f. section II-A) is that monitoring of newly deployed protocols is hard and requires adaptation of monitoring mechanisms, whereas the flow level sampling approach would instantly recognize lost packets for any IP-based traffic. Using the flow-tuple to match specific parts of the traffic allows (pre)classification by the network and dealing with it according to its needs. For example a VoIP flow constantly needs low latency and jitter, whereas a file transfer flow just needs high bandwidth on average (it does not even suffer much from frequent bandwidth variations). For scenarios where the flow-tuple is insufficient, the packets can be classified and tagged based on more complex features (c.f. [11], [12]). If different classes of traffic have been

introduced by tagging at the network edges the matching rules can also be refined to match only a subset of the tagged traffic.

Another desirable feature is selective monitoring of certain kinds of traffic, e.g. allowing to decouple statistic and network performance collection from the data plane. A network may have various monitoring systems that focus on different aspects. E.g. a system that measures the performance of telephony traffic is not required to receive any other traffic in the network, while a second monitoring system may not require the telephony traffic.

From a network operator's point of view it is desirable to recognize bad service quality as easily and universally as possible. Network operators are usually not in control of the end nodes of the connections. This condition differs from scenarios like the Google B4 [4] where traffic can be elastically delayed because of the control over the end-hosts.

III. Bringing Monitoring Functionality to SDNs

SDN, in particular OpenFlow, is expected to overcome main problems of classical networks: complexity, inflexibility, and vendor-lock-ins that cause high costs. Consequently we expect to benefit from these advantages when designing a monitoring solution for SDNs.

Software monitoring tool kits, like VERMONT [7], can easily be deployed on commodity servers, are flexible, and can thus be adapted for many different purposes including security monitoring, network logging and gathering QoS metrics (c.f. section II). However, placing a monitor to every link in order to get the complete picture of the network does not scale. Thus it is common practice to place monitors only at central nodes in the network. Therefore, in a typical scenario, the monitors are connected to one or more switches. The bandwidth of this link is orders of magnitude smaller than the backplane capacity of the switch and may act as bottleneck limiting the monitored traffic. The switch is then configured to send a copy of the forwarded packets to the port connected to the monitor. The monitoring system analyses the traffic and extracts performance metrics. These can be visualized for an operator to take appropriate actions or, in a more advanced setup, directly given to the SDN controller and its applications. For example a traffic engineering application can react to congested links by preferring alternative paths. Such an approach also provides a solution to challenges of distributed monitoring by utilizing the central controller of SDNs (c.f. section II-B).

This approach differs from another way of transferring traffic information about the network to the controller that we want to discuss briefly: The initial authors of OpenFlow [1] already intended a configuration where the controller receives all packets not matched by an OpenFlow rule on the switch. However, handling all packets that way significantly impacts the performance. To mitigate they propose an architecture for monitoring where a subset of the traffic is redirected to a programmable packet processing system (e.g. NetFPGA) as installed into the OpenFlow rules. The advantage of this approach is more flexibility as it allows modification and filtering of the network traffic but introduces extra delays, costs, and potential bottlenecks. Therefore we consider it as attractive for security motivated scenarios. On the other hand, this overhead is unnecessary if only passive monitoring and no modification or filtering is desired.

Even in scenarios where the bandwidth is sufficient, other bottlenecks and the unpredictable CPU capacity limits the monitoring capabilities even further. Braun et. al. [13] mitigated the unpredictability and demonstrated that dynamic adoption is a suitable way to avoid loss of monitoring information as long as the whole monitoring system has free capacities. Still, exceeding the link or processing capabilities leads to uncontrolled and thus random loss of packets in the monitoring components. These cannot be distinguished from real packet loss occurring in the productive network parts and are affecting the real traffic. In order to optimize monitoring performance with minimal costs packets should only enter the monitoring network and connected monitoring systems if they are likely to be processed. Our approach utilizes OpenFlow capabilities for fine grained matching of the desired packets and allows balancing the monitoring load. It provides an intelligent alternative to classical monitoring ports that are either affected by tail dropping behaviour on the monitoring link or block productive traffic if the transmit queue for the monitor port is full.

A. Northbound API

In SDN the interface between the controller and the higher level applications and network functions is the Northbound API. It is the logical consequence of the divide et impera principle in software development to hide complexity that is irrelevant for the applications behind clear interfaces. Network functionality is separated from the controller software by the Northbound API. The importance of the Northbound API increases even more with the ongoing efforts of scaling controller architectures. E.g. Kang et al. introduced the idea of providing a "One Big Switch" abstraction to the application [14]. A network operator who wants to implement a network function (e.g. security policies) does not want to think about OpenFlow rules, the underlying controller hierarchy, or the combination of these policies with others. Resulting from our monitoring application we identified the following requirements for the Northbound API:

- **Shared contexts** with different levels of (topology) abstraction should provide access to the information that is required and influenced by different applications. These levels also have to hide information, protect related configuration options for faulty access, and keep application design as easy as possible. E.g. an application for BGP routing can handle the network as one big switch [15] while traffic engineering in the network requires differentiated views of the single switches in the network [14].
- **Conflict free controller behaviour** has to be guaranteed through intelligent failover techniques [16], composition techniques for different applications [17], and prioritization of rules [18].
- **Information transparency** is required in both directions. The Northbound API not only needs to translate abstract rules into OpenFlow rules for the switches but also requires the ability to react to incoming OpenFlow packets sent from switches because none

of the installed rules matched. For `proactive` SDN applications only the translation of the rules is required while `reactive` applications need to be aware of incoming OpenFlow packets too.

Until a standardized Northbund API is established, flexible and transferable SDN applications are out of reach. The relevance of the Northbound API has been noticed by the ONF which started to analyse existing approaches for the Northbound API in 2012. The ONF classified existing Northbound APIs according to their scope and application (from OpenFlow enabled networks to general networks) and their level of abstraction. The definition of the Northbound was so unfocused in terms of the abstraction level that the spectrum ranges from the actual Southbound protocol OpenFlow, addressing a concrete switch to high level virtual network management interfaces like OpenStack (c.f. [19]). Existing SDN surveys contain comparisons of different implementations of the SDN Northbound API [20], [21]. The definitions used in the surveys assume an abstraction level somewhere in the middle of the mentioned extremes. In 2013 the ONF created a new working group with the goal to collect requirements and to implement first use cases [19].

B. Architecture

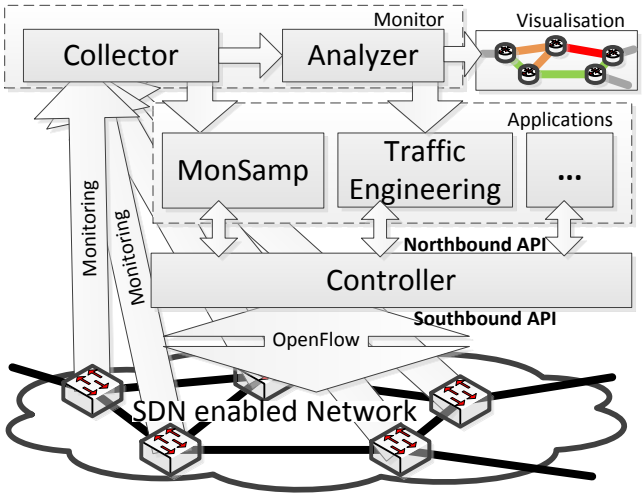

Fig. 1: SDN with integrated monitoring application

Fig. 1 displays an SDN with integrated monitoring functionality. The monitor receives parts of the network traffic for analysis. A sampling application called MonSamp decides which flows to duplicate and send to the monitor. The monitor consists of different modules (here collector and analyser) that are connected adequately for monitoring purposes. The reactive flow sampling application (MonSamp) receives information from the collectors regarding their current workload. Using this information the flow sampling can reactively decide to reduce the number of flows (to avoid random drops). If the links are not working to capacity and the collectors are not fully utilized, the amount of flows can be also be dynamically increased. The selection range for traffic replication is transformed into OpenFlow rules that are installed on the switches by the controller and the Northbound API. In order to allow different applications on top of a controller to interact within the same network slice the Northbound API has to provide abstraction and the ability to combine the behaviour of different applications to a consistent controller behaviour. For example, the monitoring rules must not overwrite or supersede rules required for forwarding of the productive traffic. On the other hand we define a specific interface for communication between the monitor and the flow sampling application. MonSamp uses thresholds to adjust the amount of monitoring load that is forwarded by the SDN enabled devices to allow monitoring without drops. Thereby it mitigates the tail drop behaviour of classical monitoring ports on network devices that occurs whenever a buffer is full. These thresholds are dependent on the concrete monitoring setup and have to be set according to it. MonSamp allows the configuration of monitoring destinations, so that the workload can be split amongst multiple monitoring instances, either though a dedicated physical monitoring network or through a virtual monitoring network. The sampling application also ensures that packets belonging to the same flow are replicated and monitored on all monitoring devices (capacity permitting), thus allowing meaningful correlation. The design supports horizontal and vertical scaling of monitoring systems: It can balance the load to both different monitors with redundant capabilities and different monitors with different objectives (e.g. to a security and a QoS monitor).

In general we cannot assume that all applications running on the Northbound API are reactive. In fact, reactive rules are expected to make the controller a bottleneck of the network [22]. So whenever rules are installed before they match flows or when rules use wildcards the flow sampling application needs information about which flows to replicate for monitoring. The use of event-based OpenFlow messages can again degrade the performance of the controller. To bootstrap the knowledge we imagine to have an ordinary monitoring link. The traffic on this link can be analysed and can serve as input for the flow sampling application. For gaining knowledge about existing flows the random drop behaviour is unproblematic. Another solution is the use of wildcard rules that may be problematic for the switch performance (c.f. section IV-E).

One of the design goals of MonSamp is to avoid any negative influence to the productive traffic. That includes the resources used on the OpenFlow enabled devices. Therefore MonSamp limits the number of installed OpenFlow rules for the monitoring. However, controllers currently do not have any awareness of the performance implications of the installed OpenFlow rules, because the OpenFlow protocol lacks this kind of information [23]. This limitation will be discussed more thoroughly in section IV-E on infrastructural requirements.

IV. Case Study

To provide a proof of concept and to demonstrate the feasibility of our proposed architecture we implemented MonSamp as a prototypic flow sampling application for SDNs and performed experiments for evaluation.

A. Prototype

As discussed in section III-A the definition of the Northbound API is an ongoing process in the community. For our

prototype implementation the Northbound API Pyretic seemed the most fitting. The domain-specific language Pyretic is a successor of Frenetic [24], was published in 2013 [17], [25], and rapidly gained attention. We decided to use it for the following reasons: Pyretic allows for automatic combination of different SDN applications. It provides the required level of abstraction and internally uses the POX controller to communicate with the OpenFlow switches. Pyretic supports both `reactive` and `proactive` applications. It can also be run in an `interpreted` mode, where every packet is sent through the controller. Both Pyretic and its applications are written in Python making things fairly easy to debug and extend in case of unexpected roadblocks. The downside is the relatively low performance, which is not critical for a prototype. We do not claim our choice of the Northbound API to be the silver bullet or a general best practice decision.

The flow sampling application is responsible for deciding whether a newly arriving flow is monitored. The flow sampling application maintains the currently free capacity of the monitor (and the link to it) in its knowledge base. Based on this information the flow sampling application limits the number of flows to be monitored. It does so by computing a direction-independent hash of the flow 5-tuple and selecting the flows within an adjustable hash-range. We achieve direction independence by lexicographically sorting of the destination and source (IP, port)-tuple before hashing. For each monitored flow MonSamp installs a rule into the OpenFlow switches that triggers the action to send a copy of the matched packets to the monitor.

The described prototype focuses on the evaluation of the MonSamp application. Therefore we implemented the monitor as a stub that runs on Linux. It gives feedback about the current level of received traffic to the flow sampling application. Currently we transmit this feedback on the same link that connects the monitor to the OpenFlow switch. There is no interference between the incoming monitoring traffic and the outgoing feedback as Ethernet provides exclusive channels in each direction. A permanent OpenFlow rule on the switch creates connectivity from the monitor to the flow sampling application.

B. Implementation of the Test Scenario

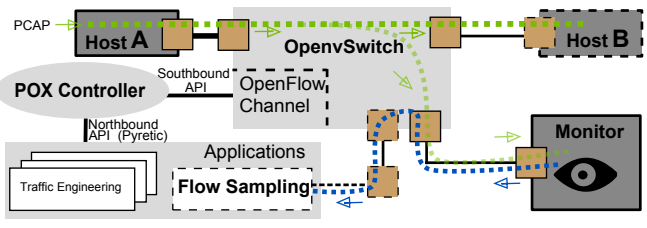

Fig. 2: Realization of the test setup with Mininet

For our case study we used the network emulator Mininet [26] as it allows execution of reproducible network experiments with real world traffic and functional realism [27]. The setup is illustrated in Fig. 2. We created a Mininet topology containing three nodes connected by an Open vSwitch. Mininet separates the hosts by using separate network name spaces, a feature provided by the Linux kernel. As the controller in the default Mininet setup is not part of separate namespace, we added an additional port to the switch and connected it to the root namespace. The flow sampling application, which runs on top of the Pyretic Northbound API, uses this port to communicate with the Monitor. To simulate an application for steering the productive traffic we implemented an application that simply forwards all traffic from Host A to Host B regardless of layer 2 addressing. This allows us to inject traffic containing multiple conversations between different hosts into our test setup. For simplicity we assumed that the productive application acts reactive. Thus the controller notifies the flow sampling application on the arrival of new flows.

C. Measurement Results

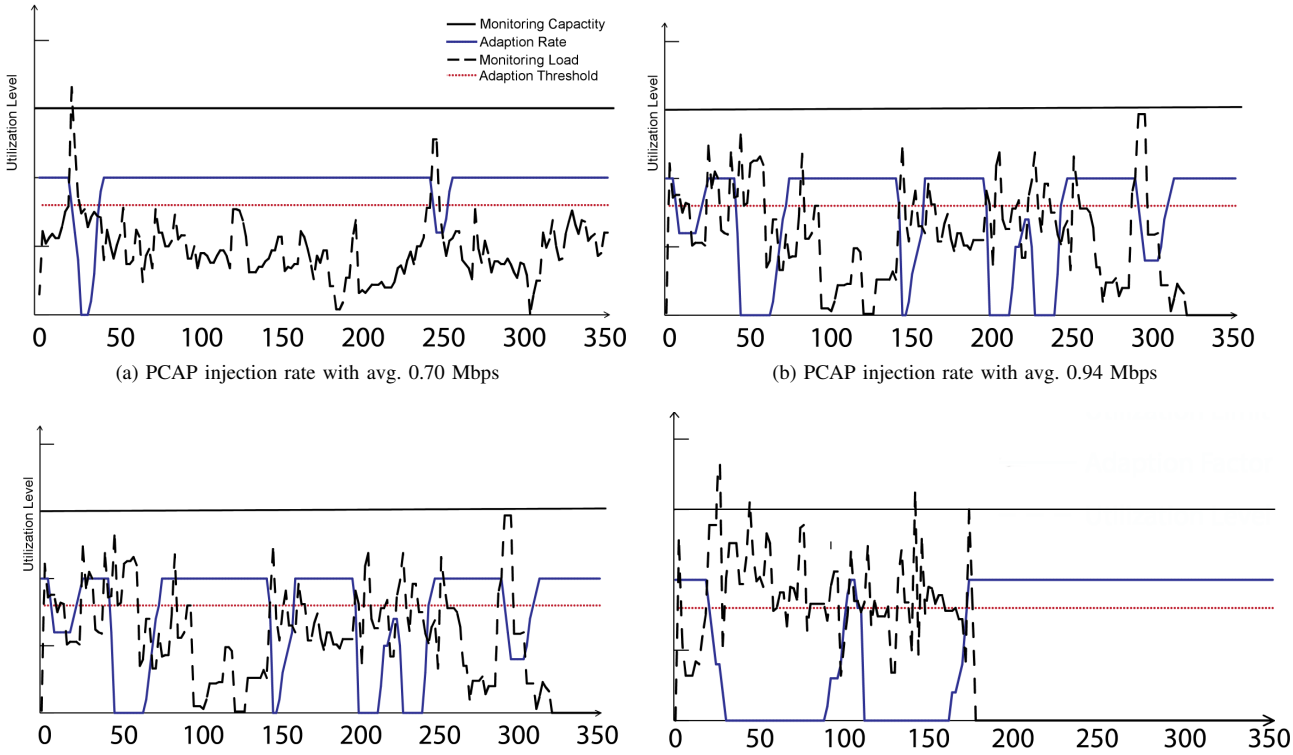
For a first concept evaluation we performed test runs with a real network trace taken from parts of our campus network. Although pseudonymized, we consider the traffic as realistic as the trace contains all connections passing our gateway node which is used by a group of more than 40 students and researchers. The PCAP trace contains 18,000 packets, distributed into 140 TCP and 53 UDP flows. Therefore we created a testing scenario where from the view of the switch and the controller not only two (host A and B) communicate with each other, but more than hundred pairwise different hosts. However, this scenario is representative for real world networks as host A and B represent next hop neighbours of the switch. The monitoring link has a bandwidth of 1.0 Mbps, which we chose as an exemplary link limitation that the Mininet tetbed still can serve without problems.

Figure 3 shows the monitoring utilization during the replay of previously recorded real world traffic through our test setup with four different average speed levels: 0.70 Mbps, 0.94 Mbps, 1.17 Mbps, and 1.40 Mbps. Our application is configured to keep monitoring utilization at 50 % of the theoretical capacity (red doted line). For these initial measurements we assume the limiting factor for monitoring to be a constant link bandwidth. Another relevant factor can be the dynamically changing CPU utilization [13]. The blue line represents the adaptation factor that is the input parameter for the decision function to determine the ratio of new flows to be monitored. The dashed line is the real bandwidth processed by the monitoring system. The Monitor reports this back to the MonSamp application.

The tests show that monitoring of flows without uncontrolled drops in the monitoring system is possible. The few areas where the monitoring load exceeds the capacity are mainly caused by the relative big impact of elephant flows, which are flows that contain a very large share of transferred bits of the overall traffic. We do not expect this to be a problem when applied to high-bandwidth scenarios where new flows are created and old flows are finished more frequently. Thus the impact of a single flow in relation to the total amount of traffic is lower.

D. Open Issues with the Northbound API

Unfortunately, Pyretic – the Northbound API we chose for our implementation – is currently not suitable for realising our



(a) PCAP injection rate with avg. 0.70 Mbps

(b) PCAP injection rate with avg. 0.94 Mbps

(c) PCAP injection rate with: avg. 1.17 Mbps

(d) PCAP injection rate with: avg. 1.4 Mbps

Fig. 3: Sampling adaptation for different bandwidth utilizations

monitoring vision in a meaningful way. The main limitation is the lack of a policy that can make a decision based on an incoming packet. The dynamic policy, as supported by Pyretic, only allows adjusting the policy for future packets, not for the one that is being processed. This means that a default policy decision for the MonSamp application is required – either the first packet of each flow is always monitored or it is never monitored. Because (unless running in interpreted mode) the default policy decision for each flow gets pushed to the OpenFlow enabled hardware, subsequent packets are handled directly on the OpenFlow hardware and not sent to MonSamp any more, rendering the policy-adjustment useless.

Furthermore, Pyretic and other reviewed Northbound APIs for SDNs lack control for the rules that are installed on the OpenFlow switch. Rules are automatically installed based on every decision and applied to the whole flow. It is not possible to define additional rules (e.g. the reverse flow) to be installed or changing the header-fields used for identifying a flow.

E. Infrastructural Requirements

The application of our vision requires both, hardware and software features that provide fields for research. Our monitoring concept requires a scalable controller architecture that provides a reasonably powerful Northbound API. We expect that the desired controller infrastructure will exist in the near future, since first steps were already taken [22], [19]. Thereby the development process of controller software and architectures benefit from the low market barriers, numerous players, and almost no proportional costs for additional features of software developments. These characteristics do not apply for hardware OpenFlow-switches. These switches may support OpenFlow 1.3 – at least after updates of firmware – but still suffer from processing in software on the general purpose CPU if certain OF rules are defined. This results in an extreme heterogeneity of switch behaviour [23] that may lead to poor forwarding performance and an unpredictable capacity for stored OpenFlow rules on the switch. As an example the HP OpenFlow Guide [28], which applies to switches in our testbed, only states forwarding to a single port, dropping, and modification of the IP TOS and VLAN-PCP field as actions that can be executed in hardware; all other actions are executed in software and therefore limit the processing capacity of the whole switch to a rate of around 10,000 packets per second. In virtual switches like Open vSwitch the replication of traffic only introduces a comparatively small and constant overhead per processed packet. The exact overhead is defined by the network stack that is used to send out the traffic to the monitoring system (e.g. to a VM, or to a physical connection). Better optimized hardware for OpenFlow and feedback channels from the OpenFlow switches via the Northbound API to the applications can solve these problems.

V. Related Work

Related work in network monitoring is primary motivated by security concerns and dates back some years. E.g. in 2005 Schaelicke et al. [29] discussed requirements for parallel network monitoring and proposed an architecture for adapting

load balancing of security monitoring traffic. Limmer and Dressler created an adaptive load balancer for NIDS systems. It uses sampling to cope with high bandwidths [30]. It dynamically maps flows to NIDS processes. To alleviate issues resulting from packet drops they use flow sampling, which guarantees loss-free analysis for selected flows.

When monitoring the QoS it is an advantage that a network problem resulting in degraded performance will affect a whole class of flows that share some properties (i.e. routed through an overloaded device and use the same QoS class). Thus, unlike for security purposes, it is sufficient to monitor a representative subset of the network flows which makes QoS-Monitoring eligible for sampling. As we do not provide a new sampling technique we just highlight the long history of sampling dating back to mathematical work on statistics over many decades. For a focused introduction we refer to work of Claffy et al. [31] (general overview), Carela-Español et al. [32] (study of sampling influence for traffic analysis), Braun et al. [13], who recently implemented an adaptive sampling within a monitoring system to mitigate tail dropping behaviour within the overloaded system, and referenced in there.

Using OpenFlow switches for load balancing services (e.g. web servers) in data centres was one of the first use cases of OpenFlow switches. In 2009 Handigol et al. used a reactive NOX controller to minimize response time for load balanced web servers without IP address rewriting [33]. Uppal and Brandon also described a reactive NOX-based load balancer that does address rewriting [34]. Wang et al. presented a NOX based, proactive load balancer that uses wildcard OpenFlow rules with the motivation that reactive approaches causes undesired load to the controller [35]. The controller assumed that the load of each server is proportional to the number of flows directed to it, but did not consider feedback from the servers. Due to their flexibility and the resulting capabilities, OpenFlow switches have also been recognized as a powerful tool for solving scalability issues in network monitoring. For instance big switch network already sells Big Tap, a network monitoring solution [36], [37]. Big Tap uses a separate OpenFlow enabled (monitoring) network equipped with monitoring systems to deliver, filter, and analyse traffic in a scalable manner. Recently Shirali-Shahreza et al. proposed a concept for OpenFlow based traffic sampling called FleXam [38], [39]. They demonstrated how OpenFlow functionality can help detecting attacks in the network [38].

VI. Conclusion

In this paper we described our vision on traffic monitoring in SDNs. Our architecture is scalable and cost efficient because utilizing the already existing OpenFlow functionality does not add any additional costs. All special monitoring functionality is provided by flexible software. We designed an SDN application for extraction and sampling of network traffic directly from the data plane that can be added to other applications via the SDN Northbound API. The application addresses unsolved and solved problems in (QoS) network monitoring with high flexibility and low costs. Thereby we also contributed to the open topic of the canon of SDN applications and requirements for them (c.f. [5]). We implemented a prototype and performed different measurements on it to demonstrate the feasibility of our approach.

Our future work comprises the transfer of our application into a real test environment which also provides more than one switch. Thus we can extend the value of our architecture evaluation beyond functionality (Mininet [27] only provides functional realism). We plan to perform a more sophisticated evaluation, transfer the application to other controller platforms like Ryu, and combining it with monitoring systems like the one proposed by Braun et al. [13]. We also plan further refining to support multiple different limits where each may dynamically interfere as bottleneck and consider sampling coordination together with vertical and horizontal balancing of monitoring loads. These steps should point out required features in future SDNs and demonstrate (e.g. technical) limitations of available SDNs.

Acknowledgments

This research has been supported by the EU as part of KIC EIT ICT Labs on Software-Defined Networking (SDN) and the German Federal Ministry of Education and Research (Bundesministerium für Bildung und Forschung; BMBF) under support code 01BP12300A; EUREKAProject SASER. We also would like to acknowledge the valuable contributions from our colleagues Peter Schaab, Florian Wohlfart, and Lothar Braun to the implementation and maturing of our vision.

***Abstract*—The paper presents POI Explorer mobile application aiding the visually impaired in spatial orientation and in urban navigation. A user equipped with a smartphone with accelerometer, electronic compass, mobile data transmission and positioning capabilities can access information on nearby points of interest. Maintaining data connection with dedicated system servers provides access to additional services facilitating the navigation in urban areas. The paper describes an overall architecture of the system. Then, the details of the user interface of the application are presented. The user interface of the application was designed to meet both the needs of visually impaired users and the requirements imposed by dynamic data changes. It employs a unique combination of text-to-speech and sonification techniques to ensure clarity of messages as well as high responsiveness of the application. The results of experiments performed in areas with different densities of points of interest proved the usability of the proposed approach.**

***Index terms*—Location-based services, mobile computing, pervasive computing, electronic aids, visually impaired**

I. Introduction

RECENTLY, a number of electronic travel aids (ETA) addressing the needs of the visually impaired have been developed [1-9]. Such systems can be used to overcome difficulties with spatial and geographical orientation and navigation, and facilitate access to various public services. Those difficulties become especially cumbersome in urban areas. Lack of good spatial orientation makes difficult to find a safe path among obstacles, and to locate and identify points of interest (POI) like bus stops, offices, restaurants, or even pedestrian crossings [1].

Dedicated electronic travel aids play a vital role in aiding the visually impaired in everyday activities. Such assistive devices are usually equipped with a GPS receiver to provide precise information on user terminal position, GSM/UMTS transceivers, inertial sensors, and a speech synthesizer enabling auditory form of presentation of various data to the user [2, 4, 8-9]. Such devices can usually be carried in a pocket [2, 4, 9] and because of dedicated user interfaces (tactile keyboards, text-to-speech and speech-to-text systems) are easy to use by visually impaired users [2, 4, 9]. Most of dedicated ETAs allow to lead visually impaired or blind users along previously recorded routes. They also store databases of POIs, which can serve as an aid in orientation. Due to the fact that such devices are produced only in short series, the build quality and functionality of such solutions may be far from that of massively produced electronic devices. The main disadvantages limiting the popularity of such systems include difficulties in upgrading software and high unit costs.

With the growth of popularity of advanced mobile phones, more and more applications aiding the visually impaired in navigation and travelling appear on the market [10-17]. Modern phones are usually equipped with advanced positioning capabilities as well as in a range of additional sensors, like accelerometers, gyroscopes or magnetometers. ETA solutions using mobile phones as user terminals may benefit from the use of detailed digital maps from different providers, like Google Maps, Bing Maps, OpenStreetMap, etc. in combination with satellite (GPS, Glonass) or network (cellular, Wi-Fi) based positioning techniques. Also, mobile phones usually are equipped with good quality speech synthesizers facilitating communication with visually impaired users.

Since most of the users use the built-in text-to-speech and sonification systems, such as VoiceOver [18] or TalkBack [19], navigation applications are adapted to work with these systems. For this reason, application user interfaces use standard system components like buttons, text boxes, lists, etc. The drawback of such an approach is the lack of adaptation of very small items (which you must specify for the sonification) to the screen reader systems, or long, scrollable lists with dynamic contents.

This article describes a novel approach to presenting information about the POIs using combination of text-to-speech and sonification techniques. The remainder of the paper is organized as follows. Section II provides an overview of the system architecture while Section III gives details of the POI Explorer mobile application functionality. A proposed approach to auditory presentation of POI data is described in Section IV, and the results of application tests are presented in Section V. Finally, Section VI summarizes our work.

II. System Architecture

The architecture of the proposed system for guidance of visually impaired in urban environment is shown in Fig. 1. The system consists of two subsystems: application servers and mobile user terminals with dedicated applications.

This work was partially supported by the National Centre for Research and Development of Poland under grant no. NR-02 0083-10 in years 2010-2013.

The mobile user terminal is an Android OS based smartphone equipped with a dedicated POI Explorer mobile application. Since the application uses Sensors API of the operating system, it can be run on devices with Android OS in version 2.3 or newer. The details of the application are provided in Section III.

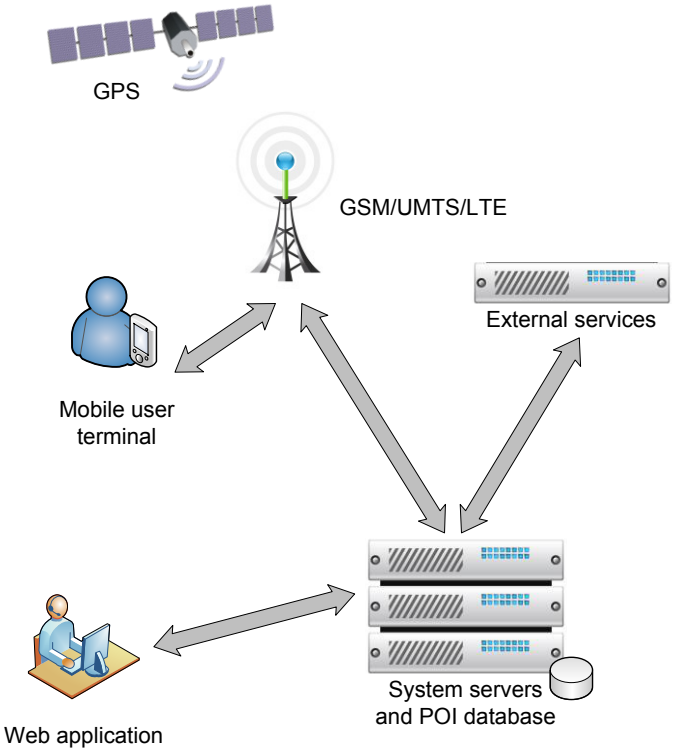

Fig. 1. Architecture of the electronic system for guidance of the visually impaired in urban environment.

The main function of the system server is storing a database of points of interest. The prototype solution uses MySQL relational database management system. POIs are organized into categories and subcategories, what allows to find necessary information easily. The POIs stored in the database can be both public and private. The public POIs are available to all the users of the system, while the private ones are accessible only to the owner. Users can also add additional personalized information to the points (text notes, voice recordings) to enrich the database.

The server also hosts web application for remote POI data management. The web based application (Fig. 2, Fig. 3) uses PHP and AJAX and is dedicated for sighted users assisting the visually impaired and blind. The management application allows to add and remove points of interest. It is also possible to define new categories of the POIs as well as hierarchy of the different categories of points. An important functionality of the system is the ability to define routes which the visually impaired can follow. This may be for example a route leading to the office, shop, etc. The routes can be created in one of two ways: from the POI Explorer mobile application and from the aforementioned web based management application. Examples of such predefined routes are shown in Fig. 2. The management application allows also to delete or change the order of the points in a route.

The data are exchanged between the POI Explorer mobile application and the system server in an XML format. Examples of XML system messages are presented in Fig. 4 and Fig. 5. Hierarchical structure of XML documents allows elastic and extensible POI category management. Moreover, such a solution allows to provide a universal application programming interfaces (API) to other, external platforms. For example, it is possible to import waypoints and routes from external sources like Loadstone database [11].

III. SMARTPHONE BASED URBAN NAVIGATION – POI EXPLORER

The first version of POI Explorer application aiding the visually impaired in moving in the urban area was developed for Symbian OS based mobile phones [20]. As Symbian based devices no longer play an important role on the market, the application had to be migrated to a new platform.

Nowadays iOS and Android based mobile phones are of a special interest for blind and visually impaired users. The reason for that is that both the systems offer built-in and well integrated with the operating system text-to-speech modules: Voice Over (iOS) [18] and TalkBack (Android) [19]. Availability of such high quality system modules allows developers to create their own applications using standard GUI elements which can be easily presented to the visually impaired users. Moreover, most of contemporary smartphones are equipped with touch screens and offer gesture-based screen readers supported by multitouch capabilities. For example moving a single finger over the list causes a list item to be read, while moving of two fingers can be used to scroll the list.

After market analysis and discussions with representatives of the target group of POI Explorer users, we have decided to select Android Operating System based devices as a target platform. According to ABI Research Android is the most popular operating system (77% share in Q4 2013) [21]. In 2013, according to Gartner Android market share was 78,4%, while iOS 15.6% [22]. Another advantages include lower costs of Android phones in comparison to iPhones as well as availability of more accessible low-end devices.

The development of the application was based on test results of previous releases for Symbian based mobile phones as well as initial releases for Android OS based devices. About 20 blind and visually impaired volunteers received the aforementioned applications for testing purposes. The volunteers from different regions of Poland were recruited through an advertisements on Loadstone [11] mailing lists. Although now deprecated, at that time Loadstone was one of most widely used applications for navigation of the blind and visually impaired. The users of competitive application positively rated the idea to use a compass to determine the direction of movements (instead of analyzing history of GPS values). There have been requests for the adding information on the number of satellites used to calculate GPS coordinates, which allows them to rate, how much they can trust the messages returned by the application. There were different opinions about the possibility of downloading lists of POIs around the current position of the user. On one hand, a visit to another city does not require prior preparation of a list of points of interest, on the other hand there were concerns that data for some reason would not be downloaded. There were a lot of positive comments about organizing POIs into categories and subcategories, because it allows to reduce the number of points to be presented to the user.

Graphical user interface layout and functionality of POI Explorer mobile application have additionally been consulted with blind and visually impaired users from the Polish Association of the Blind. As the result, the graphical user interface of POI Explorer (Fig. 6, Fig. 7, Fig. 9, Fig. 11, Fig. 14) uses large, high contrast characters aiding users with moderate visual impairment. Also, system requirements of our applications allow to run them on low cost devices.

To use the application, the user needs to set up his/her system account. This is an optional step, however it allows to store private points of interests and routes. It also enables the possibility to adding notes and voice description to POIs. When the user runs the application for the first time, a list of POI categories is downloaded from the server. Moreover, for a selected area (the user can define its radius) a range of POIs are downloaded and stored in local database. It allows the use of the application without maintaining Internet connection.

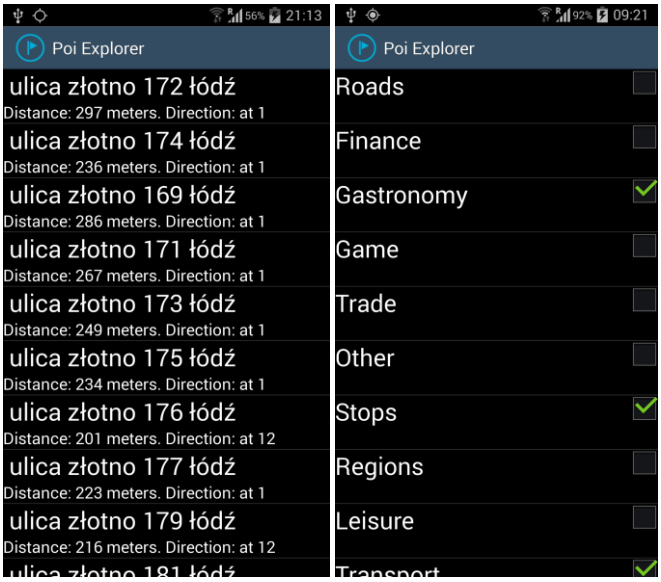

Fig. 6. Screenshots from the POI Explorer application captured by Samsung Galaxy S4 Android Phone with KitKat 4.4.2. The list of the points of interests in the front of the user (direction is calculated based on compass values) are presented in a standard listbox. On the right: list of categories, each of them can have unlimited number of subcategories.

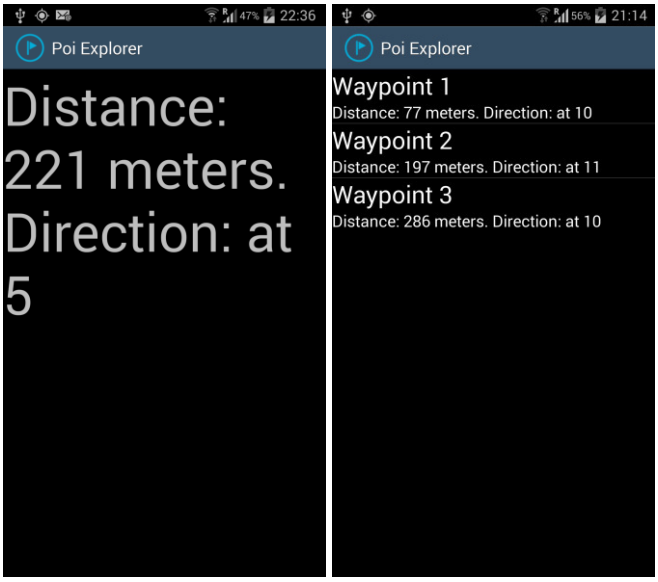

Fig. 7. Screenshots from the POI Explorer application captured by Samsung Galaxy S4 Android Phone with KitKat 4.4.2. On the left: mode distance/direction, on the right: list of waypoints obtained from the Google Maps engine.

The POI Explorer supports the navigation of the blind users in one of three different modes. The users can choose navigation: along a predefined path, to the selected point (e.g. a bus stop), or in a "look around" mode. The distance to a given POI is calculated based on readings from the built-in GPS receiver, while orientation in the area is calculated on the basis of the values returned by the compass module. The data for the user are being refreshed on demand and take into account the current readings of the two aforementioned sensors.

A. Navigation to the specific point

In this mode, the user picks from a list of points of interest any entry. Then the user receives the information about the distance of this point from the current position and direction to the point expressed in the "per hour" mode. Orientation is determined relative to the current position of the phone and the point. POI Explorer calculates the angle between the orientation of the phone (from the compass) and the orientation of the target point, which is then converted to the appropriate "hour". Example message is shown in Fig. 7. In addition, the user can designate the route to the point using Google Maps mechanism, which returns a list of waypoints.

B. Navigation along a recorded path

User have possibility to register the route and determine intermediate points like intersections, characteristic points etc. Example of such route is shown in Fig. 2. The route most often is created with an assistance of a sighted person. The user is guided to the each of the waypoints as described in section IIIA. When the waypoint is reached, POI Explorer changes the destination point to the next one from the list. This mode is most liked by the target group of users due to the possibility of creating waypoints in a supervised way.

Automatic determination of intermediate points is also possible. In this case, there is a risk that the algorithm will not take into account slight changes in direction of the route. Moreover, in this mode it is not possible to automatically add information on dangerous locations, such as defects in the roadway, etc.

C. Look around mode

Look around mode is one of the most important features of POI Explorer especially useful in unfamiliar locations, for example, in an unknown city. A list of points of interest within a certain radius with the indication of the distance and direction is presented to the user. The blind person can restrict presented points only to selected categories. An example of such filtered list is shown in Fig. 6.

POI Explorer was written taking into account the suggestion from the target group of users. Some application capabilities have been developed as the result of requests from our testers. These for example include the use of a compass to determine direction (usually applications determine direction based on the history of GPS values) or importing data from the Loadstone, very popular platform aiding blind and visual impaired people for Symbian OS [11].

Unfortunately, interaction with a touchscreen of a smartphone requires the use of both hands and may be especially uncomfortable for blind users, who at the same time are often using a white cane. Moreover, screenreaders are not very convenient for sonification of dynamic GUI controls.

The tests with the target group of users revealed that the main problem for them is the way of sonification by built-in screenreaders. Every change in the user interface (for example resulting from an update of a text field, or from appearance of a new item in the list) implies that the user is informed about that change. Finding the selected POI often requires reading of the entire list of points (Fig. 6). Any update of the interface contents may interrupt reading of the items from the list and force re-reading of the entire information about the screen elements. In addition to that, every change of position (due to changing user's position or fluctuations in GPS or compass readouts) causes, that the list frequently changes its contents. Moreover, because the list is sorted by distance from the user, the order of the points in the list can also change. The user is notified by the screen reader on every such change. Excessive information becomes hardly understandable and confusing for the user. This problem has become an inspiration to propose another approach to presentation of information on points of interest located in the vicinity of the user.

IV. Sonified Presentation of Information On Nearby POIs

When designing the new method of presentation points of interest, to avoid the previously described problems, the following assumptions have been made:

- the usage of the application interface should be possible with only one hand. Due to the safety of the blind, it is advisable that the phone should be hidden in a pocket, and voice messages could be transmitted via the hands-free set;
- amount of conveyed information should be limited to the minimum, and the number of voice messages should also be reduced. Previously conducted experiments showed that the excess of voice messages is very tiresome and discourage users to use such kind of applications;
- it should be possible to reduce the number of points from the vicinity presented to the user at a single time;
- a way to read detailed information about the point being currently sonified should be provided.

To fulfill of all of the above requirements, it was decided that a unique short sound will be assigned to the each category of the POIs. The points will be presented to the blind person in the order of increasing distance from the user. Only the points located along a straight line (within a predefined angle) from the user will be presented.

After starting of the scan, a short audio message is played. A virtual circle of search is moving away from the user and when it encounters a POI on its way, a sound associated with given category of the point is played. After completion of playing the sound, the radius of the circle of search is increased until it reaches the next point from the user vicinity (Fig. 9, 11). Fig. 9 and 11 show application screens displaying the POIs found in the user vicinity, while Fig. 8 and 10 show these points on the Google Map.

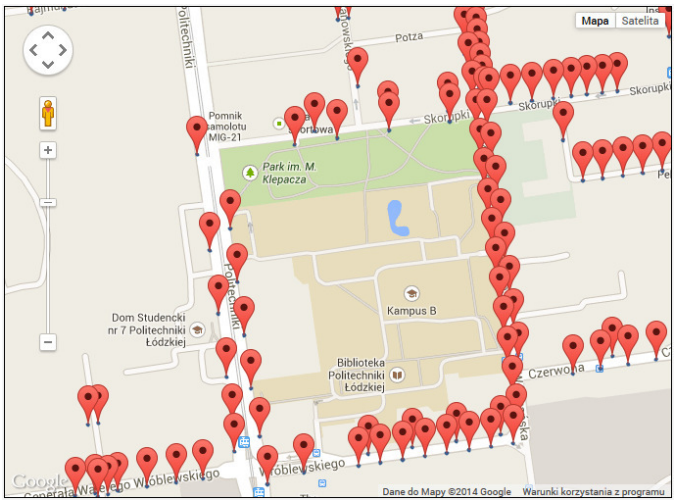

Fig. 8. POIs from the selected category Address shown on the Google Maps (screenshot from the web application). Number of POIs presented to the user is limited to 100. A fragment of the map corresponds to the area shown in Figure 9.

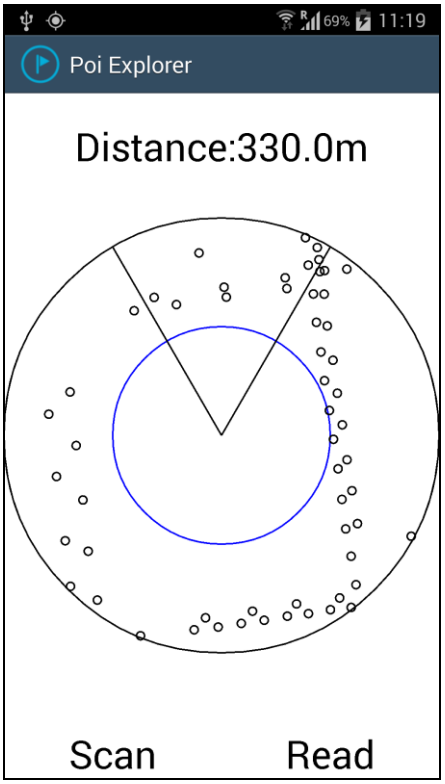

Fig. 9. Screenshot from the POI Explorer application captured by Samsung Galaxy S4 Android Phone with KitKat 4.4.2. Each point of interest from Figure 8 is marked with a circle.

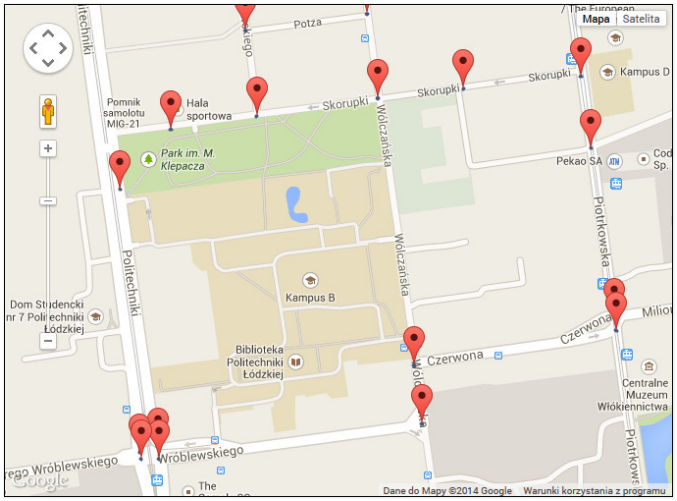

Fig. 10. POIs from the selected category Intersection shown on the Google Maps (screenshot from the web application). A fragment of the map corresponds to the area shown in Figure 11.

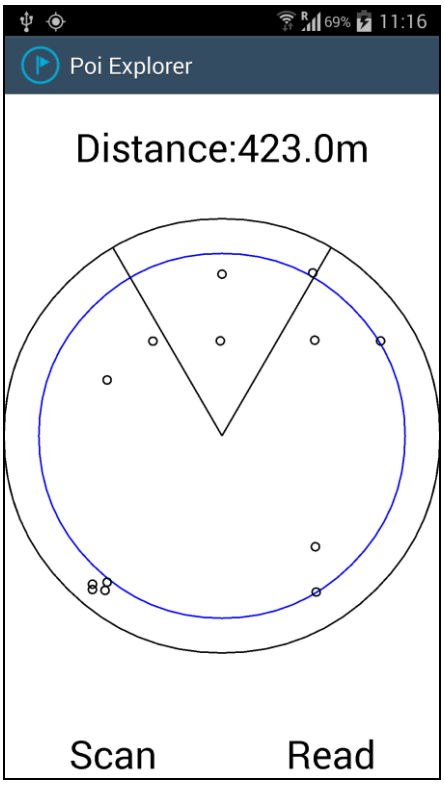

Fig. 11. Screenshot from the POI Explorer application captured by Samsung Galaxy S4 Android Phone with KitKat 4.4.2. Each point of interest from Figure 10 is marked with a circle.

Preliminary tests performed at early development stages revealed that updating the positions of points during the scan often causes confusion, because the scanning time strongly depends on the number of POIs and can take up to several seconds. For this reason, it is assumed that update of the positions of POIs in relation to actual user position occurs at the beginning of the scan.

In the application for navigation purposes we set out three control fields. The field at the top allows the user to change the scan range. The higher the x coordinate of a touch point, the larger the scan area. Change (releasing) the touch location on the screen sets the new value of the radius of the scan, the selected value is read to the user. Scan area at the bottom of the screen causes that scan starts from the beginning. It may be useful at a time when the user changes its orientation and wants to start scanning points after update their relative position. Field Read allows to read information about the recently sonified point. When the user selects this option, the distance of the point and its orientation relative to the user is read.

Internal tests have shown the system accuracy decreases with the growth of the number of points to be presented. An example of such a situation is shown in Fig. 9. Points arranged in lines represent neighboring buildings along the street. Fig. 8 shows the presented area on the Google Map (only addresses and intersections are shown).

To make it easier to read the information about points we introduced manual mode, which uses the readouts from the accelerometer to control the presentation of the POI list (Fig. 12).

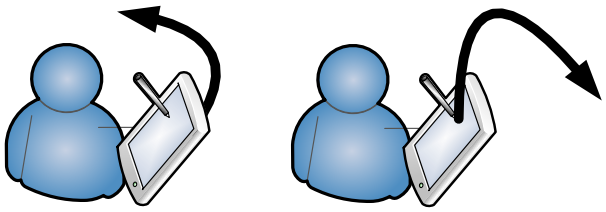

Fig. 12. Gesture based control of the device – Move to the previous POI (left), Move to the next POI (right).

A move of the phone downwards stops scanning and information about the next point on the list is read. Contrary, the upward gesture starts reading of the information about the previous point. The threshold values of data from the accelerometer readings were chosen to eliminate false gesture detection. Our solution allows to manipulate the phone hidden in the jacket pocket. At any time it is possible to finish manual mode and start automatic scanning.

A. The use of built-in motion sensors for gesture recognition

Motion sensors: gyroscope, accelerometer, gravity sensor, linear acceleration sensor can be utilized in finding user gesture patterns. They measure acceleration forces and rotational forces along three axes. Some of them are hardware-based, while others are software-based: they derive data from one or more hardware sensors. Accelerometer sensor measures acceleration force in SI units that is applied to the device on all physical axes. The values include the force of gravity. Gravity sensor (which can be a software sensor) measures only the force of gravity. Gyroscope returns device's rate of rotation around each of the three axes. Linear acceleration works like the acceleration sensor, but values exclude the force of gravity. Not all the sensors are available on every device. For example gravity sensor is not available on devices with API versions lower than 9. Android allows to determine the capabilities of sensors, like maximum range, resolution etc. These values can

differ between devices. It is also possible to get notifications on accuracy changes or when a sensor reports a new value. Each log file entry also contains a timestamp [23].

Block diagram of accelerometer based gesture recognition is shown in Fig. 13. All values (x, y, z components) returned by accelerometer are in SI units. Because a sensor measures acceleration applied to the device, the values returned by the device include gravitational acceleration. During gesture detection we take into consideration only values of y component. Initially, we expect to begin a gesture. It is a condition in which the user is holding the phone horizontally ($|y|<Th_{y1}$). Then we expect to perform the gesture. The user must tilt the phone up or down. If ($|y|>Th_{y2}$) an appropriate action is performed. To detect another gesture, the phone should return to the horizontal position. The algorithm works only when the gravitational acceleration is only applied to the device. All values not satisfying criteria (1) are ignored. During the tests with Samsung Galaxy S4 device, the Th_{y1} and Th_{y2} threshold values were set to 2 and 5 correspondingly.

$$8 < \sqrt{x^2 + y^2 + z^2} < 10 \qquad (1)$$

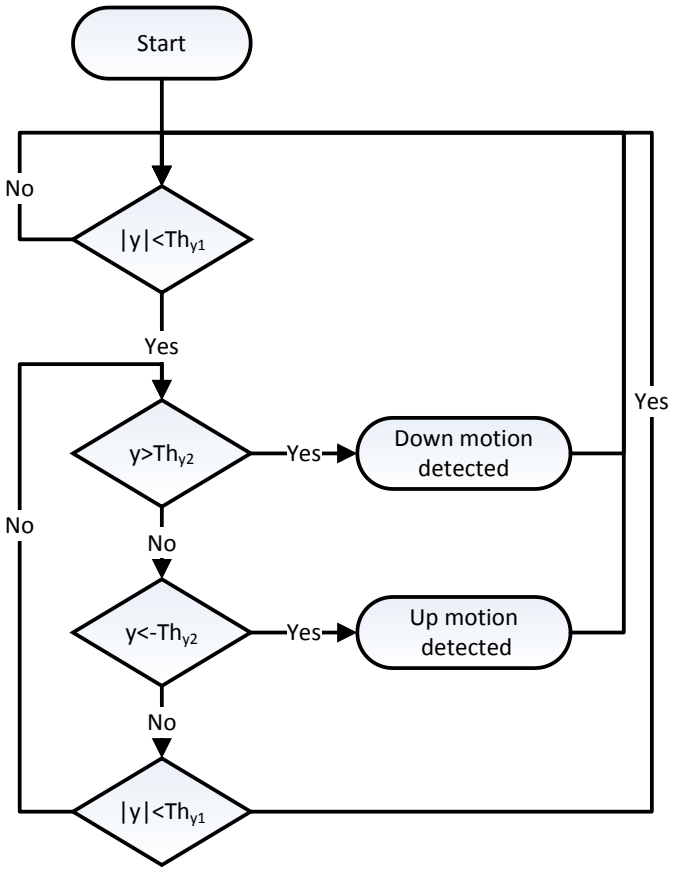

Fig. 13. Accelerometer based gesture recognition – block diagram of the algorithm.

V. APPLICATION TESTS

Application tests were carried out in selected areas of the city of Lodz, in places containing a large number of points of interest. As a test platform we have chosen Android 4.2 and 4.4.2. Fig. 14 shows POI Explorer running on Samsung Galaxy S4 mobile phone. A group of several sighted volunteers at different age and with different familiarity of mobile technologies was involved in the tests.

An option to specify the radius of the scan turned out to be a good solution. It allows to eliminate the problem of too high number of points to be presented at the time. Accelerometer-based control worked properly, there were no problems with reading information about the points in the vicinity. Testers pointed out that despite the possibility to specify the categories of presented points, there should be an option to hide unnecessary points.

During the tests of the application, time of a complete scan was set to about 15 seconds. In case of several points in the vicinity, it was the optimal time for selecting the chosen point of interest by the user.

The active fields (the slider for setting the distance, Scan and Read buttons) in the GUI seem to be well matched. We did not notice problems in locating these fields, even while the phone was kept in the user's pocket.

Fig. 14. POI Explorer launched on Samsung Galaxy S4 Android KitKat phone.

The tests of the application revealed the limitations of audio playback system on Android OS. Playing short audio samples indicating the points ran smoothly. The system allows to play several audio samples at the same time. Playing a voice message interrupts the previous message. Fortunately, it is possible to play sounds when reading messages by Text-To-Speech engine.

Since most of contemporary mobile phones are equipped with electronic compasses, these can be kept in a pocket and the user can use the compass readouts for the orientation

purposes. Text to speech TalkBack service of the phone can be used to read system messages and POI descriptions to the user.

VI. SUMMARY

Although many electronic travel aids have been developed so far, urban areas still remain hardly accessible to the visually impaired. Poor spatial orientation and inability to access textual information makes difficult to move around the cities. Development and growing popularity of new generations of advanced mobile devices opens up new opportunities to create inexpensive and efficient ETAs for the blind and visually impaired. Even inexpensive mobile phones are nowadays often equipped with reasonably good quality sensors (compass, accelerometer, A-GPS receiver). In addition, speech synthesis, text-to-speech and speech recognition systems allow to offer alternative communication interfaces to visually impaired users. Using general purpose mobile devices as platforms for development of ETAs lowers deployment costs of such systems and as a result the user can carry around only a single device instead of a range of devices dedicated to different purposes. Also cloud computing and storage solutions provide higher security and facilitate access to user data in the case of a change of the device.

The system described in the paper is primarily intended to aid the visually impaired in urban navigation. It uses a novel approach to presenting information about the points of interest in the vicinity of the user. The combination of text-to-speech and sonification techniques allows to effectively reduce the amount of excessive information presented to the user and overcome the limitations of popular screen reader systems.

Currently, our efforts are focused on preparation of the release candidate version of the application, that will be made available to a wider group of blind and visually impaired volunteer testers.

***Abstract*—Over the last years websites have evolved rapidly incorporating new content types and becoming more and more dynamic. Users today are able to access a wide variety of content and services through their web browsers. As a consequence, web traffic has become increasingly complex and, from a network perspective it can be difficult to ascertain which websites are being visited by a user, let alone which part of the user's traffic each of them is responsible for.**

Although there is an extensive literature on the new characteristics of web traffic, few works have focused on a connection level perspective even if this kind of data is easily available for network administrators. In this paper we offer a characterization of webpage download using connection level metrics. This description is a first step in developing techniques able to identify individual webpage downloads in real traffic.

We have captured an extensive dataset of more than 20,000 webpage downloads that we study in order to provide different connection level based metrics. We study how these metrics vary between different webpages of different popularity and complexity. In the end, we attempt to provide a general modelling of a normal webpage download.

I. Introduction

THE web is probably the classic Internet application that has grown and evolved the most during the past two decades. The simple and mostly static webpages of the 1990s have given way to much more complex sites. This complexity is represented, in the first place, by adding a wide variety of content types (like videos, scripts or interactive media) to the text and images that classic webpages traditionally hosted. Nevertheless, modern websites not only offer these new content types, but they do so in a dynamic way, keeping their content current and tailoring their offer to each specific visitor. The network requirements introduced by all this and the ever-increasing popularity of the web have also pushed for improvements in the web application protocols and the development of new techniques, like content distribution networks (CDNs) or analytics services, that help in its operation. As a consequence, the web application has achieved a remarkable flexibility that allows it to provide a huge range of different services aside from traditional web browsing.

All these changes have obviously affected the profile of web traffic. Recent studies [1]–[3] show that its characteristics have greatly changed from the (simpler) ones described thoroughly in the 1990s [4]. This is partially the result of the introduction of HTTP 1.1: persistent connections and pipelining have made obsolete the notion that every connection comprises a single request/response pair. But, the truth is that the profile of web traffic has been specially affected by the new contents and services provided by the application. Nowadays, from a network perspective, accessing a webpage may imply establishing multiple connections to different servers while the elements of the webpage (often coming from third parties) are downloaded and, in some cases, user information is collected. The result is a set of a variable number of connections of different durations and sizes to multiple server IP addresses. Moreover, as a sizeable amount of the content is dynamic, these connections may change if the webpage is accessed at a different time or by a different user.

In this paper we present a study of those sets of connections established by clients during the download of webpages. Although there is extensive work in web traffic characterization the approach has usually been very different to ours. Many proposals center their study on server operation, modelling the behaviour and habits of the users that access the server in order to provide them the best possible service [5], [6]. Others have taken a more user-centric perspective but have focused on application-level operation [7], [8] or the characteristics of the downloaded content [9], [10]. Finally, other works have characterized specific types of web applications, usually with the intention of being able to classify their traffic [11], [12].

In our case, we consider our research from the client's point of view in the sense that we study the connections between the client and multiple servers through Internet and we do not have any information about the relationships between those servers or the content they host. However, even if we work from a client-side perspective, we only consider data that can be captured directly from the network rather than being "inside" the client monitoring its operation. All in all what we offer is a thorough characterization of the set of connections (and by connections we are referring to bidirectional TCP flows) initiated by the client during the download of a webpage.

This TCP-level characterization is interesting because NetFlow-type records [13] are easy to collect and, specially when compared to full packet-level traces, store and process in any network. Having a good description of the connections involved in the download of a webpage can be very useful for multiple purposes. On one hand current users access multiple webpages in short periods of time, often concurrently thanks to tab-based browsers, so it is far from trivial to guess which webpages (or even how many different ones) a user visits. This characterization may allow the development of techniques that help identify each individual webpage download, offering

978-83-60810-58-3/$25.00

insight into the user's behaviour. On the other hand, nowadays multiple applications mask their traffic in order to pass it off as HTTP and avoid certain restrictions that network administrators may want to enforce. Characterizing normal webpage downloads could help in designing anomaly-based detection systems able to identify that kind of applications.

The study we present in this paper is focused on website landing pages (*i.e.* the page served when the user inputs the domain name of the website). The characteristics of landing pages can be very different to those of internal pages (*i.e* accesed via links from the landing page) of the same websites. However, we are studying a wide variety of landing pages from 1,000 websites of different popularity. We believe that this is a sample with enough diversity to be representative of the characteristics of most webpages.

The remaining of this paper is structured as follows: section II explains the methodology used to capture experimental data and gives an overview of said data; section III discusses the general characteristics of a webpage download from a TCP connection point of view; section IV presents some time-based metrics that describe when the connections that participate in the download are opened and closed; section V focuses on the accessed servers; and, finally, section VI concludes and presents future lines of work.

II. Data collection

In this section we describe the data set we are going to use for our analysis in the rest of the paper. The traffic captures that integrate it were made during the months from August to October 2013.

A. Website selection and measurement setup

In order to collect a representative sample of webpage loads, we have selected 1,000 sites from the top 100,000 websites of the Alexa global ranking [14]. We have chosen the 100 most popular websites, 300 websites selected randomly from the 100-1,000 most popular ones, another 300 from the 1,000-10,000 range and the last 300 from the 10,000-100,000 range. With this, we ensure that the most popular (and interesting) sites, like Google, Facebook, or Amazon are well represented in the sample while also collecting data from a wide variety of less popular sites from all around the world.

We have gathered our measures from a computer in the Public University of Navarra (Spain) network. This PC has a public IP address and runs Ubuntu Linux (version 13.04). We felt unnecessary to set more than one vantage point as the authors in [7] found few differences when collecting the traffic of the same websites from different locations around the world. In this PC we run an automated script which follows these steps for each webpage under study:

- Launch a network sniffer: Tcpdump [15].
- Open a web browser to the selected website. We have collected measurements for both Mozilla Firefox (version 22.0) and Google Chrome (version 29.0.1547) which are the most popular browsers for Linux systems and together are responsible for a big percentage of the global web traffic [16], [17]. Plug-ins such as Adobe Flash player were installed in order to ensure that websites render properly but, aside from that, we use clean installations of both browsers with no ad or pop-up blockers.
- Wait for two minutes. Although webpages usually load in a few seconds [3], we capture traffic while the browser is idle for longer in order to study data transfers that happen even after the webpage has been fully rendered (when, for example, refreshing dynamic content).
- Close the web browser and close Tcpdump (we leave a small guard interval before closing Tcpdump in order to capture the ending of the pending connections).

We have repeated this procedure gathering twenty captures of each webpage download in pcap format (ten for each browser). We also captured one additional 10 minute long load for each page and browser in order to study flow end times as we will explain in section IV.

B. Preprocessing

In order to obtain connection records from these packet traces, we use Argus [18]. Argus is an open-source audit tool that is able to generate connection reports with the same features (and more) than NetFlow/IPFIX. In particular, aside from the classic TCP/IP 5-tuple (IP addresses, ports and protocol) we consider: timestamps (start and end), total packets, total bytes, application-level bytes (upload and download) and TCP state at the end of the capture. As we said previously, we always consider bidirectional TCP connections. Additionally, we store the first 1,000 bytes of the upstream application data of every connection from which we will extract some HTTP header fields. As we are only interested in web traffic we select connections originated in our PC and with destination ports 80 and 443 (HTTP and HTTPS protocols). However, we also extract DNS information from the pcap traces: we consider all the different server IP addresses accessed during the load of the webpage and, by studying the DNS query responses captured, we obtain a list of related domain names and authoritative nameservers for each IP address. This DNS information will allow us to better understand the part each connection plays in the load of the webpage.

We parse the HTTP data captured for each connection so we are able to extract the name of the accessed server, the URI of the first element requested and the HTTP method. With this information we identify the *root connection* of the webpage load. The root connection uses the GET method and requests the server root ("/") of a host with the same name as the website name. We then label connections according to their *origin*: those connections whose server name is related to (*i.e.* contains) the site name are classified as *shared name connections* and, from the rest of connections, we distinguish between *same origin* and *other origin* connections by checking if the domain name of the related server comes from the same authoritative nameserver as the root connection's or not. If the root connection carries HTTPS traffic it is impossible to identify it by checking user data. In this case, the root

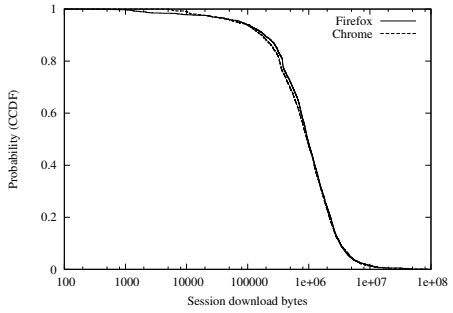

Fig. 1: CCDF of total downloaded bytes in a webpage load

connection will be the first flow opened to an IP address whose related domain name is the name of the website.

If we are unable to identify a root connection (i.e. there is no connection opened to an IP address related to the domain name of the website) or if we are able to identify it but it carries no application data we discard the capture as a failed webpage load. For the sake of simplicity in processing the data, we only consider websites that loaded successfully at every captured attempt. With this we reduce the list of considered websites from 1,000 to 912 resulting in a total of 18,240 flow records.

When comparing the total downloaded bytes for the same websites we observed discrepancies between the two web browsers. In particular, around 100KB of additional content were downloaded by Google Chrome in each capture. We discovered that this browser opens some HTTPS connections to Google servers for different purposes. Some of these connections are related to the webpage (for example, services like google translate or adsense) but others are automatic connections that are part of the browser operation and happen at fixed intervals from the start of the process. We decided to not consider these connections because, as we said previously, they are related to the browser behaviour and not to the particular websites. We also did not consider some connections opened by Firefox to Mozilla servers.

Now, figure 1 shows the empirical complementary cumulative distribution function (CCDF) for the total bytes of downloaded application data in every one of the captures of 120 seconds. This represents the total size of the different elements of each webpage. The distributions are very similar for both browsers as the effect of the browser in the elements downloaded from the webpage should be minimum.

III. General characterization

We start by providing some general connection-based metrics of webpage download. As it happened with figure 1 we have aggregated data from all our captures in order to plot the different graphs in this section. Because of this, each of the samples we use to calculate the empirical CCDFs corresponds to a different traffic capture (multiple downloads of the same webpages are present but there are the same number of them for every webpage so they are evenly represented).

Figure 2a shows the empirical complementary cumulative distribution function of the number of TCP connections initiated by the client during each webpage download. The distributions are, again quite similar: for both browsers the median is close to 40 connections while the 10 percentile sits around 10 connections (which means that for 90% of the studied webpages, at least 10 connections were used in the download). However, the tails of both distributions are long and, as we consider downloads with more connections, Firefox starts opening more of them (the 90 percentile is at 104 connections for Google Chrome and 125 for Firefox). As the total bytes downloaded by both browsers are very similar (fig. 1) this means that on average, Chrome connections are slightly bigger and more elements of the webpage are grouped in each of them. In any case, in figure 2b we can see that the difference in average connection size is small.

However, if we look at the individual connections (and, specially, the smallest ones) we do find some differences between the browsers' behaviour. In figure 2c we show the percentages of HTTPS and empty connections. These percentages have been calculated by aggregating all flows from all traffic captures of each web browser. As we can see, the percentage of normal HTTP connections is similar for both browsers however, the rest of connections are divided differently. Google Chrome has a higher percentage of HTTPS connections. By studying the servers this connections were established with, we realized that a lot of them were small connections related to services Google provides through Chrome to help the navigation process like, for example, Google Translate. However, the number of HTTPS connections initiated by Chrome to Twitter or Facebook servers is also higher.

The other kind of connections we consider are empty connections. *Empty connections* are those that, having successfully completed their initial TCP three-way handshake, carry no application data. Most of this connections (around 95%) are also properly terminated although we also consider connections ended with a reset message or still open at the end of the capture. HTTPS empty connections are a very rare occurrence for both browsers but HTTP empty connections are a quite common occurrence specially for Firefox in whose traffic they represent around 20% of all connections. In most cases empty connections are a consequence of strategies employed by browsers with the objective of reducing webpage load times and, because of that, their number depends on the particular implementation of the program. Browsers may open multiple connections to a particular server before knowing how much content is going to be downloaded from it because it is faster to have connections prepared in case they can be used to download multiple elements simultaneously. This means that, in some cases, this connections are left unused. Additionally, browsers usually try to open a new connection if the server does not respond to a previous SYN packet within a time limit. This limit is low, again in order to reduce download times.

In figure 3 we focus on the different servers accessed during a webpage download. The differences between both browsers are minimal in this case as browser implementation cannot affect where the elements of a webpage are stored. Figure 3a shows the distribution for the number of different IP

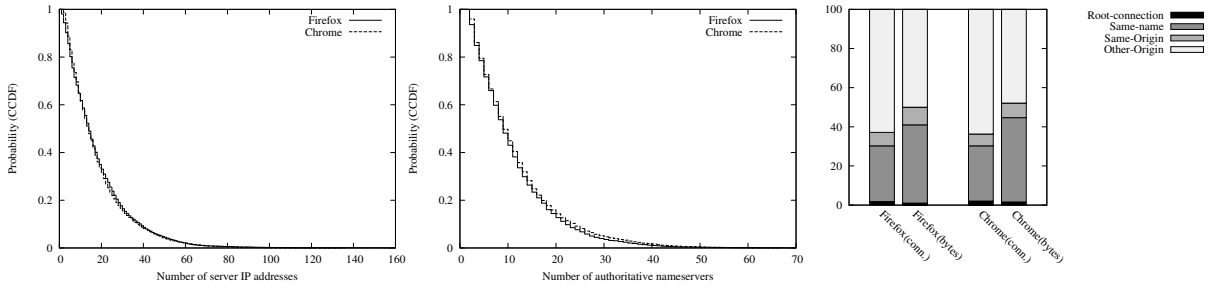
Fig. 2: CCDF of the (a) number and (b) average size of connections. (c) Percentages of empty and HTTPS connections.



(a) (b) (c)

Fig. 3: CCDF of the (a) number of servers, (b) authoritative nameservers, and (c) percentage of connections by origin.

addresses accessed during each download. The distributions, with medians at 14 IP addresses but long tails, corroborate that modern websites download elements from multiple different servers. As we explained in section II-B we use authoritative nameservers in order to distinguish between different origins for web content. Figure 3b shows the distributions of the number of different authoritative nameservers seen on the DNS responses of the server names associated with each webpage download. Two authoritative nameservers are considered different if they have a different second-level domain name (third-level for some second-level domains like "co", *e.g.* "google.co.uk"). As we can see most webpages download content from servers of different origins (medians are 9 different origins).

Finally, in figure 3c we show the percentages of connections and bytes according to their origins. As in figure 2c we have considered every individual connection from the different traffic captures. The figure shows that, on average, more than 60% of the connections made during a webpage download are directed to third-party (other origin) servers. The most popular of them include, among others: analytics, social networking, image hosting, content distribution networks or video streaming. However, when considering downloaded bytes we can see that first-party content (root-connection, shared-name and same-origin servers) represents more than 50% of the total download suggesting that connections to first-party servers are bigger on average.

In table I we offer a summary of the different per-download metrics presented in this section (number of connections, mean connection size, number of accessed IP addresses, number of authoritative nameservers) providing the median and 10th and 90th percentiles for each of them.

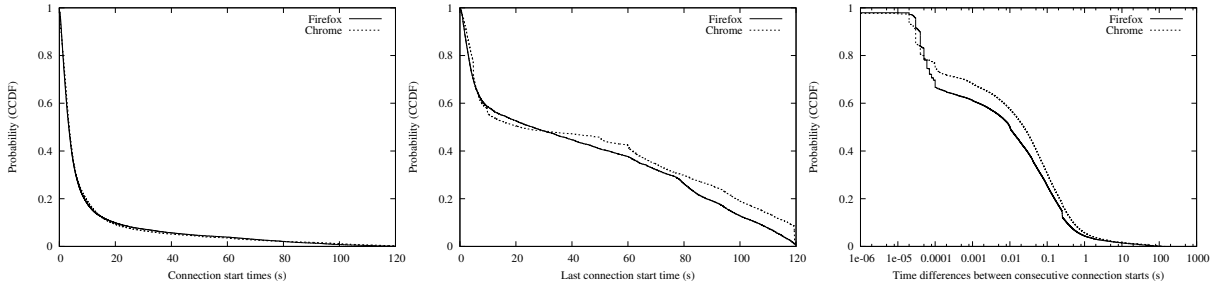
TABLE I: General characterization metrics

	Firefox			Chrome		
Metric	**P10**	**Median**	**P90**	**P10**	**Median**	**P90**
N. conn.	6	43	125	10	36	104
C. size (KB)	8.7	23.0	72.6	8.1	24.4	74.4
N. IPs	4	14	39	4	14	37
N. A.NS.	3	9	22	3	9	24

IV. Time metrics

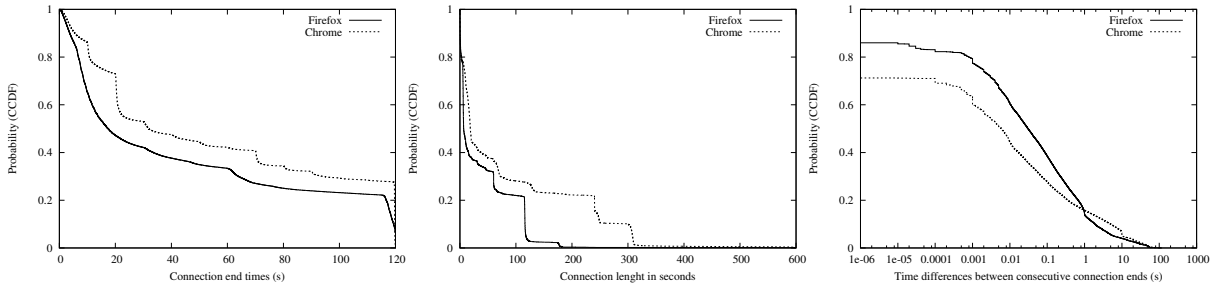
In this section we are going to discuss metrics related to the start and ending timestamps of the flows in the download of a webpage. Again, we consider the aggregated data of every download of every webpage as we want to characterize the behaviour of an average load rather than explore the differences between webpages. However, in this case, we are going to represent some parameters that are related to the individual connections rather than to the complete captures (as it was the case, for example, in figure 3a with the number of accessed servers per download). In all the figures in this section, the 0 seconds mark corresponds with the start timestamp of the first connection in each webpage download and the rest of connection timestamps in that download are calculated relative to it.

The first parameter that we are going to consider is connection start times which appears in figure 4a. In order to calculate



(a) (b) (c)

Fig. 4: CCDF of (a) connection start times, (b) last connection start time, and (c) time differences between connection starts.



(a) (b) (c)

Fig. 5: CCDFs of (a) connection end times, (b) connection lengths, and (c) time differences between connection ends.

these CCDFs we have considered the start timestamps of all the connections in every capture. As their timestamps are calculated relative to the first connection in each capture, we can compare them. We see that the majority of connections are opened during the first seconds of the download of a webpage (around 80% of connections in the first 10 seconds). This makes sense as this is an upper threshold for the time a webpage takes to load [3]. However, the tail of the distribution is long and a considerable amount of connections are opened later which suggests that even after the webpage is fully rendered some information is still exchanged. In figure 4b we represent the distributions of the start times of the last connection in each capture and we can confirm that even though most connections are opened in the first seconds, for the sizeable number of captures the last connections are opened much later. To shed some light about these late connections we used origins as defined in section II-B. We expected that the late connections could be specially related to third-party advertisment or analytics services. However, there is very little difference in the distributions of connection start times according to the different origins (aside from root connections happening always early in each capture). This suggests that the connections opened late do not only correspond to third-party content but also to dynamic content hosted in first-party servers.

In figure 4c we look at connection start times from a different perspective by representing the distribution of the time differences between consecutive connection starts. As expected, consecutive connections of the same webpage download are generally opened very close in time. Around 30% of consecutive connections are opened with less than a tenth of a millisecond between them (for smaller values, some precision/rounding artifacts appear) and only around 5% have their start times separated more than one second.

Lets now look at connection endings. Intuitively, we may think that connections are closed as soon as the elements they were opened to download are received by the client. However, this is not the case for a sizeable amount of them. Because servers and browsers implement persistent connections (all the HTTP connections observed were HTTP 1.1) some connections are kept open for longer in case they are needed for an additional download. As shown in figure 5a, both browsers keep more than 20% of the connections opened for all the duration of the capture and close them simultaneously as the browsers are closed. Nevertheless, studying the figure we saw that Firefox started ending some connections a few seconds before we closed the browser. We realized that Firefox implements a persistence timeout for HTTP connections that, by default, has a value of 115 seconds but can be tuned by the user via the configuration utility in about:config. The value of this timeout for Google Chrome is not documented.

In order to properly study the effects of these timeouts we captured one additional traffic trace of ten minutes for each webpage and browser. In figure 5b we show the distributions of connection length in seconds for these longer traces. For Firefox, the 115 seconds timeout is evident because most persistent connections have that length. The cause of the other step in the distribution (around 60 seconds) is more

difficult to pinpoint but should be related to a server timeout because it also appears in the Chrome distribution. For Google Chrome the default persistence timeout could be around 250-300 seconds. In any case, for both browsers around 60% of the connections are shorter than 20 seconds, either because they are not persistent or because of timeouts in the servers (Apache 2.0 has a default timeout of 15 seconds, for example).

Figure 5c is equivalent to 4c but this time we are representing time differences between connections that are closed consecutively. We can see that this time differences are usually very small. Because most connections are opened very close in time at the beginning of the download of the webpage, the effect of the persistence timeouts is very apparent when comparing their ending times. This, together with the fact that connections are ended immediately when the browsers are closed (note that in the figure around 20% of differences are 0), implies that the connections of the same webpage download usually end in almost simultaneous groups.

For table II we wanted to offer per-download metrics that describe the start and end timestamps of a webpage download. Again, we provide the median, 10th and 90th percentiles. The first metric we consider is the time of start of the last connection in the download (T. Last) as seen in figure 4b. However, this time may not, in some cases, represent the time interval during which most of the webpage is downloaded. In fact, if we consider the 10 and 90 percentiles we realize that we are basically covering the whole length of the capture. To give a better idea of the busiest time interval we consider the connections that carry the first 90% of the total data downloaded in each capture and provide the start time of the last of these connections (T. 90%). With this we eliminate the effect of small connections opened late in the download and give a better approximation of how close the connections of a webpage download are in time. For the time differences between flow starts and ends, in figures 4c and 5c we considered all flow pairs in every download but here we want to provide a per-download metric. We have calculated the median value for each capture and, in table II we show the median and percentiles of the distribution of said medians (T. Starts and T. Ends). As expected, the values of these two statistics are very low for almost every webpage download.

TABLE II: Time metrics (all values in seconds)

	Firefox			Chrome		
Metric	**P10**	**Median**	**P90**	**P10**	**Median**	**P90**
T. Last	1.62	25.96	105.82	2.34	21.29	117.10
T. 90%	0.61	2.67	12.51	0.76	3.36	17.85
T. Starts	0.00	0.01	0.12	0.00	0.02	0.13
T. Ends	0.00	0.04	0.32	0.00	0.01	0.22

V. SERVER METRICS

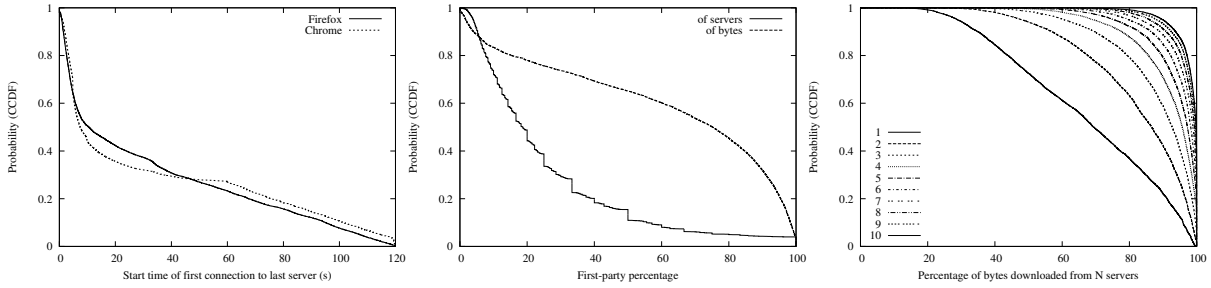
Of the classic 5-element tuple that traditionally describes an IP connection, the most interesting parameter when studying web traffic from the client point of view is the server IP address (protocol is always TCP, server port is 80 or 443 and client port is ephemeral and will not give us any information). Because of this, in this section we are going to center our study in the different servers accessed during the download of a webpage, considering that each of them corresponds to a different server IP address. Due to space constraints we only use Google Chrome data in most of the figures of this section. The results for Firefox are very similar because, aside from very specific browser services, the servers accessed during the download of a webpage should not vary depending on the used browser.

In section III we saw that multiple connections are opened to the same servers during each download. On the other hand, in figure 4b we realized that some of these connections happen very late in the captures. We wonder if these late connections are opened to servers that have already been accessed or to new ones. Figure 6a addresses this question by representing the CCDF of the start timestamp of the first connection to the last server that appears in each capture. The results are similar to the ones in figure 4b suggesting that a sizeable number of these late connections are opened to servers that have not been previously connected. However, as we said previously, these connections are usually small and the servers that host the main elements of the webpages are accessed in the first seconds of the download.

In section III we also gave information about the total number of different servers accessed in a download and the different authoritative nameservers related to them. However, it is clear that those servers play different roles in the webpage downloads depending on the elements they host or the services they provide so it should be interesting to study them individually. In figure 6b we show the distribution of the percentage of first-party servers for each webpage download (that is, the server the root connection is directed to, shared-name servers and same origin servers). We can see that, for most webpages, this percentage is low implying that most servers accessed during a download are third-party servers. However, the percentage of bytes downloaded from these first-party servers is much higher so, even if fewer first-party servers are accessed during a webpage download, they usually host a bigger part of the webpage content than the third-party ones.

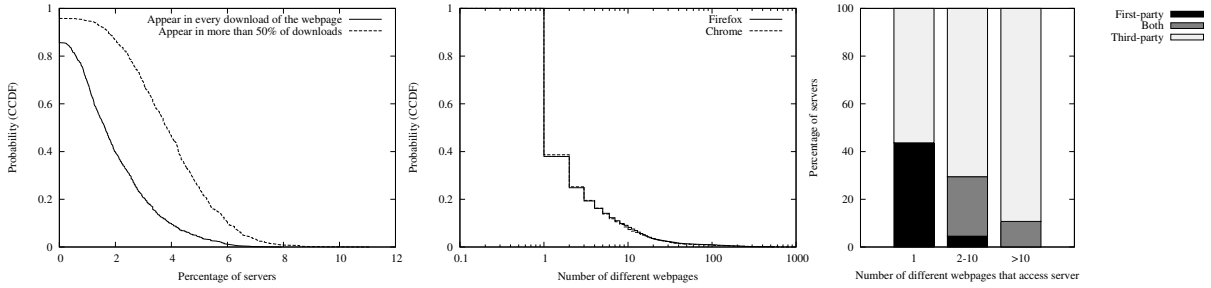
Another consequence of figure 6b is that, as we know, the content of a webpage is not equally distributed in the different servers accessed during the download. In figure 6c each CCDF represents the percentage of content downloaded from the "heaviest" server, the two heaviest servers and so on, of each capture. Even if many servers are accessed to download certain webpages, most of the content is hosted by few of them. For example, for 90% of the webpages, more than 80% of the downloaded content comes from only 5 different servers.

Until now, we have considered the servers in each webpage download independently. However, the content of many webpages is hosted in distribution networks or multiple hosts for load balancing purposes and because of this, connections to the same IP addresses are not always opened when accessing the same webpages. On the other hand, a lot of webpages use third-party services (*e.g.* analytics, image hosting, advertising, etc.) and, as a consequence, the same third party servers



(a) (b) (c)

Fig. 6: CCDFs of (a) time of first connection to last server, (b) first-party percentage of servers and bytes, and (c) percentage of bytes downloaded from heaviest servers.



(a) (b) (c)

Fig. 7: CCDFs of (a) percentage of servers that appear in all or half the captures of the same webpage, (b) number of different webpages that access each server, and (c) origins of shared servers.

are accessed when downloading different webpages. Figure 7 addresses these situations.

In figure 7a we consider all the IP addresses accessed in the ten captures we made for each website. We represent the CCDF of the percentage of servers that appear in every capture and that appear in, at least, half of the captures of each website. As we can see, both percentages are quite low. This means that most of the content in the webpages is dynamic or hosted dynamically and, because of that, the servers involved in the download change rapidly over time making very difficult to identify a particular IP address with a particular webpage.

Lets now compare all the servers accessed during the download of different webpages. Figure 7b represents the number of different webpages in whose downloads a particular IP address appears. For this figure we do not consider as different some of the webpages under study like, for example, amazon.com and amazon.co.uk, because they probably share an important part of their hosting infrastructure. A very high percentage (around 40%) of all the IP addresses appear in downloads of more than one webpage suggesting that a lot of services are shared between them. In figure 7c we have divided all the server IP addresses in three groups according to how many webpages download content from them. The servers of the first group only host content of one of the studied webpages, the ones in the second group host content of two to ten different webpages, and the servers in the third group host content of more than ten different webpages. For each group, we represent the percentage of first and third-party servers and servers that are both first and third-party depending on the webpage. As expected, most only first-party servers appear in downloads of just one webpage (the few of them that appear in 2-10 webpages are probably related to webpages that share a hosting platform like blogs). However, in a considerable amount of cases, servers that are considered first-party for a webpage appear in downloads of another one as third-party servers.

A consequence of all this is that even though IP addresses are an interesting parameter in order to group the connections of the same webpage download (as multiple connections are usually opened to the same servers) they should be used very carefully to relate different downloads of the same webpages. On one hand, the same content may be downloaded from different servers (or even the content itself may change in short periods of time). On the other, many servers are accessed by different webpages and even servers closely associated to a webpage by their name or their authoritative nameserver may host content for other webpages.

In table III we present some server metrics related to the variables we described in figure 6 providing, again, median values and percentiles. As it happened in the previous section, the time of the first connection to the last server (T. Last S.) is not very representative so we have calculated the time of appearance of the last server that, together with the ones that have already appeared is responsible for 90% of the total

download (T. 90 S.). This interval represents how long it takes for the servers that are responsible for the majority of the download to be contacted by the client. We also show the percentages of first-party servers and bytes (F.P. (S) and F.P. (B)) and the percentage of bytes downloaded from the heaviest 1, 5 and 10 servers.

TABLE III: Server metrics

Metric	Firefox P10	Firefox Median	Firefox P90	Chrome P10	Chrome Median	Chrome P90
T. Last S.	1.42	10.48	95.01	1.89	7.42	101.86
T. 90 S.	0.15	2.03	7.25	0.30	2.40	10.54
% F.P. (S)	5.26	20.0	78.57	5.26	18.75	55.56
% F.P. (B)	5.02	69.79	99.62	4.08	75.18	98.34
% 1 Serv.	30.00	61.14	95.63	34.97	69.42	95.97
% 5 Serv.	75.77	96.05	100	82.92	97.28	100
% 10 Serv.	90.43	99.72	100	93.75	99.81	100

VI. Conclusions and future lines of work

The increasing popularity of the web and the interesting complexity of its traffic have made it a popular topic of research for the scientific community. However, little work has been done in order to characterize web traffic at connection level, even though connection level data has the advantage of being easy to store and process in real time and can be collected even if the traffic is encrypted.

In this paper we have presented a thorough characterization of web traffic from the perspective of TCP connections. We have introduced various metrics that describe the set of connections involved in a webpage download focusing on their general characteristics, their distribution in time and the servers they reach. For each of these metrics we have shown its probability distribution and given some statistics to describe it. Taking into account the very limited nature of the information available in Netflow-type records, we have painted an accurate picture of the average webpage download.

We intend to apply the knowledge obtained in this work into designing a method able to identify webpage downloads in real traffic. We believe that by applying a combination of the metrics described in this paper we will be able to distinguish single webpage downloads in user traffic. A system based on this idea would be lightweight and able to process data in real time giving interesting information to network administrators about the behaviour of their users without accessing sensible information.

We also would like to explore the possibility of using these metrics in order to distinguish between websites of different categories (like social networks, news portals, etc.) or which offer different services (video streaming, games, etc.). As the normal range of the metrics is quite broad, the variability in them suggests that information about the characteristics of a webpage (indicative of the related website category or service provided) can be extracted from this kind of connection level data.

Other possible applications of this work are more related to network security as a thorough characterization as the one provided in this work can help with the tuning of anomaly-based detection systems. These systems that may be able to distinguish between normal web traffic and other applications that masquerade their traffic in order to avoid restrictions imposed by network administrators (or, in the case of malicious applications, in order to blend in and avoid detection).

3rd International Conference on Wireless Sensor Networks

A FEW years ago, the applications of WSN were rather an interesting example than a powerful technology. Nowadays, this technology attracts still more and more scientific audience. Theoretical works from the past, where WSN principles were investigated, grew into attention-grabbing applications practically integrated by this time in a real life. It could be said, that countless application fields, from military to healthcare, are already covered by WSN. Together with this technology expansion, still new and new tasks and interesting problems are arising. Simultaneously, such application actions stimulate the progress of WSN theory that at the same time unlocks new application possibilities. The typical examples are developments within the "Internet-of-Things" field as well as advancements in eHealth domain with WBAN IEEE 802.15.6 standard progress.

Wireless sensor networks, as the spatially distributed networks consisted of a number of relatively simple, low-cost, low-power components interconnected mutually, provide quite wide application portfolio for different branches of economy. As the main examples could be mentioned military, industry, transport, agriculture and healthcare. However, in the near future, even stronger expansion of WSN application assortment is expected. In order to make this expansion possible, it is necessary to continually work on the solving of typical questions/problems related to the WSN development, e.g. standardization of communication protocols; the lack of energy-efficient power sources; the development of new ultra-low-power microelectronic components; etc.

An integration of WSN within the public data networks as well as within the domains where confidential and private data are processed (e.g. E-Health) brings along problems related to the ethical and legal questions too. Therefore, the terms as social safety or ethical safety should not be neglected.

The problematic of WSN is one of actual activities getting to the fore in the European Research Area since the issue of sensor networks was covered through "IoT" in FP7 program and strong continual extension is planned to be included also in Horizon 2020 program, especially in sections such Smart Transport; Health; Climate Action covered under Societal Challenges Pillar.

It is therefore essential to create an experience-sharing platform for scientific researchers and experts from research institutes, SMEs and companies who work in WSN domain where they can exchange some relevant skills and experiences as well as discuss upcoming trends and new ideas from this field. Moreover, the conference should also serve a function of a kind of networking platform facilitating interconnectivity between participants in case of a future collaboration.

Topics

Original contributions, not currently under review to another journal or conference, are solicited in relevant areas including, but not limited to, the following:

Development of sensor nodes and networks

- Sensor Circuits and Sensor devices – HW
- Applications and Programming of Sensor Network – SW
- Architectures, Protocols and Algorithms of Sensor Network
- Modeling and Simulation of WSN behavior
- Operating systems

Problems dealt in the process of WSN development

- Distributed data processing
- Communication/Standardization of communication protocols
- Time synchronization of sensor network components
- Distribution and auto-localization of sensor network components
- WSN life-time/energy requirements/energy harvesting
- Reliability, Services, QoS and Fault Tolerance in Sensor Networks
- Security and Monitoring of Sensor Networks
- Legal and ethical aspects related to the integration of sensor networks

Applications of WSN

- Military
- Health-care
- Environment monitoring
- Transportation & Infrastructure
- Precision agriculture
- Industry application
- Security systems and Surveillance
- Home automation
- Entertainment – integration of WSN into the social networks
- Other interesting applications

Energy Harvesting for Wireless Sensor Networks Review

Saba Akbari
"MATI"– Russian State Technological University Orshanskaya 3, 121552 Moscow, Russia
Email: akbarisaba@gmail.com

Abstract— With the widespread use of wireless sensors, the management of their energy resources has become a topic of research. Wireless sensors usually use batteries as their power supply but in some applications battery replacement can be cumbersome and require considerable amount of time which can affect the process being monitored. It is possible to harvest energy from the sources in nature for wireless sensors. In this article, a review of current alternative energy sources has been demonstrated in order to address the feasibility of their integration with wireless sensor networks.

I. Introduction

Fire and toxic gas leakage may have consequences resulting in pecuniary loss or fatality. Monitoring of hazardous gases is one of the areas where wireless sensors have been used [1]. Systems based on wires have some disadvantages as being dependent on power supply, high maintenance costs, sometimes electrical power supply cut off occurrence, and long deployment time. The study of forest fires has been also considered as an important issue and since it may take place in some areas of difficult access, the development of wireless sensor technology can be applied in this field as well [2],[3]. Wildfire which occurs in the countryside or wilderness area is a topic which is not yet completely resolved [4]. The satellite technology and aircrafts can track such incidents. However, there are some advantages and disadvantages associated with each method. The deployment costs for using satellites are high [1] and due to the orbital limitations not all satellites can monitor a fire event continuously [5]. Limitations of using aircrafts can arise in some areas which are prone to low altitude clouds and this can cause more obstacles in terms of visibility [5]. Wireless sensors have become an interesting topic to tackle this issue [6],[7]. But this technology also has its own challenges. The high power consumption of combustible gas detection systems is a restricting factor which needs to be considered [8],[9]. Sensors designed for this purpose and having on board batteries cannot have a long time life cycle [1] and moreover in some applications like structural health monitoring of critical infrastructures and buildings, it is difficult to replace or recharge batteries [10]. As mentioned in [11], some sensor networks like BAN systems require low energy levels. Table 1, 2 and 3 illustrate some off- the- shell components used in sensor node design [12]. As it can be seen from Table 1, the current consumption of the gas sensors is higher in comparison with other components used in the sensor module. The operation time of the autonomous wireless sensor device is currently limited by the batteries capacity which is about 3000 mAh, 8000 mAh and 15000 mAh for the AA, C and D batteries types, respectively. Taking into account the high power consumption of sensor nodes, it is necessary to optimize the use of battery. Therefore, demands on response time require that the measurement of gas concentration for example of combustible gases be done no more than every 120 s [13]. Nature provides us with variety of energy sources which can be harvested and implemented for wireless sensor systems [14]. Some various sources which can provide the necessary amount of power include solar, piezoelectricity, thermal, wind, and radio frequency. A compilation of various energy harvesting sources is given in Table 4 [15].

II. HARVESTING METHODS

A. Solar Energy

Typically, a sensor node which uses energy from nature, consists of several blocks such as energy harvesting module, the storage unit such as a supercapacitor, sensing element, microcontroller and a transmitter as shown in Figure 1.

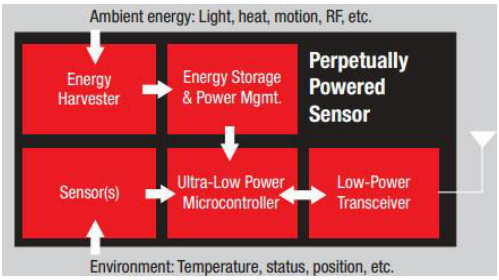

Fig. 1 Wireless sensor network with an energy harvesting module [16]

Photovoltaic is the technology that generates direct current from semiconductors when they are illuminated by photons. Most of the solar cells today are made of crystalline silicon (c-Si). Silicon has been the most widely used material in the production of photovoltaic modules. The mono- crystal, multi-crystal, micro-crystal and amorphous are the most widely used forms of silicon in the production of photovoltaic cells [17].

TABLE I.
POWER CONSUMPTION OF SOME OFF – THE - SHELF GAS SENSORS[12]

TYPE	COMPANY	POWER (mW)
DTK-2 Catalytic Sensor	NTC-IGD, Russia	120 mW
SGS-21XX Semiconductor Sensor	Delta, Russia	200 mW
TGS2610 Semiconductor Sensor	FIGARO, Japan	280 mW
NAP-66A Catalytic Sensor	Nemoto, Japan	360 mW
MQ-4 Semiconductor Sensor	Hanwei Electronics, China	750 mW

Nanotechnology based semiconductors including nanowires, nanocrystals, nanorods and nanodots have been opening a new perspective for scientists to design solar cells [18].

TABLE II.
CURRENT CONSUMPTION OF SOME OFF – THE - SHELF TRANSCEIVERS[12]

TYPE	COMPANY	CURRENT CONSUMPTION (mA)
CC2500 Transciever	Texas Instruments	Tx: 21.2 mA @ 0 dBm Rx: 13.3 mA
CC2430 Trasnceiver	Texas Instruments	Tx: 27 mA, Rx: 25 mA
ETRX35x Transceiver	Telegesis	Tx: 31 mA @ +3 dBm, Rx: 25 mA @ 12 MHz clock speed
TR1000 Transceiver	RF Monolithics	Tx: 12 mA @ 0 dBm, Rx: 3.1 mA
JN5148-001-M00/03 Transceiver Sensor	Jennic	Tx: 15 mA @ +2.5 dBm, Rx: 17.5 mA

Solar energy can generate enough amount of power necessary for wireless sensors [19]. A solar panel is used as an energy harvesting source for the wireless sensor in [20].

Solar energy harvesting provides direct DC voltage and therefore additional circuit rectifications are not required. This type of energy scavenging is free of emissions since it does not produce contaminants or bypass products that are harmful to the environment [21].

One of the limitations of solar energy is its dependency on solar radiation, which can be degraded in areas where enough sunlight is not available. Solar energy is characterized by having a varying nature [22]. The other issue associated with solar cells and for which some research is ongoing is the cooling of solar cells and recovering heat [23].

TABLE III.
POWER CONSUMPTION OF SOME OFF – THE - SHELF COMPONENTS USED IN SENSOR NODE[12]

TYPE	COMPANY	CURRENT CONSUMPTION (mA)
MSP430F247 Microcontroller	Texas Instruments	Active mode: 321 uA @ 3 V / 1 MHz Low power mode: 1 uA @ 3V / 32768 Hz
ATmega168P Microcontroller	Atmel	Active mode: 1.8 mA @ 3 V / 4 MHz Power-save mode: 0.9 uA @ 3 V / 32 kHz
ATxmega32A4 Microcontroller	Atmel	Active mode: 1.1 mA @ 3 V / 2 MHz Power-save mode: 0.7 uA @ 3 V / 32 kHz
ADuC824 Microcontroller	Analog Devices	Active mode: 3 mA @ 3 V / 1.5 MHz Power-down mode: 20 uA @ 3 V / 32 kHz

B. Piezoelectricity

Piezoelectricity stems from the Greek word “piezo” for pressure and the word “electric” for electricity. The main advantage of piezoelectric materials as shown in Figure 2 is the high amount of voltage they can provide. Some materials which have piezoelectric effect are quartz, soft and hard lead ziconate titane piezoceramics (PZT-5H and PZT5A), barium titanate (BaTiO3) and polyvinylidene fluride (PVDF)[24].

In the piezoelectric effect the usable output voltage can be obtained directly from the material and there is no need for applying multistage post processing for generating the desired amount of voltage [25]. Piezoelectric materials require dynamic forces in order to retain the output voltage and a notable drawback of piezoelectric sensors is their inability to respond to static loads [26].

C. Radio Energy

The possibility of harvesting RF energy, from ambient, enables wireless charging of a sensor node [27].

Having a transmitter set, one can harvest energy from radio waves and the advantage of this alternative is the fact that the scavenging mechanism can be flexible and it is

TABLE IV
SOME ENERGY HARVESTING SOURCES [15],[16]

Energy Source	Conditions	Performance
Solar	Outdoors	7500 μW/ cm^2
Solar	Indoors	100 μW/ cm^2
Vibration	1m/s^2	100 μW/ cm^3
RF	WiFi	0.001 μW/ cm^2
RF	GSM	0.1 μW/ cm^2
Thermal	$\Delta T = 5\,^{\circ}C$	60μW/ cm^2

possible to control the amount of transferred energy by making it continuous i.e. on regular intervals or the amount of radiated energy can be adjusted according to the requirements of the relevant application [28].

It is necessary to note that, according to the Friis equation, the amount of power collected at the receiver side is not equal to the exact value sent by transmitter [29].

D. Thermal Energy

Thermal energy produces electricity when there is a temperature difference (Seebeck effect).

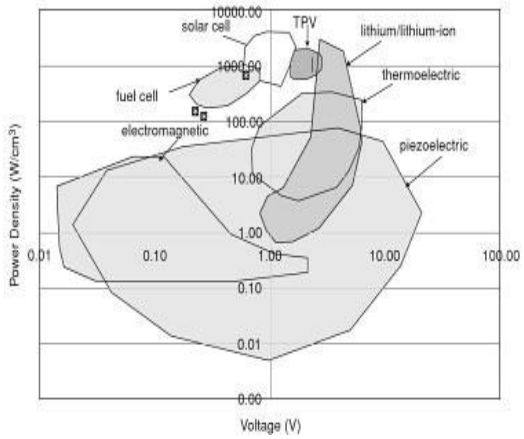

Fig. 2. The voltage generated by the piezoelectric material itself is greater than the value produced by some other harvesting sources [25]

Most thermoelectric generators consist of n type and p type an array of p- and n- type semiconductors in series. Heat from a hot source reaches the hot shoe and is conducted through to the semiconductors. The hot shoe has a high thermal conductivity and as well as a high electrical conductivity. Electrons are released from n type semiconductor and establish a current through p type semiconductor. Cold shoes transfer the current to the electric load [30].

Commercially available thermoelectric generators require a temperature difference of 10 – 200 ºC [31].

This type of energy is able to provide supply DC power continuously but temperature differentials can be difficult to generate in enclosed environments [32].

D. Wind Energy

Among the various forms of existing renewable energy sources, wind energy is one of the remarkable sources in the macro scale for generating electricity. Countries like Germany, Spain and Denmark have provided a significant amount of their required electricity by using this type of energy.

Having evaluated the given possibilities in high power electronics, its application can be also surveyed for miniaturized devices.

In the study presented in [33], different wind turbine blade configurations (two, three and six blade propellers) within a wind speed interval of 3.5 to 7 m/s were tested. The propeller with six blades output the maximum power. The authors propose to add a solar panel to the harvesting system in case the amount of energy provided by wind energy will not suffice.

During the analysis of alternative sources for wireless sensor networks, an experiment to survey the feasibility of using wind energy as a complementary system for wireless sensor systems was performed. In this experiment, two types of blades were tested. The measured wind speed was 3.7 m/s and 4.5 m/s. In the first case, the length of each blade was 4.35 cm and in the second one, it corresponded to 8.85 cm.

Figure 3.a shows power generated by the wind turbine as a function of load. The peak power for the propeller with smaller blades at the speed of 4.5 m/s is 7.2 mW.

At 3.7 m/s, the peak value of power for the first type of blade is 5.5 mW and for the second type of blade, the maximum amount of power at the speed of 4.5 m/s is approximately 5.5 mW (Figure 3.a). As the rotor of the DC motor starts rotating, the AC current flows in the circuit which consists of motor windings and the load.

As a result of this, self induction takes place. This effect can be seen in Figure 3 a and b for the first type of propeller when the load resistance is less than 500 Ohm and in the meantime the experimental points and the approximation do not converge. The experiment indicates that a microturbine based on a DC motor can be represented as a voltage source and an internal resistance according to the Thevenin theorem. Two factors which have caused less amount of power in our experiment in comparison with [33] are the wind speed and motor. It can be also observed from Figure 3.a that the larger propeller provides maximum output at smaller values of load (~60 ohm) and the smaller one reaches its power peak values at higher loads (~250 ohm), i.e. depending on the load value, the necessary blade can be chosen.

This model is valid only in cases when the induced current is greater than the self induction current. Wind is a free energy that nature provides us and there is no limit in using it. It produces no polluting emissions of any kind [34]. Wind energy in some environments cannot be considered as a primary source for electricity generation due to its intermittent behavior which causes instability to the power system [34].

III. APPLICATIONS

Alternative sources can be used along with batteries as a complementary system or in case of existence of enough energy from the environment, they can be employed as primary power sources. Pipeline monitoring in industrial complexes is a remarkable example where wireless sensors can be deployed [35]. It is quite plausible to employ energy harvesting techniques as primary or secondary power

supplies for the sensors in this scenario. In case of battery replacement, the harvesting technologies increase the possibility of continuous operation of the system and consequently the process will not be stopped.

Bridge health monitoring is another example discussed in [36]. In the Jindo bridge project, eight sensors out of 70 are equipped with solar panels. The charging process of the solar system is working well except one node which is not receiving enough sunlight due to its location. It is suggested that in the next deployment, either a more sensitive solar panel can be used or another type of energy harvesting may be considered [37].

IV. ENERGY STORAGE

At the moment, batteries are still the most common way to provide energy for low electronic devices. The specifications of Li – ion and thin film batteries are shown in Table 5.

The majority of wireless sensor networks are powered by batteries. As mentioned at the beginning of the article, the batteries used in wireless sensor networks have a finite lifetime which requires replacement or recharging.

Primary cells which cannot be recharged may cause a huge amount of work associated with replacement if used in a large network [38] like in the case of pipeline monitoring. Secondary batteries are rechargeable but they have a lower energy density than primary batteries [38].

The combination of an energy harvesting scheme with a rechargeable battery or with another storage system such as a thin film rechargeable battery or a supercapacitor can be implemented for wireless sensor networks. Figure 4 shows a comparison of several storage schemes. It is assumed that the volume of energy storage scheme is 1 cm^3. If the energy consumption is 100μW then the operation time of the primary battery lasts just for only a few months. The combination of an energy harvester with a rechargeable battery ensures a long term operation of the system.

Developing this strategy maybe necessary since sometimes the output power from the energy harvesting due to their intermittent nature may not be enough to compensate for the current consumption at receive and transmit periods. This scenario is illustrated in Figure 5.

V. CONCLUSION

An overview of the alternative energy sources was presented in this review article and the experiment using wind energy demonstrated the potentiality of this source to power low electronic devices. It is necessary to note that systems for harvesting and storing energies shall be designed based on the combination of two or more sources of alternative energy. For instance, for those electronic systems performing outdoor, solar and wind energies can be considered as sources for powering the devices or in the case of low power electronic devices located indoor, radio waves and thermal energy can be designated.

The hybrid energy sources increase the probability of having uninterruptible power supply because each source can compensate some fluctuation of energy of its counterpart transmitted to the powered device.

In addition to the conventional applications of energy harvesting, this technology can be used in the concept of “Smart Homes” as well as the management and powering of real objects in the Internet of Things [40].

In order to optimize the harvesting process using this type of energy, the following points can be considered in the future research:

1. Implement a micro wind turbine model. This defines a system where one can enter an input parameter such as wind speed and blade radius and based on that the output power can be obtained.

2. Develop hybrid models in order to feed the sensor simultaneously from more than one source. As a result, more energy can be stored for the node and this leads to storing more energy as well as providing a more realistic battery – less operation of the overall system

3. In order to ensure a continuous operation of the sensor,

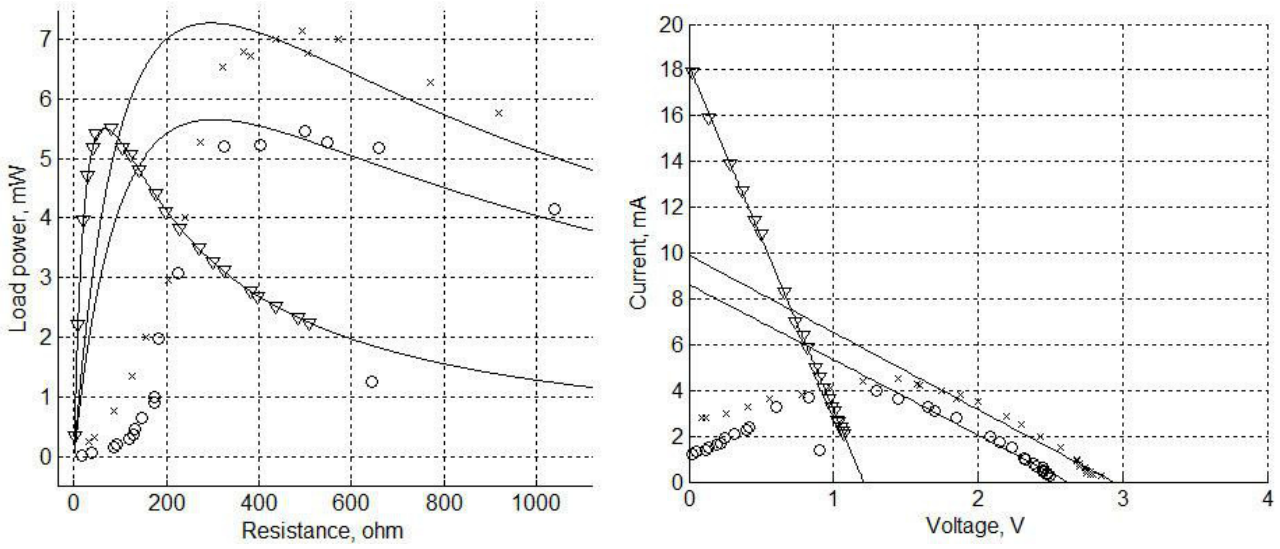

Fig.3. a) Power versus resistance for two types of propellers b) Current versus voltage for the same propellers x - Propeller with blade size of 4.35 cm at 4.5 m/s o - Propeller with blade size of 4.35 cm at 3.7 m/s ▽ - Propeller with blade size of 8.85 cm at 4.5 m/s - Linear approximation

a combination of an energy storage scheme and the harvesting system may output a steady operation of the sensor node.

4. In terms of applications, a system composed of solar cell and micro wind turbine can be designated for pipeline monitoring since replacing batteries in these areas can take a long time and stop the process. In some areas which have enough sunlight and wind, this model can be applied to provide a continuous operation of sensors.

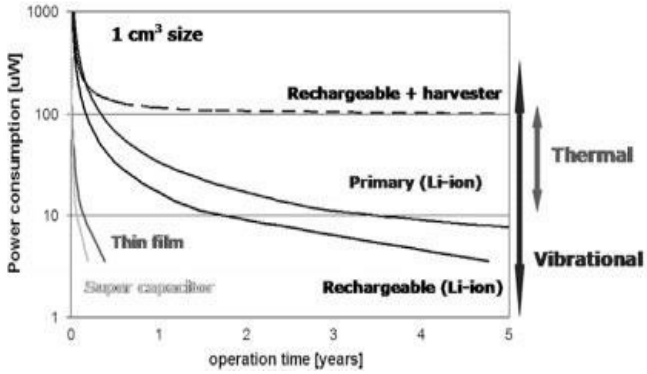

Fig. 4. A comparison of the operation time versus power consumption of various storage systems [39]

5. Thermal energy harvesting has also gained popularity for powering microelctronic devices. This technology can be also used in pipeline monitoring as a source to power sensors in which case it is feasible to use the temperature difference between the pipes and surrounding environment.

The possibility of harvesting energy from nature is fascinating but the cost issues of deploying such a technology shall be considered as well.

A scientific approach to implementing this feature for low electronic applications has to evaluate it and decide if energy scavenging proves better results in both technical and economical aspects in comparison with other technologies.

The research which have been carrying out in different microelectronics fields such as transmitter, microcontroller, storage schemes along with the advancements in energy harvesting technology will demonstrate more compelling results in the future.

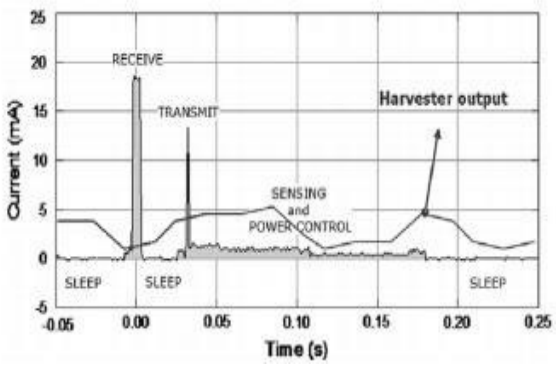

Fig. 5. In some cases the amount of harvested energy is not enough to provide the necessary power for the transceiver module [39]

ACKNOWLEDGEMENTS

The author would like to express the deep gratitude to Prof. Alexander Baranov from "MATI"– Russian State Technological University for the help in the manuscript preparation and useful discussion. This work was supported in the frame work of Russian Federal Program Grant No. 14.577.21.0022.

***Abstract*—This paper aims to introduce some key parameters for the tracking application in wireless sensor networks. In this paper, the Nearest Closer protocol has been implemented in J-sim simulation platform, and consequently some useful trade-off analysis results among the density, reliability and lifetime have been obtained. Based on these results, two evaluation models are proposed.**

***Index Terms*—J-Sim; Nearest Closer; Evaluation Model**

I Introduction

A WIRELESS sensor network consists of a number of sensors deployed either randomly or in a pre-determined state in a given two or three dimensional space, thus forming a network of sensors. The sensors are designed to measure one or more physical quantities in the space, such as temperature or location. The sensors need to transmit this collected data to the end-user, who often will be outside of the space being measured, which could well be a dangerous environment. As the sensors concerned are wireless they are typically powered by a battery with a finite lifetime and power output, it may be impossible or impracticable to recharge or replace such batteries. Thus in a real wireless sensor network a number of parameters naturally need to be considered such as energy consumption, network lifetime and network throughput. The network may be assigned a routing protocol. There exist a lot of routing protocols, so to choose the suitable routing protocol has become a significant problem.

The routing protocols can be divided into three main types: flat protocols, location-based protocols and hierarchical protocols. Single-hop, Nearest Closer and LEACH are typical and basic routing protocols for these three types respectively.

We have integrated the Single-hop and LEACH [1] protocols into the simulation tool J-Sim and provided mathematical models for each protocol. This paper will focus on the multi-hop routing protocol.

The multi-hop protocol we realized in J-Sim is called Nearest Closer protocol. To implement this protocol each node has to know: its own position, the position of its neighbours within its transmission range and the position of the sink node. The main idea in the Nearest Closer protocol is that the distance between the receiver sensor node and the sink node is shorter than the distance between the transmitter sensor and the sink node. In addition, the transmitter sensor will transmit to its nearest neighbour that is closer to the sink node.

In this paper, the relationships among density, lifetime, and reliability will be investigated for the Nearest Closer protocol by simulating the tracking application. Based on the results of these parameters, two intelligent evaluation models will be proposed. This means that wireless sensor network users can predict lifetime and reliability directly. Thus sensor nodes can be deployed in such a network without further simulations.

The rest of this paper is structured as follows: Section 2 describes some details of J-Sim. Section 3 defines the evaluation parameters. Section 4 focuses on the experimental set-up information. Section 5 describes the results which have been obtained so far. Section 6 proposes the Lifetime model. Section 7 proposes the Reliability model. Section 8 concludes this paper.

II J-Sim

J-Sim [2] (formerly known as JavaSim) is an open-source, component-based compositional network simulation environment. The system is based on the IEEE 802.11 [3-4] implementation provided with J-Sim. IEEE 802.11 is the first wireless LAN (WLAN) standard proposed in 1997. J-Sim is implemented on top of the autonomous component architecture (ACA), components are the basic elements in this architecture and through these J-Sim implements the data transmission process. J-Sim provides a script interface that allows its integration with Tcl, and has been developed entirely in the Java platform. Java is a general purpose object-oriented computing language that is specifically designed to have as few implementation dependencies as possible.

This work selected J-Sim as its simulation tool for the following reasons:

The authors of J-Sim have performed detailed performance comparisons in simulating several typical WSN scenarios in J-Sim and ns-2. The simulation results indicate J-Sim and ns-2 incur comparable execution time, but the memory allocated to carry out simulation in J-Sim is at least two orders of magnitude lower than that in ns-2. As a result, while ns-2 often suffers from out-of-memory exceptions and was unable to carry out large-scale WSN simulations, the proposed WSN framework in J-Sim exhibits good scalability.

978-83-60810-58-3/$25.00

J-Sim models are easily reusable, so users can combine the components in the framework freely. J-Sim also provides a Graphical User Interface (GUI), which makes it easy to operate the simulation.

J-Sim is a Java-based platform. The Java-based sensors could be integrated with Java-based simulation tools in the future.

III. Evaluation Parameters

In this section, the evaluation parameters of Reliability Lifetime and Density will be defined for use in the following sections. This paper will focus on the parameters of Energy, Density, Lifetime and Reliability. Based on the results of experiments measuring these parameters, an intelligent evaluation model will eventually be constructed.

This work has completed power control over the radio components on the J-Sim simulation platform, which makes simulation of power consumption possible.

There is no need to assume that all sensors in a WSN measure the same phenomena; however, in this paper it is assumed that all sensors can transmit data about the phenomena they detect and can receive and retransmit data from other sensors about any of the phenomena detected in the system.

A. Reliability

In this work, experiments are conducted using the concept of reliability, defined by:

Reliability = the number of packets received by the sink node / the number of packets sent to the sink node

The advantages of using reliability are two-fold. Firstly, this definition can be used in the field and laboratory. In the field provided the sink node (end-user) knows how many cluster heads or sensors there are and the average number of packets of sensed data per sensor per time unit, then reliability can be estimated at any time during the lifetime of the network using the number of time units elapsed. Any difference between reliability measured in the field and laboratory could be used to detect how many packets of data are lost between sensors and cluster heads or the sink node (this would include counting sensors that have failed or have otherwise been lost to the system). Secondly, this simple definition of reliability can be used in a network where there are sensors of various types monitoring different things to produce a single simple measure of accuracy. In this situation our definition gives a systemic measure of accuracy for the network as a whole independent of the applications. This definition also makes it easy to analyze communication among the sensor nodes; in particular it makes the estimation of data collision in the wireless sensor network possible.

A frequently used definition for tracking accuracy is to set the tracking error equal to the Euclidean distance between the estimated and actual locations of the target. The chief advantage of our definition for the tracking application, that this paper is going to simulate, is that it is independent of the target position.

B. Lifetime

Network lifetime has become the key characteristic for evaluating sensor networks in an application-specific way. In particular the availability of nodes, and connectivity have been included in discussions on network lifetime. In fact, even quality of service measures can be reduced to lifetime considerations. Network lifetime is the time span from the deployment of the sensors to the instant when the network is considered non-functional. When a network should be considered non-functional is application specific. It could be, for example, the instant when the first sensor dies, a percentage of sensors die. Conserving sensor energy and increasing tracking accuracy are the two main goals for the research of target tracking applications in wireless sensor networks. Simulation is a common way to compare these two parameters. Before the real deployment of sensor nodes, users always perform some simulation tests for the tracking application. In the simulations, finding the trade-off point between energy consumption and tracking accuracy is one of the key questions to be addressed. In addition, evaluation analysis will be performed here among all the related parameters.

Sensors need to send packets to other sensors or sink node in a WSN. On the other hand, the sink node will receive packets from sensors. Thus, the definition for network lifetime we have taken in our experiments is the time when the last packet is received by the sink node. Last packet here means the sink node cannot receive any packet from sensors after receiving this packet.

C. Density

The number of sensors deployed in a fixed area will be taken as the Density parameter in this paper. Obviously as the number of sensors increases, so does the average number of sensors per square metre.

IV. Experimental Set-up

The simulated area for the experiments in the following sections is a 10 metre × 10 metre square with randomly deployed nodes. The sink node for this application is located in the middle of this square. One of the primary reasons for selecting this setup is to allow the results to be generalized to large areas by concatenation of networks similar to this. For example, a 50 metre × 50 metre square region could be configured using 25 instances of the setup used here in a 10 × 10 grid formation. All the points (in the figures) in the following section are the average value from at least 5 separate experiments.

In the following section, reliability and lifetime will be evaluated using density as a parameter. As the number of nodes increases in a fixed space, the efficiency of the sensor network may become better or worse. So in some simulations the researchers may care about the number of sensors they are using in the network. It is obvious that

some of the nodes will be out of power in a real wireless sensor network. Thus attention will move to the number of sensors that are alive.

V. RESULTS

A series of experiments were carried out with the number of sensors starting at 10, and increasing in increments of 10 to 300 sensors. The transmission radius for each sensor was fixed at 15 metres.

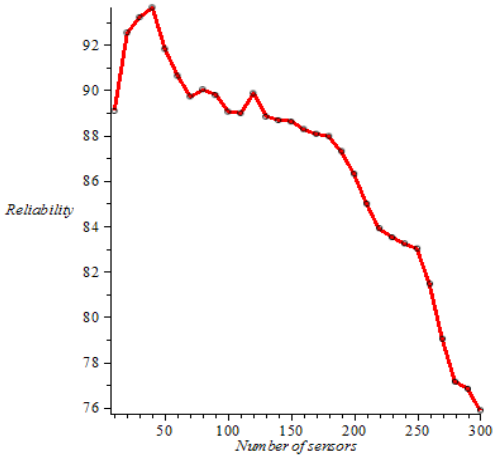

Figure 1. Density, Reliability relationship for NC.

In Fig. 1, the relationship between the number of sensors and Reliability is very clear. Reliability for this application increased as the number of sensors increased to 40, when it reached its highest value. It then essentially decreased as the number of sensors increased from 40 to 300, when it reached its lowest value. This may be explained by observing that as the number of nodes increases in the fixed space more sensors will join the data transmission process and consequently communication among the sensors will become more and more complex. Consequently dropped data due to data collision and latency cannot be ignored. We conclude that it is reasonable to expect reliability to decrease with density. In addition, the variance for Reliability is 23.3978 and the standard deviation for Reliability is 4.83713.

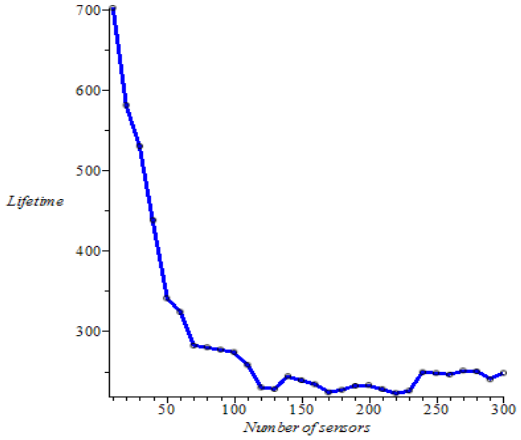

Figure 2. Density, Lifetime relationship for NC.

In Fig. 2, Lifetime reached its lowest value when the number of sensors equalled 220, whereas the highest value of Lifetime occurred when there were 10 sensors. When the number of sensors equalled 40, Reliability was 93.64%, its highest level, but with this number Lifetime is fairly short. This illustrates that it is possible for users to choose an optimum density value for this application depending on the Reliability and Lifetime required. In addition, the variance for Lifetime is 13602.64483 and the standard deviation for Lifetime is 116.63038.

VI. LIFETIME MODEL

Hop count is one way to measure the energy requirement of a routing task, thus using a constant metric per hop. However, if nodes can adjust their transmission power (knowing the location of their neighbours) the constant metric can be replaced by a power metric $u(d) = e + d^{\alpha}$ (or some variation of this) for some constants α and e that depend on the distance d between nodes. The value of e, which includes energy loss due to start up, collisions, retransmissions, and acknowledgements, is relatively significant, and protocols using any kind of periodic hello messages are extremely energy inefficient.

The basic idea for the NC protocol model to be constructed in this section is that the energy consumed by an average sensor in sending all its data to its nearest neighbour is of the form $w(s)E(d^2)$, where $E(d^2)$ is the expected value of the square of the distance between sensors and $w(s)$ is the average number (weight) of packets of data to be sent to its nearest neighbour. This figure also represents the average amount of energy to send one packet of data to the sink node.

Now in the NC protocol one possible parameter that could affect Lifetime is the number of paths or trees formed by the sensors. This is not the case as demonstrated by the following experiments, which are of independent interest. Using J-Sim it is difficult to extract the paths that sensors transmit along to the sink node. For this reason a program was written in the algebraic software package Magma [5] to not only compute the individual paths, but to marry them together to form the initial distinct trees.

Of course during the Lifetime of the network various sensors will die, normally from the centre outwards, and new trees will be formed. The mean number of trees corresponding to different numbers of sensors is given in Table 1 below. This mean number of trees was found by running the program 1,000 times for each given number of sensors. It could be seen from this table that the number of trees is almost independent of the number of sensors (excluding very small values) and is of the order of 2.55 trees.

TABLE I
MEAN NUMBER OF TREES

No. of sensors	Trees
10	2.537
20	2.527
30	2.561
40	2.559
50	2.531
60	2.550
70	2.542
80	2.534
90	2.553
100	2.549
110	2.568
120	2.578
130	2.555
140	2.543
150	2.574
160	2.550
170	2.557
180	2.552
190	2.575
200	2.582
210	2.574
220	2.600
230	2.571
240	2.573
250	2.569
260	2.551
270	2.575
280	2.543
290	2.563
300	2.562

The conclusion from Table 1 is that the mean number of trees is independent of the number of sensors and therefore can be discounted as having any effect on Reliability or Lifetime. The reason that on average two or three trees occur can be satisfactorily explained by considering the diagram below.

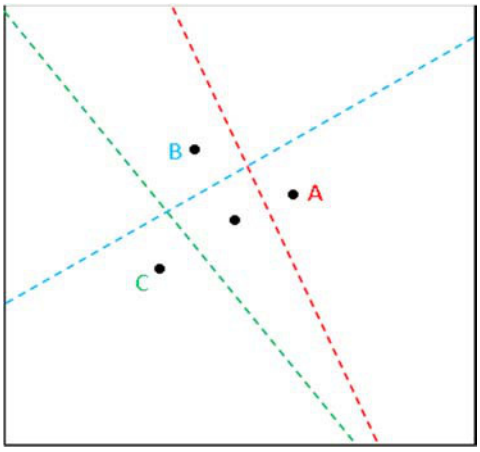

Figure 3. Typical Tree Zones

In Fig. 3 the points A, B and C represent the three nearest sensors to the sink node in the centre of the square amongst the randomly distributed sensors in the region. The perpendicular bisectors of the line segments joining A, B and C to the sink node have then been constructed. The next furthest sensor will with high probability be in one of the three zones containing A, B or C and its corresponding perpendicular bisector. Thus, in this diagram that three trees will probably result with A, B and C as the roots. Then, in 'zone' A it may be the case that further out in the tree that sensors cross over into zone B or C. It is fairly easy to draw diagrams where two or four trees will result, but only a very lop-sided distribution will result in just one tree if a reasonable number of sensors are being distributed.

For the NC protocol the relation 'is the closest neighbour to' is not symmetric, that is B can be the closest neighbour to A without A being the closest neighbour to B. Thus for this protocol it is necessary to find the closest neighbour to a sensor A, but with the stipulation that the neighbour is closer to the sink node than A. It is also the case that the sink node could be the closest neighbour to A, but the sink node is a fixed point and therefore does not fit in with the assumption that this work is dealing with a random distribution of sensors.

The expected distance d between a sensor node and its closest neighbour that is closer to the sink node (including the sink node itself) is given in the second column of the table and the expected distance of the square of the distance is given in the third column. Finally in the fourth column the average weight of the sensors is given, where each branch in the various trees count as weight one. This is then a measure of the number of packets of data an average sensor has to transmit to its nearest neighbour and it is also the average number of hops from the sensors to the sink node. The results of these simulations are tabulated in Table 2.

TABLE II
EXPECTED DISTANCES AND WEIGHTS, VARIABLE SENSORS

Sensors	$E(d)$	$E(d^2)$	$w(s)$
10	2.1945	6.0533	2.3526
20	1.5985	3.2761	3.3421
30	1.3223	2.2444	4.0821
40	1.1512	1.7023	4.7152
50	1.0264	1.3535	5.2218
60	0.9402	1.1350	5.7941
70	0.8672	0.9679	6.2249
80	0.8104	0.8450	6.6531
90	0.7657	0.7545	7.0685
100	0.7256	0.6759	7.4110
110	0.6926	0.6155	7.7859
120	0.6618	0.5634	8.1589
130	0.6360	0.5200	8.4701
140	0.6124	0.4817	8.7956
150	0.5910	0.4485	9.0999
160	0.5724	0.4210	9.4502
170	0.5553	0.3957	9.7218
180	0.5394	0.3734	9.9967
190	0.5240	0.3525	10.3059
200	0.5108	0.3346	10.5684
210	0.4983	0.3183	10.7823
220	0.4874	0.3046	11.0709
230	0.4759	0.2904	11.2847
240	0.4658	0.2785	11.5108
250	0.4562	0.2670	11.8269
260	0.4466	0.2559	12.0056
270	0.4393	0.2475	12.2536
280	0.4308	0.2378	12.4573
290	0.4231	0.2296	12.7054
300	0.4160	0.2216	12.9399

It should be noted that for those sensors whose nearest neighbour is the sink node that the distribution of the distance and distance squared to the sink node is slightly different to those between sensors, and the averages are always slightly higher than those given in Table 2, with the exception of the 10 sensor case when there is a significant difference.

Two results emanate from this table. The first is that $w(s)E(d)$ is nearly constant as it only ranges from 5.16 to 5.45 and is a measure of the average distance from a sensor to the sink node measured along the hop path. The second is that $w(s)E(d^2)$ decreases as the number of sensors increases, this shows that the energy expended by a sensor in receiving and sending received packets to its nearest neighbour decreases as the number of sensors increases. It also represents a measure of the average amount of energy needed to transmit one packet of data to the sink node. Two theories are proposed to explain why the lifetime decreases as the number of sensors increases.

A. *Early Termination*

To explain early termination it is useful to consider the situation when two trees occur and the nearest (root) sensors to the sink node. These two sensors have to receive and transmit all the sensor data to the sink node and therefore have long transmission times with one time slot per packet. A transmission break, which in our definition of lifetime is interpreted as the end of lifetime, could result when both of the root sensors do not possess sufficient energy to transmit their data to the sink node. In a sense this is like the situation for the LEACH protocol with the root sensors acting as fixed cluster heads and the lifetime being controlled by the lifetimes of those sensors. A transmission break could also result if there is a catastrophic data collision in which all the packets of data from the root sensors collide with each other at the sink node and from which the system cannot recover. It is highly probable in a large system that some data collisions will occur at the sink node.

B. *Data build up*

As explained above the tree root sensors have long transmission times to transmit their data in a number of slots. Each sensor can transmit and receive data, but cannot do both simultaneously, also in the slotted ALOHA [6-8] MAC design transmissions in a tree are sequenced. So the sensors immediately prior to a root sensor will receive more data than previously when the root sensor transmits, which will subsequently be transmitted to the root sensor and then the pattern will be repeated. The situation will become more complicated higher up the tree, but generally the amount of data to be transmitted by a sensor will increase with time in a non-linear manner. In particular the root sensors will have more and more packets of data to transmit as data builds up in the tree. So for a fixed number of sensors the amount of energy required for a root sensor to transmit its packets of data to the sink node will increase with time. Delays in the slotted ALOHA protocol will lead to data build up and data collisions will result in retransmissions.

If a varying number of sensors is considered then the amount of energy needed to send a frame of packets may increase with the number of sensors despite the fact that $w(s)E(d^2)$ decreases with the number of sensors. The energy required to transmit such a frame of data (in reality such a frame may not be transmitted in consecutive slots) will increase with the number of sensors if the frame length (the number of packets) exceeds the ratio between $E(d^2)$ for the corresponding number of sensors; this latter ratio is always less than 1.85 between successive values in Table 2 and approaches 1 as the number of sensors

increase, so that it is reasonable to expect that the corresponding ratio of frame lengths will exceed this. This effect is balanced by the fact that in a smaller system sensor will transmit and receive data more often than in a larger system. It is also of note that most energy is used in data transmission rather than reception, however, energy used for data reception could be significant when compared to energy use in a small system.

The conclusion is that $w(s)$ may not be the correct weight to be attached to an average sensor, but instead represents a lower bound for the weight.

The two theories can be related in that with data build up the root sensors may end up transmitting a large amount of data to the sink node using a lot of energy in the process. This could ultimately lead to root sensors having insufficient energy to transmit the frame or a catastrophic data collision, in either case this will lead to early termination of the system. In reality both theories proposed here contribute to the lifetime figures obtained with the latter theory difficult to quantify in a model because of the complexity of the trees.

Anyway lifetime in general can be modelled by only considering the roots of the normally two or three trees. The case of just one tree occurring is of interest for a small number of sensors, for in this scenario the system should run until the only root sensor dies naturally, at that time the system might interpret the death as a transmission break or the next sensor(s) out will take over the role of the root(s). The basic model constructed here is of the form

$$\frac{E(T)K}{nE(d^2)}$$

where n is the number of sensors, K is the total initial energy of a sensor and $E(T)$ is the expected number of trees. Here $n/E(T)$ represents the average weight per tree and since we know that $E(T)$ is nearly constant, the model should roughly resemble the curve $1/n$. Our model in particular assumes that the sensors are evenly distributed amongst the trees and disregards data build up, it should therefore represent an upper bound for the lifetime once the system is running at full capacity. This would imply that lifetime decreases monotonically as the number of sensors increases; however, this basic model assumes that the system runs at full capacity from the start and ignores idle slots in the slotted ALOHA design. Thus there is a base value below which lifetime will not fall, as the system will behave like a smaller system during its initial phase and there will also always be a number of idle slots, this base value will be taken to be the smallest lifetime value of 223 that occurs when $n = 220$. So the revised model is

$$(1 - \lambda(n))223 + \lambda(n)\frac{E(T)K}{nE(d^2)}$$

where $\lambda(n)$ is a proportionality measure with $\lambda(220) = 0$. Now from the lifetime data $\lambda(n)$ will be very close to 0 for all $n \geq 120$. Setting $\lambda(10) = 1$ yields the value $K = 16750$. Computation gives the following values for $\lambda(n)$:

TABLE III
EVALUATION OF THE PROPORTIONALITY MEASURE

n	10	20	30	40	50
$\lambda(n)$	1	0.846	0.741	0.529	0.292
n	60	70	80	90	100
$\lambda(n)$	0.250	0.146	0.141	0.133	0.125
n	110	120	130	140	150
$\lambda(n)$	0.085	0.017	0.012	0.051	0.038
n	160	170	180	190	200
$\lambda(n)$	0.027	0.002	0.009	0.021	0.024
n	210	220	230	240	250
$\lambda(n)$	0.012	0	0.007	0.062	0.059
n	260	270	280	290	300
$\lambda(n)$	0.055	0.064	0.065	0.040	0.059

The parameter $\lambda(x)$ can be piecewise approximated by

$$1.1438571428571 - 0.01501071428514x$$

for $10 \leq x \leq 70$, and

$$0.3954 - 0.0029514285714286x$$

for $80 \leq x \leq 130$ by fitting straight lines through the given values. An alternative that will yield better local approximations is to interpolate between the known values of λ. Thus if $n \leq x < n + 10$, then

$$\lambda(x) \cong \left(1 - \frac{x - n}{10}\right)\lambda(n) + \frac{x - n}{10}\lambda(n + 10).$$

The general equation obtained for $10 \leq x \leq 133$ is

$$(1 - \lambda(x))223 + \lambda(x)\frac{42712.5}{xE(d^2)}$$

and the value of $E(d^2)$ for x sensors can again either be interpolated between the known values in Table 2 or by using the fitted formula

$$\frac{4918141600.24}{6653x^2 + 68674970x + 125057800}$$

for $10 \leq x \leq 300$. Using the latter formula (which is a good fit) yields at worst an implicit equation for the lifetime for $10 \leq x \leq 130$.

Finally we are stating that lifetime is essentially constant for $x \geq 140$ with a value between 223 and 250 depending on the topology of the sensors.

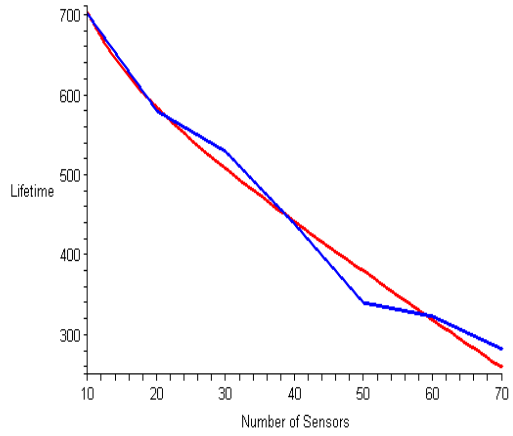

Figure 4 (a). Lifetime model (red), Lifetime (blue).

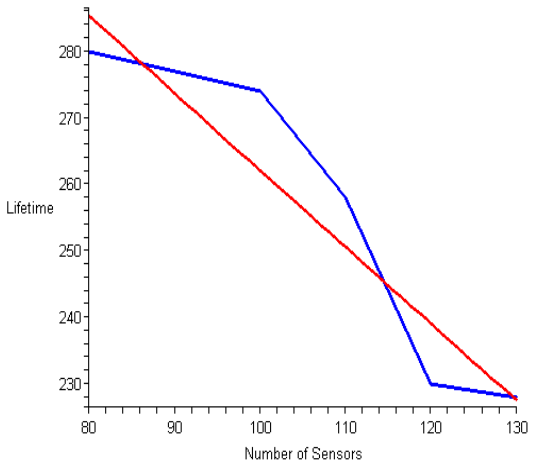

Figure 4 (b). Lifetime model (red), Lifetime (blue).

In both Fig 4 (a) and (b) the lifetime model is nearly a straight line and is clearly a better fit for ≤ 70 sensors.

VII. Reliability Model

In the following Table 1 Reliability (as a percentage) divided by Lifetime is listed for the 15 metre transmission radius case, which gives (100 times) Reliability per unit Lifetime $R(n)/L(n)$:

TABLE IV
Evaluation of Reliability per Unit Lifetime

n	10	20	30	40	50
$R(n)/L(n)$	0.1269	0.1593	0.1759	0.2138	0.2692
n	60	70	80	90	100
$R(n)/L(n)$	0.2797	0.3182	0.3215	0.3241	0.3250
n	110	120	130	140	150
$R(n)/L(n)$	0.3449	0.3911	0.3896	0.3634	0.3708
n	160	170	180	190	200
$R(n)/L(n)$	0.3773	0.3932	0.3875	0.3763	0.3704
n	210	220	230	240	250
$R(n)/L(n)$	0.3728	0.3763	0.3695	0.3343	0.3348
n	260	270	280	290	300
$R(n)/L(n)$	0.3311	0.3149	0.3086	0.3202	0.3060

In the first of these regions the function $R(n)/L(n)$ may be approximated by

$$0.12609 + 0.002226n$$

or equivalently since we have determined $L(n)$ in the previous section

$$R(n) = 0.12609 * L(n) + 0.002226 * n * L(n)$$

for $0 \leq n \leq 120$.

This indicates that 12.5% of the Lifetime figure represents a lower bound for Reliability, but that Reliability per unit Lifetime will increase by about 2% of the Lifetime as the number of sensors is increased by 10.

In the next region the rate $R(n)/L(n)$ reaches its highest level and stays constant at about 0.3779, so that Reliability is about 38% of the Lifetime figure for $130 \leq n \leq 210$.

In the last region the rate decreases, this can be satisfactorily explained by the fact that Lifetime may be considered to be constant in this region and thus increasing the number of sensors just increases the complexity of communication to the sink node and the rate can be approximated by

$$0.549282 - 0.000832666n$$

for $220 \leq n \leq 300$. So in this region 55% of the Lifetime is an upper bound for Reliability, but this decreases by about 0.8% for each extra 10 sensors.

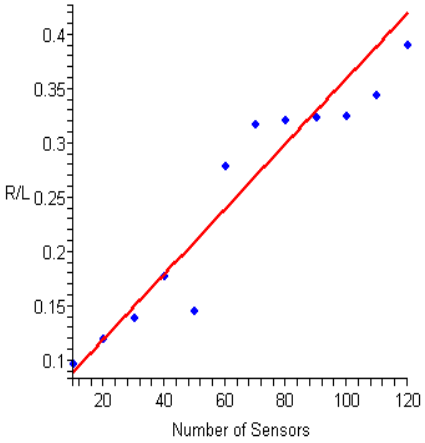

Figure 5 (a). R/L model (red), R/L data points (blue).

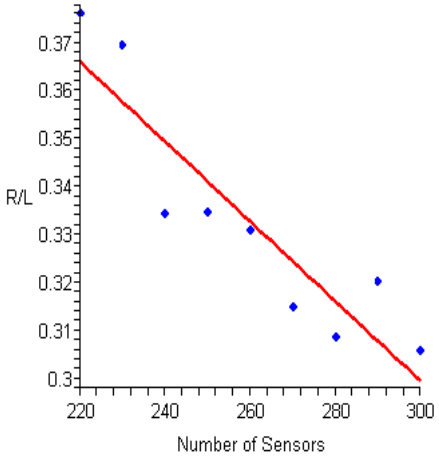

Figure 5 (b). R/L model (red), R/L data points (blue)

The model for R/L in Fig. 5 compared to the actual data point is fairly good with one exception of the point with 50 sensors, which either is genuinely exceptional or it may represent a data error.

VIII. Conclusions

In this paper, from a series of experiments using the J-Sim simulation tool several conclusions for NC were reached: (i) Reliability for this application increased as the number of sensors increased to 40, when it reached its highest value. It then essentially decreased as the number of sensors increased from 40 to 300. (ii) Lifetime decreased as the number of sensors increased to 130 and then it fluctuated slightly as the number of sensors increased to 300. Lifetime reached its lowest value when the number of sensors equalled 220, whereas the highest value of Lifetime occurred when there were 10 sensors.

Based on these simulation results, two evaluation models among the parameters of lifetime, reliability, and density have been proposed. Thus, wireless sensor network users can predict the lifetime and reliability directly. This means that sensor nodes can be deployed in such a network without further simulations.

***Abstract*—Synchronization, in general, is the process of event coordination so that a system performs in unison. In wireless sensor networks (WSN), the network topology often changes dynamically in time. This brings technical hitches and challenges into time synchronization of the sensor nodes in the WSN. In such networks, data routing scheme is either data fusion, fusion of decisions or hybrid fusion. No matter, what data routing scheme is utilized, the time synchronization among the sensors is highly desirable. This paper presents an advanced synchronization algorithm for WSN. Hierarchical as well as decentralized network topology can be used with this algorithm. The designed algorithm is versatile, scalable and easy for implementation. At first, application area of the proposed synchronization algorithm is described. The detailed explanation of the synchronization algorithm at the node level and the network level is supported by the simulation results along with the implementation remarks.**

I. Introduction

HAVING wireless sensor networks (WSN), regarding their nature, they belong to the category of systems with a great measure of parallelism [1]. In order to effectively utilize the parallelism nature, to ensure real-time communication ability and to focus nodes' computational power to application-oriented algorithms, it is necessary to synchronize the sensor nodes. The time synchronization is crucial for any distributed system. In particular, WSN make extensive use of synchronized time in many contexts [1] (e.g. for data fusion, fusion of decisions, hybrid fusions, time division multiple access (TDMA) schedules, synchronized sleep periods, etc.).

This paper describes a new synchronization algorithm based on the fireflies synchronization process. The described algorithm is versatile regardless the network topology. This means, hierarchical networks with master nodes that control the synchronization process as well as fully distributed homogeneous-sensor-type networks are usable for the proposed synchronization algorithm. This new algorithm has been given the name *"Firefly-based Universal Synchronization Algorithm (FUSA)"*.

A. Application area

WSN represents an application area of a great potential. The increasing number of WSN deployment, recent advances in micro-electro mechanical systems (MEMS) and new energy harvesting possibilities make WSN very topical issue [2]. The WSN application potential as well as implementation potential of the proposed synchronization algorithm FUSA includes the following application areas:

- Health-care;
- Transportation;
- Military applications;
- Wearable electronics;
- Industrial applications;
- Intelligent automation/buildings;
- Monitoring of objects and environment (detection of floods, illegal logging, fires, etc.);
- and many other applications.

Health-care WSN applications are modern and interesting application area of WSN [3]. These applications mostly include wearable electronics such as intelligent watches, drug pumps, motion sensors monitoring elder people and those with diseases and disabilities so that they can be kept under the track of their vitality status without major limitations [4]. This modern application area and increasing popularity of health-care applications allow us meeting also WSN that monitor human body vital signs, track patients, monitor hospital environment and many more [5], [6], [7].

Transportation represents a significant portion (at least one third) of the national gross income in the developed countries [8]. Therefore, the need for efficient control of the traffic flows and intelligent monitoring of the traffic is in place. WSN help accomplish aims of the intelligent transportation systems such as traffic mirrors and intelligent traffic crossroads [9], traffic flow classification and quantification, intelligent car park systems and many more.

WSN concept originates in the military application field. Sensor network applications like sniper localization or battle-field monitoring are typical [10].

Wearable electronics include already mentioned health-care applications. However, large application field include sports equipments as well.

Industrial control systems that implement wireless technologies and sensors with actuators represent an advantage over the traditional distributed control systems [11], [12].

This work was supported by Tatra banka Foundation Slovakia

Mostly various diagnosing systems and production line control systems create the industrial application field of WSN.

The energy consumption of the whole society is a crucial problem in terms of the long-term sustainability of the environment. A big portion of the problems related to the environment connects to the energy consumption and energy requirements of the buildings [13], [14]. Intelligent control of the whole building ecosystems represents quite new and very interesting application field not only for the WSN [15], [16].

Property surveillance, object monitoring, environment monitoring (floods detection, fire detection, illegal logging detection, etc.) including protected areas monitoring is another significant application field of WSN [17], [18]. From functional point of view it is very important not to have only algorithms for monitoring - image recognition, voice recognition [19], but also the proper algorithm for increasing the function potential of the whole network [20].

Having in mind WSN for monitoring open area, it is necessary to consider the main characteristics of WSN [8]:

- The network is spread in outdoor terrain, where the energy resource is limited;
- The sensor and actuator nodes have limited energy storage, memory capacity and computational power;
- The network throughput and RF communication bandwidth are limited;
- The interference, path-loss and diffraction phenomena applies in RF communication;
- The environmental conditions as well as network attributes vary in time.

Synchronization algorithm demands are application specific. Typically, applications monitoring environment have the following characteristics [20]:

- Energy efficiency - time needed for synchronization, communication window length and active power modes should be are minimized;
- Scalability - usable for different number of nodes;
- Precision - the nodes are able to send the data in proper time;
- Synchronization time - the amount of time needed for synchronization should be as short as possible.

This paper assumes that the application field of the proposed synchronization algorithm is an application for monitoring forests in order to prevent the illegal wood logging situations. All simulations and application remarks are based on this assumption. However, this fact is not in contrary with the versatility of the proposed synchronization algorithm. The mentioned application field is for the illustrative and interpretation purposes.

B. Related work

Since the WSN applications are specific, not every synchronization algorithm is suitable for WSN purposes. The following paragraphs mention synchronization algorithms whose nature allows WSN utilization.

Cristian's Algorithm [21] and *Berkeley Algorithm* [22] are considered as essential synchronization algorithms and we will not discuss them. Computer networks very often use *Network Time Protocol (NTP)* [23] for time synchronization. However, the standard computer networks do not suffer from limited energy constraints.

Well known and very often used algorithms in WSN are *Reference Broadcast Synchronization (RBS)* [24] and *Timing Synchronization Protocol for Sensor Network (TPSN)* [25]. In RBS, the master node called the beacon node is used for synchronization. The synchronization of the whole network is performed from the beacon node that sends the reference broadcast towards one-hop-distant nodes from beacon node. Large networks with many sensor and/or actuator nodes are usually divided into smaller virtual networks called clusters. TPSN synchronization algorithm works with synchronization master as well. This master node is elected by all nodes. As soon as the mater node is elected, the spanning tree of the network is created. The children nodes are being synchronized by their parent node. In case any change in the network topology happens (e.g. a node becomes unavailable) a new master has to be elected again.

A reference point and the construction of the network tree is also used in *Tree Structured Referencing Time Synchronization (TSRT)* [26] and *Lightweight Tree-based Synchronization (LTS)* [27].

Other class of synchronization algorithms that use master node for synchronization or the group of master nodes contains *Time Diffusion Synchronization (TDP)* [28] and *ETSP* [29], which use both TPSN and RBS methodology. They switch between the TPSN and RBS based on the threshold value. The hierarchical structure of WSN is also used in [30], where the big accuracy of synchronized clock can be achieved, but only in simulation environment. Some of the algorithms use conditional probability estimation as well [31], [32], [33].

II. Synchronization Algorithm - FUSA

The synchronization algorithm proposed in this paper can be used in hierarchical as well as in network with fully distributed cooperation and coordination.

Since the communication subsystem in active mode consumes the significant, and in many cases the most, energy of all sensor node subsystems, minimizing active RF communication minimizes the energy consumption of the whole node too. The presented algorithm is based on the fireflies synchronization process - [34] (main idea), [35] (simple practical implementation), [36] (theory).

Each node periodically transmits synchronization packet (any data can be used). Let the basic time period be T. By using crystal-based clock, it is possible to set the period for each node precisely. However, each node starts at random time instant. This phenomena results in different timing phase start. Despite having crystal-based clock, small deviations in every clock source create deviations in time phase, thus getting all nodes out of the synchronization. This presents a problem and therefore synchronization algorithms are being used to suppress the unwanted effects.

Let's denote the phase for N nodes by $\phi_n \in < 0, 1 >$. Then, the maximum phase error in the network can be defined as:

$$\phi_{max}(t) = max_n(\phi_n(t)) - min_n(\phi_n(t)) \quad (1)$$

This definition can be represented as network synchronization quality.

The network is fully synchronized when $\phi_{max}(t) = 0$. After this point, all nodes are allowed to switch to a sleep mode and they wake up only for a short period of time. In discrete time domain, the best way how to divide the time period T is to divide it into D count of the same parts (frames) T_d, i.e. $T = D \cdot T_d$. For the reason of simple practical implementation, in simulations, the dividing factor D has been equal to $D = 128$. The nodes have transmitted the data in $1s$ time period, which implies $128Hz$ interrupt timer frequency. Each node is allowed to transmit data only in its time frame, while the rest of the time frames (assigned to other nodes) this node is expected to respect the radio silence (usually turns into the sleep mode).

Each node has a time counter which is incremented periodically in the timer interrupt routine. When it reaches the maximum, then the timer starts decrementing the counter value and at the same time the synchronization packet is transmitted. When the counter reaches the minimum value, the timer starts incrementing. The described process generates triangle wave output, which can be transformed into a phase represented as the sawtooth wave. The triangle (sawtooth) wave is important, as presented in [34], the function cannot be homogeneous (fe. time = time%128 will never work).

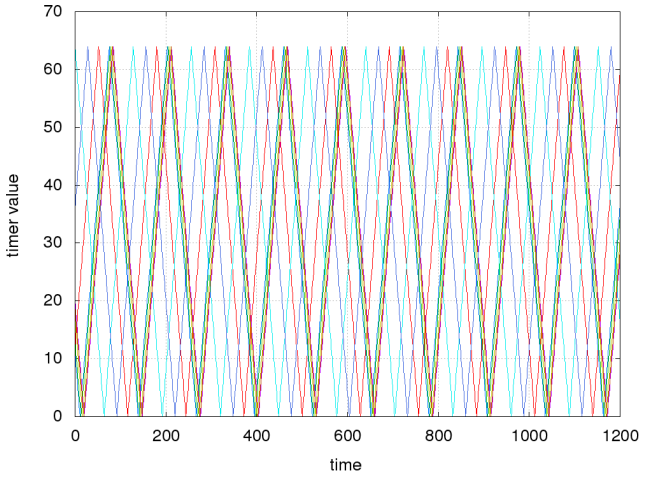

Fig. 1. Phases of nodes without synchronization

Simulations were performed with 64 nodes, in a $8x8$ grid network topology, where each node can see only four neighboring nodes. This grid network topology is called an *anuloid grid*. Fig. 1 and Fig. 2 demonstrate the network without synchronization - random initial phases. Fig. 1 represents phase values of first 8 nodes. Synchronization quality can be evaluated using (1) and is show in Fig. 2. It is obvious that the maximum phase error oscillates around the maximum phase value (128) and the average phase is in the center (64).

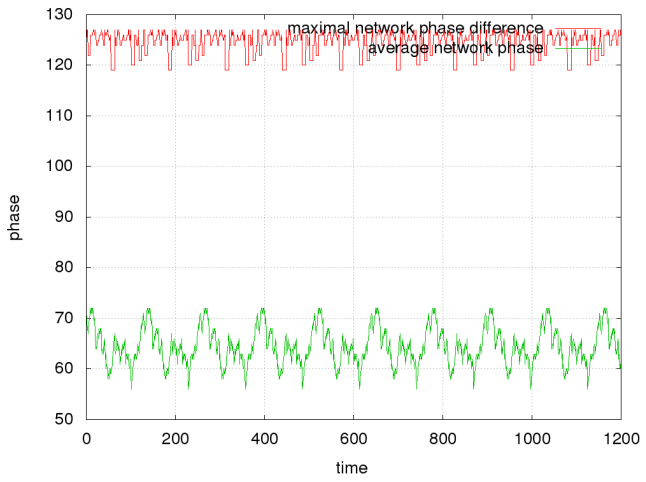

Fig. 2. Maximum and average phase of the network without synchronization

The source code (Algorithm 1) demonstrates the synchronization process in Ruby programming language.

Algorithm 1 The node synchronization

```
def tick(fired)
    @fired_tmp = false

    if fired
        @timer = TIMER_MAX
    end

    if (@state == 0)
        if (@timer >= TIMER_MAX)
            @timer-= 1
            @state = 1
            @fired_tmp = true
        else
            @timer+= 1
        end
    else
        if (@timer <= 0)
            @timer+= 1
                @state = 0
            else
                @timer-= 1
            end
    end
end
```

The method *tick* is called periodically, in discrete time, on each node. The input parameter *fired* has two values:

$$fired = \begin{cases} true\ when & node[j][i+1].fired\ or \\ & node[j][i-1].fired\ or \\ & node[j+1][i].fired\ or \\ & node[j-1][i].fired \\ false & else \end{cases}$$

When any of the neighboring nodes fires (timer is on top), this node sets the timer counter to $TIMER\_MAX$ value. Depending on the state, in the next step, the timer is either decremented, or incremented and compared to the top value. If the counter reaches the maximum value, the node fires, and the state is switched.

Algorithm 2 Network synchronization

```
for j in 0..@net.size-1
 for i in 0..@net[j].size-1
  if (@net[(j+1)%@net.size][i].get_fired) or
     (@net[(j-1)%@net.size][i].get_fired) or
     (@net[j][(i+1)%@net[j].size].get_fired) or
     (@net[j][(i-1)%@net[j].size].get_fired)

   fired = true
  else
   fired = false
  end

  @net[j][i].tick(fired)
 end
end
```

The network synchronization must work in discrete time so *fired* flag is stored in $@fired\_tmp$ first. After all nodes call the method *tick*, the $fired$ flags are updated.

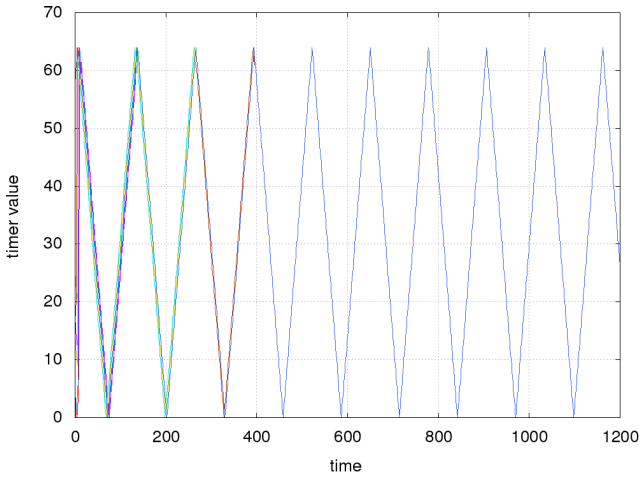

Fig. 3. Phases of nodes with synchronization

Fig. 3 and Fig. 4 demonstrate the network synchronization process. Fig. 3 illustrates the phase of the nodes when synchronization process applies On Fig. 4 we can see fluent decreasing of the phase error, until it reaches 0.

The following figures Fig. 5, Fig. 6, Fig. 7 and Fig. 8 represent the phase synchronization process and demonstrate the *synchronization wave* in the network in different iterations of the synchronization algorithm. As it can be seen, the waves with the increasing number of synchronization algorithm iterations slightly disappear.

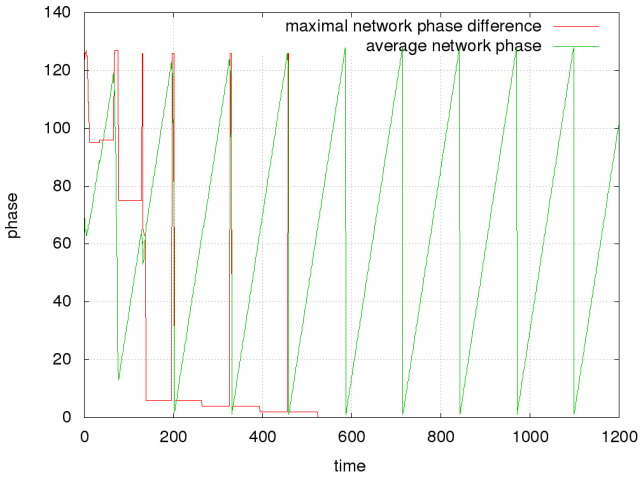

Fig. 4. Maximum and average phase of the network with synchronization

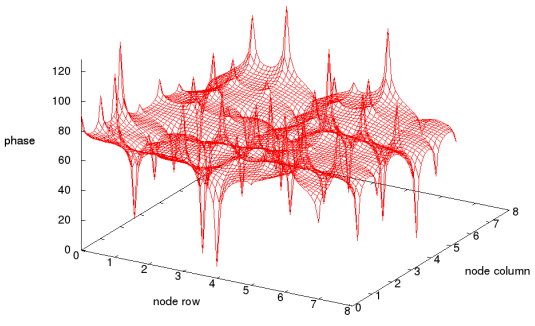

Fig. 5. Network initial phases, iteration 0

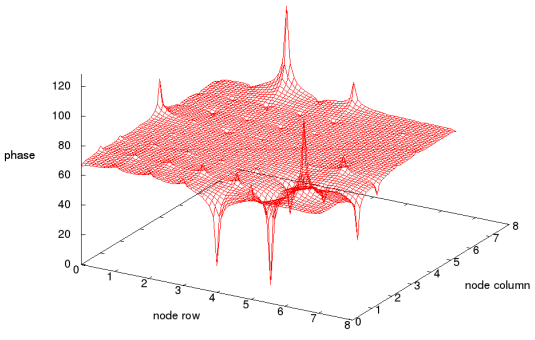

Fig. 6. Network synchronization, iteration 10

By comparing Fig. 6 and Fig. 7 we can see the *synchronization wave*. When the network is fully synchronized, all

phases are the same and we get a straight plane as illustrated in Fig.8. During the simulations performed on the self-developed simulator, we found out that the proposed synchronization algorithm is fully functional despite of node failure. This has also no effect on the overall WSN operation.

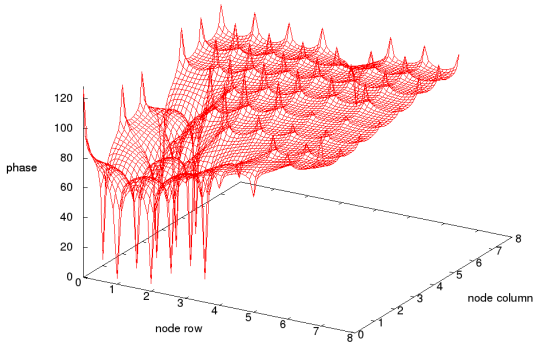

Fig. 7. Network synchronization, iteration 70

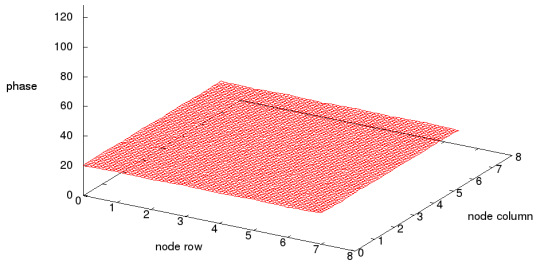

Fig. 8. Network synchronization, iteration 1180

III. Node Implementation

The experimental evaluation of the proposed synchronization algorithm has been performed on wireless sensor nodes based on Texas Instruments MSP430 family microcontrollers (MSP430F2232, 8kB FLASH, 512b RAM) (Fig. 9). The communication subsystem (RF) part is based on Texas Instruments transceiver CC1101 - a low power transceiver operating at $868MHz$ ISM band. Other sensor node subsystems built-in on-board are $3.3V$ low-drop regulator, three-axis magnetometer, two LEDs and an UART peripheral for debugging. Further details about the nodes can be found in [9]. Red board in Fig. 9 was used as a power supply and for debugging purposes.

After general input/output peripheral (GPIO) initialization and RF module initialization, the $timer0a$ interrupt is set to $256Hz$ periodic invoke (derived from external $32.768kHz$ crystal-based clock source). This initialization is described in the Algorithm 3.

Algorithm 3 Low power timer initializiation

```
/* f = ACLK (32768Hz) / TACCR0*/
TACCR0 = 128;

/* select ACLK/1, up mode, and clear the TAR */
TACTL = TASSEL_1 + MC_1 + TACLR;

/* enable timer interrupt*/
TACCTL0 = CCIE;
```

The Algorithm 1 described in the previous paragraphs is implemented in three program subroutines as follows:

- Synchronization with received packet (in GPIO pin interrupt routine);
- Periodical packet transmission and timer control (in timer interrupt routine);
- Higher-level network functions (in the main loop routine).

In GPIO initialization phase, RF receive pin is configured as an interrupt pin. After this steps the microcontroller (MCU) is allowed to enter the LPM3 sleep mode, which it can wake up from with $256Hz$ period and/or on the packet receive interrupt. The received packet processing is described in the following algorithm - Algorithm 4.

Algorithm 4 Packet receive interrupt service rutine

```
interrupt (PORT2_VECTOR) Port_2 (void)
{
  if ((__state__ == 2) &&
    (TI_CC_GDO0_PxIFG & TI_CC_GDO0_PIN))
  {
    u8 len = PACKET_LENGTH-1;
    if (RFReceivePacket((u8*)rxBuffer,&len))
    {
      __state__ = 0;

      i16 add = TIMER_MAX - __phase__;
      __phase__+= add;

      if (__phase__ > TIMER_MAX)
        __phase__ = TIMER_MAX;

      if (__phase__ < TIMER_MIN)
        __phase__ = TIMER_MIN;
    }
  }

  TI_CC_GDO0_PxIFG &= ~TI_CC_GDO0_PIN;
  LPM3_EXIT;
}
```

This routine (Algorithm 4) is executed only when the program is in $\_\_state\_\_ == 2$. That means packet receiving is enabled, which maximizes the sleep time. When a packet from other node is received, this interrupt routine is executed.

The phase synchronization is done on the following source code lines:

$$i16\ add = TIMER\_MAX - \_\_phase\_\_;$$
$$\_\_phase\_\_ += add;$$

In the timer interrupt routine the timer phase control is processed. This routine is exemplified in Algorithm 5.

Algorithm 5 Timer interrupt service rutine

```
interrupt(TIMER0_A0_VECTOR)
TIMER0_A0_ISR(void)
{
  __phase__+=__sh_output__/(i16)TIMER_MAX;

  if (__phase__ > TIMER_MAX)
    __phase__ = TIMER_MAX;

  if (__phase__ < TIMER_MIN)
    __phase__ = TIMER_MIN;

  if ((__phase__ + DEVICE_ADDR) == TIMER_MAX)
    __state__ = 1;

  if (__sh_output__ == TIMER_MAX)
  {
    if (__phase__ >= TIMER_MAX)
      __sh_output__ = TIMER_MIN;
  }
  else
  {
    if (__phase__ <= TIMER_MIN)
      __sh_output__ = TIMER_MAX;
  }

  LPM3_EXIT;
}
```

There is important to add a small phase difference, to avoid transmission collision, which is done as follows:

$$if((\_phase\_ + DEVICE\_ADDR) == TIMER\_MAX)$$
$$\_\_state\_\_ = 1;$$

When program enters into $\_\_state\_\_ = 1$ the received packet can be released to the main loop.

IV. Conclusion and Future Work

For the proper function of each WSN, the node synchronization is very important part of proposed solution. In this paper the algorithm for the synchronization was proposed, which is very easy for implementation. This algorithm is not only for hierarchical networks, it is universal and scalable. Functionality of synchronization algorithm was tested on mesh network up to 1024 nodes. It is good to note that in this paper only part for synchronization process is written. In future the authors would like to extend the algorithm and use algorithm together with monitoring techniques. That means that the communication window should be divided into the smaller slots for sending the data.

***Abstract*—Indoor localization and navigation using wireless sensor networks is still a big challenge if expensive sensor nodes are not involved. Previous research has shown that in a sparse distributed sensor network the error distance is way too high. Even room accuracy can not be guaranteed.**

In this paper, an easy-to-use generic positioning framework is proposed, which allows users to plug in a single or multiple positioning algorithms. We illustrate the usability of the framework by discussing a new hybrid positioning solution. The combination of a weighted (range-based) and proximity (range-free) algorithm is made. Both solutions separately have an average error distance of 13.5m and 2.5m respectively. The latter result is quite accurate due to the fact that our testbeds are not sparse distributed. Our hybrid algorithm has an average error distance of 2.66m only using a selected set of nodes, simulating a sparse distributed sensor network. All our experiments have been executed in the iMinds testbed: namely at "de Zuiderpoort". These algorithms are also deployed in two real-life environments: "De Vooruit" and "De Vijvers".

I. Introduction

COMBINING wireless sensor network nodes with the upcoming trend of smartphones creates a totally new range of possibilities. Normally, wireless sensor networks are used to monitor a certain environment and measure e.g. the temperature and humidity. But also tracking of persons and equipment can be done by sensor networks. GPS [1] is the traditional way of tracking people or vehicles outdoor, however this does not work properly indoor because line of sight (LOS) is required to receive the GPS signals.

Sensor nodes inside buildings can fix this issue, however other factors have to be taken into account: interference, infrastructure, the amount of sensor nodes that is required, energy consumption,... It will always be a trade-off between cost and accuracy. Further, a myriad of positioning algorithms have been developed in the last few years. A standalone solution generally does not offer sufficient accuracy in different environments (indoor/outdoor, different type of buildings,...). In this paper however, we will try to find a solution with an acceptable accuracy when only a sparse distributed sensor network is available. Our algorithm described in this work is a combination of two already existing algorithms. Each belonging to a different subdivision, namely range-free and range-based. Both solutions show too many defects in thinner environments. Combining them results in a noticeable improvement. In this way, room accuracy can be guaranteed.

The rest of the paper is organized as follows. In section 2, the already existing algorithms are clarified. Section 3 describes our generic architecture framework. The hybrid algorithm build in this framework whereby the two previous are combined is discussed in section 4. Section 5 handles about our different testbeds. The experiments with their results are summarized in section 6. Finally, some conclusions can be made. These are, together with the future work, clarified in section 7.

II. Related work

In this section, we conclude the work that is essential to comprehend our hybrid solution. Localization algorithms can be subdivided in two different categories. The first category is called the "range-based"-algorithms. In order to calculate a position pertaining to multiple fixed nodes, a distance measurement is essential. Then, on the base of this distance, a position can be determined by means of trilateration. Trilateration is a method to find the intersection of three circles whose center and radius are known. There are many different ways to measure the distance. The most familiar techniques are Received Signal Strength Indication (RSSI), Time of Arrival (ToA), Time Difference of Arrival (TDoA) and Angle of Arrival (AoA).

The second category, "range-free"-algorithms, does not require a distance measurement to calculate the position of a sensor node. They are based on the information of the connection. If two sensor nodes can connect to each other, than the maximum distance between them is the maximum transmission range. Thus the position of the mobile node can be estimated with this information. This is a very simple and cheap technique. Moreover the accuracy will depend on the density of the wireless sensor network. Centroid, triangle elimination and proximity are common range-free algorithms.

The hybrid solution uses both techniques. A combination of a range-based and a range-free algorithm is made. In the following two sections, both algorithms will be explained more in detail.

A. Range-based: weighted

The first one is a range-based solution described by Tareq Ali Alhmiedat et al. in [2]. The proposed algorithm is based on weighted RSSI values. The main idea of RSSI is that the transmission power P_T directly affect the received power P_R

978-83-60810-58-3/$25.00

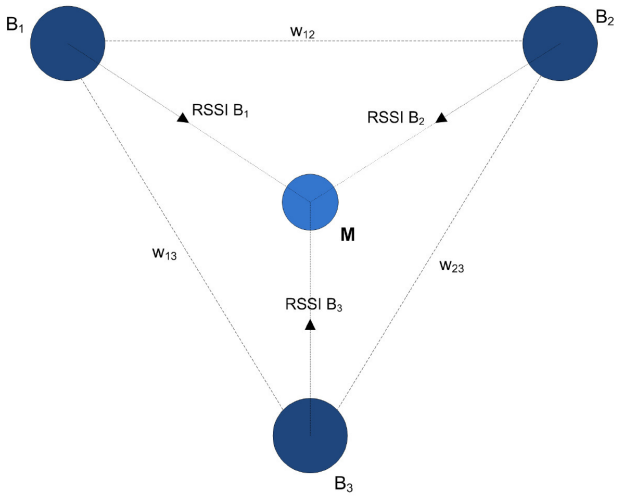

Fig. 1: Weighted algorithm: schema

of a signal. Via the Friis transmission equation, also defined in [2], the linear relationship becomes clear:

$$P_R = P_T * G_T * G_R \left(\frac{\lambda}{4\pi d}\right)^2 \tag{1}$$

where G_T, G_R are gain of transmitter and receiver respectively. λ is the wavelength of the signal and d is the distance between sender and receiver. The received signal strength indicator (RSSI) can be defined as the ratio of the received power to the reference power P_{Ref}.

$$RSSI = 10 * \log \frac{P_R}{P_{Ref}} \tag{2}$$

Each RSSI value can be matched with a certain distance. The proposed algorithm in [2] not only uses the RSSI-values to measure the distance between a fixed and mobile node, but also the distance between the fixed nodes mutually is measured. These values function as weight factors for the distance calculation between the fixed and mobile node. These weight factors are shown in Figure 1 as w_{12}, w_{13} and w_{23}. The distance from M to, for example, B_1 can be calculated as follows:

$$Distance(M, B_1) = \frac{RSSI\, B_1 * w_{12} + RSSI\, B_1 * w_{13}}{2} \tag{3}$$

Their results prove that these weight factors add value to the accuracy. A drawback of the RSSI technique is that these measurements are very sensitive to the environment and potential changes in it. The relationship between the distance and RSSI depends on the room. For example, in a long corridor, the fixed nodes their signals will have a greater range because they reverberate through the long walls. In this way, completely different results can be obtained.

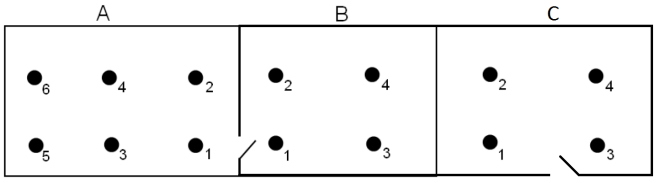

Fig. 2: Three neighboring offices

B. Range-free: proximity

In contrast to the previous category, range-free algorithms do not take RSSI-values into account. If a mobile sensor node has a range of 10 meters, than a fixed node can only receive his messages if the mobile node is maximum 10 meters away. This is the only information that is used to calculate the position of a mobile node. This technique is used by J. Wyffels et al. in [3]. A proximity-based algorithm is used to localize the patients and the nurses in a healthcare environment. Important here is that the transmission power is well configured. If the power is too low, the mobile node could be out of range between two fixed nodes. And also vice versa if the power is too high, too many fixed nodes will receive the beacon and a wrong estimation could be made.

The latter problem can be solved by using a centroid algorithm [4]. This is only useful if there is a set of fixed nodes with an overlapping coverage area. The beacon of the mobile node is received by multiple fixed nodes. In order to determine the position, the centroid of all the receiving fixed nodes is calculated (Eq. 4).

$$[x_M, y_M] = \left[\frac{\sum_{n=0}^{k-1} x_n}{k}, \frac{\sum_{n=0}^{k-1} y_n}{k}\right] \tag{4}$$

Normally would this algorithm give a 100% guarantee that room-accuracy is ensured. However, experiments have shown that this is not always the case. If the walls are small enough and/or not made of concrete, signals can go trough and a fixed node in a different room can catch up the beacon. In order to prevent a wrong location estimation, some extra logic can be implemented in the algorithm.

To implement the extra logic, some extra information is necessary as well. Suppose we have the exact coordinates of all the walls, doors and nodes inside a building. Knowing that every beacon has an index number, the direct path could be checked between the two fixed nodes who received the consecutive beacons. If the mobile node goes from one room to another, without using a door, then the last beacon can be dismissed. For example (Fig. 2) when node A_2 receives a beacon and the next beacon is received by node B_2. It is impossible to move directly from A_2 to B_2 without passing nodes A_1 and B_1. So the message that was received by beacon B_2 will be rejected.

With this optimization room-accuracy can be guaranteed. Still, this solution has the drawback that a lot of fixed sensor nodes are necessary to retrieve good results. If the network is sparse distributed, then the algorithm would not work properly.

III. Positioning framework

The framework is developed in Java and consists of three parts: the positioning server, the web server and the client application (Fig. 3).

The positioning server has two functional blocks. The interconnection gateway is responsible for the retrieval of positioning information gathered by the network infrastructure or mobile unit that is being located. The interconnection gateway further incorporates an abstraction layer which hides the underlying technology (ZigBee, Wi-Fi, Bluetooth, ...) from the positioning server. In Figure 3, two different approaches for positioning in wireless sensor networks are shown. On the left side, a mobile device broadcasts positioning beacons and the sink node of the WSN forwards the beacons to the interconnection gateway. On the right side, the infrastructure nodes broadcast beacons and the mobile unit collects and forwards the beacons to the interconnection gateway. The interconnection gateway further passes the positioning information to the position calculator, which consists of pluggable positioning algorithms. Multiple positioning algorithms can be active at the same time. A reasoner is used to select the algorithm giving the most accurate position or to intelligently combine the results of multiple algorithms into a more accurate (hybrid) position. Map info can also be taken into account when calculating the position.

The web server can poll the positioning server for the user's position. And the client application can either run on a smartphone or a central monitoring station. The client communicates with the web server through e.g. Wi-Fi or Ethernet.

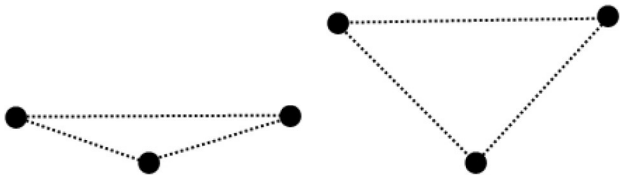
Some advantages of the framework:

- Existing smartphone applications can use position information by implementing a simple interface allowing the application to request a user's position from the web server.
- Conversion of relative coordinates to GPS notation is possible. This implies that client applications developed to work outdoor (GPS), can easily use this framework.
- The user of the client application can pinpoint his correct location on the floor plan (for testing purposes). The application then calculates the difference between the estimated and the real position, thus allowing the user to evaluate the algorithm.

IV. Hybrid algorithm

Having this framework described above, designing a hybrid solution is very efficient. The reasoner allows the position calculator to combine the results of different algorithms and other available information. In the hybrid solution the reasoner has two choices: if the mobile node is in range of a fixed node we use the result of the proximity algorithm. If no fixed node can hear the proximity node, the reasoner will decide to use the weighted RSSI algorithm, where the mobile unit has a wider range.

The biggest problem of the stand-alone weighted algorithm, is the selection of the nodes. An ideal situation would be that the proximity node would be surrounded by the closest fixed nodes. As discussed in subsection II-A, selecting the closest nodes is not possible if only the RSSI values are available. The proximity algorithm can give extra information whereby finding the closest nodes can be realized. Hence, the node selection can be optimized using the latest information of the proximity algorithm. In that way, the first node of the triangle is determined. In order to have a good coverage of the area, the two other nodes must be well selected. If the angles of the triangle are too sharp (Fig. 4a) than the weighted algorithm will not function properly. In certain situations, the two last nodes will have to be reselected until a good triangle (Fig. 4b) is founded.



(a) Bad triangle (b) Good triangle

Fig. 4: Node selection

Data: Three circles of each fixed node
Result: Position of the mobile node
if *three circles do not intersect* **then**
  while *smallest circle does not intersect with the second smallest circle* **do**
    increase the smallest circle
  end
end
`// Now at least two circles intersect`
Calculate the intersection of the two smallest circles
position mobile node = intersection of the two smallest circles closest with the biggest circle

Algorithm 1: Adapted trilateration

Once the three fixed nodes are selected, a distance measurement is the next step in the procedure. This is done the same way as the stand-alone weighted algorithm (Eq. 3) except for one thing. The RSSI values are slightly adapted because results of previous experiments have shown that the calculated distance was almost always too big. This adaption is estimated experimentally. After the distance calculation, the three circles can be created and trilateration can be applied. In perfect circumstances, the three circles will intersect in exactly one point. However, in practice this is never the case. Due to the environment and interference, the three circles will never intersect in one single point. Therefore, an adapted trilateration technique is shown in Algorithm 1.

Finally, if the reasoner has access to other input, such as information about walls, rooms, doors, we can use this to influence our position estimate.

V. Environment descriptions

This positioning framework including the hybrid solutions has been tested in two wireless testbeds and also in two dif-

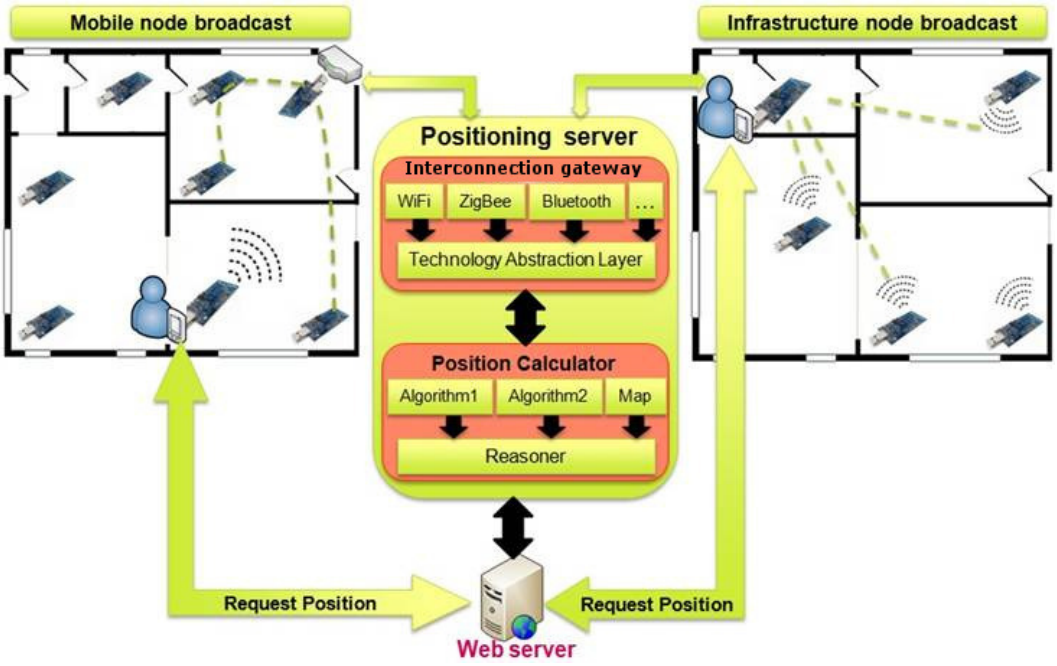


Fig. 3: Framework architecture

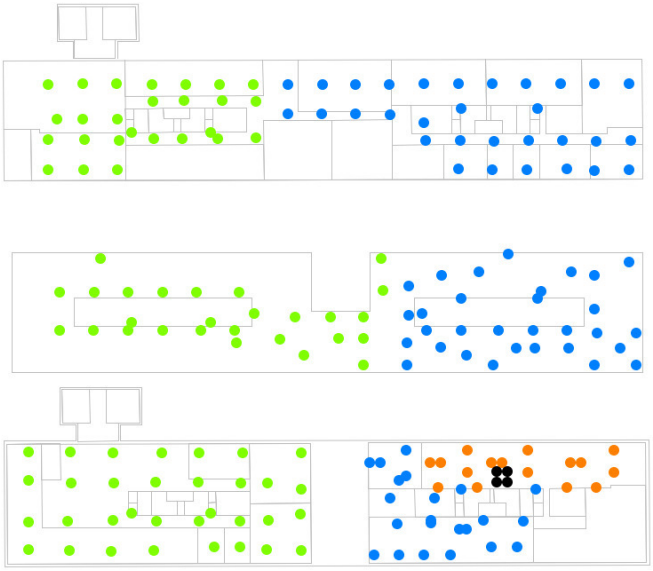

Fig. 5: w-iLab.t at the "Zuiderpoort". 200 nodes on three floors (18m x 90m). The different colors indicate the nodes can be divided in groups for executing tests.

ferent real-life situations. Each environment will be explained further in detail in the next sections.

A. *w.iLab-t at the "Zuiderpoort"*

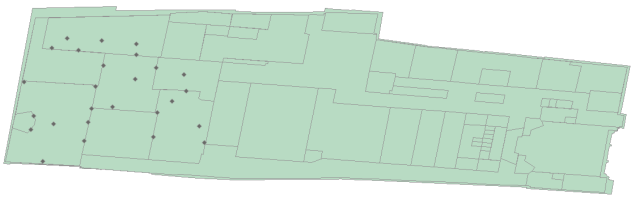
The w.iLab-t is an extensive facility that is introduced in detail by S. Bouckaert et al. in [5]. The infrastructure is distributed on three floors of the iMinds office in Ghent, Belgium (Fig. 5). The network consists of 200 nodes. Each node has (i) a Tmote Sky IEEE 802.15.4 mote, (ii) two Compex WLM54SAG 200mW AR5006XS 802.11a/b/g 54/108 Mbps miniPCI wireless cards and (iii) an environment emulator. The latter one is self-made and used for simulations: environment (e.g. temperature change), battery drop, user input, etc. These nodes are centrally managed for control and monitoring purposes and remote access by using an Intel x86 architecture (PC Engines Alix Boards).

B. *"De Vooruit"*

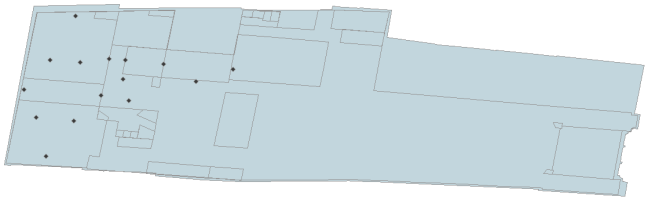
De Vooruit is an ancient building close to the historical center of Ghent [7]. In the past, this building was a place for the working class where they could eat, drink and enjoy culture at democratic prices. Since 1982 De Vooruit is recognized as a monument and nowadays it is still used to organize lectures, debates, concerts, parties, ... This location was a perfect use case to test the indoor localization solutions. Due to the fact that the building was recognized as a monument, it was not allowed to use a cabled network. In this situation, wireless sensor networks were the only solution to handle this problem. 50 nodes, distributed over four different floors (Fig. 6), were used to locate the mobile nodes worn by the visitors. In this use case, Sentilla JCreate nodes in combination with battery packs were used.

C. *"De Vijvers"*

As a second use case, the positioning was tested in a home for the elderly. The goal here was to track people with dementia that are not allowed to leave the home. When a person goes in a restricted zone, an alarm was sounded. The position of the person could then be seen on a map in the reception. In this building (Fig. 7), 25 Sentilla JCreate



(a) Fourth floor of De Vooruit



(b) Sixth floor of De Vooruit

Fig. 6: Floorplan of the fourth and sixth floor of De Vooruit, the diamonds represent the fixed nodes installed in the building.

Fig. 7: The southern part of "De Vijvers" where 25 nodes were attached in the central and eastern part of the building. Their positions are marked with red dots.

nodes were attached to obtain the required accuracy for this application.

VI. Results

In this section, we present the results of all the interesting measurements. First, the two algorithms are tested separately, followed by the results of the hybrid solution. All these measurements are done at De Zuiderpoort (Section V-A) on the third floor.

A. Range-based: weighted

The results from [2] showed that the weighted RSSI-values give a more accurate position than the normal RSSI-values. For

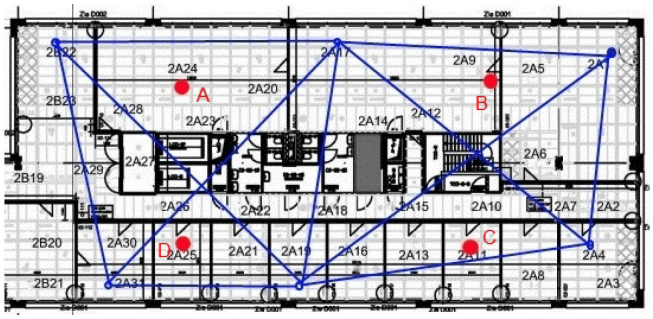


Fig. 8: Dividing the third floor in big triangles for the second test of the weighted algorithm.

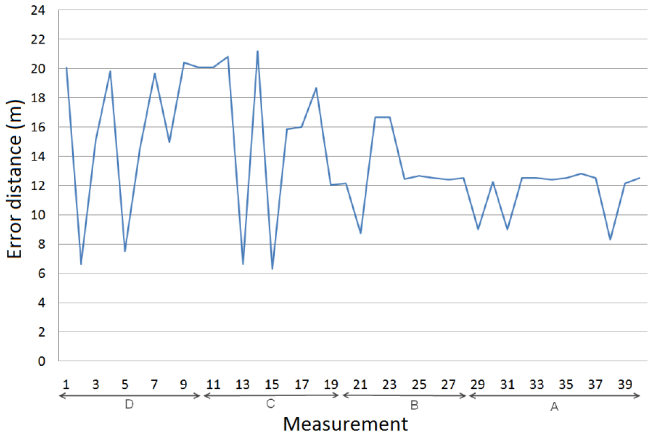

Fig. 9: Graphical overview of the results of the weighted algorithm using a sparse distribution of the fixed nodes

those reasons, only the results of the weighted algorithm will be shown.

Several tests have been executed. First, all available nodes on the third floor were used. This, however, gave very poor results so they are not published in this work. Some measurements had an error distance of more than 20 meters. An explanation for these large error distances is multipath fading of the nodes in the corridor. The setup of the second test is shown in Figure 8. The third floor is divided in big triangles (marked with blue lines) to calculate the position of A, B, C and D (marked with a red dot). The results of these measurements can be found in Figure 9. For each location, ten measurements are executed. The smallest error distance is $6.3m$, the biggest is $21.2m$ with an average error distance of $13.8m$. These results are not acceptable because room accuracy cannot be guaranteed. The large error distance is due to the fact that a high transmission power was necessary to communicate trough the concrete walls in the center of the building. The concrete walls has a strong influence on the RSSI measurements. For those reasons, a third test was implemented that avoids the concrete walls.

The triangles of the third test can be found in Figure 10. In this way, the signals do not need to go through the concrete walls so a lower tx-power can be used. The results of this

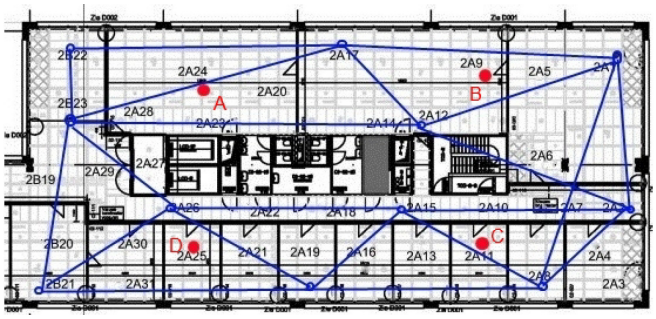

Fig. 10: Dividing the third floor in small triangles for the third test of the weighted algorithm.

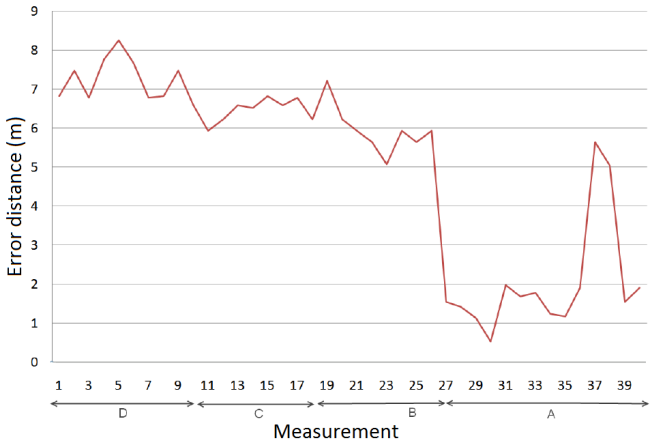

Fig. 11: Graphical overview of the results of the weighted algorithm using a dens distribution of the fixed nodes

setup are represented in Figure 11. Again, in this test, ten measurements at each location are recorded. The smallest error distance here is only $0.5m$, the largest one $8.2m$. The average error distance is $4.8m$. These results are much better than with the large triangles, but still, an error distance of $8m$ is unacceptable.

In these results, it became clear that this single algorithm was not capable to deliver the room accuracy.

B. Range-free: proximity

The results of the proximity based algorithm are completely dependent of the used infrastructure. The density of the fixed nodes determines the accuracy of the localization. Our algorithm is tested in the w-iLab.t at De Zuiderpoort (Section V-A) where the fixed nodes have an intermediate distance of 5 meters. This means that the maximum error distance is about $2.5m$. In the best case, the mobile node is located right under the fixed node, meaning that the error distance is $0m$.

C. Hybrid algorithm

The hybrid algorithm is designed to work properly in sparse distributed sensor network. However, the w-iLab.t is not sparse distributed. For this reason, it was hard to retrieve results using the whole testbed, the proximity beacons were always

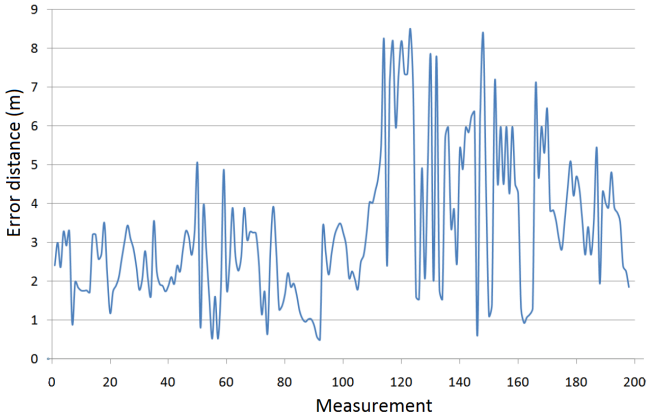

Fig. 13: Graphical overview of the results of the hybrid algorithm using a sparse distribution of the fixed nodes

reachable whereby the hybrid algorithm almost never switched from the proximity to the weighted algorithm. This produced the same results as in Subsection VI-B. In order to test this algorithm its full functionality, some artificial tests are done. From the moment a fixed node received a proximity beacon, the transmitting of proximity beacons by the mobile node will be stopped. Hereby, the weighted algorithm has to come active to calculate the final location of the node.

The mobile node is placed at different locations on the third floor in De Zuiderpoort building, these are marked in Figure 12 with the blue spots. The results of these measurements can be found in Figure 13, these are the worst possible results because the proximity is often disabled in order to activate the weighted part of the hybrid algorithm. 200 measurements were made across the different locations. The minimum error distance was $0.49m$ and maximum $8.5m$. The average of all the measurements together was $3.28m$. The worst results are due to the fact that some fixed nodes are placed in ventilation ducts. These are hard to reach for the signals of the mobile node. The RSSI-values of these messages are extremely low causing a greater error on the distance calculations from the mobile node to the fixed node in the ventilation duct. This affected the results significantly, when we drop all the results of the fixed nodes in the ventilation ducts, the new average error distance is $2.66m$.

Hence, this algorithm has also some drawbacks. Each algorithm uses a different transmission power. It is very important that the proximity algorithm his transmission range can be limited to the half of the distance between the fixed nodes. The idea is that only one fixed node can receive the beacons at a time. But with the weighted algorithm, enough nodes need to receive the beacons from the mobile node in order to make triangulation work properly. The tx power of a Tmote Sky can be programmed dynamically, but in our case, extra attenuators were necessary to reduce the transmission range. To fix this issue in our situation, two mobile nodes were used.

D. Summary

A summary of all the experimental results can be found in Table I, all the minimum, maximum and average error

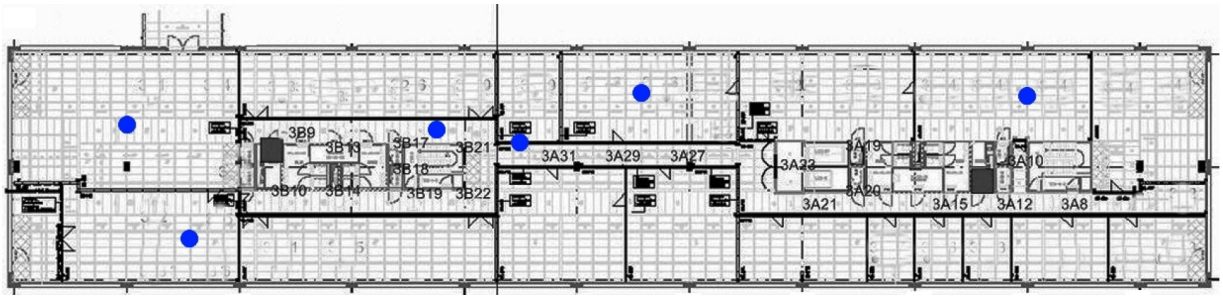

Fig. 12: Positions of the mobile node for testing the hybrid localization solution

TABLE I: Summary of the experimental results

Localization Solution	Error Distance (in meter)		
	Minimum	Maximum	Average
Weighted algorithm *(big triangles)*	6.3	21.2	13.8
Weighted algorithm *(small triangles)*	0.5	8.2	4.8
Proximity algorithm	0	2.5	-
Hybrid algorithm *(all nodes)*	0.49	8.5	3.28
Hybrid algorithm *(filtered nodes)*	0.49	8.5	2.66

distances are collected in one organized table. It becomes clear that the hybrid solution has an improvement (if you compare the average error distances).

VII. Conclusion and Future Work

This paper presents a hybrid indoor localization solution designed to achieve room accuracy using sparse distributed sensor networks. Hereby a positioning framework is developed to accomplish a hybrid solution, based on two existing solutions.

The positioning framework consists of two functional blocks: the interconnection gateway and the position calculator. The interconnection gateway gathers all the necessary data from the fixed and mobile node in order to calculate the position. This data can come from any kind of hardware device/technology. The position calculator contains all the different localization algorithms that calculate the position of the mobile node using the data from the interconnection gateway. This calculator includes also a reasoner that decides which algorithm calculates the most accurate position at a certain moment, it can also combine multiple algorithms to improve the accuracy even more.

The hybrid solution is based on a range-based and range-free algorithm. The former is a category of techniques that requires distances measurements in order to calculate the position of a mobile node. These distance measurements can be done in different ways. In this paper, the range-based "weighted" algorithm is proposed. It uses RSSI measurements to calculate the distance between the nodes. The higher the value, the shorter is the distance between the nodes. Innovative here is that RSSI measurements are also used to calculate the distance between the fixed nodes mutually. Using this extra information, a *weighted* distance calculation can be done using triangulation.

The range-free solution "proximity" does not require these distance calculations, the localization is only based on the information of the connection. This means that the reception range of a fixed node is as well as the maximum error distance. However, an extra optimization is possible, if multiple fixed nodes receive a beacon, then the centroid of all the fixed nodes can be calculated and be assumed as the point closest to the mobile device.

Both algorithms show issues in sparse distributed sensor networks. The accuracy of the weighted algorithm is far from acceptable because it is not easy to determine the correct triangle for the calculation and the proximity solution is completely depended on the density of the fixed nodes. Therefore, combining both algorithms can resolve the biggest issues of both solutions. First a proximity beacon is received by a fixed node, this is the first corner of the triangle. Then the other two corners are determined in order to get a good triangle.

In the results, it became clear that the improvement of the hybrid solution is significantly. The average error distance dropped from $13.8m/4.8m$ to $3.28m/2.66m$. Still, some future work can be done. First, the issue with the transmission power must be tackled. Further, comparative tests using WiFi or other technologies are in progress.

***Abstract*—The article is dedicated to the analysis of design of WSN road transportation system for developing applications related to parking management, traffic flows and emergency vehicles monitoring, weather and environmental conditions monitoring as well. The analysis is done for all units of sensor node. Many technical aspects of the design are discussed in the paper.**

I. Introduction

COMPARING to railway, civil aviation and marine transportation modes, road one is characteristic by the most of accidents and passenger fatalities, passenger and freight transport as well as CO_2 emission production. This is reason why safety, effective transport and environmental questions are core topics of research and development activities in the field of the Intelligent Road Transportation Systems (IRTS), [1].

In the ninetieth of last century, public and industry authorities decided about deploying electronics, information and communications technologies to improve negative situations by developing new V2X technology (V2V- vehicle-to-vehicle, V2I – vehicle-to-infrastructure sensor/dedicated short-range communications technology), [2] [3]. The technology is expected to guarantee reliable driving car coordinating movement and timing, particularly through detection of the vehicle´s position relative to other vehicles, intersections and infrastructures behind 250 m as well as self-driving car in case of critical situations, smooth traffic flows based on V2V and V2I communications to inform driver about recommended driving speed, in order to reduce unnecessary acceleration or slowdown. Unfortunately, V2X research and development works has still not been finished by now. It is expected that practical deployment of the technology could become reality in the second half of next decade. In present days it is possible to follow intensive discussion about future of V2X technology. Many other sensor, communications technologies have been developed during last fifteen years. No one expected so fast growing of especially mobile communications. Using personal digital devices is standard today. Simply said, situation has changed during last 25 years.

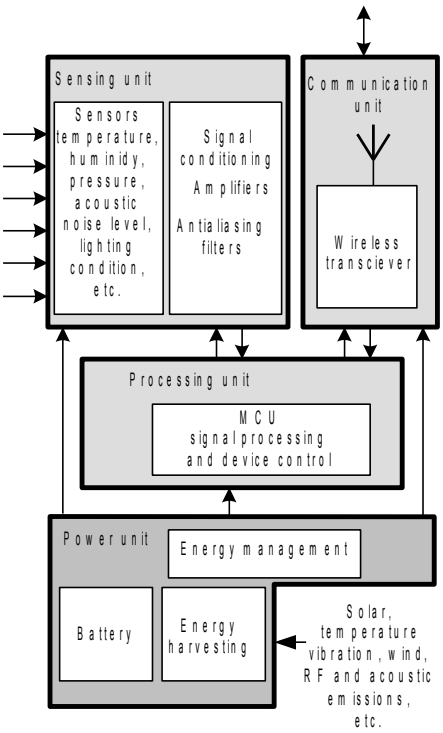

Fig 1.Block structure of wireless sensor node

This is reason why research and industry authorities in the USA and EU split into two groups concerning future development of V2X technology. While the goals of both of them are the still the same: decreasing traffic accidents, traffic congestion and improving fuel economy, European authorities focused on developing Advanced Driver Assistance Systems (ADAS) supported by mobile communications 4G

LTE technologies and services for upcoming events within 250 meters. The USA authorities prefers developing V2X technology for communication distance 1000m. It is expected that both of above mentioned technologies will be developing simultaneously to operate independently concerning V2V services and cooperating with each other in case of V2I ones.

Referring to above mentioned information, it would be suitable to answer question if WSN could be integrated in sensor/communication platform of future intelligent transportation systems. Since road transportation mode is dominant one in ITS, next part of article will be focused on analysis of specific features of WSN, particularly core subsystems of its sensor node (figure 1), supporting development of road traffic services keeping in mind value added complementary character of WSN.

II. Sensor Node – Sensing Unit

Mote is sensing of selected signals values by proper sensors and transforming of measured signals to ones which are suitable for additional processing (most often electrical voltage).

Respecting two facts:

- Sensor node is stationary in WSN
- Vehicle acts as mobile mote of ad-hoc wireless network

sensing of chosen signals must cover larg area. In such case WSN keeps value added complementary character to V2X and ADAS technologies. Selection of sensors is closely related to precision of measurement and developing applications. Thinking about road traffic, it is clear that WSN will be optimally used for monitoring purposes to support control, maintenance and planning processes. Core applications could be defined as follows:

- Parking monitoring and management
- Traffic flows monitoring
- Emergency vehicles monitoring
- Weather conditions monitoring
- Environmental conditions monitoring.

Parking monitoring and management

Vehicles detection at parking places is main task of the application. Sensors choice depends on indoor or outdoor detection. Magnetometer is proper sensor for both of cases. Measurement accuracy is not depended on weather conditions using the sensor. Numerous other ones are available for indoor detection: infrared, ultrasonic, acoustic, cameras, etc. Collected data are processed and information about free spaces can be presented on navigation tables (signs) in the street or distributed via communication channels to personal devices. Entry gate to parking lots is controlled on the basis of occupancy of them.

Traffic flows monitoring

mainly supports:

- *Vehicle detection* – at stop lanes of intersections
- *Vehicles counting* – counting number of vehicles waiting in queues of intersections, valued information for traffic lights control
- *Vehicle classification* – vehicle type identification for planning applications
- *Traffic flow intensity measurement* – in vehicles per time period, necessary information for effective road surface maintenance, planning of road network extension, traffic light control, see figure 2 and figure 3
- Vehicle speed measurement – supports safety and effective driving.

Referring to precision measurements, magnetometer sensor is proper for traffic flows monitoring.

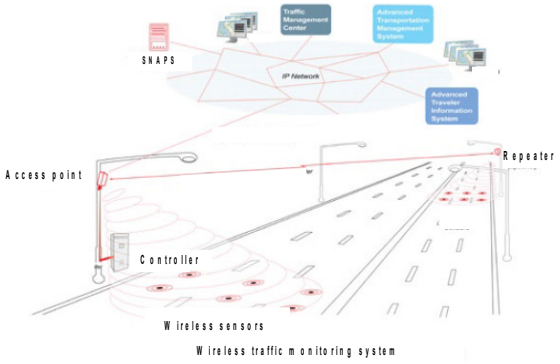

Fig2. Wireless traffic flows monitoring system

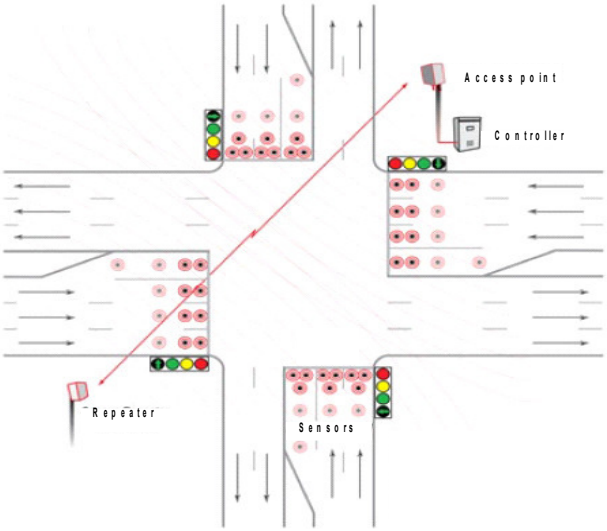

Fig3. Traffic lights control system

Emergency vehicles monitoring

Due to using sirens, emergency vehicles are effectively detected and classified by acoustic sensors. Monitoring of them allows safety crossing intersections.

Weather conditions monitoring

allows drivers to adapt style of driving in time to avoid accidents.

Environmental conditions monitoring

collects information about air pollution: CO_2 emissions, dust concentration, acoustic noise related to traffic in the area. Information is valuable for:

- Developing applications in compliance with citizens health protection
- Planning of reconstructions of historical buildings plasters.

III. Sensor Node – Processing Unit

Basic functions of processing unit are: digital processing of measured signal values, control of sensor node units, security of transmitted data, potentially another additive functions required by particular applications.

Keeping in mind value added complementary character of WSN to V2X and ADAS technologies (high speed transmission), processing unit very often uses reformatting, compression, classification technics and algorithms to transmit low amount of data. This approach supports low data rate transmission over communication channel (will be discussed in communication unit section). Referring to mentioned monitoring applications, number of transmitted bits vary from 1 bit to maximally 16 bits. It opens possibilities for developing of variable and reliable communication strategies.

IV. Sensor Node – Power Unit

Energizing of sensor node by electrical energy is main function of the unit. Time period of network operation without maintenance is important WSN feature.

Energy sources could be split as follows:

- *Mobile* – energizing of sensor node from primary batteries, rechargeable batteries, system exploitation for collecting energy from surrounding environment – energy harvesting, combination of rechargeable batteries and energy harvesting. This approach is standard in WSN applications.
- *Static* – energizing of mote is from standard electrical network. The option could be used in case of nodes responsible for communications services. They represents communication backbone of WSN. Such solution outgoing from the fact that communication unit consumes the most of energy of the battery. This option of motes energizing would be used, if necessary, in case of requirements for: increasing communication distance among nodes (to compensate path losses on frequency channels), guarantee of reliable communication and life time of motes operation as well.

Selection of energy source is strongly depended on requirements of application which WSN is designed for. Primary battery is expected to be preferable solution for road transportation applications (operational life time could be even 10 years).

V. Sensor Node – Communication Unit

Any sensor node must be able to communicate with adjacent ones, potentially with base station via wireless communication channel. Communication unit is main consumer of energy of the battery.

Analysis of WSN features, assuring successful communications in road transportation, area will be done in several steps.

Frequency bands allocation for WSN road transportation applications

In 5.8.2008, EU Committee decided to allocate frequency band from 5875 to 5905 MHz for ITS applications, which is going to be used on non-exclusive basis. Referring to 5.9 GHz center frequency, channel bandwidth is 10 MHz and default data rate 6 Mbps. Detailed information about V2X communication frequency band as well as maximum limit of mean spectral power density (EIRP) and European channel allocation is presented in [4].

It is clear that for 2-byte useful information transmission (low data rate is expected for WSN applications) above mentioned frequency channel parameters are not defined properly. That is why lower frequency bands are subjects of interest for successful WSN communication in road traffic applications.

Selecting lower frequencies for communication among communication units of motes has positive influence in general:

- *Channel bandwidth is more narrow* – saving frequencies for other applications, increasing number of channels for defined frequency range
- *Communication distance is increased* – competitive argument for WSN, development of cooperative services
- *Path Loss is decreased* – less energy losses higher quality and reliability of communication
- *Lower influence of obstacles on signal strength*
- *Improved radio receive sensitivity* – increased communication distance, weaker signal could be successfully received
- *Better resistance against weather conditions*- lower Bit Error Rate

Lower frequencies require larger antennas to achieve the same gain and improve signal robustness against interference in general. On the basis of above mentioned information it is possible to state that lower frequency band is attractive solution for design of WSN road transportation services, especially, when low data rates are required. It strengthens competitiveness of designed solutions.

For assuring successful wireless communications, it is suitable to mention practical path loss rules of thumb, [5]:

- To ensure basic fade margin in a perfect line of sight application, never exceed 50% of the manufacturer´s rated line of sight distance. This in itself yields a theoretical 6dB fade margin – still short of the required 10dB.
- Decrease data rate more aggressively if you have obstacles between the two antennas, but not near the antennas.
- Decrease data rate to 10% of the manufacture´s line of sight ratings if you have multiple obsta-

cles, obstacles located near the antennas, or the antennas are located indoors.

Defining frequency band for wireless communications in the ITS field must take into account one very important actuality. 5.9 GHz frequency band for V2X technology is used in non-exclusive basis. Drivers do not pay monthly recurring charges for using services requiring the band. This is reason why WSN road transportation applications must typically operate in "license free" frequency bands, also referred to as ISM (Industrial, Scientific and Medical). The most common frequencies encountered are:

- 2.4 GHz – nearly global coverage
- 915 MHz – North America, South America
- 868 MHz – Europe.

For any given distance, a 2.4 GHz installation will have roughly 8.5 dB of additional path loss when compared to 900 MHz. However, lower frequencies require larger antennas to achieve the same gain. Antenna type must be selected during in a proper way and earlier physical installation on site. Antennas increase the effective power by focusing the radiated energy in the desired direction. This fact could be evaluated during time period of WSN application design.

Table 1 presents result of simulations described in [6]. Mathematical backround is covered in the article as well. The paper is easily accessible via Internet in IEEE Digital Library, respectively in SCOPUS one.

Communication distance of V2X technology is required up to be 1000m. From the table is clear that no theoretical model satisfied expectations. Testing of V2X communication reliability was done at road infrastructure in California two years ago. Unfortunately, reliability of wireless communication was on the level of 85%. Still not satisfactory. It is discussed that the technology could be practically operating even in 2027. This is reason why European authorities prefer developing of ADAS system supported by mobile 4G LTE communication technologies.

Lack of reliable communication up to 1000m has negative influence on cooperative services development. This is chance for WSN road applications.

Selection of RF technology for WSN based road transportation applications

Table 2 presents chosen RF transmission systems applicable in the field of transportation.

Referring to battery life item, only ZigBee® technology is applicable in WSN networks in present days. It is designed for short range low power operation. The radio is relatively low data rate (up to 250 Kbps); the packets are short (< 128 bytes) and low energy. For example, sending a few bytes of sensor data, with routing, cryptography and other headers takes less than 1ms and burns less than 30µJ of energy, including receiving a secure link-layer acknowledgment. Sensors can forward radio packets from peers, extending the range of the network far beyond the range of single radio and providing the network with immunity to any single radio link failure.

TABLE I.
COMMUNICATION DISTANCE LIMITS AT MAXIMAL TRANSMIT POWER

Models	**Communication distance limit [m]**	
	G_R = 5 dBi	**G_R = 8 dBi**
Free-space model	1278	1805
ETSI model	405	523
ECC model ***Urban***	279	328
ECC model ***Suburban***	471	565
ECC model ***Rural***	933	1033

Every ZigBee standard and specification is the powerful IEEE 802.15.4 physical radio standard. It delivers raw data throughput rates of 250Kbs at 2.4GHz (16 channels), 40Kbs at 915MHz (10 channels) and 20Kbs at 868MHz (1 channel). Further information about Zigbee technology is possible to find in [7].

Design of WSN road transportation monitoring/control systems must meet a four core performance targets:

- *The first, the system must meet a minimum reliability goal.* For industrial applications, the target is typically to receive at least 99.9% of the generated data. Referring to RF communications, 99.5% link availability is defined as standard. 99.9% availability is considered as high one. This target is not met in current V2X technology.

TABLE II.
COMPARISON RF TECHNOLOGIES SUITABLE FOR INTELLIGENT ROAD TRANSPORTATION SYSTEMS

Market Name **Standard**	**ZigBee®** **802.15.4**	**---** **GSM/ GPRS/ CDMA / 1xRTT**	**Wi-Fi™** **802.11b**	**Bluetooth ™** **802.15.1**
Application Focus	Monitoring & Control	Wide area voice& data	Web, Email, Video	Cable replacement
System Resources	4KB-32KB	16MB+ 1-7	1MB+	250KB+
Battery Life (days)	100 - 1000+	1-7	1-5	1-7
Network Size	Unlimited	1	32	7
Maximum Data Rate (KBps)	20-250	64-128+	11000	720
Transmission Range [m]	10-1600	1000+	1-100	1-10+
Success Metrics	Reliability, Power, Cost	Reach, Quality	Speed Flexibility	Cost Convenience

- *The second, the system must support a certain throughput, a number of sensor data packets per second.* In low rate ITS applications only a few data packets are expected to be transmitted, so that performance criteria will be satisfied. BER (Bit Error Rate) is expected to be equal and better than 10^{-6}.
- *The third, these data packets are only useful if they are received within a maximum latency period.* It must be verified for every project.
- *The fourth, many systems must operate under severe conditions and intrinsic safety restriction*.

All of four mentioned targets must be satisfy to continue in further design evaluation. For detailed information read [8].

VI. Experimental Part

Figure 4 presents sensor node developed for measuring of traffic flows parameters. Referring to sensing of magnetic field changes and vibration, sensor LSM303 is used. Magnetometer measurement interval is adjustable in range from ±1.3G to ±8.1G. Acceleration-meter range is possible to adjust in interval from ±2g to ±8g. Signal processing and control unit is realized on the basis of 32-bit microcontroller STM32F100 in small pocket LQFP48. MCU is realized on the basis of ARM-Cortex M3 core with maximal frequency 24MHz. SRAM memory capacity is from 4 to 8 KB. Flash memory capacity is from 16 to 128 KB. Memory subsystem is extended by microSD cart whose allows saving of big data content. Basic PCB consists of connector for connection of communication unit. This solution allows to experiment with various communication modules. XBee PRO communication module in 2.4GHz band was used. Sensor node is realized on 2-layer PCB with dimensions 32x38 mm.

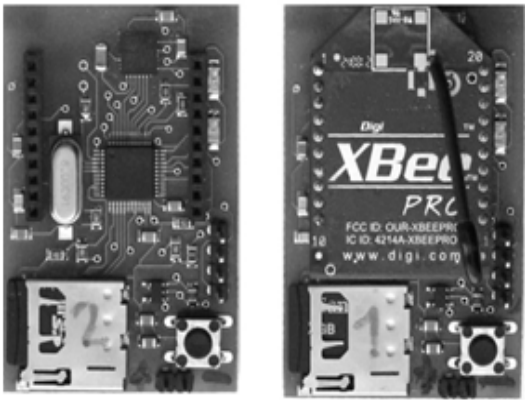

Fig4. Wireless sensor nodes

Proving functionality of the nodes, average speed of vehicle calculated on the basis of measured signals of magnetic induction is presented. Two nodes were well-situated at road side in the distance of 10m from each other. Synchronization of them was secured by RF communication. Both of sensors were sensing changes of Earth magnetic field in axes x, y and z depending on car detection, in case of sampling period 50ms. Measurements were transmitted to PC via communication module XBee. All measured data including time mark were stored on microSD card in the same time. Magnetometer measurement range was set to value ± 2.5 G. Direct components of waveforms were filtered. Cars moving about 1.5m far away from sensor nodes evoked changes of magnetic field induction in order of ten-miliGauss (mG). Amplitude of magnetic induction range is related to the distance between vehicle and a sensor.

Time difference between measured signals is depended on localization of sensor elements and speed of passing vehicle. Average speed of vehicle passing the sensors can be calculated on the basis of the evaluation of time difference between corresponding changes of magnetic induction measured by sensors 1 and 2. Comparing behaviours of magnetic induction both of sensors can be used to filter incommensurate signal elements related to other influences than vehicles movements (pedestrians on pavement, inverse direction moving vehicles, etc.). Average vehicle speed could be stated on the basis of total magnetic induction change (S) calculation:

$$S = \sqrt{(x2 + y2 + z2)} \quad . \tag{1}$$

Figure 5 shows plots of total magnetic induction change for sensor1 and sensor2. Average speed of vehicle between sensors1 and 2 can be derived on the basis of measured signals of magnetic induction. Time shift of maximal induction change between sensor1 and 2, for the first vehicle, is 1.28s. Average speed of first vehicle is (for 10m distance between sensor1 and 2):

$$v = 10/1.28 = 7.8 \quad [m/s] \quad . \tag{2}$$

In case of the second vehicle, for its average speed is valid:

$$v = 10/1.01 = 9.9 \quad [m/s] \quad . \tag{3}$$

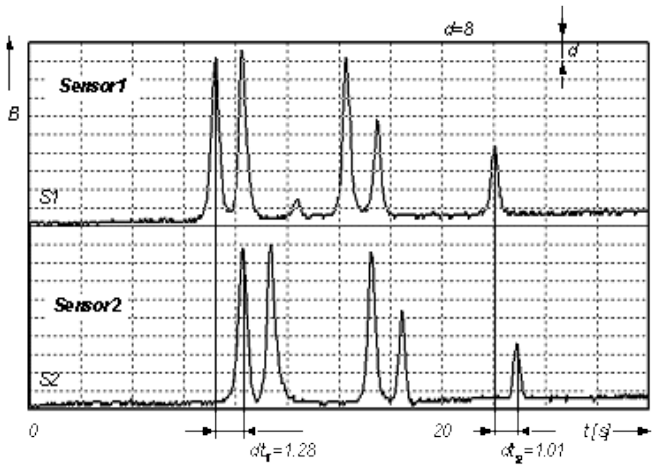

Fig5. Plots of total change of magnetic induction for sensor1 and sensor2

For more precise calculation of time shift could be used more sophistic method of estimation error elimination. It is

necessary to notice that the precision is always limited by real period of sampling frequency. Precision of vehicle average speed calculation between two nodes could be increased by decreasing sampling frequency as well as increasing of distance between sensors.

Presented measurements illustrate usability of sensor nodes with magnetic induction sensing for monitoring of traffic flow parameters. Vehicles classification is presented in literature [9]. Firmware reprogramming is described in [10].

VII. Conclusion

Presented paper is focused on design of WSN road transportation systems for parking management, monitoring of traffic flows, emergency vehicles, weather and environmental conditions. The design must meet many targets and requirements principally discussed through the paper. The system must be value added and complementary to V2X technology as well as ADAS system.

***Abstract*—This paper introduces low-cost non-intrusive sensory that can collect traffic data based on Raspberry Pi single board computer. Image information acquired by Raspberry Pi HD camera module is analyzed for moving objects presence. After evaluation of detected object count, size, class and motion vector object properties are sent to server node by RF transceiver. Sensor low-power consumption ensures possibility to operate from battery for an extended period of time.**

I. Introduction

TRAFFIC flow monitoring and analysis has been active research and engineering topic for more than two decades. Main information acquired from traffic flow monitoring includes: traffic volume, vehicle type identification (bike, car, light van, truck) and vehicle speed. Traffic volume data is used for a variety of purposes including historical trend analysis, forecasting, planning for future infrastructure improvements and expansions. Whereas transport remains the largest producer of CO emissions in EU, traffic monitoring becomes important also from the environmental point of view [1]. Also the World Health Organization has officially decreed that inhaling diesel fumes can cause lung cancer and puts diesel plumes in the same category as arsenic, strontium-90 and neutron radiation. [2] This has given traffic monitoring significant importance.

Other traffic data parameters, such as speed and vehicle classification, are becoming more important as a measure of traffic safety and roadway pavement use. Recent traffic flow analysis systems are able to perform vehicle number plate recognition which can provide information about main ways of traffic flow through cities and can help to optimize road infrastructure. Collecting this data can be done using a variety of different technologies. Traffic detection technology methods scoring biggest interest in this area includes: Doppler radar (measures the relative velocity of an object moving through its target range), magnetometer sensors (detects vehicles based on the disruption of the Earth's magnetic field by metal vehicles), video camera (processes images using sophisticated computer algorithms), side-fire radar (side-fire beams placed along a roadway reflect back to the sensor to detect vehicles), pneumatic tubes (transmits information to a counting device after a pulse is created when vehicles drive over a tube).

With the advent of powerful single board computers like: OLinuXino, Galileo, PandaBoard, Raspberry Pi, Odroid and others it is possible to design reliable, low-cost traffic monitoring system. Low-power consumption of these boards ensures possibility to operate from car battery for an extended period of time often more than one week.

This paper introduces low-cost non-intrusive option that can collect traffic data based on Raspberry Pi. We have chosen this board for its easy and powerful HD camera handling, good performance to power consumption ratio affordable price and wide community.

II. System overview

Traffic flow monitoring system consists of Raspberry Pi based sensor nodes used for acquisition of image information from environment and their analysis. Traffic flow parameters including volume, speed and vehicle class are then sent to main server via RF transceivers [5]. RF connection offers also configuration and diagnostics of sensor nodes.

The main priorities while designing the traffic flow monitoring sensors were:

- low cost of sensors
- low power consumption of sensors
- high reliability

"Fig. 1" shows complete Raspberry Pi based sensor node including camera module, 12V battery 9Ah, stem down 5V converter and ARDUPILOT 3DRADIO RF transceiver (without antenna).

Rasberry Pi single board computer offers these key features [3]:

- ARM1176JZF-S core CPU @ 700 MHz
- Broadcom VideoCore IV GPU @ 250 MHz
- 512 MB (shared with GPU)
- 5Mpix Camera module capable of full HD video @ 30fps
- USB, GPIO, UART, I2C and SPI bus
- 700 mA (3.5 W) power rating

978-83-60810-58-3/$25.00

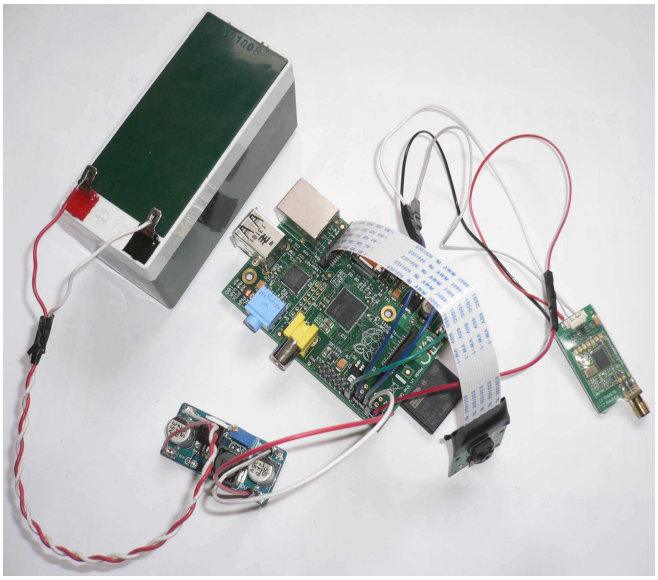

Fig. 1. Raspberry Pi based sensor node

Since processing of high-definition video streams for real-time applications is a challenging task with computationally demanding algorithms it was necessarily to perform as much as possible image processing tasks on GPU. Modern GPUs are very efficient in dealing with computer graphics and their highly parallel structure makes them more effective than general-purpose CPUs for algorithms where processing of large blocks of data is done in parallel.

Raspberry Pi GPU resources can be accessed by Multi-Media Abstraction Layer (MMAL) C library which has been used to implement video data acquisition and processing. Description of the video data processing is shown on "Fig. 2"

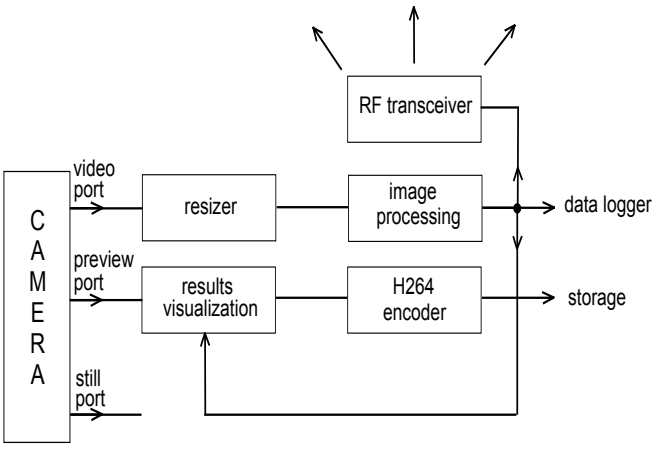

Fig. 2. Video data processing overview

Camera has three output ports (video, preview and still port). Due to the hardware limitations all of these ports must be set to the same resolution, this was in our case 1280x720 at 30 frames per second. Camera still port was not used. Since sufficient resolution for reliable vehicle detection is much lower (640x480 has been used in our system) image processing block has been connected to camera port through resizer block. The results of image processing – detected vehicles are visualized by modifying (drawing into) data stream flowing from camera preview port. Encoder block provides compression of raw YUV video data stream into H264 steam which is stored on Raspberry PI's SD card. For demonstration of system functionality encoder block can be easily replaced by previewer block. Showing the traffic live stream with recognized results and statistics is then possible through HDMI. Traffic flow statistics are stored on SD card and also send by ARDUPILOT 3DRADIO RF transceiver [7] to monitoring center main server for further evaluation.

III. Image Processing

Image processing block ("Fig. 3") performs moving objects detection and classification.

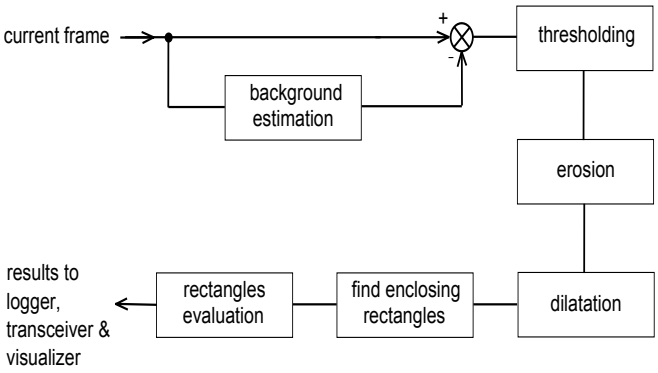

Fig. 3. Image processing block overview

The most important procedure in the moving objects detection task is background estimation. Detection of moving objects is made from the difference between the current frame and a reference frame – background image [8]. Background subtraction is a widely used approach for detecting moving objects in videos from static cameras. Our background estimation model is based on the idea that the small changes in frame sequence (e.g. illumination changes) should be retained while relatively fast changes caused by e.g. moving object should be suppressed. Background image is periodically updated according the following equation:

$$\underline{B}(m) = \underline{B}(m) - f[\underline{F}(m) - \underline{B}(m)] \tag{1}$$

where $\underline{B}(m)$ and $\underline{F}(m)$ are background and current frame matrices in time m, function $f(\cdot)$ can be described by following equation:

$$f(x) = \frac{\gamma \cdot \frac{x}{\alpha}}{\left[1 + \left(\frac{x}{\alpha}\right)^2\right]^2} \tag{2}$$

where function argument x is the difference between current frame and background image pixel values, function parameters were set as follows $\alpha = 64$, $\gamma = \frac{25}{2}$.

Graph of function $f(\cdot)$ is shown on "Fig. 4"

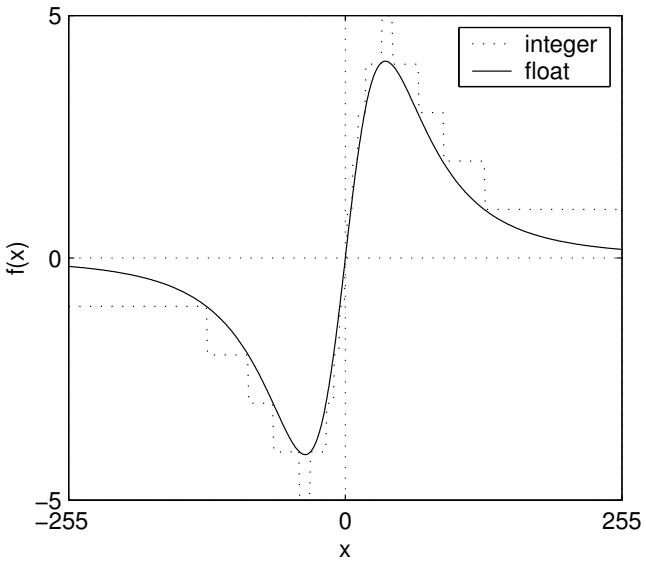

Fig. 4. Image processing block overview

It is clear that the background image function $f(x)$ is raising nearly linear for small x values but for big values of x is decaying.

This background image function has been implemented in integer (shown by dotted line in "Fig.4") which significantly helps to improve speed of whole system.

After subtraction of estimated background image ("Fig.6") from current frame ("Fig.5") the thresholding has been applied so black & white image has been obtained ("Fig.7").

Fig. 5. Original (current) frame

Since most cameras produce a noisy image, motion has been detected in such places, where there is no motion at all. To remove random noisy pixels, erosion filter followed by dilatation has been used. So the resulting image contains only the regions where the actual motion has been present.

Fig. 6. Background image

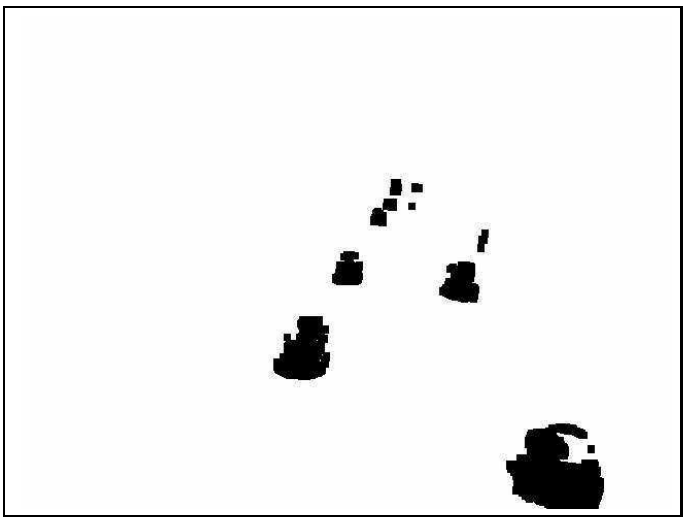

Fig. 7. Image after thresholding

Motion regions are then bounded into minimal enclosing rectangles. These rectangles are then the subject of evaluation where size, position and motion vector is being calculated. Traffic flow informations obtained are stored on SD card, visualized into encoded live video stream ("Fig.9") and transmitted to server node using RF transceiver.

IV. Experiments & results

Described sensor node was subject to one day real traffic monitoring test.

It has been attached to the bridge construction over the road and it was monitoring traffic flow in both direction. Power was supplied from 12V 12Ah rechargeable sealed lead acid battery.

feature	recogniton correctnes in [%]
traffic volume	95.7%
vehicle class	93.2%
vehicle speed	not evaluated

Fig. 8. Recognition correctness

Results obtained are summarized in “Fig.8” Above-mentioned table presents promising recognition results of traffic volume and vehicle class.

Fig. 9. Visualization of recognition result

Unfortunately vehicle speed was not evaluated because of non-functional microwave speed detector which was intended to be the reference for speed comparation. Sensor average current draw during the test was 440mA.

VI. Conclusion

An approach for the traffic monitoring based on Raspberry Pi single board computer was proposed in this paper. Video signal processing and analysis were proposed with the focus on low power consumption and reliability of the system. This is still far from being final version of traffic monitoring system and there is lot for us to improve. In future we plan to perform further experiments including speed evaluation and testing sensor node in different weather conditions.

***Abstract*—Indoor environment is from the point of the wireless communication an extremely hostile environment. Despite this fact, wireless sensor network applications in the indoor environment are very common. Having signal propagation in a real environment, without considering interferences from other sources, we meet (not only indoors) four basic phenomenons - path-loss, reflection, diffraction and scattering. Each of these effects impact on the spread of the signal and contributes to attenuation and distortion at the receiver side. Detailed description of the electromagnetic wave propagation can theoretically obtain the solution of Maxwell's equations. However, this is too demanding and for practical cases unusable. In practice, to describe the signal propagation, the approximate models are used, which are often based on experimental results. This contribution includes case study on indoor radio frequency signal propagation at 2.4GHz ISM Band with related math, supported by implementation of the propagation models and experimental results.**

I. Introduction

INDOOR wireless sensor network (WSN) applications, despite unfavorable conditions of indoor radio signal propagation, constitute the very attractive area. As an introduction, let us mention at least some of the frequently occurring applications that the authors consider representative.

A. Intelligent Buildings

In recent decades, an increased attention to matters related to sustainable environment has been dedicated. A large part of the environmental problems is related to the energy consumption of the society. It is worth to emphasize that the effective regulation of the overall energy consumption of the society is able to achieve significant advances in the state of the environment [1].

One of the dominant energy consumption components is the operation of residential and non-residential buildings. According to [2], in 2012, the energy consumption of buildings in the U.S. was 39%, followed by 32% energy consumption share of an industry and transportation sector with portion of 29% of the total consumption of the energy. In Europe, the situation is quite similar. In 2010, the buildings operation took 41% of total energy consumption, 32% in transportation and an industry energy consumption shared 25% [3].

Remark 1.1: Note that compared to the U.S., the energy consumption intended for buildings operation in Europe is slightly higher. Also, an interesting fact is that the annual energy consumption of the residential buildings is about 200 kWh/m^2, non-residential buildings are characterized by higher annual energy consumption of about 300 kWh/m^2.

Since 1990, the energy consumption increases annually by around 0.6% in the residential sector and by around 1.5% in the non-residential sector [2], [3]. The presented statistical data show that the highest energy burden in the developed countries lies in operation cost of buildings. Based on the predictions presented in [2], it is expected that within the next 20 years, the energy consumption share of the buildings will not be reduced, just to the contrary, we can assume a slight increase in the energy consumption (increase in about 1%).

Based on the above, it is clear that the operation of buildings consumes huge amounts of energy. Therefore, it is extremely important to address the issues of intelligent buildings control so that the user comfort and the effective energy sources utilization can be ensured.

In order to be able to reduce the energy consumption, it is necessary to know why, where and when the energy consumption occurs. Finding the answers to these questions is possible thanks to the new technologies in the field of ICT (Information and Communication Technologies) such as [4], [5] or [6]. Using new ICT means in buildings we get intelligent monitoring and control systems of the buildings that enable increasing user comfort while cutting energy and environmental burden. Buildings equipped with modern control and monitoring systems are often labeled as "intelligent" or "smart".

An extensive control, communication and monitoring system installed in modern intelligent buildings today is often divided into the following six subsystems [1]:

- *Lighting control* subsystem (lights, blinds, etc.);
- *Heating, Ventilation and Air Conditioning (HVAC)* subsystem - creates a psychometric chart to help determining the optimal environmental parameters;
- *Security and safety* subsystem (entrance authorization,

This work was supported by Centre of excellence for systems and services of intelligent transport II. ITMS 26220120050 supported by the Research & Development Operational Programme funded by the ERDF.

fire alarm, personnel tracking, etc.);
- *Metering* subsystem (electricity, gas, water and other parameters with connection to the energy control);
- *Indoor climate monitoring* subsystem (temperature, humidity, dust, concentration of CO_2, NO_x ("Green Building Monitor^{TM}" - Siemens system to inform staff, clients and visitors about the energy consumption, environmental load of the building and about the state of the building indoor climate);
- *Guest control* subsystem (navigation, information for visitors, access control, motion tracking, etc.).

It is obvious that the provision of these subsystems implies the utilization of the latest technologies in the field of ICT. It is necessary to sense a large number of parameters in the intelligent buildings and based on the values, the actuator elements drive the building so that the optimal operation of the building is assured [1]. Sensors gathering the information create an extensive network with defined rules of communication. Nowadays, more and more, we meet the wireless communication technologies in the area of building control, which, in comparison to a wired network, is characterized by lower installation cost, higher flexibility and scalability [7]. Thus, even in the intelligent building environment, there are gradually used technologies known under the names of WSN or WSAN (Wireless Sensor and Actuator Networks).

B. WSN in the Industry (Industrial Automation)

Industrial applications represent another promising area of an efficient use of the WSNs [8]. Industrial control systems that integrate WSAN offer several advantages over conventional distributed control system [9], [10]. These are in particular easiness of the sensors' and actuators' installation, self-organization of the network, a simple modification, easy expandability of the network, efficient distributed and parallel data processing and lower cost compared to the conventional solutions [11], [12], [13]. There are also some disadvantages of wireless solutions, which we can find in the occurrence of interferences, not only in the industrial environment, unpredictable delays in packets, limited capacity of transmission channels and so on [9], [11]. However, the mentioned drawbacks, are not substantially limiting for the development and the implementation of WSN applications in industry. According to [9], it is essential to address, in particular, the following issues:

- Limited sources of the energy, the limitation of communication attributes, computing and storage capacity of the network nodes (channel capacity, limited communication range, etc.);
- Network operation in high interference industrial environments and related dynamic change of network topology;
- High demands on Quality-of-Service (QoS), especially requirements on packet deliverability in a defined time;
- Effective utilization of data redundancy to increase system reliability and accuracy of the status information of the controlled/monitored system;
- Effective addressing of the related issues to the error rate (BER $\in \langle 10^{-2}; 10^{-6} \rangle$) and variable transmission capacity of individual transmission channels (adaptive modulation schemes, channel coding, etc.);
- Security in industrial applications is a key issue. It is necessary to protect communication from intentional active and/or passive attacks;
- Large-scale deployment and ad-hoc network functionality. Many industrial applications consist of a large number of randomly distributed nodes, so it is advantageous if the network is able to build autonomously the communication links and to control the communication among the nodes;
- Integration with other networks (e.g. the Internet). This point is very important from the perspective of effective control of the enterprise approach to the technological level, which represent also a WSN.

In the field of the industrial automation and in the context of WSAN implementation, there are arising new problems (distributed processing of variables, redundancy utilization to increase system reliability, problems with delayed packets), whose solutions are interesting from the theoretical and application point of view [9]. Based on the current development, a sharp increase in wireless solutions even in industrial applications is expected [14] [15], [16], [17].

C. Health Applications and Senior Assistance Services

Electronic health-care is a broad and interesting application area of WSNs. Let us mention a few representative examples of such WSN utilization [11]:

- Monitoring of vital signs and other selected parameters of patients in hospitals;
- Telemonitoring of the patients without hospitalization;
- Tracking patients, visitors and hospital staff;
- Indoor climate monitoring within the hospital premises;
- Controlling access to medicines and identification of time and kind of medication use through patient node(s).

WSN networks are able to monitor the behavior of older people and those with disabilities and enable to keep track of their health status without significant restrictions on their lives and quickly identify the signs of disease [18], [19]. Because of the above examples, it is clear that in health-care we meet growing number of interesting WSN applications indoors and outdoors - modern applications of WSN that monitor vital signs of a human body, track patients, monitor hospital environment, serve as medical access control systems and many more [20], [21].

Almost all mentioned applications have one thing in common, WSNs operate in indoor environment. Indoor environment is from the perspective of the wireless communication subsystems, an extremely hostile environment [7]. Despite this fact, WSN applications in indoor environments are highly desired.

Further investigations dealing with the properties of the indoor signal propagation assume the wireless sensor node based on Texas Instruments' (TI) CC2511 transceiver that is highly suitable for the indoor environment implementation.

It is possible to list a number of other interesting and prospective application areas of WSNs related to the currently popular term "Internet of Things" (IoT), but due to the limited extent, we do not.

II. Indoor Signal Propagation

If we consider wireless transmission channel for evaluation, we come to the conclusion that its features do not fully meet the media properties for reliable high-speed communication. The transmission channel is sensitive to noise, interference generated by the obstacles, communication distance, etc. [22]. Moreover, those adverse effects vary in time and space at random, as a result of the change in position of the receiver and/or transmitter and dynamic environmental changes.

Having signal propagation in a real environment, without considering interferences from other sources, we meet four basic phenomenons [22]. These are:

- Path-loss;
- Reflection;
- Diffraction;
- Scattering.

Each of these effects impact on the signal propagation and contributes to the path-loss and the distortion of the received signal. Answering the question of which of the above-mentioned effects has the most significant impact on the quality of reception is not possible in general. The answer depends on the wavelength, the environment type and many other specific conditions. It is obvious that the electromagnetic waves do propagate in the real environment attenuated, reflected, diffracted and scattered from and by the terrain, buildings and other objects. The detailed description of the propagation of electromagnetic waves can be theoretically obtained by solving Maxwell's equations with constraints [23]. The detailed description is only possible in case of having all physical characteristics of the objects affecting the propagation in mind and implemented into the equations. Unfortunately, this is computationally demanding and in practical cases not usable. Therefore, in practice, approximate models, which are often based on experimental results, are used to describe the radio frequency wave propagation.

For determining the signal path-loss in the line-of-sight (LOS), a sufficient solution is the radio signal propagation model at outdoor environment that assumes that other propagation effects can be neglected [23].

Remark 2.1: Other propagation effects can be neglected when an open area transmitter and/or receiver antennas are placed at a sufficient height above the ground.

In this case, it is possible to determine the signal power at the receiving antenna out of the Friis equation:

$$P_r = A_e S_r = \frac{\lambda^2}{4\pi} G_r \cdot \frac{G_t P_t}{4\pi d^2} = \left(\frac{\lambda}{4\pi d}\right)^2 G_r G_t P_t, \qquad (1)$$

where,

d is *distance between the transmitter and the receiver*;
λ represents *signal wavelength*;
P_t represents *transmission power*;
P_r represents *power at the receiving antenna*;
G_t represents *transmitting antenna gain*;
G_r represents *receiving antenna gain*;
$A_e = G_r\lambda^2/4\pi$ is *receiving antenna effective area*;
$S_r = G_t P_t/4\pi d^2$ is *signal power density at the receiving antenna*.

If the propagating radio waves reach an surface that is larger than the radio wavelength, then the wave partially reflects and partially penetrates the obstacle material. In case the material is the perfect conductor, the wave reflects into the primary environment without the energy loss. Of course, in this case the reflection law applies. In general, the electromagnetic field strength of the reflected and passing waves can be expressed by the Fresnel reflect and transfer coefficients that depend on the material properties, the wave polarization, the angle of radio wave impact and the frequency. A more detailed analysis of the effect of reflection can be found in [11]. The reflection significantly affects the radio frequency signal propagation in the indoor environment.

The diffraction occurs when there is no direct path (line-of-sight) for the radio waves between the transmitter and the receiver antennas - the transmission path is limited by an obstacle. Due to the diffraction, in the shade of the perfect obstacle with the limited dimensions, the radio signal strength has a non-zero value. The effect of the signal diffraction can be neglected at high frequencies.

Signal scattering is present in cases where the electromagnetic waves pass through or reflect from the objects that have comparable or smaller dimensions than the wavelength. Scattered waves occur when rough surfaces and small objects appear in the space of the transmission channel. The signal level varies at the receiver antenna because of the signal scattering and the levels are usually different from the values predicted by the propagation models that even take into account the path-loss, reflection and diffraction.

Remark 2.2: Note that the larger signal energy is scattered, the more the energy of the reflected waves is reduced. All the above mentioned effects, affect the propagation of the electromagnetic waves indoors. The way how they impact depends on the signal wavelength and the environmental properties and circumstances.

III. Case Study

To investigate the case of the electromagnetic wave propagation we used the hallway scenario illustrated at the Fig. 2. The antennas (the transmitter and the receiver antenna) have been placed at the center line of the corridor in the height $80cm$ above the floor.

For measurements we used the system-on-chip solution based on TI CC2511 (see Fig. 1) that operates in the ISM band starting at the frequency equal to $2.400GHz$ and ending at $2.4835GHz$. This ultra-low power solution integrates a full-speed USB controller, I^2S interface USART and 12-bit A/D converter. However, more important information for us are the radio peripheral attributes. Besides the mentioned frequency range, the radio solution is capable of 2FSK, GFSK and MSK

Fig. 1. Wireless system-on-chip used for experimental results

modulation techniques, programmable transmission power up to $+1dBm$, high receiver sensitivity ($-100dBm$ in average) along with the 128-bit AES security co-processor.

In the first step, we will try to describe the propagation of the electromagnetic waves with Five-Ray propagation model (see Fig. 3), in which we consider a simple reflections from the side walls, floor and ceiling of the hall.

Then the impulse response function of the transmission channel can be written in the form:

$$h(t) = A_1 \cdot \sigma(t - T_1) + A_2 \cdot \delta(t - T_2) + \\ + A_3 \cdot \delta(t - T_3) + A_4 \cdot \delta(t - T_4) + A_5 \cdot \delta(t - T_5) \quad (2)$$

where an expression $A_1 \cdot \sigma(t - T_1)$ represents a received signal portion (from line-of-sight);

expressions $A_2 \cdot \delta(t - T_2)$, $A_3 \cdot \delta(t - T_3)$ and $A_4 \cdot \delta(t - T_4)$ represent reflected signal portions from the both side walls and the hallway floor;

$A_5 \cdot \delta(t - T_5)$ represents a reflected contribution from the hallway ceiling.

Given the same length of the transmission path, it is possible to assume that the reflections from the both side walls and the floor have the same signal time delay (T_2=T_3=T_4). Then, it is possible to rewrite (2) into the following form:

$$h(t) = A_1 \cdot \sigma(t - T_1) + A_v \cdot \delta(t - T_2) + A_5 \cdot \delta(t - T_5) \quad (3)$$

where $A_v = A_2 + A_3 + A_4$.

Then, the frequency response of the transmission channel is:

$$H(j\omega) = A_1 e^{-jT_1\omega} + A_v e^{-jT_2\omega} + A_5 e^{-jT_5\omega}. \quad (4)$$

For the times T_i aplies:

$$T_1(d) = \frac{d}{3 \cdot 10^8} \quad [s], \quad (5)$$

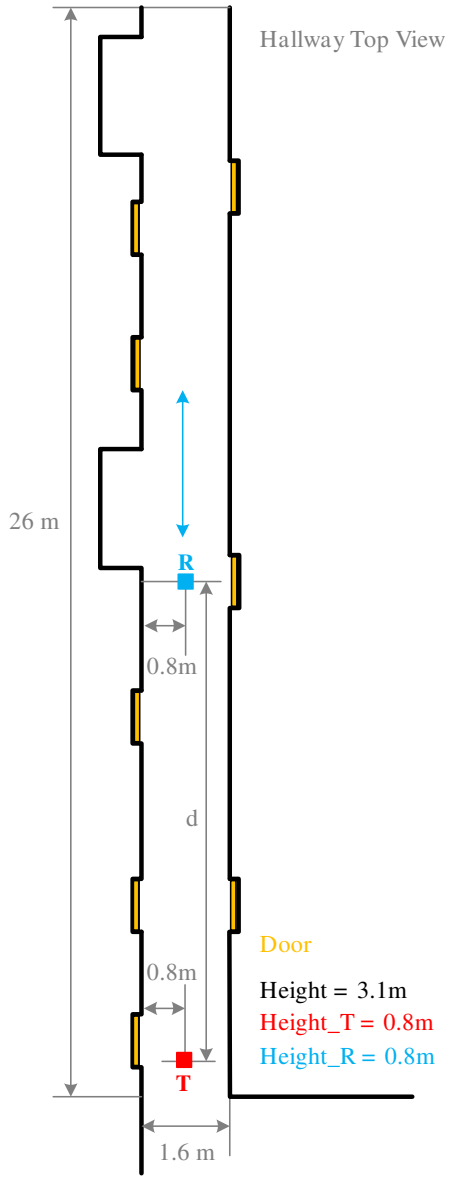

Fig. 2. Topology of the measurement indoor environment

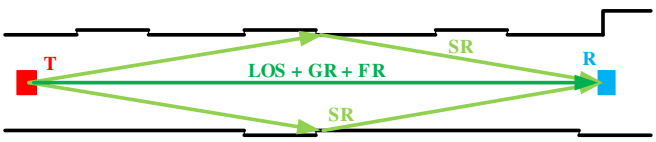

Fig. 3. Five-Ray propagation model illustration

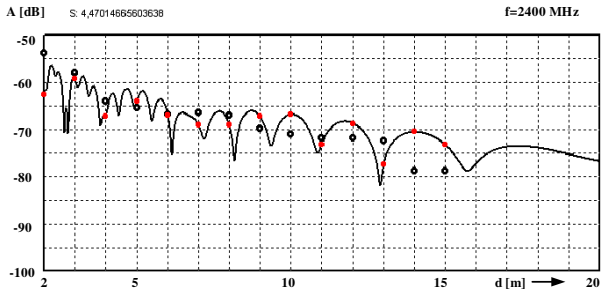

Fig. 4. Transmission power dependency on the distance d

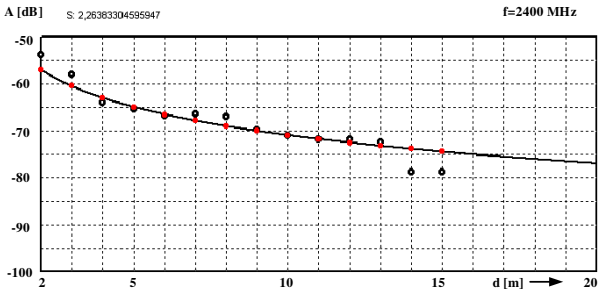

Fig. 5. Transmission power path-loss dependency on the distance d

$$T_2(d) = \frac{\sqrt{d^2 + 4 \cdot 0.8^2}}{3 \cdot 10^8} \quad [s], \tag{6}$$

$$T_5(d) = \frac{\sqrt{d^2 + 4 \cdot 2.3^2}}{3 \cdot 10^8} \quad [s], \tag{7}$$

With respect to the (1) and if assuming that the antennas gain equal 1, it is possible to write for A_1 the following:

$$A_1 = C \cdot \left(\frac{\lambda}{4\pi d}\right)^2, \tag{8}$$

where the constant C depends on the antennas gain (transmitting and receiving antenna).

For all reflected radio waves applies:

$$A_i = K_i \cdot C \cdot \left(\frac{\lambda}{4\pi d_i}\right)^2, \tag{9}$$

where the coefficient K_i is the reflection coefficient that depends on reflection plane material, reflection plane surface, the frequency, etc.)

Based on the mathematical representation of the Five-Ray signal propagation model, the experimental results have been acquired. These results show the dependency of the channel path-loss on the distance between the receiver and the transmitter. The graphical representation of the data with reflection coefficient values set to 0.5 and the frequency $2400MHz$ is shown on the Fig. 4.At the same time, the Fig. 4 shows the measured values in the specific measurement points (black circles). The red dots represent the values predicted by the propagation model at the specific measurement points.

As the measure of the propagation model match with the experimental results, we selected the relationship (10). Having the zero-mean error of the propagation model this relationship represents a selective standard error deviation of the model.

$$S = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(M_i - M_o)^2}, \tag{10}$$

where M_i represent the measured values at the specific measurement points;

M_{o_i} represent the model calculated values at the specific measurement points.

When comparing the measured values with the values obtained from the Five-Ray propagation model, we received an average standard deviation value equal $S \approx 4.5dB$. We can conclude that the indoor environment is too complex for the transmission path with strong scattering and multiple electromagnetic waves reflections. Therefore, it is impossible to describe these effects using any analytical propagation model, unlike the possibility in case of the urban environment (urban mikro-cell).

Let's analyze an option of describing the electromagnetic wave propagation through the Friis equation to calculate the path-loss of the electromagnetic waves in the free space. Then, the mathematical model describing the signal path-loss dependency on the distance between the transmitting and the receiving antenna will be in the form:

$$A_{dB}(d) = 10log_{10}\left(\frac{P_r}{P_t}\right) = \\ = 20log_{10}(\lambda) - 20log_{10}(d) + K, \tag{11}$$

where P_t is the transmission power;

P_r is the power at the receiving antenna output;

K is a constant representing the antennas' parameters (receiving and transmitting antenna; $K = 20log_{10}(4\pi) - 10log_{10}(G_rG_t)$)

A graphical illustration of the $2400MHz$ electromagnetic wave path-loss dependency on the distance between the transmitting and receiving antenna d is shown in the Fig. 5. Similarly to the Fig. 4, this figure shows the measured values in each specific measurement point (black circles) and the propagation model calculated values (red dots). The propagation model is defined in (11).

Likewise, as in the previous case of the Five-Ray propagation model, for this one we determined the standard error deviation of the model $S = 2.26dB$ based on the model calculated values and measured values.

According to [11], in most cases, we can use a simplified model of the wave propagation in the form:

$$A(d) = K \cdot \left(\frac{d_0}{d}\right)^{\gamma}, \tag{12}$$

TABLE I
TYPICAL VALUES OF γ EXPONENT FOR DIFFERENT ENVIRONMENTS

Environment	γ value
Urban area (macro-cells)	3.7 - 6.5
Urban area (micro-cells)	2.7 - 3.5
Office space (same floor)	1.6 - 3.5
Office space (different floors)	2 - 6
Commerce	1.8 - 2.2
Industrial	1.6 - 3.3
Household	3

$$A_{dB}(d) = 10\ log\ K - 10\ \gamma\ log\left(\frac{d}{d_0}\right), \tag{13}$$

where K is a function of the average environment path-loss and takes into account the characteristics of the antennas;

d_0 is the reference distance that for the indoor environment should be in the interval $1 - 10m$. (for 2.4GHz frequency, it is recommended to set the value d_0 at the lower interval boundary, for outdoor environment d_0 should be from the interval $10 - 100m$).

The value of the coefficient K may be set approximately in the reference distance d_0 based on the Friis relationship:

$$K = \left(\frac{\lambda}{4\pi d_0}\right)^2, \tag{14}$$

Better way of the path-loss value $K(d_0)$ determination in the reference distance for certain conditions is to measure it. Similarly, also the γ value depends on the specific environmental conditions and can be set by measurements. The easiest way is to minimize the sum of difference squares of the measurements in the specific measurement points d_i and model predicted values ($\sum(M_o(d_i) - M_i)^2$), where M_i represent the measured values).

Available literature on propagation models gives approximate values of the γ exponent - Table I.

Considering that the random environmental factors contribute to the path-loss propagation given by the value E_{dB}, then the relationship (9) turns into the following form:

$$A_{dB}(d) = 10\ log\ K - 10\ \gamma\ log\left(\frac{d}{d_0}\right) + E_{dB}, \tag{15}$$

where E_{dB} is a random variable with a Gaussian distribution with zero mean and standard deviation S. Then, based on the experimental measurements it is possible to create the mathematical model (9) that minimizes the sum of difference squares of the measured values and the model calculated values. It can be proved that for this criteria based on the $N + 1$ different measurements in different distances $d_i = 0, 1, 2, ..., N$ it is possible to determine γ value as follows:

$$\gamma = \frac{\sum_1^N \left(K(d_0) - M(d_i) \cdot log_{10}\left(\frac{d_i}{d_0}\right)\right)}{10\sum_1^N \left(log_{10}\left(\frac{d_i}{d_0}\right)\right)^2}, \tag{16}$$

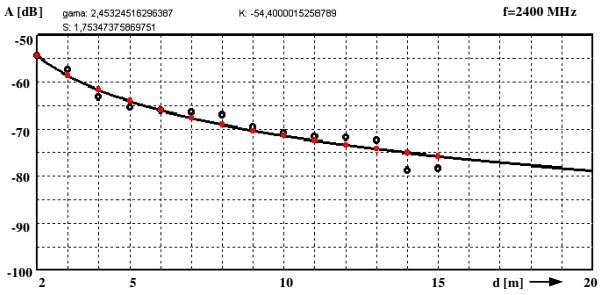

Fig. 6. Transmission power path-loss dependency on the distance d (black circles represent the measured values and the red dots represent the predicted values from the propagation model (17))

where $K(d_0$ is the path-loss in the reference distance d_0 (it can be obtained by measurements eventually it is possible to determine its approximate value according to (10),

$M(d_i)$ is the measured path-loss value at a distance d_i from the transmitter.

Remark 3.1: Note that the above model is applicable only for distances $d > d_0$.

Based on the (11) and (12) a transmission channel model can be written in the form:

$$A_{dB}(d) = C - 10\ \gamma\ log\left(\frac{d}{2}\right), \tag{17}$$

where the reference distance has been chosen $d_0 = 2m$. Fig. 6 illustrates the obtained results.

Similarly, as in the previous cases, based on the measured and calculated values the standard error deviation of the model has been determined $S = 1.753dB$. It is obvious that the present model is the most appropriate for determining approximate path-loss of radio signal propagation in indoor environments.

Remark 3.2: However, in practical implementation of the latter model, prior to implementation, it is necessary to perform sample measurements in the the investigated environment.

During the verification of the model, there have been measurements in 9 frequency channels performed. The investigated channels were spaced by $10MHz$ from the range beginning at $2400MHz$ up to $2480MHz$. The obtained parameters of the propagation model for different frequency channels are shown in Table II.

Remark 3.3: Propagation model used in Table II is in the form: $A_{dB}(d) = C - 10\ \gamma\ log_{10}(d/2), P_t = +1dBm, 2FSKmodulation$.

It is obvious that for each channel in the investigated ISM frequency band, we receive a propagation model characterized by different parameters. This situation arises from the fact that the values obtained during the measurements in each channel are slightly different. The path-loss in the individual channels (1-9) at distances of $2 - 15m$ is illustrated in Fig. 7.

TABLE II
PROPAGATION MODEL PARAMETERS

Channel	Frequency [MHz]	γ	C
1	2400	2.5492	-53.9
2	2410	2.4096	-53.5
3	2420	2.9357	-50,5
4	2430	2.6661	-53.0
5	2440	2.6640	-50.1
6	2450	2.5445	-51.8
7	2460	2.6750	-49.3
8	2470	3.0334	-50.1
9	2480	3.4085	-49.7

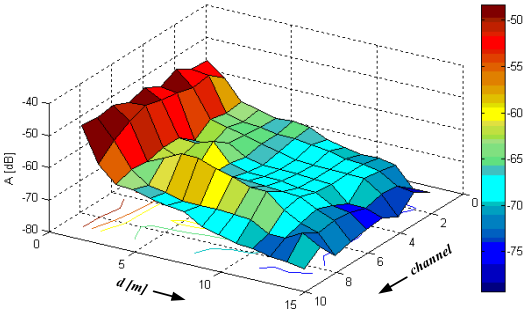

Fig. 7. Measured channel path-loss dependency on the distance d varying from $2m$ to $15m$

The situation where each channel is characterized by a model with optimal γ parameter and C according to Table II is illustrated in Fig. 8. This figure models path-loss propagation in the $2400 - 2480MHz$ frequency range (channels 1-9).

Remark 3.4: Note that the standard error deviation of the model has been $S = 2.46dB$.

Let's simplify rather complicated approach for the modeling of the wave propagation that uses different models for every

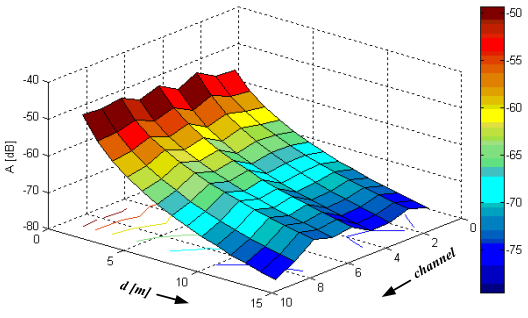

Fig. 8. Modeled channel path-loss dependency on the distance d varying from $2m$ to $15m$

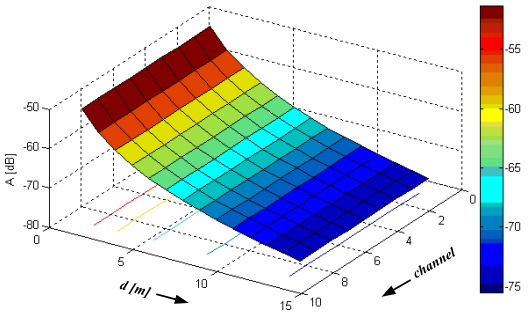

Fig. 9. Modeled path-loss dependency on the distance d varying from $2m$ to $15m$

single channel. Let's try to substitute all 9 previous propagation models with one valid for the entire frequency range $2400-2480MHz$. During the new model description, average values of the coefficients γ_p=2.7629 and C_p=-51.32 are used. Then, the model characterizing the whole frequency range is in the following form (18):

$$A_{dB}(d) = -27.629\ log\left(\frac{d}{2}\right) - 51.32. \tag{18}$$

Fig. 9 is based on the model values defined by (18) and shows the dependency of path-loss propagation in the frequency range $2400 - 2480MHz$ at different distances d.

Remark 3.5: Note that the standard error deviation of the model in this last case is $S = 2.9dB$. It is obvious that there is a slight deterioration in the accuracy of the model compared to the previous one.

IV. CONCLUSION

A comprehensive description of the electromagnetic wave propagation solve Maxwell's equations. However, this approach is computationally demanding and impractical. In real life situations, the approximate models are deployed to describe the signal propagation. These models are often based on the experimental results. This paper shows case study on indoor radio frequency signal propagation at 2.4GHz ISM Band supported by the related math, implementation of the propagation models and experimental results.

To investigate the case of the electromagnetic wave propagation, a specific hallway scenario has been used. The measurements were performed by the system-on-chip solution based on TI CC2511 that operates in the ISM band starting at the frequency equal to $2.400GHz$ and ending at $2.4835GHz$.

Based on the evaluation of the conducted experiments we can conclude that Multi-Ray (Five-Ray) propagation model describing a signal path-loss in indoor environment is unusable. Model based on Friis relationship is indeed easy to apply, requires no measurements, but in the case of indoor environment is applicable only in case of line-of-sight between the receiver and the transmitter. This model does not reflect the

characteristics and topology of the environment and therefore its use is not recommended in indoor environments. Simplified model of propagation of radio waves can be used to determine the approximate communication range. The successful application requires performing the sample measurements of the path-loss.

Let's point out that the radio frequency signal propagation models are dependent on specific environmental conditions. The achieved results cannot be applied directly. It is necessary to carry out experimental measurements of path-loss at multiple locations of protected area by measuring and using the relations (15) and (16) and the optimal model parameters. Then, based on the simulation experiments with propagation models, it is possible to find a suitable deployment of the WSN nodes. Based on path-loss measurements at different distances, we can also conclude that typical signal fading due to the multi-path propagation is caused by greater distortion in the indoor environment and occur to a lesser extent than in the urban areas. However, potential signal loss cannot be suppressed by the frequency channel alternating. By changing the channels (using frequency diversity), it is possible to suppress the effect of interferences from other sources, which are now in the indoor environments strongly present at the $2.4GHz$ ISM band.

***Abstract*—The paper presents a prototype mixed-mode wireless indoor positioning and navigation system. The main goal of the system is to provide accurate and reliable location information for visually impaired users. The system also enables access to location related context information. The radio nodes of the network can operate in two power modes providing basis for both rough and precise user positioning. The paper describes an overview of the system architecture and the user interface suited to the needs of the visually impaired. Then, the details of the implemented positioning methods are presented. Finally, the results of experimental evaluation of positioning accuracy obtained using different classification strategies are discussed.**

***Index Terms*—Context-aware services, indoor radio communication, location services, personal communication networks, pervasive computing, radio navigation, wireless sensor networks**

I. Introduction

Recently, a number of wireless indoor positioning systems have been developed and numerous research works are reported in the literature. One of the first indoor positioning systems that used radio beacons and Received Signal Strength Indicator (RSSI) measurements was the RADAR system developed by Microsoft Research [1]. From that time the problem of indoor positioning and navigation has been widely addressed around the world [2-14]. Hence maintaining low deployment and maintenance costs is among the most important objectives of the research, majority of the solutions reported in the literature rely on radio signal strength measurements [23-32].

Received signal strength (RSS) measurements can be incorporated to location services in several ways. First of all, radio wave indoor propagation models can be used to determine the possible location of the terminal. This approach requires detailed description of the propagation environment and thus is difficult to implement. Another approach involves the use of database search methods to calculate user terminal position. Therefore, it is necessary to provide reference RSSI measurements (i.e. measurements taken in predefined locations) that are stored in the reference database, and which are then used by location estimation algorithms.

This work was partially supported by the National Centre for Research and Development of Poland under grant no. NR-02 0083-10 in years 2010-2013

One of the application areas of indoor positioning systems is aiding the visually impaired and blind in navigation [22] and orientation and thus in their everyday activities. Almost all electronic travel aids (ETA) for the visually impaired [15-20] require accurate information on current user location. Obtaining precise information on user location can for example facilitate access to public services offered in large buildings (e.g. city halls, hospitals) by aiding to locate rooms or by giving a remote guidance on how to reach the destination. Contemporary satellite navigation systems like GPS provide positioning services sufficient for successful navigation in outdoor scenarios. However, the use of satellite positioning systems is usually impossible in indoor and densely built-up urban areas only. Thus, most of ETAs offered on the market make use of local networks of reference stations that transmit infrared [15] or radio signals [16-18]. The transmitters are used to identify various points of interest (POI) like bus stops, entrances to public buildings, etc.

In the paper, we present a mixed-mode RSSI-based wireless positioning system developed as a part of a complex solution aiding the visually impaired in indoor navigation. The remainder of the paper is organized as follows. Section II presents an overview of the positioning system architecture. Section III provides details of the proposed positioning approach, while Section IV gives details of the user interface module dedicated for visually impaired users. Section V describes experiments conducted to evaluate the performance of the system, while Section VI discusses the results of these experiments. Section VII summarizes our work.

II. System Architecture

The general architecture of the proposed indoor positioning system consists of a local localization server, a local database server and an optional global localization server, as previously described in [21]. A wide range of portable user devices (smartphones, notebooks, tablets etc.) may be used as system terminals, however the terminals should have the capability to measure strength of the signals transmitted by system reference stations mounted inside a building. Thus, a dedicated software or hardware is necessary to read the measurement data and pass the results to the local positioning server.

The key tasks of the local positioning server include

- storing information about the layout of the area (a digital map) it serves (e.g. of an office building);

978-83-60810-58-3/$25.00

- making use of the local database engine to store reference measurement data;
- computing the probable user location based on the RSSI measurement values reported by the terminal;
- management of communication with the global localization server, if available.

The general architecture of the proposed system is shown in Fig. 1. All the components of the system communicate and exchange data using XML/JSON and SOAP-based Web Services.

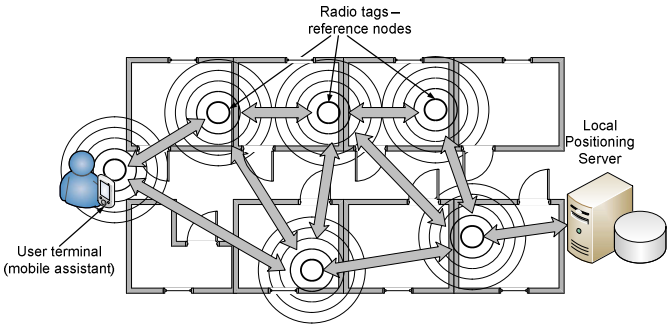

Fig. 1. General architecture of the indoor positioning system.

III. POSITIONING TECHNIQUES

A variety of techniques can be employed to estimate the position of a wireless network terminal. Majority of systems described in the literature base on measurements of signal parameters transmitted by system reference stations. Then, the distances of the terminal to at least some of the reference nodes can be calculated and the approximate position of the terminal can be estimated. Among the most commonly used signal properties are propagation time, angle of arrival, and signal strength, however due to low deployment and maintenance costs, majority of the solutions reported in the literature rely on received signal strength measurements [2, 23-32].

The most straightforward method to estimate the position of a radio terminal is to determine whether it is within the coverage of some reference station. The accuracy of positioning with this approach strongly depends on the range of reference transmitters. However, when reference stations transmit signals with relatively low power, the position of the user terminal may be well approximated by the known location of the reference transmitter. This approach is called *proximity detection*. Practical implementation of this positioning technique involves installation of many reference nodes, often called *radio tags*. However, due to simple tag's construction the overall system installation cost might remain low. This technique offers good accuracy, however it strongly depends on the number of installed reference tags. The idea of positioning system using proximity detection is shown in Fig. 2.

As previously mentioned, distance estimation techniques involving radio wave propagation modeling are widely used in positioning systems. However, due very high complexity of indoor radio wave propagation environment, applicability of these methods is limited to outdoor areas. In typical indoor scenarios, strong multipath propagation effects make it impossible to unambiguously relate measured signal parameter value to a distance from the transmitter. Even along short propagation paths, signal parameters may exhibit very strong variability. Another factor limiting performance of positioning methods is time variability of indoor radio channel characteristics. For example, depending of the time of the day, the offices may either be crowded or almost empty what may result in significant changes of the reported values.

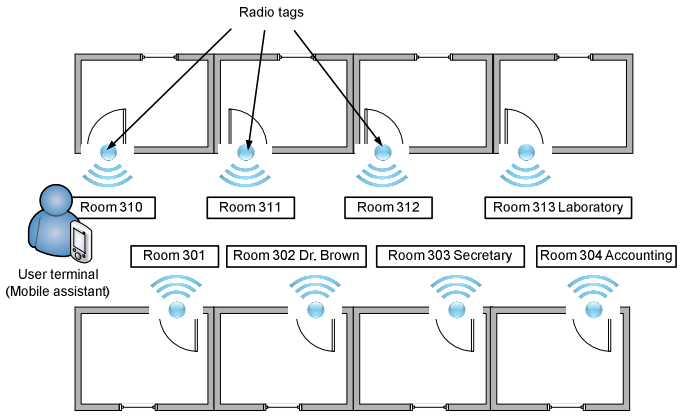

Fig. 2. Proximity detection – presentation of indoor location of the terminal and position related context information (room number).

Therefore, there is a need to search for new positioning methods for indoor applications. One of the approaches that is adequate for indoor systems assumes the use of correlation analysis of reported signal parameter values with some reference data recorded at predefined locations. As database search methods (Fig. 3) rely on evaluation of similarity of measured signal characteristics at actual location to the reference datasets, these methods are not so prone to multipath and shadowing effects as the methods based on radio wave propagation modeling.

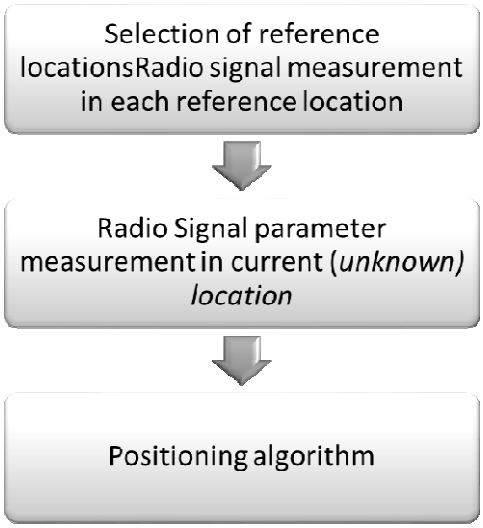

Fig. 3. Block diagram of DCM positioning method

Despite of the fact that database correlation methods may be based on analysis of any available signal parameters, most of practical implementations involve received signal strength

measurements. The advantage of the use of RSSI is that most of contemporary radio receivers provide possibility to monitor RSSI level and a wide range of devices can be used with a positioning system without a need to implement any hardware modifications.

The use of database search methods makes it also possible to reduce the influence of RSSI time variability by the use of normalization to the value read from a given reference signal source.

A. *Proposed Positioning Technique*

The proposed implementation of a wireless indoor positioning system involves received signal strength (RSSI) measurements to estimate terminal position. It makes use of the advantages of both aforementioned approaches, i.e. proximity detection and database search methods.

Hence proximity detection is most effective and accurate when area served by a single reference tag is relatively small, the tags should be equipped with radio transmitters supporting low transmit power modes. On the other hand, database search method accuracy increases with the number of sources of reference signals. In that case, the nodes should be capable to transmit reference signals over relatively large areas. Moreover, the coverage areas of neighboring transmitters should overlap.

It is worth mentioning, that position information in the form of absolute geographical coordinates of the user is not the most expected output from indoor navigation and positioning systems. Geographical coordinates are more suitable for outdoor positioning, mainly due to easy integration with GIS systems.

Moreover, in indoor applications accurate and reliable altitude estimation is required. Although in outdoor scenarios the use of absolute altitude above ground or sea level as altitude descriptor is the most convenient, in indoor scenarios floor index should be considered as the natural way of expressing in-building altitude of travelling people.

Therefore, the proposed indoor positioning system makes use of area-based context-related positioning. Area-based positioning systems provide end users with context information related to the current zone of the building. The system output data set includes but is not limited to:

- floor index or name (if applicable),
- zone within a building (e.g. “north wing”),
- room or office number or its name (e.g. “kitchen” or “auditory no. 416”),
- additional site-related information (like name of current lecture in an auditory room).

Web based application for management of context information is presented in Fig. 4.

Moreover, the proposed system returns absolute coordinates of the user terminal to ensure backward compatibility.

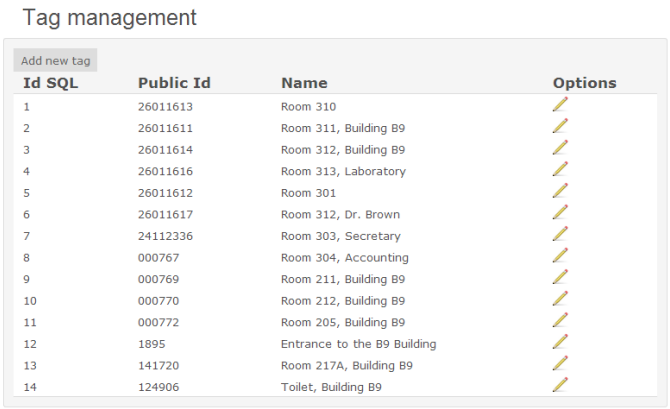

Fig. 4. Web application interface for the management of the radio tags database. Each tag has its unique id and public id (address). Each of the database entries can be edited or deleted.

IV. Positioning Network Interface Module

To enable access to the dedicated positioning network from popular mobile devices (smartphone, tablet, etc.), a dedicated interfacing PilotIE (Fig. 6) device was designed. Proprietary communication protocol with the network of radio beacons enables variable output power settings and provides access to the received signal strength (RSSI) and link quality (LQI) indicators. PilotIE is designed as a device interfacing the radio beacons scattered in the building and the user’s mobile device (via Bluetooth).

Another feature of the PilotIE device is the ability to control selected functions of dedicated mobile applications. Most of the modern smartphones are equipped with a touchscreen and they do not have physical keys. Interaction with a mobile phone requires the use of both hands and may be especially uncomfortable for blind or visually impaired users, who at the same time are often using a white cane. In our solution mobile phone can be hidden in a pocket, which significantly improves the safety of the blind and protect the device in case of falling. Because modern mobile phones are usually equipped with very good quality speech synthesizers, voice messages could be transmitted to the users via the hands-free set. Built-in physical keyboard allows to change systems parameters, like speech speed or volume. It also enables the possibility to re-read the previous message.

Device is built based on the Texas Instruments low-power, 16-bit microcontroller (MSP430F5438A) with the external CC1101 radio transceiver and the TiWi-uB2 Bluetooth 2.1+EDR and BLE 4.0 module. Bluetooth dual mode module can be switched to work in the new, energy efficient Bluetooth 4.0 Low Energy standard (only available in the newest mobile devices) or classic Bluetooth 2.1+EDR mode (most of older devices). It is equipped with two status LEDs and eight user buttons. Device is assembled in a 78mm × 48mm × 20mm enclosure with a single BL-5C (1020 mAh) Li-Ion battery.

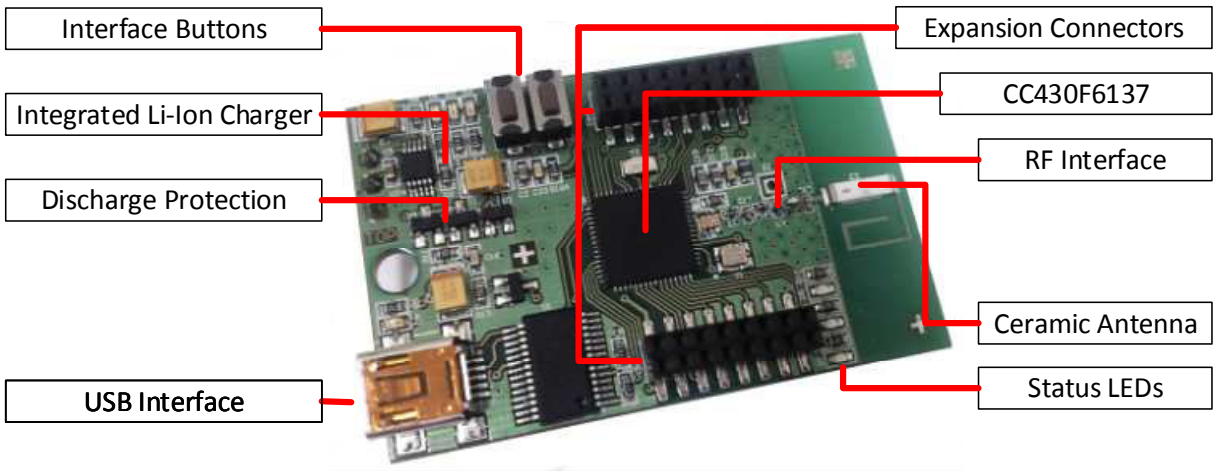

Fig. 5 Radio beacon unit – construction details.

Fig. 6. PilotIE – an interface module for positioning network and mobile phone communications.

V. Experiment Setup

In order to verify the proposed positioning algorithms a number of experiments were undertaken with the use of self-made radio beacons and dedicated user interface module (Fig. 6).

Our prototype radio beacon modules (Fig. 5 and Fig. 7) were built based on the ultralow-power microcontroller system-on-chip (CC430 family, developed by Texas Instruments) with integrated RF transceiver core (CC1101) for the sub-1-GHz industrial, scientific and medical (ISM) radio bands. The CC430F6137 core MCU features 32KB of flash memory, 4KB of RAM, two 16-bit timers, a high-performance 12-bit analog-to-digital converter (ADC), universal serial communication interfaces, a real-time clock module and 44 I/O pins.

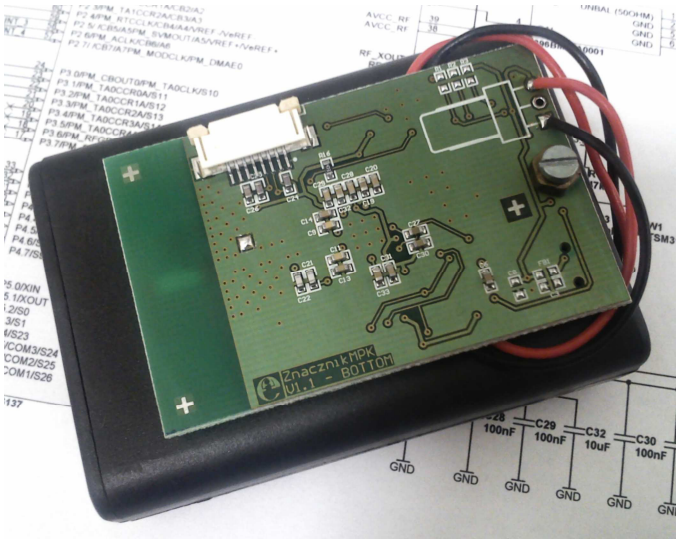

Fig. 7. Radio beacon unit.

Integrated radio module ensures easy implementation of proprietary communication protocols with variable output power settings and provides access to the received signal strength (RSSI) and link quality (LQI) indicators. CC1101 RF transceiver is able to work with programmable data rates ranging from 0.6 to 500 kBaud, programmable output power levels from -30 to +12 dBm, and high sensitivity (up to -117 dBm at 0.6 kBaud for 1% Packet Error Rate).

Radio beacon was optimized to achieve extended battery life. Integrated lithium-ion battery charger and battery discharge protection circuit enables the use of cheap Li-Ion batteries. Device is able to communicate with the PC over the FT232R USB UART interface bridge. Three programmable LEDs and a single TACT switch are provided for status indication and optional configuration. All unused A/D inputs, I2C/SPI buses, GPIOs, and external interrupt inputs are routed out to the expansion connector on top of the module for possible future applications.

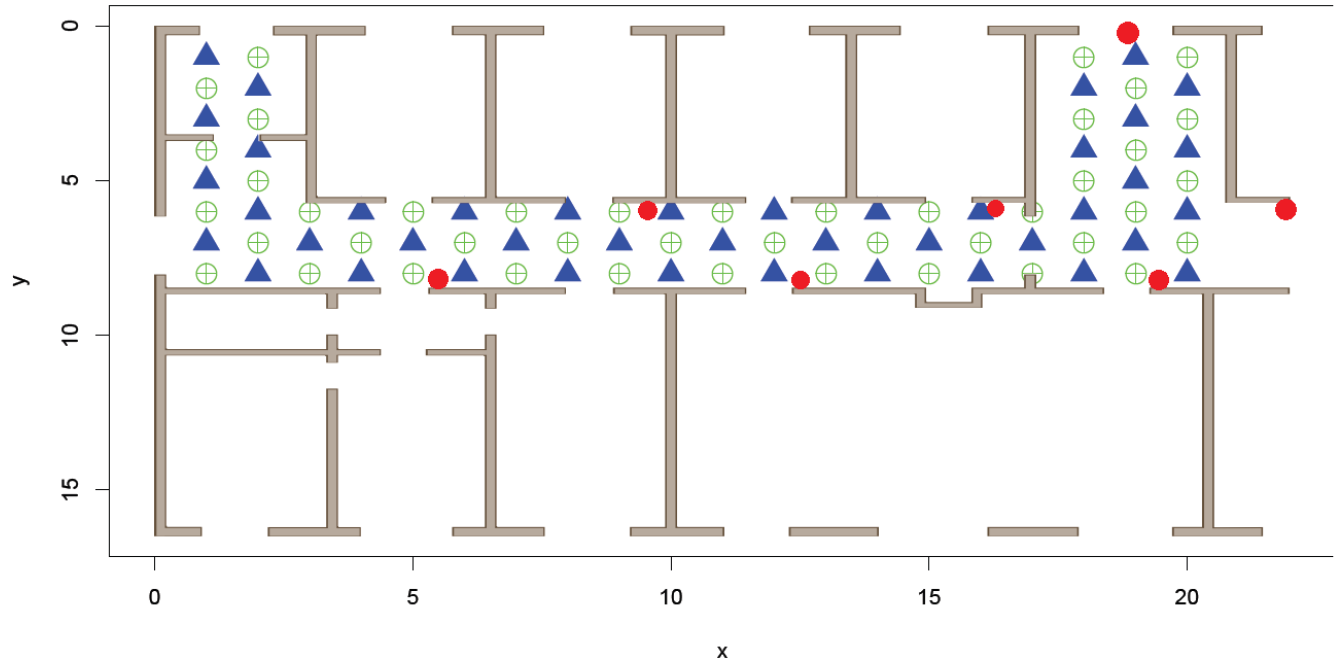

Fig. 8. Experimental setup - RSSI measurement locations (blue - training subset, green - test subset, red - radio beacons)

Device integrates a small ceramic antenna (Johanson Technology 0868AT43A0020, with a peak gain of -1.0 dBi and average gain of -4.0 dBi) or can be used with an optional unipol wire antenna. In the presented application radio beacons are pre-configured for the 868MHz band with the data rate of 38.4 kBaud and 2-GFSK modulation (20 kHz deviation).

Device was designed on a small PCB (55 × 35 mm) which perfectly fits 3xAA battery holder or can be mounted in the KM-27 housing (64.5mm × 46.8mm × 22.3mm) with a single BL-5C (1020mAh) Li-Ion battery.

Each of the fourteen radio beacons used in experiments was equipped with omnidirectional wired antenna. The nodes were distributed across test bed area (seven locations are marked in Fig. 8). All the beacons transmitted packets with two power levels: -30 dBm and -12 dBm. This approach benefits in ability to combine proximity-based methods with database search within a single machine learning algorithm.

Experiment was settled in office building with long and narrow corridor in its central part and number of offices at the sides of that corridor. RSSI measurements were collected in test points arranged in two grids. Fourteen radio beacons were placed in the experiment area. Placement of radio beacons and locations of the measurement points is shown in Fig. 8.

While one dataset was used for training the algorithms, the second one was intended to be used to verify positioning accuracy. Nevertheless, each measurement record contained 10 RSSI readouts taken with the sampling interval of 2.5 seconds.

On the basis of previous research [21] two positioning algorithms were developed. The first one employs Multilayer Perceptron Artificial Neural Network (MLP). The other one was Random Forests (RF) [33]. Moreover, k-Nearest Neighbors (kNN) algorithm with $k=7$ was used as a reference method. All the algorithms were trained using records from learning dataset and positioning accuracy was verified with separate testing set. We examined and compared positioning accuracy for the following three scenarios:

- Using DCM-only system, i.e. only the subsets of RSSI measurements for packets transmitted with the power of -12 dBm were used.
- Using proximity-only system, i.e. only the subsets of RSSI measurements for packets transmitted with the power of -30 dBm were used.
- Using proposed fusion method, i.e. complete datasets containing RSSI measurements for packets transmitted with both -12 dBm and -30 dBm were used.

VI. EXPERIMENT RESULTS

Experimental results show that Multi-Layer Perceptron Neural Networks underperform Random Forests in indoor positioning applications. Random Forests classifier provides the lowest overall average error as well as each of the quartile errors. It is worth to notice that Random Forests classifier achieves better results when mixed-mode input data (i.e. proximity-based and DCM-like) are used. This is in opposite to MLP, where the highest accuracy can be reached with the use of proximity mode only. It is also noticeable that in case of MLP classifier, the biggest averaged positioning error was achieved for the mixed mode.

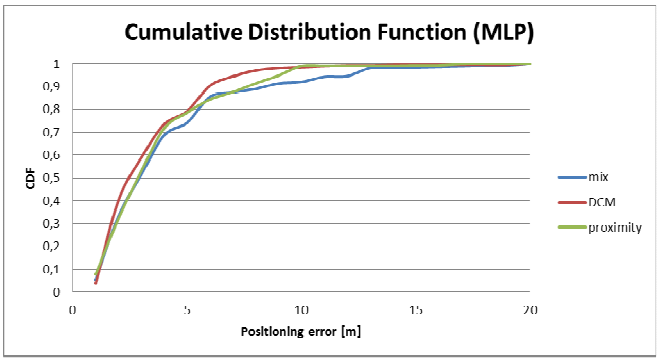

Fig. 9. Cumulative Distribution Function (CDF) of positioning error for MultiLayer Perceptron Artificial Neural Network classifier

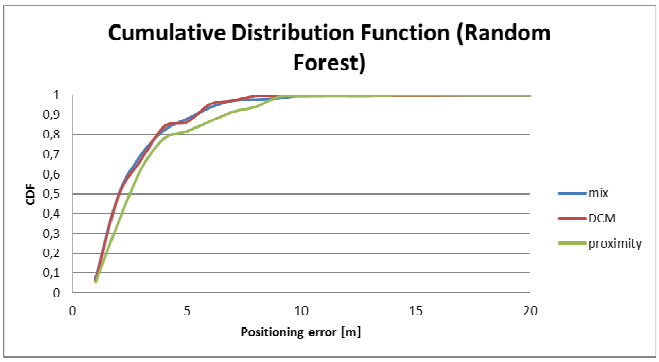

Fig. 10. Cumulative Distribution Function (CDF) of positioning error for Random Forests classifier

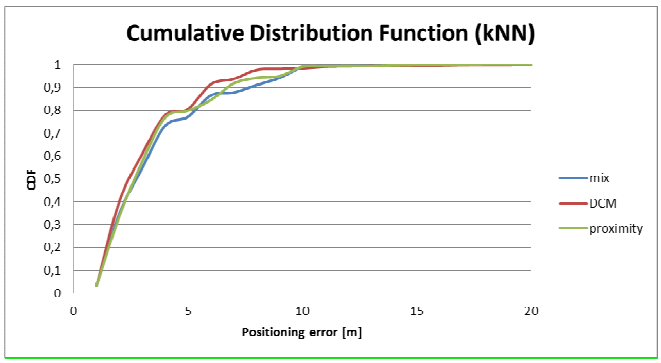

Fig. 11. Cumulative Distribution Function (CDF) of positioning error for k-Nearest Neighbour classifier

Simple kNN classifier outperforms MLP when average error is considered. On the other hand, the maximum positioning error (4th quartile) for kNN classifier was as high as 19.42 meters for DCM-like dataset, which is significantly higher than for Random Forest classifier.

Random Forest classifier takes all the benefits from combined proximity and DCM modes and outranked MLP and kNN in all accuracy indicators i.e. mean positioning error and the values for all considered quartiles.

Averaged positioning error and error quartiles for the three examined approaches and two proposed algorithms were summarized in Table I.

When CDF functions are considered (Fig. 9 to Fig. 11) a number of features might be observed. First of all CDF for Random Forest classifier outperforms CDFs for MLP and kNN while growth rate in the area of positioning error ranging from 0 to 10 meters is considered. This results in high accuracy in real applications, which is reflected in low average positioning error. It can be also observed that RF underperforms when proximity-only mode is used, however combining proximity mode with DCM methodology results in increasing positioning accuracy. On the other hand, combining proximity and DCM methodologies results in significant increase of location estimation inaccuracy when MLP classifier is involved.

Besides positioning accuracy, Random Forests are also computationally very efficient when compared to MultiLayer Perceptron network, especially when the training time is considered.

TABLE I.
ERROR INDICATORS OF THE TESTED POSITIONING METHODS

	-30 dBm			-12dBm			mixed -30 dBm and -12 dBm		
Indicator	MLP	RF	kNN	MLP	RF	kNN	MLP	RF	kNN
Average positioning error [m]	3.16	2.79	2.95	2.83	2.27	2.70	3.53	2.32	3.10
Average positioning error (25 %) [m]	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
Average positioning error (50 %) [m]	2.24	2.24	2.24	2.24	2.00	2.24	2.24	2.00	2.24
Average positioning error (75 %) [m]	4.12	3.16	3.16	4.12	3.00	3.00	5.00	3.00	4.12
Average positioning error (100%) [m]	17.00	13.34	17.03	19.10	16.03	19.42	19.00	14.00	14.04

VII. SUMMARY AND CONCLUSION

In this paper indoor positioning system for short range radio communications network has been proposed. The system uses radio beacons transmitting packets with two different power levels of -12 dBm and -30 dBm. This approach gives possibility for joint use of positioning methods based on proximity detection and database search. While packets transmitted with output power of -12 dBm covers relatively large area, transmit power of -30 dBm strongly distinguish small areas of interest.

The positioning system combines proximity sensing and database search methods. The experiments conducted in a large office building resulted in average positioning error not exceeding 2.32 meters when Random Forest classifier was used with combined proximity sensing and database search methods. Since the system uses custom device coupling radio beacons with modern smartphones via Bluetooth connectivity, it is possible to present the results to the users in the form of voice messages.

Future development works assume incorporation of multi-system opportunistic positioning. As the result, the positioning algorithms will benefit from the use of data from generally available radio networks, like public Wi-Fi or mobile cellular telephony networks.

***Abstract*—Planing the topology of wireless sensor networks (WSN) for a specific application is a complex task. Each application defines requirements to its WSN. Some of these requirements have to been fulfilled by the wireless technology, e.g., energy consumption and throughput, and some by the network topology, e.g., redundancy and latency. Topology makes restrictions to the wireless technology and the wireless technology makes restrictions to the network topology.**

In this paper we present an algorithm to select a network topology and a wireless technology depending on application's requirements automatically.

The algorithm is part of the Sens4U approach, which aims to simplify and possibly automate the process of building WSN applications and support applications development done by non-WSN-experts.

I. Introduction

WIRELESS SENSOR NETWORK (WSN) in enviromental monitoring consists of a large number of nodes with sensors and a wireless network device. These nodes are deployed over a large area, take measurements, and send the data to a sink node where the data is stored and can be analyzed. Planing of such networks is a complex and error prone task.

There are two approaches to deploy the nodes. For the first approach the sensor nodes are randomly distributed over the area, e.g., abandoned from airplane. After arriving final positions all nodes determine their geographic coordinates automatically and set up a network topology autonomously. Advantage of the approach is needlessness of a proper design.

However, the main disadvantage of this approach is the higher demand of the network nodes for systems resources. Dedicated hardware and software components are required to obtain the geographic position of the node. Furthermore, each localization method has an inherent inaccuracy which leads into divergences between the measured and the real coordinates of the node. Moreover, maintenance of network is complicated due to a lack of documentation.

The second approach contains a design phase to prepare the deployment. In this phase the positions of the network nodes are determined. During the deployment phase each sensor node is installed at its predefined location. Thus, deployment of nodes is well documented.

The toolchain introduced in the project Sens4u[1] follows the second approach. The project aims to simplify and possibly automatize the process of building a WSN application. It brings together WSN-experts and non-WSN-experts. WSN-experts can develop modules for WSN register them to the Module Pool. Non-WSN-experts are enabled to specify and build their WSN. The Sens4u toolchain transforms the WSN application specification into an implementation using the Module Pool. Thus, as a result of the project usage of WSN applications have been made available for a wide spectrum of scenarious. The proposed toolchain is given in Figure 1.

In the design flow the customer expertise into the application domain expertise is owned by the actual customer and the, at least basic, WSN expertise is owned by the integrator. The integrator role is introduced to support the customer in requirement specification. The customer explains the target application to the integrator. They identify features of the application and provides these to the planning tool as input. The planning tool generates the set of technical requirements containing the required functionalities and their required parameters. The set is forwarded to the expert system. In this component the hardware/software configuration is generated, based on the available modules in the module pool and the technical requirements. An important part of the configuration is the proposed network topology. On the one hand, several technical requirements reduce the number of allowed topologies. On the other hand, not all topologies are supported by all wireless technologies. In addition, the selection of a wireless technology results can cause side effects by including several hardware and software modules for the wireless technology. Therefore choosing a topology for the WSN application is a challenging task.

This paper focus strictly on topology selection in context of the Sens4U toolchain. All other aspects are outlined briefly only.

The remaining part of the paper is structured as follows. The following section describes the concept in detail. Section 4 represents details about the Proof-Of-Concept followed by an application example in Section 5. A section with an overview of related work follows. The paper ends with a conclusion and an outlook for future work.

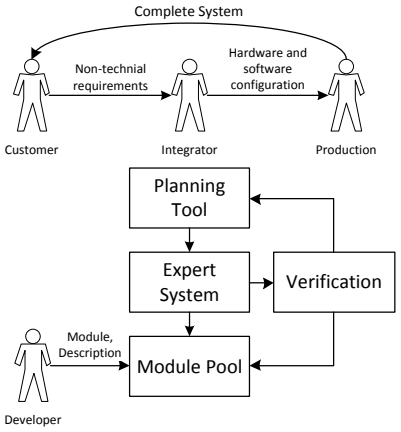

Fig. 1. The detailed tool-chain-oriented development flow and user roles.[1]

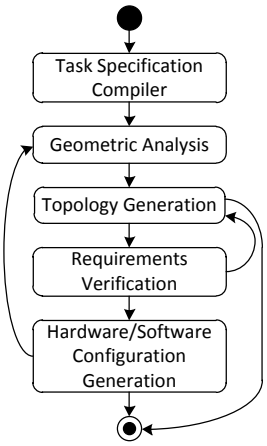

Fig. 2. Data flow in the Expert System

II. Concept

A. Input Data

The expert system receives specifications of WSN applications from the planning tool. In this paper a network specification is definied as a tuple $S_0 = (M, s, \{R_0, R_1\}, p, t, B, R)$ consisting of

1) A set of measurement points M.
2) A sink $s \in M$.
3) Two reference points R_0 and R_1 with given geographically coordinates. These points are used to map the coordinates of the specification to geographically coordinates by applying cross-multiplication.
4) A function $p : M \cup \{R_0, R_1\} \rightarrow (x, y)$ which maps measurement points to coordinates.
5) A function $t : M \rightarrow T$ which maps measurement points to measurement task definitions.
6) A polygon B describing the outer borders of the area.
7) A set of requirements R. Current status is that equations $key = value$ are supported. The supported keys are given in Table I. If no requriement defines a value for a key, the default value is used for the key.

B. Architecture of the Expert System

The expert system component is the core of the Sens4U toolchain. The expert system is composed out of five subcomponents which are given in Figure 2. The figure also shows the dataflow between the subcomponents. The functionality of each subcomponent is described in the following text.

- The *Task Specification Compiler* builds from the task definition of each measurement point an application modell. In addition it calculates the expected datarate during measurement operation. The result is extended to tuple $S_1 = (M, s, \{R_0, R_1\}, p, t, d, B, R)$. The function $d : M \rightarrow \mathbb{Q}$ maps each measurement point to the calculated datarate. The functionality dealing with the generated application modell is not covered by this paper. For this reason the applciation modell is not declared as an element in S_1.
- During the *Geometric Analysis* the network specification is analyzed. The set M is treated as a fully connected undirected graph G_0. The distance between its incident nodes is assigned to each edge. A graph G is created as a copy from G_0 but without all edges with a distance longer then $maxrange$. For G the values in Table II are calculated.
- *Topology Generation*: This subcomponent creates topology suggestion according to the information received from the geomtric analysis. If no topology suggestion can be made, the process exists returning an empty result. The exact behaviour of this subcomponent is described in the text later.
- The component *Requirements Verification* looks for violations of requirements caused by the topology. If a violation is found the topology suggestion is rejected and topology generation will try to create another suggestion. The utilization of defensive programming simplifies the development of new algorithm for creation of topology suggestions and defining new requirement keys. Due to this addtional requirements verification the algorithms need only evaluate subsets of R.
- The *Hardware/Software Configuration Generation* trys to create hardware/software configuration for the wireless sensor nodes. It looks up the module pool for a hardware/software plattform which firstly is able to implement the application modell and secondly supports a wireless network technology able to form the given topology suggestion. This step can result in three different states.
  1) Firstly, there can be no solution. In this case the expert system terminates and returns with no solution.
  2) Secondly, the Expert System have found one or more possible solutions. In this case the process ends and returns the solutions to the planning tool.
  3) The third case means that there can be solutions with additional requirements. The topology suggestion is discarded and the additional

TABLE I
KEY/VALUE PAIRS SUPPORTED AS REQUIREMENTS

Key	Description	Default Value
$maxrange$	The maximum range of the wireless network technology.	$+\infty$
$rmaxdegree$	The maximum degree of a network node in the topology.	$+\infty$
$maxhops$	The maximum number of hops between a network data and the data sink.	$+\infty$
$maxdatarate$	The maximum throughput supported by the network technology.	$+\infty$
$minredundancy$	The minimum path redundancy of the topology.	1

TABLE II
PROPERTIES DETERMINED IN STEP 1.

Key	Description
$maxdistance$	The largest geometrical distances between two measurement points in G_0.
$diameter$	The longest path between two nodes in G.
$pmaxdegree$	The biggest degree of a node in G.
$components$	The number of components in G.
$nodescount$	The number of vertices in G.

requirements are added to R. Then the process restarts at the geometric analysis.

C. Subcomponent Topology Generation

In this subcomponent two tasks have to be processed. The network nodes are placed and a topology suggestion for the network is created. The topology suggestion is stored as a Directed Acyclic Graph(DAG) $G_T = (V_T, A_T)$. Each vertex $v \in V_T$ represent a network node. Each directed edge $d \in A_T$ describes a suggested network link. The data flows from source to target of each edge. The root node of G_T is the data sink.

The rules how a topology suggestion is derived from a network specification are implemented in several Topology Creators. The Topology Creators are registered at process chain a priori. The Topology Creator is selected according to the requirements in M and the properties of G. For this purpose each topology creator stores a set of constraints for requirements and properties. Only under the given constraints the topology creator can create a topology suggestion.

A prolog engine is used to identify topology generators unable to fulfill given reguirements. Constraints, properties, and requirements are loaded as predicates to the prolog engine. From the set of topology generators fulfilling requirements one is randomly choosen and executed. The result is sent to requirements verification component. If no topology generator is able to fulfill the requirements, the expert system terminates and return an empty result to the planning tool. The behaviour described above is given in Algorithm 1.

In the parargaphs folloqing two Topology Generators are introduced in detail.

a) Single-Hop Star Topology Creator: This generator implements the most simple way to create a topology suggestion. On each measurement point a network nodes is placed and all nodes are connected directly to the sink. This algorithm works only if each node is within range of the sink.

The constraints of the Single-Hop Star Topology Generator are given in Figure 3. Lines 1 to 3 define constants. First parameter gives the name , second parameter gives the value, and third parameter gives the unit of the constant. Lines 4 to 7 define the constraints. First parameter of a constraint gives the name of the generator. The other parameters of each constraint define an equation between requirements, properties and constants. In Line 4 a constraint limiting reachable redundancy is given. A star topology does not provide any redundancy which implies a maximum value of 1 for the requirement $redundancy$. Due to, the generator does not place any repeating nodes and generates a Single-Hop topology, line 5 declares that G_1 must consists of only one component. Line 6 gives an essential but not sufficient constraint over the diameter of G. The diameter of a star is 2. Due to, the diameter of G must be less or equal to 2. However, the constraint does no check for the sink as the central node. From all measurement points data should be sent to the sink. As follows, the sink node will have a degree equal to the number of measurement points. Line 7 ensures that the requirement $rmaxdegree$ allows such a topology.

b) Multi-Hop Tree Topology: This generator gets a minimum spanning tree from G_1 as topology suggestion. As described for the previous generator the nodes are placed at the positions of the measurement points. The constraints are given in Figure 4. This definitions differs in two points. There is no constraint on $rmaxdegree$. The generator has to check for degree of each in node in the spanning tree itself. If no valid spanning tree can be found the generator has to return an empty result. Even, there is no constraint on $diameter$. The existence of a spanning tree in a graph can not be derived from equation with the diameter of that graph.

c) Topology Generator Selection: The Prolog source to find topology generators, which can not fulfill the given requirements, is shown in Figure 5. Determining the suitability of a generator needs a proof of all constraints. Showing the inadequacy needs one failed proof of constraint, only. Thats why $choose(T)$ checks for violations and has all unusable topology generators as its result. Each valid value for T in the formular $choose(T)$ gives an topology generator which cannot be used with given requirements.

```

Fig. 6. GUI of the expert system.

III. Proof-Of-Concept

At first this section gives an overview on the implementation of the expert system. Secondly, the result of processing a application specification is presented.

A. Implementation

The expert system has been implemented as a web application based on Java Server Pages running on an apache-tomcat server. The user interface is shown in Figure 6. The left side of the window contains a list with uploaded application specifications are or being processed. When a request get the state "PROCESSED" the data for the planning tool can be downnloaded using the link in the last row. The right side of the window contains the upload dialog. Here data from the planning tool is imported to the expert system.

The process described in the previous subsection has been implemented as part of Network-Analyzer in project Sens4u. The data is stored in GEXF[2] format. Requirements are stored in RuleML[3], which is inserted in GEXF file.

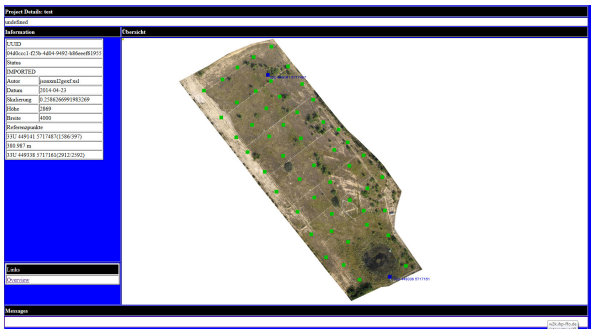

Fig. 7. GUI of the expert system.

B. Example

In context of the project a wireless sensor network is planned at the artificial catchment Hühnerwasser[1]. The application specification received from the planning tool and imported to the expert system is given in Figure 7.

In figure 8 the topology suggestion produced by the Sens4U toolchain is shown. There are still no requirements defined for the application, the topology is a star.

[1]http://www.tu-cottbus.de/projekte/en/oekosysteme/startseite.html

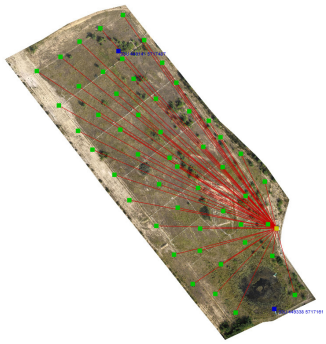

Fig. 8. A generated star topology for Hühnerwasser WSN application.

IV. Related Work

In [4] the software environment POWER for planning and deploying wireless sensor networks is introduced. POWER implements an iterative process. Firstly, nodes are placed in a virtual environment. Secondly, the network in virtual environment is simualeted and evaluated. If an optimal solution is found the process terminates at this point. If not, the network in the virtual environment is optimized in the third step and the process starts again. Unlike the Sens4U toolchain POWER do not enable non-WSN-experts to specify its WSN application.

The framework FLEXOR[5] defines a software architecture for wireless sensor nodes and development environment with tools dealing with WSN applications based on the FLEXOR software architecture. Like Sens4U it addresses non-WSN-experts as users of WSN applications. However, while the expert system decides about hardware and software components to use, FLEXOR supports software modules only. Furthermore, the FLEXOR-toolchain does not support topology design.

Algorithm 1 Selection of a topology generator

Require: TC is the set of all registered topology generators.
Reset Prolog Engine
Load R to Prolog Engine
for each $tc \in TC$ **do**
  Load constants of tc to Prolog Engine
  Load constraints of tc to Prolog Engine
end for
$TC_0 \leftarrow$ Query Prolog Engine
$TC_1 \leftarrow TC \setminus TC_0$
if $TC_1 = \emptyset$ **then**
  return $\emptyset$
else
  $G_T \leftarrow \emptyset$
  while $G_T \neq \emptyset$ **do**
    $tc_0 \leftarrow$ first element in TC_1
    $TC_1 \leftarrow TC_1 \setminus \{tc_0\}$
    $G_T \leftarrow$ Call tc_0
  end while
end if

[6] defines a design flow and an user model for a component-based and composition-driven design process. The goal is also let non-WSN-experts specify and develop WSN applications.

GENSEN[7] is a topology generator for realiastic WSN deployments for the network simulator NS2[8]. Input data are not an application specification, but three parameters for node distribution. The parameters specify the distribution strategy, the number of different atenna orientations, and the number of different energy levels. GENSEN is an example for a family of topology generators for simulations.

V. Conclusion and Future Work

This paper presents a solution for the difficult technical problem of topology selection that occurs in each WSN application. The approach itself and its integration into the Sens4U-toolchain are described in detail. An implementation is introduced as Proof-Of-Concept and an example calculation is given.

Several issues are still open. Sensor node placement can be prohibited by restricted zones or can become expensive by problem areas. Likewise, disturbance zones can exist where wireless communication is impossible. For these cases more sophisticated strategies for node placement have to be developed. Complex measurement tasks can be distributed in more than one node. Furthermore, generators for more effective and reliable topologies must be implemented to fulfill survivability resiliance requirements.

***Abstract*—This study aims to find the relationship between energy consumption level and object tracking success in an object tracking sensor network (OTSN). Convenient use of energy proposes a great challenge for wireless sensor network (WSN) design and the balance between successful object tracking and low energy consumption is a tight one. To address this issue, we propose a new network operation scheme for object tracking, implement this scheme in Network Simulator 2 (ns-2) and present the obtained results of the conducted simulation experiments. The simulation results show that the proposed method can be used to track objects in a WSN network in an energy conservative manner.**

I. Introduction

WIRELESS Sensor Networks (WSN) are mainly composed of a large number of sensor nodes as a network structure whose nodes are limited in terms of memory, processor and power resources. Nodes that are distributed in the environment can communicate unrestrained in short distances and adapt to its environment. By communicating with each other, they compose a variable topology layout and take form of a network themselves [1].

A sensor network provides a set of high level information processing tasks such as event detection, environmental monitoring, object tracking, or classification [2]. Sensor networks today have numerous application areas including health, military, home and various commercial applications [1]. Object tracking in WSNs have become one of the killer applications in this aspect. Although achieving object tracking using WSNs may be relatively hard depending on the object's speed, size, sensors' quality, and also the environmental conditions, it may become widespread with the right technology and methodologies in place. As a top view of the general solution to object tracking problem, a group of sensor nodes can be utilized to sense the environment for an object's location and track it along its journey in a predefined area. Meanwhile, knowing that the most critical constraint of a WSN is its lifetime, we see any study devoted to increasing it as well worth the effort.

During object tracking, a key factor is minimising energy consumption while making sure that the object is monitored. A number of metrics can be monitored to determine the energy consumption such as average number of active sensors during network operation and average length of operation per sensor node. These two provide a good performance assessment in determining energy efficiency of a WSN. There are also some other important metrics that help us determine whether an object tracking application is successful. We need to make sure the time period between the moment an object enters a monitored area and the moment it is detected by the network is kept at a minimal. Another metric is the precision of the object tracking data. This can mainly depend on the following two factors: the localization method in use and the schema used within the network for the tracking the object.

A WSN is quite an ad-hoc type of network which is built for a specific aim. The network should be designed and built with this aim in mind, in our case object tracking, the protocols and methods utilized should be in line with this aim.

WSNs vary in the way they are designed, the equipment used and ultimate goal of operation. Moreover, the way they are deployed to the area, routing protocol used or prediction algorithm used may make the difference between success and failure in object tracking scenarios. Each of these variables can affect the performance of the particular network application in question.

Some researchers [3]–[6] chose to tackle the problem of energy efficiency in object tracking in WSNs from a prediction based point of view. They based their hypothesis upon the fact that if we can predict the object's location for a given period of time, this enables us to activate only the minimal set of sensors thereby minimising energy consumption of each node.

To accomplish effective object tracking, different points of views have emerged such as using a tree-based formation [7], [8] a cluster-based formation [9] or a prediction-based method [3]–[6]. The advantage of tree based methods is in their network coverage rate and minimization of energy consumption under ideal situations. The cluster based methods aim to balance energy consumption among clusters and clusters can be formed dynamically in order to track objects. While the prediction based methods can be used to achieve successful object tracking, it calls for high rates of prediction accuracy and precision to limit energy consumption during an object tracking operation. The prediction based mechanisms can also be added onto cluster-based formations to propose a mixed or multi-phase approach for object tracking. Besides, some heuristics about predictions may also be considered to preserve energy. A short literature review on tree-based, cluster-based and

978-83-60810-58-3/$25.00

prediction-based approaches to object tracking in WSNs can be obtained from [10].

The rest of the paper is organized as follows: In Section II, Literature Review, we discuss some of the protocols and methodologies invented for object tracking in WSNs. In Section III, Factors Affecting Object Tracking Success, the main performance metrics to evaluate the object tracking scenarios in WSNs are explained. Section IV, Proposed Network Model and Operation, clarifies the whole operation process of the sensor network in our approach to track the corresponding object within the predefined environmental boundaries. Section V, Simulation, details the simulation environment considered in our object tracking scenario. Section VI, Experiment Results, gives the results and evaluations of the experiments conducted for different network topologies. Finally, Section VII, Conclusion and Future Work, concludes the paper.

II. Literature Review

This section mainly presents a literature review in target, object, or location tracking in WSN. Some background on the use of energy in an efficient manner in general WSN applications is reviewed as well.

In the Leach protocol [9], the cluster head (CH) in each cluster serves as the main node for data processing and transmission. This results in quick energy drain for the cluster head. To overcome this problem, they proposed randomized rotation of the cluster head role amongst the nodes of a cluster where each node takes on the cluster head role based on a threshold value determined by a probabilistic function. This threshold value T(n) is basically given by the following [9, 11, 12] :

$$T(n) = \frac{P}{1 - P * \left(r \bmod \frac{1}{P} \right)} \quad \forall n \in G$$
$$T(n) = 0 \quad \forall n \notin G \tag{1}$$

where n is node number for which the threshold value is to be computed, r is the current round, P is the percentage of cluster heads and G is the set of nodes that have been cluster heads in the last 1/P rounds. The operation of the Leach protocol is divided by rounds. Each round starts with a set-up phase where the clusters are organised, followed by a steady phase where the collected data is sent from the clusters to the base station. Based on the probabilistic threshold value computed by each node in distributed sensor network area, the use of energy in each cluster head node gets balanced and the network lifetime gets increased by making the nodes survive longer with probabilistic energy conservation.

Two clustering approaches for object tracking are given in [8] and [13]. In [8], a tree-structured cluster is created following the entry of an object in the monitored area. An explicit leader election mechanism is used that selects the sensor closest to the object as the CH. Afterwards, a minimum cost tree is created that includes all the sensors within a predefined range. The tree is set to be reconfigured when distance between target and CH exceeds a pre-set value. In [13], in contrast to using dynamic clusters, the use of static clusters is proposed, where each cluster is activated based on detection of a target. The currently elected CH uses linear prediction to determine whether to keep on tracking or to switch the tracking task to another CH.

There are some protocols that take into account quality of data for nodes which aim to reduce the amount of data being transferred in energy efficient target tracking scenarios in WSN [14]. The redundant data, which is the one collected by closely stationed nodes need only be transferred once to the cluster head. For this purpose two algorithms were proposed in [14]: Reduced Area Reporting (RARE-Area) and Reduction of Active Node Redundancy (RARE-Node). The first one limits the number of nodes taking part in object tracking by monitoring the data quality. Sensor data is assigned with a weight and the nodes that have a weight above the threshold value can participate in tracking. The second one aims to reduce the amount of redundant data by means of identifying spatial relationships between neighbouring nodes.

In Dual Prediction-based Reporting [3], both the sensor nodes and the base station make predictions about object movement to track the object. When the base station makes an error in its prediction, it is corrected by the readings of the sensor nodes.

In the Prediction-based Energy Saving scheme (PES) [4], firstly object movement is predicted to determine the suitable nodes called target nodes. After this, the selected nodes are awakened based on energy and performance metrics. Finally, a recovery mechanism is carried out if the object is missing. This recovery mechanism depends on two modes, namely ALL_NBR [4] which wakes up all the nodes surrounding the estimated route of the moving object and if this one fails, flooding recovery that wakes up all the nodes in the network in a more aggresive fashion is used.

In [10], the authors propose a distributed tracking algorithm which is run at each node of the network. This protocol distinguishes between inner nodes and the border nodes and keeps the border nodes at active state the whole time. They also propose a three level recovery system based on the positions of the nodes in the monitored area.

Another prediction-based energy-efficient target tracking protocol (PET) was proposed in [5] to derive the travelling path of the target and utilize the target's moving patterns for energy saving. Cooperation amongst sensor nodes is the key characteristic for this protocol. A linear predictor is used to predict the target's next location. As not all sensors may have useful information, sensor nodes with the best data possible are selected in order to conserve energy.

In [15] and [16], the prediction is based on the object's movement direction. In [4] and [17], the first node which senses the object wakes its one hop neighbours at first, if the object cannot be located then some more-hop neighbours are awaken, if this also fails, all the nodes are awaken at the worst case. An alternative way to choose the appropriate

nodes to wake is selecting the nodes that have more energy for the recovery process [18].

Another study [6] proposes a prediction algorithm that is divided in clustering and prediction stages. They keep all nodes inactive except the selected CH nodes and when one of CH nodes senses an object, it becomes active and activates three more nodes using the tracker node selection algorithm. The activated nodes carry out the tracking until the current CH node selects the nearest CH node as new current CH node to carry out tracking.

Reference [19] proposes an energy efficient technique to predict the future movements of a mobile object using its inherited behavioural movement data patterns stored. The proposed prediction based tracking technique using sequential pattern (PTSP) offers object tracking with the efforts of a minimum number of sensor nodes in the network; meanwhile the rest of the nodes sleep to preserve the total energy.

Another target tracking approach based on a hybrid predictive model is proposed in [20] to be used in grid wireless sensor networks intrinsically. The proposed model divides the surveillance area into grids and applies a hybrid approach combining the Markov chain and the Grey Theory to predict the target path probabilistically.

A performance comparison between different kinds of tracking algorithms for tracking an object with relatively fast speed in wireless sensor networks is given in [21]. The use of cluster based versus spanning tree based target tracking algortihms are compared mainly. The corresponding cluster-based tracking algorithms involved in the comparisons use etiher a static network where the clusters are formed at deployment time, or a dynamic network where the clusters and the backbones are constructed dynamically in case of an event. Reference [21] also compares the results of adding different filtering techniques, i.e., linear, extended Kalman, and particle filters, into a proposed dynamic lookahead tree based tracking algorithm. The corresponding spanning tree based tracking algorithm is used for degrading the target miss ratio; moreover the filters are used to raise the prediction accuracy.

Another up-to-date proposal for a fast and energy efficient target tracking model based on location prediction is presented in [22]. It is pointed that the proposed method leads to a good accuracy with low energy consumption and it has low missing rates compared to linear and extended Kalman filter predictors.

III. Factors Affecting Object Tracking Success

With the knowledge of the approaches and mechanisms presented in Section II, this section explains the factors and the main performance metrics to evaluate the object tracking scenarios in WSNs.

The monitoring scheme deployed in a WSN setup is equally important regarding energy consumption and object tracking success rate. The sensors can be set to monitor their surroundings in scheduled monitoring mode, where all the sensor nodes are well synchronised to the base station. A dynamic clustering monitoring may be employed where sensor nodes are organised into cluster of nodes reporting to a common cluster head. A prediction based monitoring may be employed which uses a wake-up mechanism to activate specific sensors specified to be within sensing range of the object. This requires a recovery mechanism that is activated in case the object is missed. A prediction based monitoring can only be successful given the internal object location prediction algorithm is producing reliable results, otherwise the sensors will be depleted due to having to carry out a large number of recovery operations. Moreover, the object's trajectory can become the main factor affecting network lifetime, assuming an object can follow similar paths each time it enters the monitored area. There are some main factors effecting object tracking success which are explained in the following subsections.

A. Energy Consumption Efficiency

Energy consumption is directly related to how the network is designed and how it operates. Every communication made between each node in the network incurs a cost in terms of energy to nodes in the network thus should be minimised. The efficiency of the prediction algorithm as well as the mechanism used for the task of object tracking can be taken as base points to measure the energy efficiency of a sensor network.

B. Accuracy of Target Tracking

In order to keep a low probability of missing the object and for an effective target tracking application a good degree of target tracking accuracy should be achieved. This measure is also directly related to the infrastructural mechanisms used for tracking the object, i.e., using prediction based, cluster based or tree based approaches.

C. Scalability

Some applications may require huge numbers of sensor nodes. This can present different challenges compared to networks with smaller number of nodes. Scalability is about how well the network copes with high numbers of nodes. This study made use of a fixed number of nodes, which is relatively small to take into account scalability issues of the network.

D. Interconnectivity

Nodes in a sensor network need to be interconnected for the network to function properly. If there are nodes which have no route to forward packets to the access point, data collected by them will be of no use. Maximum connectivity should be achieved in the deployment stage and it should be preserved as much as possible through energy savings and congestion control.

E. Network Lifetime

Each node in a wireless sensor network is powered by a battery. This means when most of the nodes deplete their batteries the network will not be functional. Therefore it is crucial that nodes make the best use of their batteries by turning off (sleep mode) their microcontroller and transceiver when these are not needed.

IV. Proposed Network Model And Operation

WSNs typically consist of a large number of sensor nodes dispersed in a large field. This study involves simulations made using nodes distributed in 50 x 50 m^2 and 100 x 100 m^2 fields populated with a fixed number of nodes. Comparisons between two deployment methods: grid and random were made. None of the nodes are mobile and each node in the network is set to be equal in terms of initial charge level, computation capability and communication range, namely the network only involves homogeneous sensor nodes. The sensor nodes used in the simulations have identical features to Mica2 [23] motes in terms of energy usage in active and sleep modes. Sensor nodes don't require the use of a GPS device and network lifetime diminishes when any node runs out of energy. Due to the way the ns-2 simulation is configured (area of the simulation is set in the ".tcl" scenario file) the object stays inside the boundaries of the monitored area for the duration of the simulation.

A network built for the purpose of object tracking has basically two subsets of tasks to accomplish, namely monitoring the area and reporting of the object's location to the sink node. If considered on the node level, each node is tasked to listen to its environment and report about object movement when necessary. In the most energy draining scenario, all the nodes have to be listening all the time for potential object movements. If we employ a node wise and network wise mechanism where all the nodes perform in a specific way, we can limit the time necessary to have a node in listening state. According to this specification the network can be in one of the three states: not tracking, tracking or recovering. The recovery mode works by first waking up the neighbouring nodes of the latest active nodes and goes on to wake up all the nodes in the network following a spiral route. This recovery mechanism is similar to [4] but not necessarily the same. The border nodes are the ones that are active continuously in order to make sure there is no object to track in the monitored area.

In order to track an object in the network the first requirement is to sense it and to sense the object at least some sensor nodes should be awake, for instance border nodes or randomly selected nodes. If all nodes are awake the whole time, the network lifetime shortens. If some of the nodes are sleeping in some conditions to save their power, the object could be lost again after having been found. In this situation, a recovery phase is initiated that aims to relocate the object however this leads to extra energy consumption. To achieve energy conservation and minimise object missing rate, some nodes can be awaken before the object enters their sensing territories and some nodes can be put into sleep mode after the object leaves their boundaries'. This mechanism can be triggered as follows: the active node that is sensing the object activates some other sleeping nodes. To select the appropriate nodes to put to sleep or activate requires a good prediction about the object and achieving the best possible prediction estimation means more energy can be conserved.

The nodes that have the possibility to locate the object are first predicted on the sink node. The sink node awakens a sensor node according to the initial prediction results. This is similar to the Wang's model [18], however in their model, when the predicted nodes fail to sense the object, neighborhood nodes are awakened according to the results of the genetic algorithm they use and are awakened on a one by one basis, while we take an approach in which they are awakened based on one of the three approaches we implemented.

A. Prediction Model

Our prediction algorithm is executed at the sink node, based upon the information received from tracking nodes. All the nodes depend on the sink node to determine which state they are in.

The prediction algorithm uses the well-known formula to compute velocity, which is:

$$v = \frac{\sqrt{\left(x_i - x_{i-1}\right)^2 + \left(y_i - y_{i-1}\right)^2}}{t_i - t_{i-1}} \tag{2}$$

We use a linear prediction method as our prediction mechanism that we coded inside the ns-2 code framework. According to the prediction algorithm results, a new set of sensor nodes are given the wake-up signal.

B. Tracking Model

When a border node detects an object in its sensing range, it initially awakens neighbour nodes so that they can carry out localization. The result of this localization is sent to the base station, which in turn uses this data to predict the location of the object. Once the newly activated nodes start sensing the object, they send it to the base station and the base station concludes that the prediction was correct and puts the previous group of nodes into sleep state. A new prediction is made in the same manner, and this loop continues until the object is lost.

The proposed tracking mechanism is based on measuring received signal strength (RSS) at the tracking nodes. RSS which is known to decrease exponentially based upon distance to the tracked object is calculated by [24]:

$$r_i = a.\| x - x_i \|^{-\alpha} + n_i \tag{3}$$

where r_i is the value of the RSS in the i^{th} sensor node, a is the strength of the signal emitted from the target, x refers to the real (yet to be found) coordinates of the target, x_i is the known coordinates of the i^{th} sensor, α is the attenuation coefficient and lastly n_i denotes the white Gaussian noise with zero-mean and variance σ^2.

C. Recovery Model

When the object is lost, the recovery mechanism is triggered which activates all the nodes starting from the neighbour nodes of the last active nodes, after activating all the nodes, if still there is no object detected, the base station concludes the object had left the area, and takes all the nodes except the border nodes back to sleep mode.

There is a second mode of operation of the proposed system which is power saving mode. In this mode, the network acts in a way to further limit the energy consumption by increasing node deactivation frequency and decreasing number of nodes involved in the recovery process at the cost of less accurate tracking. Our simulations focused on finding the trade-off between energy conservation and accuracy of target tracking along with how the two perform for objects travelling at high and low speeds. Those two alternative modes are referred to as "Powersaving" and "Non Powersaving" while we present the measurements of our simulations via graphical results in Section VI.

The recovery mechanism we propose is analogous to the proposed model [4], in which they try to cover misprediction of object's speed and movement in their recovery phase. They propose three models: Heuristic DESTINATION, Heuristic ROUTE and Heuristic ALL NBR. Each of these has different energy efficiencies. The first one assumes the speed and direction of the object is predicted correctly and wakes up one node on the predicted path. The second one assumes the speed of the object is mispredicted and the current node informs nodes on the predicted path. It assumes the direction is correctly predicted. The third one assumes both the speed and the direction of the object are mispredicted and the current node informs the neighboring nodes that surround the route. The sink node, wakes up a node (current node) based on the prediction result, and when this node loses track of the object, it first informs a neighbour node and based on the result it gets from the other node, it either informs the sink node or doesn't. If it informs the sink node, this shows that this node also failed to sense the object, if it doesn't inform, it means the node sensed the object and there was no need for further recovery. The node that sensed the object now becomes the current node.

The difference of our model compared to the energy conservative approach proposed in [4] is that the prediction is done on the sink node and the sink node determines the current node except in situations where the object is lost temporarily and found (neighbour node becomes the current node) or when a node detects a new object by chance in the area. In addition to this, we adapt a more aggressive approach for recovery where we begin to wake up all the nodes as well the ones on the predicted path.

The difference we propose compared to the recovery mechanism of [4] is that, we define a spiral route that begins from the closest neighbour of the last current node (nearest place where the object was lost) that continues to wake up all the nodes in the network until the object is found. We aim to minimise the time it takes to wake up all the nodes in this manner and put them to sleep if the object had already left the area. We also aim to make transitions between these states (prediction, tracking, recovery) as fast as possible in order to make sure the object is tracked for the time it is inside the network and also to increase energy efficieny.

V. SIMULATION

The IEEE 802.15.4 [25] medium access control (MAC) protocol is used for our scenario implementation on ns-2.34 [26]. Different from the IEEE 802.11 [27] protocol which is used for WLAN networks, IEEE 802.15.4 protocol is a low tier, ad hoc, terrestrial, wireless standard for wireless networks and other ad hoc networks such as WSNs. The main simulation parameters used in our different scenarios are given in Table I below.

TABLE I.
SIMULATION PARAMETERS

Description	**Value**
Simulation Environment	ns-2.34
PHY-MAC Layer	IEEE 802.15.4
Field Size	50 m x 50 m, 100 m x 100 m
Tracking Node Number	21
Sink Node Number	1
Sensor Node Deployment	Uniformly Distributed, Randomly Distributed
Energy Consumption (Active Mode)	8 mA
Energy Consumption (Sleep Mode)	< 15 uA
Communication Range	40 m
Sensing Range	~15 m
Velocity of Target	5 m/s - 16 m/s
Duration of Simulations	200 s
Number of Trials	5
Number of Tracked Target	1

A sensor network consisting of 21 tracking nodes uniformly distributed in a field of 50 x 50 m^2 and a sink node at the lower left-hand side is considered. All the sensor nodes are homogeneous and immobile. The topological deployment of the nodes can be seen below in Fig. 1. The tracked object is denoted by a full circle and the sink node is

TABLE II.
STATE TRANSITION TABLE OF THE FSM

	Time_Out	Wake_Up	RSS> Threshold	RSS < Threshold	On_Predicted _Path	Object_Found	Object_Lost	Object_ Left_ Area
SLEEP	-	SENSE	-	-	-	-	-	-
SENSE	SLEEP	-	DETECTED	-	-	-	-	-
DETECTED	-	-	DETECTED	WAIT_MESSAGE	-	-	-	-
WAIT_ MESSAGE	-	-	-	-	SENSE	-	RECOVERY	-
RECOVERY	-	-	DETECTED	-	-	SLEEP	-	SLEEP

designated as a pentagon to differentiate it from the ordinary tracking sensor nodes. Sink node, in our proposal, is responsible for running the prediction algorithm and activating the sensor nodes according to the prediction results.

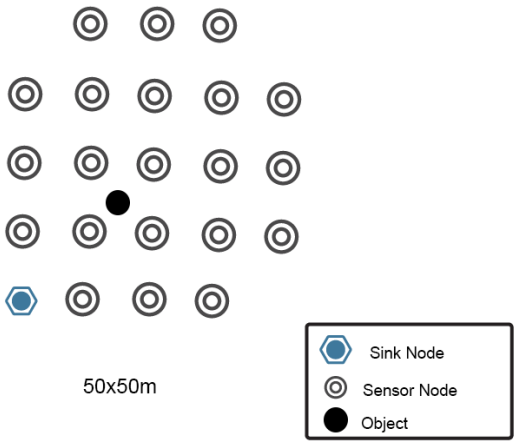

Fig. 1 Main Network Topology

In preparation of the simulation, modifications to the ns-2 code base and implementations of additional functions were defined. An application layer based on the proposed scenario was implemented on top of ns-2.34's IEEE 802.15.4 MAC layer. For transport layer, we modified the message agent which sends packets in similar way to UDP. The most important function is the process message which processes incoming messages and changes the states of nodes. We completely rewrote the message processing functions along with all the functions on the application layer.

Each node is simulated as having five different states during network operation. It is drawn as a finite state machine (FSM) and coded inside the ns-2 code base along with the prediction algorithm. The finite state machine is depicted in Fig. 2, a corresponding state transition table is provided in Table II and detailed descriptions of each state and message used are given below.

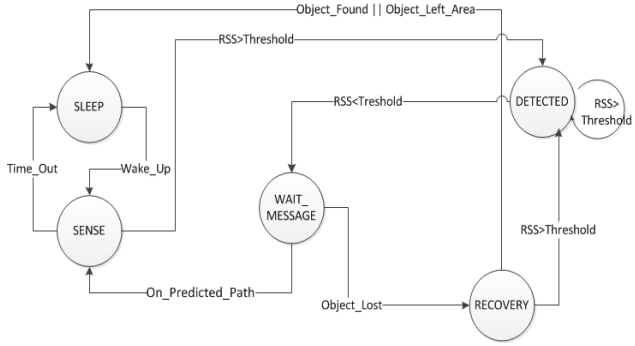

Fig. 2 Finite State Machine

1) States:

SLEEP: In this state, sensor node does not receive or send any messages and keeps energy efficiency at maximum. In order to receive messages from the network, sensor nodes change state to SENSE periodically.

SENSE: In sense state, a sensor node can send and receive messages and periodically changes its state to SLEEP. The sensor nodes selected by the prediction algorithm are in this state and they are expected to have the object in close proximity. If a sensor node senses an object in this state, it changes its state to DETECTED.

DETECTED: Sensor nodes stay in this state as long as their RSS value is greater than the threshold value. If a sensor node cannot sense the object anymore then it changes its state to wait message.

WAIT_MESSAGE: In this state, sensor nodes wait for the sense message of the next node on the predicted path. If it receives On_Predicted_Path message then it changes its state to SENSE and if it receives Object_Lost message it changes to RECOVERY.

RECOVERY: In recovery state, unless Object_Found or Object_Left_Area messages aren't received from the sink node, sensor node stays in this state. If RSS value is greater than threshold value then it changes its state to DETECTED and sends data about object's position.

2) Messages:

Time_Out: When the predefined timeout value in a node runs out the node is given the timeout signal.

Wake_Up: Sink node sends this message to nodes in the predicted path.

On_Predicted_Path: This message is for nodes that no longer sense the object but may still be on the predicted path and be required to continue to sense.

RSS>Threshold: When the RSS value of a node is above the threshold value it means it can start tracking the object.

RSS<Threshold: When the RSS value of a node is below the threshold value it means it no longer tracks the object.

Object_Lost: This message is sent to specified nodes depending on the stage of the recovery mode to inform that recovery mode is initiated.

Object_Found: This message is sent in recovery mode to searching nodes which were unsuccessful in sensing the object.

Object_Left_Area: This message is sent to all sensor nodes if the recovery mode fails to recover the object in a specified time.

VI. Experiment Results

Different scenarios were setup and each one involved objects with two different speeds: 5 m/s and 16 m/s. The first one stands for low speed objects and the latter stands for high speed objects respectively. The main purpose was to compute average energy loss and average recovery time after measuring their absolute values by running each simulation scenario for 5 times. The experiments were also conducted with medium speeds, i.e., 8 m/s and 12 m/s.

At the end of each simulation, data on total energy spent and time lengths of recovery for each object were obtained. The data gathered from the simulation was analysed and put on graphs for better visualization. The object moves following linear paths and bounces off at area boundaries. For localization, trilateration [28] is used to determine target

position along with RSS value to measure distance to the target.

Simulations were mostly conducted on one (main) topology and later on the simulation was extended to include three more different topologies. The decision to extend the simulation emerged from the need to compare obtained results with results from a different deployment model (random). The main topology used is given in Fig. 1. This first topology (referred to as Topology1) includes nodes that are uniformly distributed in the area.

In the second topology (Topology2), the field was increased to an area of 100 x 100 m^2, increasing the length between nodes but keeping the same formation as the first topology. The third topology (Topology3) covers randomly distributed nodes in a 50 x 50 m^2 field. The last topology (Topology4) involves nodes randomly distributed in a field of 100 x 100 m^2.

By conducting various simulation experiments, the aim was to measure the success of our approach and to compare the results for low speed and high speed objects. In addition, two modes of operation have been taken into consideration, namely powersaving and non powersaving modes for the operation of the network. Each node in the network has the same starting energy of 20 Joules at the beginning of any simulation. The average remaining energy per node, average recovery delay, and packet delivery ratio results of simulations conducted on Topology1 are given in Fig. 3, Fig. 4, and Fig. 5.

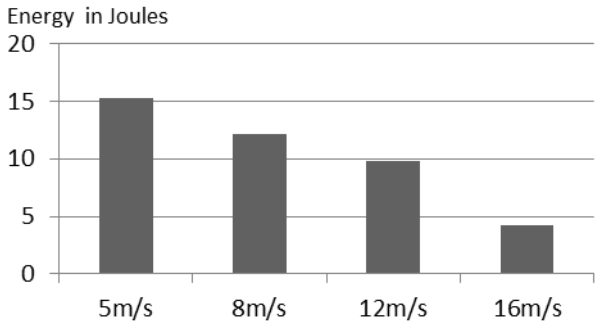

Fig. 3 Average Remaining Energy per Node

In Fig. 3, the displayed energy levels regarding the related speed values of the moving object belong to the average remaining energy per node. The remaining energy value of each node is measured at the end of each simulation and the corresponding average remaining energy value per node is calculated for the whole network. The average values of the calculation results for 5 repeated simulations are given in Fig. 3. The relationship between object speed and the total remaining energy of all the nodes can be seen in Fig. 3, object's speed has a direct relationship to energy consumption levels. This is due to increased object loss rates for objects travelling at high speeds. As the recovery frequency increases, so does the total energy consumption. Taking the results shown in Fig. 3 as an example, for an object travelling at 16 m/s the average remaining energy drops as low as 4.2 Joules, where the energy consumption in the whole network is greater than the other cases for slower speeds.

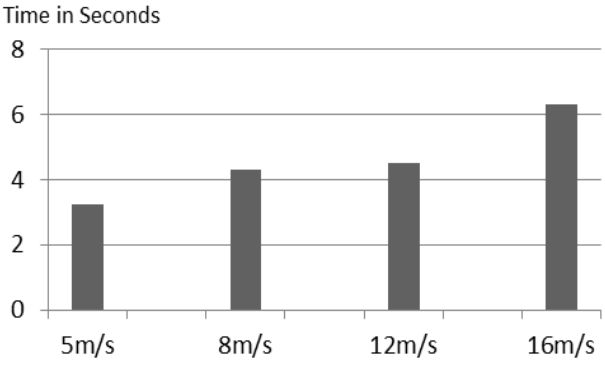

Fig. 4 Average Recovery Time

In Fig. 4, we can see the direct correlation between object speed and average recovery time in seconds. For objects travelling at 5 m/s average recovery time is as low as 3.23 seconds and for objects travelling at 16 m/s the corresponding duration is 6.32 seconds which is significantly higher compared to the former. For objects travelling at 8 m/s and 12 m/s average recovery times of 4.32 and 4.39 seconds are observed respectively.

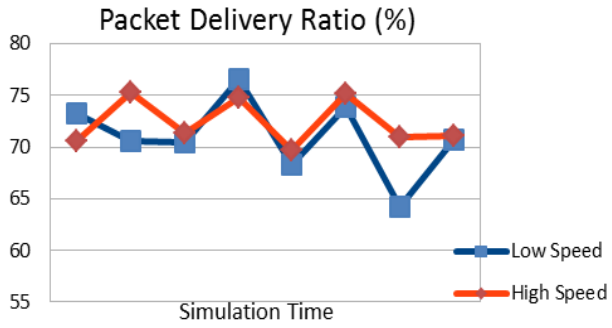

Fig. 5 Ratio of Packets Successfully Delivered

Fig. 5 shows the packet delivery success ratio in the network. Since the prediction in our model is done on the sink node, the tracking object's location data is delivered to the sink when it's detected by any node or group of nodes. Meanwhile, the data may be lost in the network due to the interference and collision of the packets. Besides, IEEE 802.15.4 PHY and MAC layers inherit the packet drops of the wireless media. To us, on average a 72% success ratio for the packet delivery seen in Fig. 5 makes sense regarding the collisions intrinsically available in the wireless channel. We also deduce from Fig. 5 that the oscillation of the packet delivery success during the whole simulation is due to random variation of the number of collided packets at random times.

By adding three other topologies, as mentioned before, we extended our study; Fig. 6 and Fig. 7 show the comparison of results obtained for objects travelling at low speeds and high speeds, respectively. The aforementioned "Powersaving" and "Non Powersaving" terms in Fig. 6 and Fig. 7 refer to the two different running modes of the system explained in Subsection C (Recovery Model) of Section IV.

When running in the non powersaving mode, the system does its best to track and detect the object and uses its all resources to achieve this task. This means the system rigorously awakens all the nodes if necessary regarding the procedures of the recovery algorithm used. On the other hand, if the system is adjusted to run in powersaving mode, the recovery task will be switched into a way to limit the energy consumption at the cost of less accurate tracking. The simulations of which the results are depicted in Fig. 6 and Fig. 7 focus on finding the trade-off between energy conservation and accuracy of target tracking along with how the two perform for objects travelling at high and low speeds.

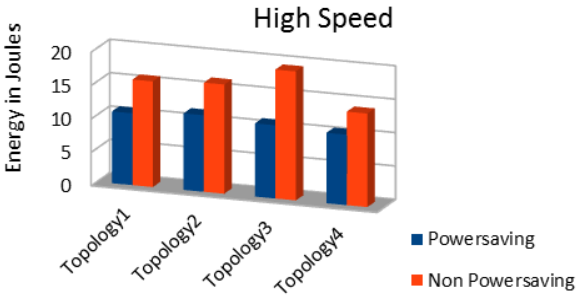

Fig. 6 Average Energy Consumption for High Speed Object

The graph in Fig. 6 shows the amounts of average energy consumed per node with different topological simulation setups for objects travelling at high speeds. Regarding each different topology, energy preservation algorithm makes a considerable difference in terms of energy savings in the network. The disadvantage of powersaving mode compared to non powersaving mode is reduced tracking accuracy. All four topologies have similar energy consumption levels for powersaving mode, whereas for non powersaving mode, energy consumption is more varied across different topological setups. Topology3 has the highest amount of total energy consumption for non powersaving mode.

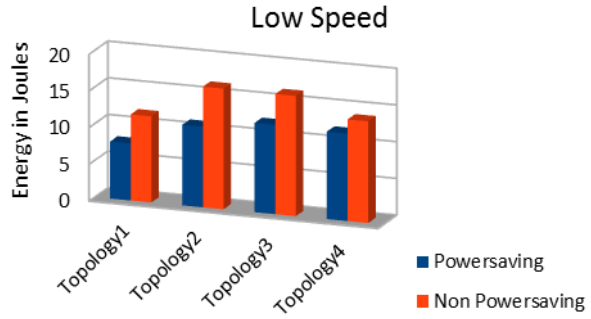

Fig. 7 Average Energy Consumption for Low Speed Object

The top-view of the graph in Fig. 7 seems similar with the one in Fig. 6, except that the exact results are different for the case that the object moves at a low speed. According to Fig. 7, all eight different simulation scenarios (four topologies within two operating modes) show varied energy levels. The minimum energy consumption in total for both running modes is observed in Topology1, whereas the maximum energy consumption is measured in Topology3 among the eight different scenarios.

The disadvantage of powersaving mode is its reduced tracking accuracy due to the adjusted awakening algorithm involved in the recovery model to limit energy consumption. As a result of the trade-off observed between tracking accuracy and energy consumption, the advantage of powersaving mode is significantly less energy consumption. As evident in Fig. 6 and Fig. 7, regarding the energy consumption levels, powersaving mode has a distinctive advantage both for objects travelling at high speeds and low speeds. It can also be inferred from Fig. 6 and Fig. 7 that non powersaving scenarios in which the tracking object moves with high speeds usually consume more energy than the non powersaving scenarios involving a tracking object with low speeds. This is mainly because of the higher number of recovery stages incurred in high speed scenarios. By using powersaving mode in such high speed scenarios, we can limit energy consumption to the levels observed in low speed scenarios.

VII. Conclusion and Future Work

This paper presents a network simulation based study aiming to answer the question of "how can energy efficiency be improved in an OTSN through implementing various scenarios for object tracking". Having presented our initial work at the national conference of Academic Computing in Turkey [29], we extend our work to include the proposed network operation and simulation results. This network setup was simulated in ns-2.34 and associated graphs of obtained results are given.

Different scenarios were considered where target speeds and moving patterns vary. The main focus has been on energy conservation which has been mostly achieved by reducing the average energy consumed by sensor nodes.

As future work, we wish to improve our tracking method to track multiple objects simultaneously. We also think that, a dynamic clustering of nodes before or after the prediction phase may make a difference in terms of improving tracking success and energy efficiency.

Acknowledgment

This project initially started as a senior project at Izmir University of Economics involving six people in total. We would like to thank to Utkan Surgevil, Yetkin Hafizoglu and Nihal Pacaman for their efforts.

***Abstract*—The paper proposes the concept of adaptive message aggregation for telemetry applications that use GPRS connectivity. The method optimizes the power consumed during data transmission, what is useful in the modern telemetry devices powered from renewable energy sources. The concept has been verified in the levee monitoring scenario.**

I. Introduction

THE PURPOSE of telemetry systems is to transparently convey measurement information from a remotely located sensor to receiving equipment for further processing and visualization. Development and miniaturization of electronic devices has allowed for the high penetration of telemetry solutions in the surrounding world in order to increase the quality of life. In typical telemetry solutions, remote stations are powered from external power sources and use industrial communication protocols such as Modbus to gather data from these devices to the central system. The communication to the remote location is achieved by the GPRS network as a low cost and easily accessible communication layer [1]. These protocols provide data by polling, so it requires the remote stations to be available all the time.

Currently, such devices are designed to be powered by energy harvesting thus they must be power efficient and they might temporarily go asleep to preserve power [2], [3]. Because of the differences between these types of devices, the legacy polling protocols might not be effective. We argue that the communication protocols should (1) leverage the power usage characteristic of GPRS technology, (2) handle the sleepy nodes and (3) provide high level addressing of nodes. We think that these requirements might be fulfilled by the message oriented communication. Sending messages across channels decreases the complexity of the end application, thereby allowing the developer of the application to focus on true application functionality instead of the intricate needs of communication protocols. *Message-oriented middleware* (MOM)[4] allows application modules to be distributed over heterogeneous platforms and reduces the complexity of developing applications that span multiple operating systems and network protocols. The middleware creates a distributed communications layer that insulates the application developer from the details of the various operating systems and network interfaces. Message-oriented middleware may provide reliable asynchronous communication mechanisms that might be used to carry i.e. measurement data or other remote communication messages.

In the paper we propose the concept of adaptive message aggregation method for MQTT-SN protocol that optimizes power used by GPRS wireless connection during data transmission. The preliminary research (presented later in the paper) showed that sending data using short IP packets consumes much more energy than using longer packets. Because of the fact that messages containing measurements are relatively small, we propose the concept of adaptive data aggregation prior to sending via GPRS.

The research presented in this paper is a part of ISMOP [5] research project which objectives span construction of an artificial levee, design of wireless sensors for levee instrumentation, development of a sensor communication infrastructure, and a software platform for execution management, data management [6] and decision support [7]. Scientific and industrial consortium in the ISMOP project conducts research on a comprehensive monitoring system enabling evaluation of current and forecasted state of flood levees. This paper focuses on issues related to the organization of data acquired from the sensors located in the levees in order to optimize the power consumed by GPRS modem during data transmission to the central system for later analysis.

The paper is organized as follows. Section II discusses the motivating scenario, where Section III presents the related work. Section IV presents the concept of power-aware adaptive message aggregation, which is then evaluated in the use case

978-83-60810-58-3/$25.00

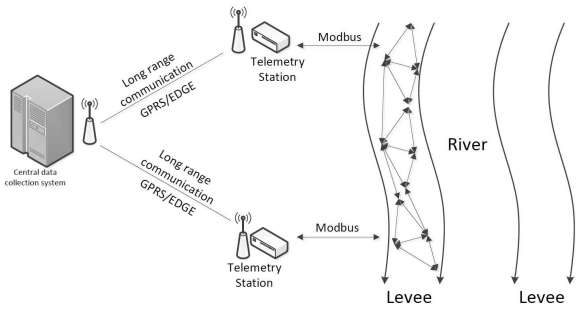

Fig. 1. Telemetry system for flood control levees

in Section V. Finally, the paper is summarized and further research steps are presented.

II. Motivating scenario

Recently, the importance of sensor network for monitoring various areas, objects or devices, has significantly increased. One of the areas in which telemetry and sensor network begin to fulfill a major role is monitoring systems for hydrologic engineering facilities in particular dams and flood levees[8], [9]. The overall concept of hydrological monitoring facilities was the starting point for the assumptions and implementation of the ISMOP research project which will result in guidelines for creating a telemetry system that enables continuous monitoring of levees. Research addresses the collection of massive measurement data in continuous mode, optimized transmission methodology, interpretation and analysis of monitored data with computer simulation and finally providing visualized results for the relevant authorities.

The biggest threat in the context of the levees is their leaking which could lead to their break. A typical application in this area is monitoring system of flood levees containing sensors that measure, among other things, temperature inside the levee. This measurement allows us to detect the rate of change of temperature in the levee. In the case of leakage when the water entering inside of the levee, water is the carrier of heat energy and increases or decreases the temperature in the levee. During the continuous measurement of temperature anomalies can be observed for a specific point in the levee, which deviate from the results of measurements made by the nearby sensors and observed the trend changes. This may indicate the presence of too much water in the levee and thus the danger of burst of the levee. The temperature and other physical values (such as pore pressure) allow to determine the condition of the levees and detect potential risks of leakage. An example scenario of telemetry system containing sensors placed inside the levees and the central data collection system is shown in Figure 1.

The role of the telemetry station is to acquire data from sensor networks which contain information about levee condition and to transmit these data to the central station. The data is generated by the sensor network for an *epoch*, which results in bursts of data each time the epoch changes. Apart from that, telemetry station also sends periodically information about its current condition e.g. battery level, CPU usage and others. The data from sensor networks, due to their importance, should be reliably delivered while the condition information may be transmitted on the best effort basis.

The use of telecommunications networks (including GPRS) for communication from/to telemetry stations is associated with specific energy consumption. It depends mostly on the time during which radio circuits are powered on and on the number of transmitted data. The motivation to our research is to reduce energy consumption during communication using GPRS from/to telemetry station.

III. Related Work

Energy consumption of a wireless transmission device greatly depends on such factors as chosen communication standard, protocols used, and amount of transmitted data. Providing a medium-range or wide-area network connectivity requires a different approach. It is not a demanding task provided that a network infrastructure is available with appropriate SLA (Service Level Agreement) guaranties [10]. However, in remote areas a cellular connection is a common solution for industrial telemetry systems. Typical activities on a smartphone platform (sending a message, making a voice call, transmission over GPRS, etc.) are evaluated in [11]. An in-depth analysis o energy requirements for GPRS and UMTS services is provided in [12] and [13].

High-level protocols over cellular network also have an impact on overall energy requirements of a system [14]. A review of various middleware protocols for telemetry applications can be found in [15]. Message-oriented Middleware (MOM) is widely used as a communication layer for a variety of information systems which require event-driven message and data exchange, and more loose coupling than e.g. remote procedure calls. Examples of commonly utilized technologies for MOM are:

- Java Message Service (JMS) [16],
- Data Distribution Service [17],
- Extensible Messaging and Presence Protocol (XMPP) [18],
- MQ Telemetry Transport (MQTT) and its variation, MQTT-SN [19].

These technologies provide several other functionalities such as transaction management, broker clustering, additional message paradigms including point-to-point, publish/subscribe and request-response. Nevertheless, only MQTT has been designed especially for transferring telemetry-style binary data from the pervasive devices with limited computational resources. It should be noted that utilizing the MQTT protocol over a standard TCP connection may provide redundant message delivery guaranties. As TCP is intended to provide a reliable link and has built-in retransmission mechanisms, setting the MQTT's QoS parameter to 1 or 2 provides another (redundant) layer of persistence. In contrast, those higher levels of QoS seem very useful in MQTT-SN variation which by design uses UDP datagrams. In our research we have chosen MQTT-SN messaging protocol (formerly MQTT-S [20]) because it is promising due to its simplicity. MQTT-SN clients can

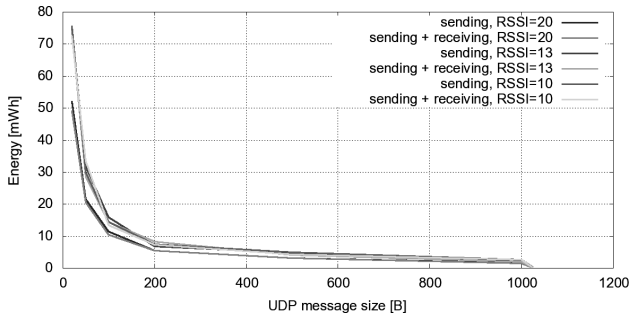

Fig. 2. Power necessary to send 10kB of data using GPRS communication as a function of packet size

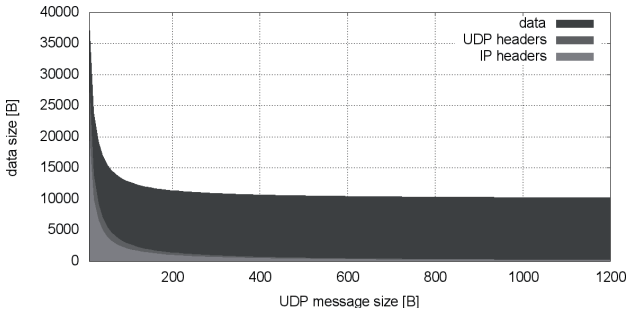

Fig. 3. Overall data necessary to send 10kB of data as a function of packet size

be implemented in resource-constrained hardware (embedded systems), and there are available plenty of its implementations.

However, it is difficult to find any power efficiency considerations for MQTT-SN. By far many solutions dedicated to the MOM technology have been optimized to limit the data transfer and save energy. The MQTT-SN is an example of protocol that was optimized in terms of quantity of data to be transmitted. It results from using short-distance wireless protocols for sensor-based data transmission, including the IEEE 802.15.4 protocol. All these issues, not previously mentioned in MOM solutions, and particularly in the MQTT-SN protocol, have been analyzed in this article and relevant solutions have been suggested.

IV. Adaptive message aggregation

The main goal of the research was to decrease the amount of energy necessary to send the data using MOM over GPRS connectivity. The results of the base research aimed to analyze how much energy is used by GPRS modem as a function of packet data size is depicted in Figure 2.

The nonlinearity in the power consumption is caused by two factors: overhead of the appropriate headers of OSI/ISO stack and purely technical considerations related to the physical communication with the GPRS modem in embedded devices (e.g. the time of data preparation, inter frame gaps and others). Figure 3 shows the overall data size that are necessary to send 10 KB of data payload. The overhead is related to the headers of UDP and IP protocols for each packet. Consequently, from an energy consumption point of view, it is much better for fixed amount of data to send it using as large packet size as possible.

On the other hand, the amount of measurement data that need to be transmitted is usually small i.e. typically 20 B. The previous measurements show that sending such small packets would be inefficient. Based on these data, we propose the concept of data aggregation before transmission.

Our concept, as presented in Figure 4, can be applied to MQTT messages with QoS 0 and 1. In QoS 0, messages are not acknowledged, so client may aggregate several messages before sending them. In the second case, with QoS 1, all the messages had to be acknowledged so, we propose also aggregating the acknowledgment packets on the broker side.

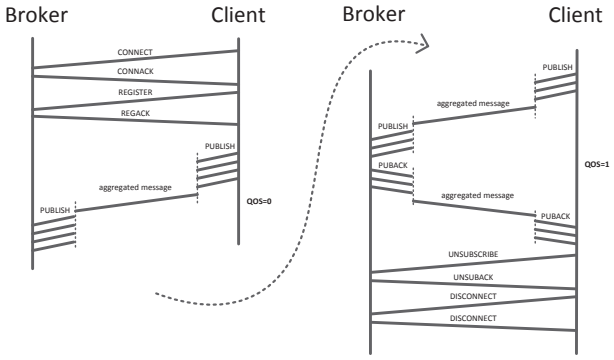

Fig. 4. Message aggregation concept for MQTT-SN

We have assumed that larger, important data to send appear in the bursts, while less important data are sent on regular basis in small chunks. This is dictated by the fact that underlying sensor network (installed in the levee) wakes up in time intervals to preserve power. The naive approach to data aggregation is presented in Figure 5. The main idea is that new messages are not send immediately but first copied to the buffer B with fixed length L and then sent as an aggregated packet. There are two conditions that decide of sending data: buffer is overflowed or buffer timeout T^I has ended. During the *period 1* and *3* aggregated messages are sent because of the timeout condition, while during the *period 2* aggregated message is sent because of the overflow condition. The drawback of the method is that in the *period 3*, the messages that belong to the burst are sent with longer delay then previous ones because overflow condition did not occurred. Such a situation is unwanted if the data has to be analyzed in the real-time.

In our method, we propose adaptive timeout calculation that adjust itself to the frequency of incoming data. The main concept is that buffer overflow situation decreases the buffer timeout meaning that messages should be send faster, while decreasing the frequency of incoming new data recovers the timeout to its previous value. Such a policy results in the situation that messages belonging to the data burst are received by the broker in the burst as well. The concept is depicted in

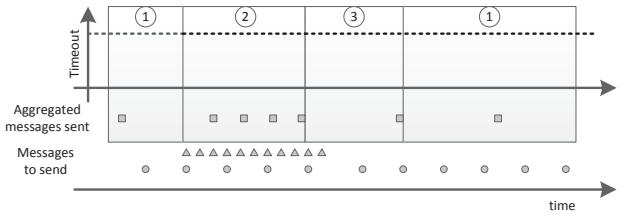

Fig. 5. Naive approach to data aggregation (time periods are marked with numbers, telemetry data are represented by small grey circles, triangles represent bursts of measurement data, packed and transmitted data are depicted as squares)

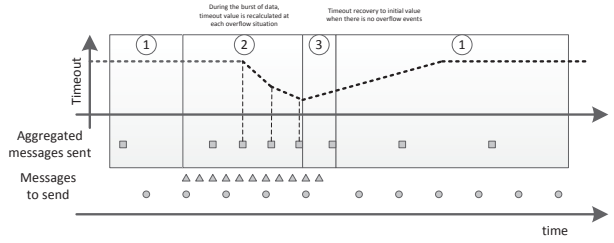

Fig. 6. Adaptive approach to data aggregation (time periods are marked with numbers, telemetry data are represented by small grey circles, triangles represent bursts of measurement data, packed and transmitted data are depicted as squares)

Figure 6. During the *period 3*, the aggregated message is send earlier than in naive approach to the aggregation.

As can be noticed, the presented adaptive message aggregation does not generate any additional overhead. On the contrary, it contributes to reducing the overhead introduced by the OSI/ISO network communication stack when transmitting small chunks of data. Another aspect is the latency of data arrival. It results directly from the fact, that data needs to be packed in a buffer. In our solution, the latency is controlled with the variable timeout value. The timeout automatically decreases as more data arrives. This can be utilized to keep latency and overhead ratio at reasonable levels.

More formally, the algorithm is composed of the two parts and might be presented as follows. The input to the algorithm is provided by four values: T^I is the initial timeout value, T^R is the recovery time to the initial value, the factor α, and a buffer length L. In the MOM client there is global timer T that represents actual timeout value – at time t this value is denoted as T_t. When the aggregated message buffer B of length L is created at time t, it has assigned timeout that equals T_t. Length of the buffers is constant.

First part of the algorithm is responsible for recovering (i.e. increasing) timeout T to the initial value of T^I and is formulated as follow: for each time k, the timeout T_{k+1} is calculated using the equation 1, where ΔT is the time step.

$$T_{k+1} = \min(T_k + \frac{T^I}{T^R}\Delta T, T^I) \tag{1}$$

The second part of the algorithm is responsible for decreasing timeout T to the value that is similar to the time of sending overflowed buffers when data burst is observed. The equation 2 is used only when the overflow of the buffer is observed. Value d in the equation is the time from the last overflow event.

$$T_{k+1} = \min(\alpha T_k + (1-\alpha)d, T^I) \tag{2}$$

Having in mind, that data usually comes from remote telemetry stations to the central point, we propose to use adaptive aggregation method on the client side to aggregate messages, and to use naive aggregation approach on the broker side to aggregate acknowledgments. The evaluation results of the proposed algorithm are presented in the next section.

V. Evaluation

We have evaluated the proposed concept on the scenario similar to the one presented in the previous section. We have assumed that data from levee monitoring sensors are gathered and sent in two stages:

- at the beginning, for QoS 1 in MQTT/MQTT-SN, 1000 PUBLISH messages with a length of 20 B are sent and received confirmation of these messages (PUBACK),
- later, for QoS 0 in MQTT/MQTT-SN, in 12 minutes epoch and for every 30 s PUBLISH messages with a length of 20 B are transmitted.

During tests we used a popular GPRS modem (SIM900D) and, in order to verify the results obtained, we also used an industrial GPRS Modem (Wavecom Fastrack Supreme 20). In order to develop test software we extend implementation of MQTT-SN – Eclipse Mosquitto [21] (which we call *A-MQTT-SN*) to support adaptation.

Above presented testing scenario was carried out for three cases using:

- MQTT protocol (Eclipse Mosquitto),
- MQTT-SN protocol (Eclipse Mosquitto),
- A-MQTT-SN protocol with adaptation for sent and received data (message type PUBLISH and PUBACK).

The adaptive aggregation algorithm for A-MQTT-SN was initiated with values: $TI = 120\ s$, $TR = 240\ s$, $\alpha = 0.5$, and $L = 1000\ B$. The naive aggregation algorithm was initiated with values: $T_I = 2\ s$ and $L = 250\ B$. The values are application-specific, and should be tailored for different conditions, such as: amount of transmitted data, real-time boundaries and the maximal accepted latency by the application.

The measurements were made with a custom multichannel current and voltage sensing module and tailored for energy measurements of various embedded devices. Data for all of the presented tests was acquired from the GPRS modems (Class 10) connecting to public GSM network with a throughput of 25 Kb/s (2 timeslots in uplink direction).

The result of these tests is shown in the following figures:

- for MQTT protocol (using TCP and PPP protocols) – Figure 7,
- for MQTT-SN protocol (using UDP, PPP protocols and AT commands on the GPRS modem) – Figure 8,

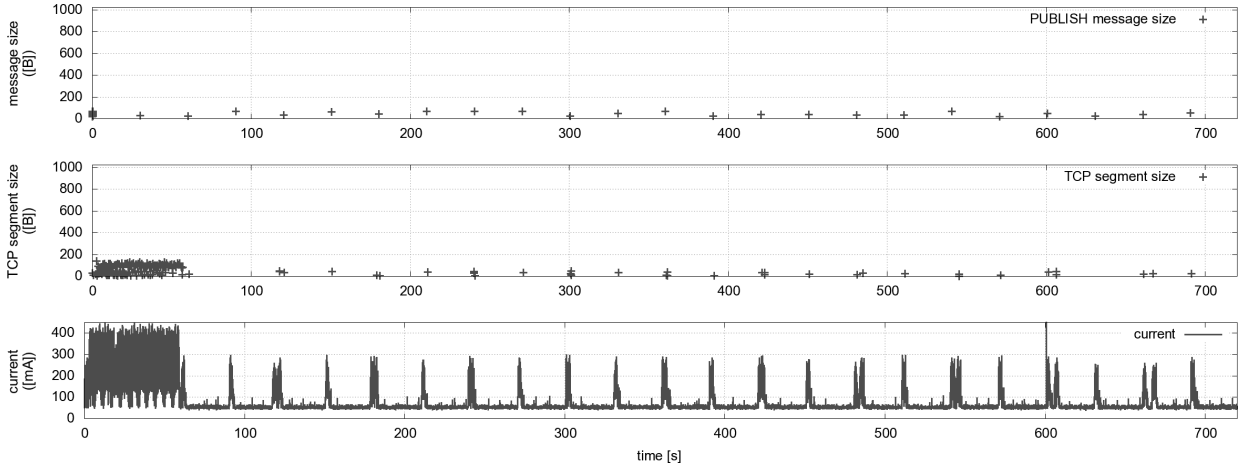

Fig. 7. The current consumption for the MQTT protocol

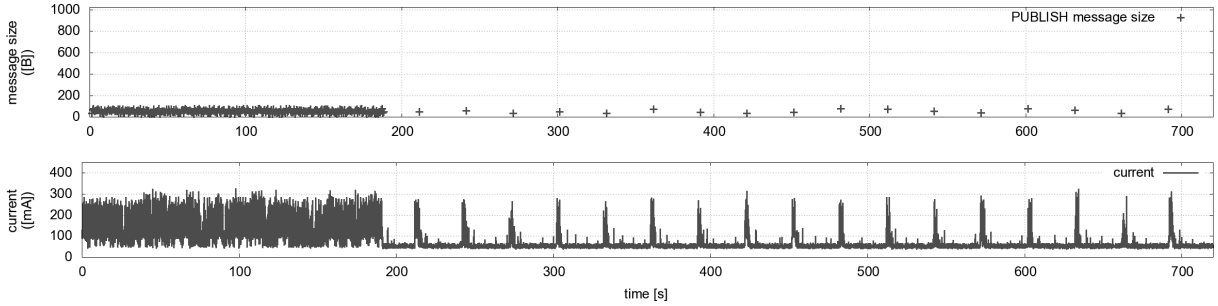

Fig. 8. The current consumption for the MQTT-SN protocol

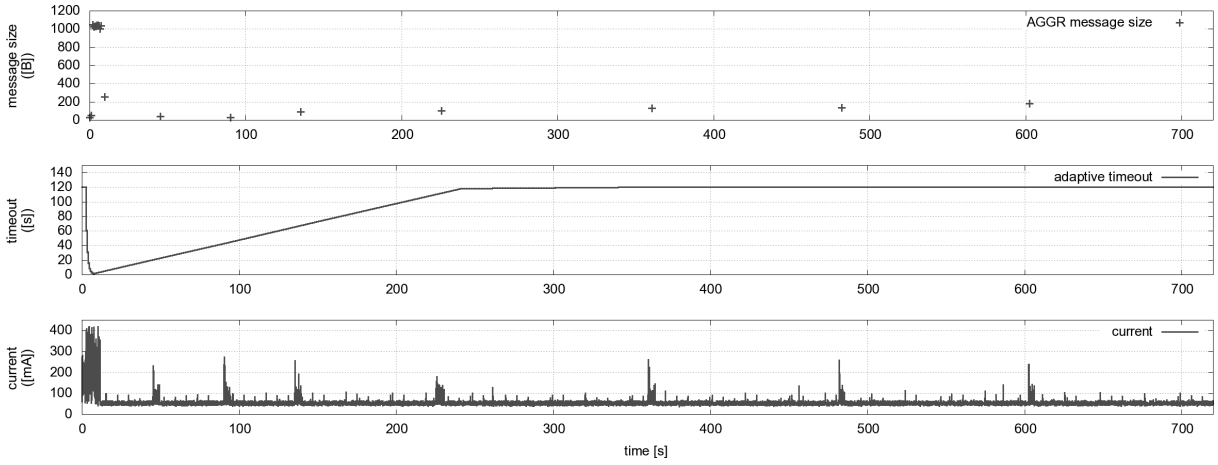

Fig. 9. The power consumption for the A-MQTT-SN protocol

- for A-MQTT-SN protocol (using UDP, PPP protocols and AT commands on the GPRS modem) – Figure 9.

Analyzing the results we can observe that the power consumption of a GPRS modem for data transmission is higher for MQTT and MQTT-SN than A-MQTT-SN protocol. In our opinion higher power consumption for MQTT protocol is the result of using TCP and its complexity (call setup, retransmissions). It can be seen that in the case of sending

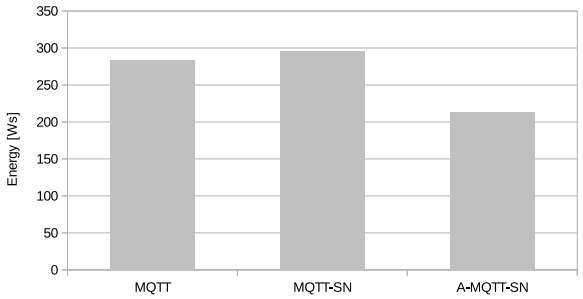

Fig. 10. Energy consumption for MQTT, MQTT-SN and A-MQTT-SN protocols

MQTT messages with QoS 0 should not be a retransmission of messages which, however, are made because of the use of TCP protocol. In the second case, where we used UDP and MQTT-SN protocols, increased energy consumption via modem is related to the size of transmitted data. In case of sending a large number of small packets the overhead associated with packet header is visible. The developed A-MQTT-SN protocol variation aggregates data transmitted and significantly decreases the number of headers and thus gives the best result as regards the energy consumption during transmission by GPRS modem (Figure 10).

VI. Summary and Future Work

The paper discusses the problem of sending the data using GPRS connectivity from remote telemetry stations. We have analyzed various communication protocols and finally selected MQTT-SN. The paper proposed the extensions to the communication protocol that adjust its behavior to the GPRS connectivity profile in order to decrease the data transmission-related energy consumption.

The motivating scenario presented in the paper is only one of the possible applications of our concept. The solutions might be successfully applied to e.g. multilayer telemetry solutions where due to the sleepy nodes, data have to be pushed rarely but efficiently.

Acknowledgment

The research presented in this paper was partially supported by the National Centre for Research and Development (NCBiR) under Grant No. PBS1/B9/18/2013 and by the Polish Ministry of Science and Higher Education under AGH University of Science and Technology Grant 11.11.230.015 (statutory project).

***Abstract*—This paper describes the design of the wireless sensor network node (WSN) for distributed active vibration control (AVC) system for the automotive application. The approach of the system is presented in details. A WSN node using one piezoelectric element provides several features (sensing, shunting and energy harvesting). Integration of the vibration sensing capability for active vibration control system with the energy harvesting capability is described here. Simulation results are compared with the prototype design.**

I. Introduction

WIRELESS Sensor Networks (WSNs) are made up of intelligent and autonomous nodes. Each node is able to work independently in distributed area, and is an energy aware and a low-power device. Nodes are able to establish autonomously an efficient wireless connection, which is used to send measured values. WSNs are commonly used to monitor the physical or environmental conditions like temperature, sound and vibration [1].

WSN nodes are commonly supplied from batteries. It is the last "wire" which should be cut, to provide long lifetime and maintenance-free systems. Nowadays, batteries need to be charged or replaced [2]. It introduces additional costs in the use of WSNs. Despite this inconvenience WSNs are applied in Structural Health Monitoring systems (SHMs), Environmental Monitoring systems which provide new features compared to existing wired solutions [3].

Active Vibration Control (AVC) systems become a very important issue in many engineering fields (SHM, automotive and industrial applications) which provide smart solutions for vibration and noise damping systems. Several solutions for AVC have been proposed and tested with promising results [4]. However those systems are centralised, wired and need a lot of computing power. Implementation of the AVC in a WSN is a challenge for designers. The entire vibration control system must be designed in order to pass very stringent requirements of the WSN and control law [5].

II. Research Assumptions

The usage of the active vibration control can reduce the weight of conventional passive methods, helping to push towards lighter, more fuel efficient vehicles [6]. Active methods include vibration sources which are driven by the control strategy algorithm to provide destructive interference of real vibrations. There are two possibilities to implement the control strategy: feed-forward (open-loop) and feedback (closed-loop). A variety of algorithms have been used to adapt the controller, most are based on adaptative filtering methods: least mean square (LMS) and filtered reference LMS (FxLMS) [7]. Conventional AVC systems based on wired networks (sensors and actuators) with high-power controller and fast data processing need a lot of energy. Replacing a big centralised (wired) system with a low power nodes can improve the AVC in the scope of functionality, maintenance costs and energy consumption.

III. System approach

WSNs have rather low transmission rates. Due to delays, an implementation of the real-time system which is necessary to provide data processing for centralised AVC systems is not possible [5]. In spite of, WSNs could be used to provide active control. A distributed approach used in place of the centralised one can be a solution. In our approach, intelligent nodes provide local action, which reduces the amount of the information to transfer, compared to the centralised approach. The feasibility of the distributed autonomous nodes with sensing feature coupled to semi-active vibration control dissipation is the aim of the work.

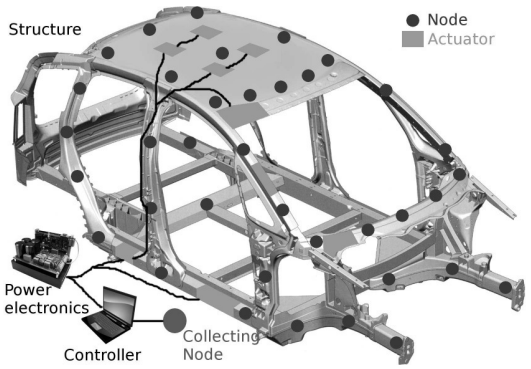

Fig. 1. System structure

978-83-60810-58-3/$25.00

Figure 1 presents the approach of the global system structure for distributed AVC system for automotive application. Wireless nodes are implemented in the body of the car. Nodes are in the star topology towards the collecting node. Each node in the system is powered from the harvested energy and provides mechanical damping. It is a first level of the AVC system. Nodes measure the value of vibrations and if necessary send data to the collecting node, which is responsible for second level of the AVC system (high power, wired actuators). If there are no vibrations in the system, the nodes do not have energy to work but there is no need to cancel the vibrations. When vibrations occur, the WSN nodes are initiated and provide first level of the mechanical damping. If necessary they send measurements to the collecting node, and ask for a second level of the AVC.

IV. WSN NODE DESIGN ASSUMPTIONS

The WSN node provides several hardware features: sensing, energy harvesting and local damping using one piezoelectric element. The following paragraphs describe these features and provide description of the chosen solutions.

A. Sensing vibrations

Sensing vibrations requires understanding two issues. The first one is the environment of vibrations; the second is a piezoelectric effect.

Various vibration noises have been already investigated in literature [7]. Body car vibrations are low frequency signals. Noises inside a car under operating conditions have low frequencies (less than 300Hz) and are mostly determined by acoustic resonances and body vibrations modes [8], [9].

The piezoelectric element can be used to track mechanical vibrations [10]. The output voltage of the piezoelectric element corresponds to the mechanical acceleration. It makes the piezoelectric element proper for sensing vibrations.

B. Energy Harvesting

The piezoelectric element can be described as a current source with an inbuilt capacitance. The existence of this capacitance suggests using the shunt inductor to achieve maximum power flow. However, the large value of the inductor, does not allow to use this solution in the real design. Several solutions for harvesting energy from the piezoelectric element have been already proposed. So-called "synchronised switch damping" (SSD) are semi-passive methods developed to address the problem of vibration damping. Techniques based on SSD method provide efficient energy harvesting by increasing the energy flow between the piezoelectric element and load [10].

C. Mechanical damping

Shunting the piezoelectric element (provided by the energy harvesting method) can be used for structural damping. The efficiency of dissipation energy in the shunt connected to the piezoelectric element is currently an issue of research. We distinguish passive and active methods. Passive methods use passive electrical elements to provide mechanical damping [11] whereas active methods use non-linear circuits like negative-capacitance [12] or switching methods [13].

D. Chosen solutions

The design of an autonomous and intelligent WSN node must consider requirements mentioned in previous paragraphs. Low frequency vibrations in the body of the car suggest the use of efficient energy but slow and low-computing, 8bit low-power microcontroller with internal analog-to-digital converter (ADC). It provides low power consumption. Moreover, the sensing vibrations capability needs the piezoelectric element in the open circuit.

The choice of the energy harvesting method requires to take under consideration several parameters: efficiency of the energy harvesting, capability of vibrations damping, efficiency in the power consumption, facility of implementation and sensing capability. The series switching over the inductance (Series SSHI) method is chosen for the design. It is semi-passive technique, based on non-linear processing on the piezoelectric voltage.

V. WSN NODE DESIGN

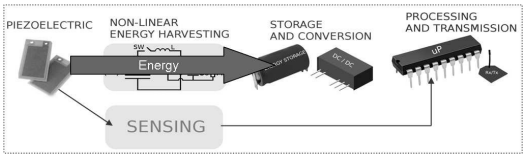

Fig. 2. WSN node schema

Figure 2 presents the schema block for WSN node. We distinguish two parallel systems. The first one for energy harvesting and damping vibrations, the second one for sensing vibrations. Both are connected to one piezoelectric patch transducer. Harvested energy is kept in the storage and used to supply the microprocessor and wireless transmission. The following paragraphs describe the design of the WSN node.

A. Piezoelectric element

Piezoelectric effect can be considered as a bidirectional energy conversion. A strain on the piezoelectric element generates the electrical tension and respectively the electrical tension over the piezoelectric element generates the mechanical strain.

To understand electrical properties of the piezoelectric patch transducer several measurements have been done. Figure 3 and figure 4 presents achieved results.

The current and voltage values are measured over the piezoelectric patch transducer in function of the resistive load for constant frequency (figure 3). The piezoelectric element is a real current source and for the optimal resistive load provides the maximal power (figure 4). It clearly shows that the energy harvesting circuit must be designed in accordance with the electrical properties of the piezoelectric patch (optimal load).

According to figures 3 and 4 we can observe that the high value of the resistive load reduces the amount of the energy

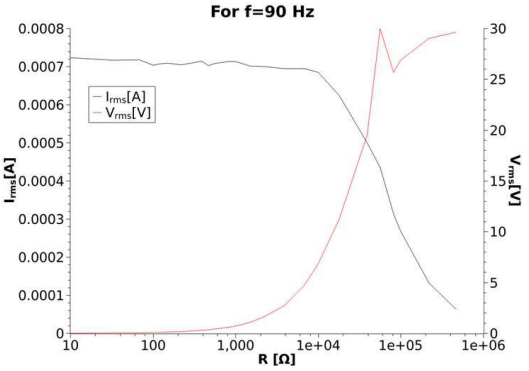

Fig. 3. Output electrical characteristics for piezoelectric patch transducer

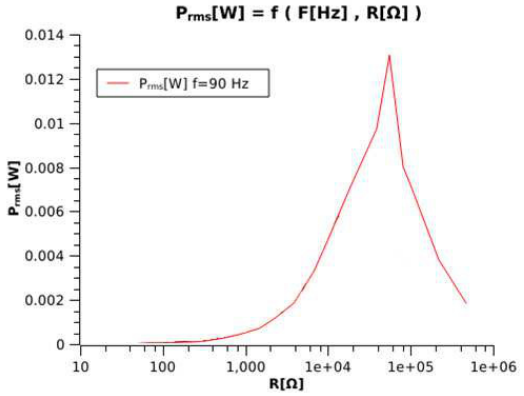

Fig. 4. Power received from the piezoelectric patch transducer in function of resistive load

received from the piezoelectric element. It proves the usage of the piezoelectric element with high resistive load for sensing. This solution provides a good resolution of measurements due to high voltage values and low energy leakage.

B. Sensing vibrations

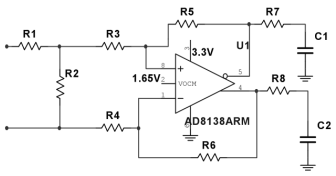

Fig. 5. Sensing circuit

The designed circuit for sensing vibrations and signal conditioning is presented on figure 5. It is composed of the voltage divider (R1 and R2) and the AD8138 low distortion differential analog-to-digital (ADC) driver from Analog Devices. The low pass filter is used to cut-off high frequencies over the output of the ADC driver (R7 with C1 and R8 with C2). The differential ADC driver provides also offset voltage (Pin 2 connected to the 1.65V). Hence, the negative and positive values are measured, it is necessary to provide active vibration control. In the designed circuit the piezoelectric element is not connected directly to the circuit ground. The low-power differential amplifier is supplied from single 3.3V, which simplifies the supply circuit. An internal ADC of the microcontroller is used. This solution provides low energy consumption since there is no additional ADC to supply.

C. Switching circuit for SSHI method

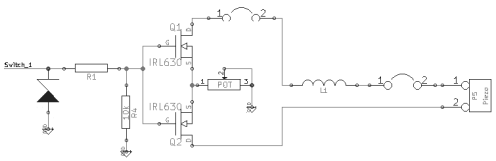

Fig. 6. Switching circuit for SSHI method

The series SSHI circuit is presented on the figure 6. It contains two IRL630 NMOS transistors driven by the microcontroller (the full-wave switch circuit with low current leakage and low short-circuit resistance). The usage of the logic-level transistor simplifies the circuit; the output of the microcontroller can be used to drive the switch. The zener diode D1 is used to protect the microcontroller pin, the R1 resistor sets the current value (it is correlated with the turn-on time). The R4 is used to reduce the turn-off time.

In the series SSHI method, the inbuilt piezoelectric capacitance and external inductance creates the series resonant circuit. The switch keep the circuit in the open-circuit. While the extremum of the mechanical displacement is detected, the switch is closed for half of the electrical resonant period. It causes inversion of the piezoelectric element voltage. The period of the mechanical displacement is much longer than the period of the electrical circuit.

VI. Simulations

Designed circuits: vibration sensing and energy harvesting are simulated in the NI Multisim Component Evaluator 13.0 from National Instruments [14]. Devices used in the design are implemented using SPICE models. The sensing circuit and the series SSHI switching circuit are connected in parallel with the model of the piezoelectric element.

Figure 7a shows simulated signal for sensing vibrations. The 1.65 V offset is used for signal conditioning, hence positive and negative parts of the signal can be measured in the ADC of the microcontroller.

Figure 7b shows simulation results for switching circuit while the switch is open. The sinusoidal signal is a voltage over the piezoelectric element. The second wave - small peaks represents the current in the circuit.

Figure 7c shows simulation results for switching circuit while the switch is closed. The sinusoidal signals presented on figure correspond to the voltage and current in the circuit. The shift phase between them proves existence of the capacity (inbuilt capacity of the piezoelectric element).

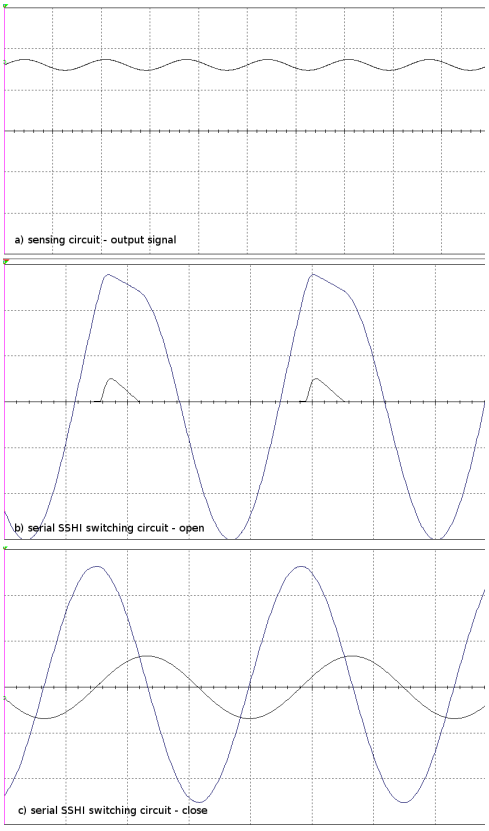

Fig. 7. Simulation results

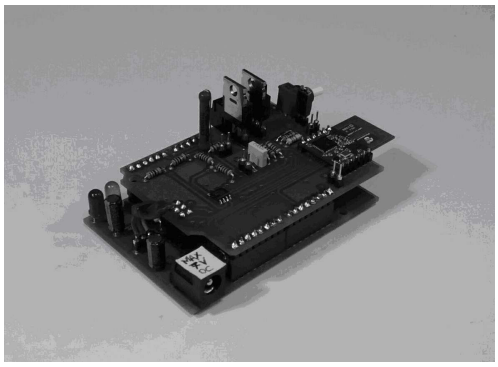

Fig. 8. Photo of the prototype WSN node

VII. Implementation

Figure 8 presents the photo of the real prototype device. It is composed of two PCB boards. The first board contains microcontroller and supply circuit, the second provides the SSHI circuit, sensing circuit and wireless communication. In designed prototype series SSHI circuit and sensing circuit are connected in parallel with the piezoelectric patch transducer which corresponds to the simulations.

For wireless communication we used the MRF24J40 radiofrequency transceiver from Microchip. It provides hardware support for IEEE 802.15.4 physical layer. The node is equipped with low-power microcontroller PIC16LF88 with internal 10bit ADC.

A. Measurement station

Fig. 9. Measurement station: metal plate with two piezoelectric patches

The measurement station used for tests is presented on figure 9. It contains two PI-876 piezoelectric patch transducers from PI Ceramic [14]. Vibrations are generated by an attached electric vibrator which is connected with the signal amplifier and function generator. Acceleration is measured by the external accelerometer connected directly to the plate next to the piezoelectric element (accelerometer sensitivity 10,43 mV/g).

B. Validation of sensing circuit

Figure 10 presents the validation of the sensing circuit. The WSN node is supplied; the transistor-switch is open (sensing capability). The first channel (CH1) presents the voltage over the ADC (with 1.65 V offset). It corresponds to simulations (figure 7a)

C. Validation of the switching circuit

Figure 11 presents waveforms of voltage and current while the transistor-switch is open. The value of the current is measured over the small series resistance added to the switching circuit. The CH1 channel presents the piezoelectric voltage, while the CH2 channel presents the current in the switching circuit. The values obtained from measurements are in keeping with its simulated counterparts. (figure 7b)

Figure 12 presents waveforms while the transistor-switch is closed. In this case the CH1 channel presents the acceleration waveform; while CH2 presents the current in the circuit. Figure 12 also presents the phase shift between voltage and current waveform (the capacitance character of the piezoelectric element). Obtained measured values correspond to simulations (figure 7c)

VIII. Discussion, perspectives

The sensing circuit and switching circuit have been designed separately to provide the best solution for each one. Both circuits have been simulated and implemented in the prototype

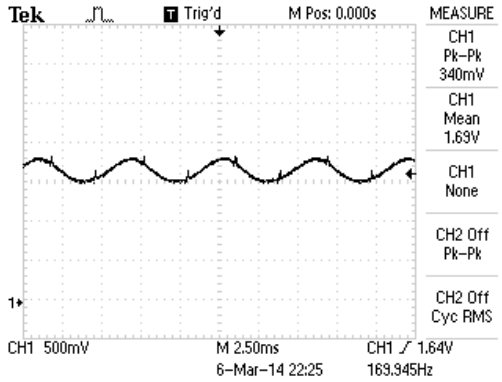

Fig. 10. Validation of the sensing circuit

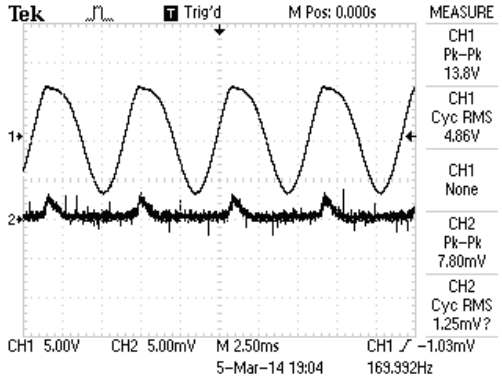

Fig. 11. Transistor-switch open

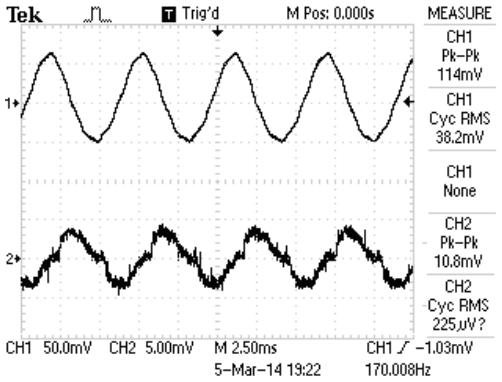

Fig. 12. Transistor-switch closed

design. Achieved measurements correspond to the simulations. According to figures 7b, 11, 7c and 12 the relative error between simulations and real measurements is 9.2 %.

The CH2 trace on figure 11 presents current in the switching circuit while the switch is open. It is default current caused by lack of the insulation between ground referenced switch, floating-source piezoelectric generator and differential-mode sensing circuit.

To provide galvanic separation (switch circuit not referenced to the ground) two solutions are considered: optical isolation [16], [18] and transformer [17], [18].

The optical isolation is recommended for its reliability and simple implementation. The disadvantage of this method is requirement of the second separated supply circuit to drive the MOSFET switch. It would add additional devices in the supply circuit. Since the WSN node is designed in order to verify the self-supply capability, the use of the additional devices which introduce energy losses should be avoided.

The second approach is to use the transformer to drive NMOS transistors. A pulse transformer is, in principle, a simple, reliable and highly noise-immune method of providing isolated gate drive. It can be advised for applications were the duty cycle is small. As a stand-alone component it can be used for duty cycles between 35% and 65% [19].

The series SSHI is a system with low duty cycle because the period of the mechanical displacement is much longer than period of the electrical circuit. It makes the pulse transformer a promising solution for our design.

Simulations have been realised to validate the circuit with the chosen solution (pulse transformer). The NI Multisim Component Evaluator 13.0 from National Instruments is used. The sensing vibrations circuit and the series SSHI circuit are in parallel with the piezoelectric element (design contains a switch not referenced to the ground). The entire simulation schema is presented on figure 13. The individual parts of the design are marked on the figure. We distinguish the switch driver composed of the voltage source V1 (corresponds to the microcontroller output signal in the real design). The series SSHI circuit contains two transistors and the inductor L2. Additionally, the bridge circuit (diodes: D1, D2, D3 and D4) is used to transform voltage from AC to DC. Finally, the load is simulated by the resistor R1 and the capacitor C1. The sensing circuit is connected in parallel with the SSHI circuit. Figure 14 compares the theoretical waveforms with the simulation results of the series SSHI method. Simulation results correspond to the theoretical waveforms but RLC and diode impacts are visible. The results justify the correctness of the integration of the sensing circuit with the energy harvesting circuit.

IX. Conclusion

Big centralised and wired systems for active vibration control are costly and use a large quantity of energy. A distributed solution based on an energy aware wireless sensor network has been proposed as a replacement for the centralised system. The autonomous WSN node needs to be designed to provide efficient wireless network for distributed active vibration control.

In this paper the global approach and the system assumptions are established and used as input data for the design. The proposed design of the WSN node is in accord with the prescribed requirements.

Designed node provides: vibration sensing, shunting the piezoelectric element and wireless communication. Furthermore, the series SSHI technique, chosen for the design, provides damping of the mechanical vibrations and the energy harvesting capability.

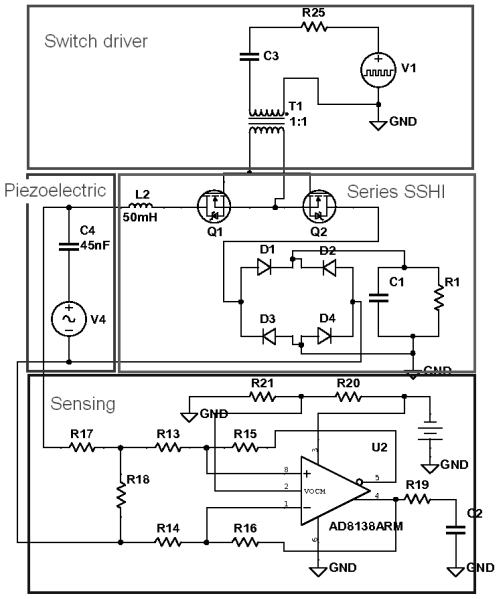

Fig. 13. Simulated circuit

Designed circuits for sensing vibrations and shunting the piezoelectric element are presented and described in details. The WSN node is modelled using the SPICE models. Achieved simulation results are consistent with the expected ones and validate the design.

The WSN node prototype has been constructed. The simulation results are compared with the measurements. The metal plate with the attached piezoelectric element is used as a measurement station. The measurement results correspond to the simulation results. The correctness of the simulations is proved with the measurements (relative error is 9.2 %).

Finally the separation problem for self-powered circuits has been indicated. Possible solutions are taken under consideration. The circuit with the chosen solution (pulse transformer) is simulated; obtained results correspond to the theoretical research (expected results).

The next step of the work would be modification of the prototype device according to the presented simulations. The galvanic separation for non-ground referenced switch will be used. The measurements would be compared with the simulation results. The following step would be validation of the energy harvesting and mechanical damping capability.

***Abstract*—In the recent years, Wireless Sensor Networks (WSNs) have become a great field of interest for scientific community. This kind of network provides a panoply of applications in different areas of human life. However WSNs must ensure the quality of service (QoS) to give the requested performance for the final user. Among different issues presented in the literature to provide high QoS, multipath routing is commonly used. But such a solution could be not enough efficient if the multipath routing design does not consider the phenomena of interference. Indeed the constructed paths can have an interference zone, mainly a shared carrier sense range. In this paper we show by analytical and experimental results, that using multipath routing can never overshoot the performance of single path when the interferences are not taken into account. Also, we show how the carrier sense range can influence the network performance.**

***Index Terms*—WSN, Carrier sense range, Interference, Multipath routing, QoS.**

I. Introduction

NOWADAYS Wireless Sensor Networks (WSNs) attract more and more researchers as being an interdisciplinary research of interest. This kind of networks offers countless applications like precise agriculture, system monitoring and many others. One of the most challenging issue in these networks is that the routing techniques must satisfy some QoS metrics. Especially in the case of multimedia applications that require the best performance in terms of energy consumption, delay, jitter, reliability and bandwidth.

There are many solutions that can be included in the protocol design to ensure QoS requirements as using multipath routing. This technique consists of giving a source node the possibility to use any of several paths to reach a particular destination at any time. According to [1], [2], the use of a multipath routing has many benefits such as aggregation of bandwidth by splitting data to the same destination into multiple streams. Also, the use of the multipath principle can reduce the end to end delay in case of route failure because there is no need to restart a new path discovery process. In addition, multipath routing has the ability to improve the reliability of the transmitted information by sending multiple copies of the same data on multiple paths, which increases the accuracy. Another interesting benefit of multipath techniques is the load balancing which allows a better use of available network resources in order to reduce traffic congestion.

To enhance the multipath routing scheme design, many works [3], [4] use the notion of disjoint paths. This notion reflects the independence of paths in terms of shared resources. The higher is the degree of independence, the more the multipath strategy promotes an adaptive use of the network resources. With such a feature, the multipath solution can avoid congestion by balancing the load among the multiple disjoint paths. In the literature, several techniques based on the degree of disjoint paths are used to classify the set of paths between a source node and a destination node. Among them we cite Link-disjoint, Node-disjoint, Maximally-disjoint and Radio-disjoint Multipath [1].

However multipath solution hides a serious drawback. In fact since a single channel is used in the wireless network, the sensors nodes share the medium of communication. And due to the broadcast nature of radio communication the level of interference is more pronounced [5], [6]. Also, when several paths are used simultaneously, even if the node disjoint priority is satisfied, it remains a significant risk of collisions that results in high packet loss rate. So the concurrent use of multiple paths constructed from source to destination results in intensive inter-path interference [7]. Therefore performances will decrease seriously. Authors in [8] concluded that transmitting data over multiple paths is not a synonym of result improvement unless the effects of the wireless communications are taken into account. This phenomena is also known as the route-coupling problem [9]. It occurs when simultaneous communications through multiple paths are ongoing, and these paths are located physically close enough in order to interfere with each other.

Another aspect that must be considered, is the effect of the carrier sense range on communication performances in sensor networks, mainly in routing protocol. Indeed, while the carrier sense range is usually more larger than the transmission range, there is more chance that interferences occur in this range, especially in the case of high density. We mean by carrier sense range effect the fact that a node cannot transmit as an other node in its carrier sense range is already in a transmitting phase.

In this work we study how the carrier sense range can influence the communication in a sensor network. We show by analytical and experimental results that using multipath routing can never overshoot the performances of a single path when

978-83-60810-58-3/$25.00

the carrier sense range effect is not considered in the routing design.

The remainder of this paper is organized as follows: in section II, some routing protocols with the aim of reducing the interference problem in the multipath case are presented. In section III, we describe by analytical model the effect of both wireless interferences and carrier sensing. Simulation results are shown in section IV. Finally in section V, we draw the conclusion and give some perspectives.

II. Related work

In the literature, there exists some solutions that aim to reduce the effects of interference such as directed antennas [10]. The authors try to find a zone-disjoint multipath to avoid collisions between paths. Another solution consists of using multi-channel transmission [11]. But these both methods cannot be easily used due to the resource-constrained propriety of the WSNs. An alternative technique is to calculate the degree of independence between a set of paths using the correlation factor or the coupling metrics. The correlation factor between two node-disjoint paths is defined as the total number of shared links of the paths [5]. It represents the chances that the transmission along the different paths could interfere with each other in a shared channel. The coupling between two paths (Pl and P2) is defined as the average number of nodes that are unable to receive data along P2 when a single node in P1 is transmitting [9]. The more the path has lower correlation factor or coupling effect, the more suitable is for multipath construction allowing better performances.

In the following, we will review some studies about routing protocols that aim reducing the interference problem in the multipath case.

- Energy Efficient Collision Aware Multipath Routing for WSN (EECA) [12]:
  The EECA is an on-demand routing protocol that constructs multiple paths using request/reply cycles. This protocol has two aims:
  - Reducing the flooding of route request messages by restricting it to the neighbors of nodes iteratively added to the route being discovered.
  - Saving energy by adjusting power needed to transmit the data and the control messages and so reducing the potential collision area of each node.

  The author makes assumption that each node can adjust the radio transmit power to vary its communication range from 0 to a specific transmit range. The EECA algorithm attempts to find two collision-free routes using the node position information. The source starts by checking if there are two groups in its neighbor list satisfying the following three conditions: 1) all these nodes are close to the destination; 2) The nodes of the two groups are opposite and separated by the source-destination line; 3) each node is distanced more than R/2 from the source destination line.
  However such restrictions limit the chance to find two paths far away from each other. So many nodes for the first constructed path remain in the carrier sense range of other nodes for the second path.
- Interference-Minimized Multipath Routing with Congestion Control in Wireless Sensor Network for High-Rate Streaming (I2MR) [13]:
  This protocol tries to increase the throughput by discovering zone-disjoint paths and adopting the load balancing scheme, while requiring minimal geographic information to reduce overheads. Localization support is only required at the source nodes, which are the most powerful sensor nodes equipped with Electro-Optic devices. The basic idea is to mark-out the interference zone of the nodes of the first path after it has been discovered. Then subsequent paths cannot be discovered within this interference zone. I2MR tries to construct zone-disjoint paths and distributes network traffic over the discovered paths by assuming a special network structure and the availability of particular hardware components. In I2MR, the source node tries to find three paths, but uses the two first paths for data transmission and keeps the third one as a backup path. However, this work needs a special network structure and particular hardware components making this protocol not applicable to all types of sensors. In addition, due to the high complexity of the introduced zone-marking mechanism, and the different type of packet control, the generated overhead is more pronounced.
- Maximally radio-disjoint multipath routing for wireless multimedia sensor networks (MR2) [14]
  The main objective for the MR2 protocol is to provide the required bandwidth for multimedia applications through non-interfering paths. MR2 utilizes an adaptive incremental technique to construct minimum-interfering paths. To do so, only one path is built for a given session. Additional paths are built when required, typically in case of congestion or bandwidth shortage. Interference awareness and energy saving are achieved by switching a subset of sensor nodes in a passive state in which they do not take part in the routing process. The passive state is represented by switching the sensor node to a sleep or an idle mode. Thus enabling increasing the network lifetime. However, MR2 is only suitable for query-driven applications. Also, the utilized flooding strategy for constructing non-interfering paths implies a high control overhead. And as the bepassive message is received only by the neighbors of each node forming the path, the constructed paths are spaced by a distance approximately equal to the transmission range. So the carrier sense range effect is not considered.

So for all discussed works the constructed paths are spaced by a distance equal to the transmission range or at most the interference range. Thus the carrier sense range has never been treated.

III. Analytical model

In this section, we will give a model for a wireless sensor network as a connectivity graph. After that by using the

protocol model of interference and the physical model of interference we will describe the effects of wireless interferences and of carrier sensing. And finally by a conflict graph we will present the different relations between the wireless links in the network.

A. Connectivity graph

We consider a wireless network with N nodes randomly located on a plane space. We denote our network by $G(V, E)$ where V is the vertex that represents a set of N nodes and E is the edge that represents set of directed links connecting the nodes in V. Let n_k where $1 \leq k \leq N$ denote the nodes in V, and l_{ij} and d_{ij} denote respectively the directed link and the distance between nodes n_i and n_j with $i, j \in [1, N]$. The notation l_{ij} means also that the node n_i sends packet to node n_j, so l_{ij} has not the same meaning than l_{ji} . Each node, $n_k \in V$, is equipped with a radio having three levels of range centred at the node n_k:

- The transmission range $R_{Tr}(k)$, is the range where a successful communication can be achieved.
- The interference range $R_I(k)$, is the range where every node that attempts to start a communication will cause collision at node n_k when it receives packet.
- The carrier sense range $R_{CS}(k)$, is the range where every node that attempts to start communication will prevent node n_k to transmit.

The relationship between the three ranges is $R_{Tr}(i) < R_I(i) < R_{CS}(i)$. We notice that the nodes are homogeneous, so each node has the same ranges than others. In our study we consider the case of a single wireless channel.

According to the protocol model of interference [15], there is a successful transmission between nodes n_i and n_j if the following conditions are satisfied:

- $d_{ij} \leq R_{Tr}(i)$.
- no transmitting nodes in the potential zone of interference of node n_j.
- no nodes in the $R_{CS}(i)$ that sends packet concurrently with the node n_i.

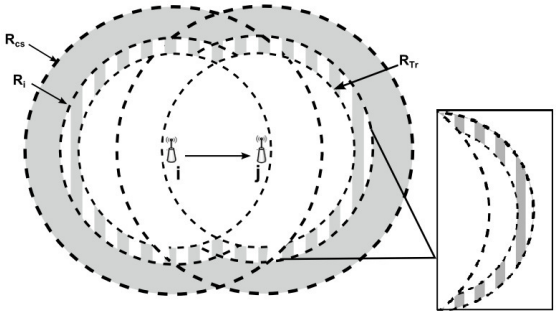

Fig. 1: Potential zone of interference

The potential zone of interference is shown in Fig.1. It is delimited by the intersection of carrier sense range of transmitter (node n_i) and the interference range and transmission range of the receiver (node n_j). The area of this zone depends on the distance between the transmitter and the receiver.

If we consider the physical model of interferences [15] a successful transmission arises only if the signal strength of the received frame at node n_j is stronger than RxThresh_. Otherwise if signal strength is less than RxThresh_ but greater than CSThresh_, the receiver will not be able to decode correctly the signal and the channel is considered as busy. In the case when multi-frames are received simultaneously by node n_j, it calculates the ratio of the strongest frame signal strength to the signal strength sum of other frames. If it is larger than CPThresh_, the frame will be received correctly and other frames are ignored. Otherwise, all frames are discarded. This case represents the interference that can be occurred at the receiver. The three values RxThresh_, CSThresh_ and CPThresh_ are specific thresholds for the wireless node. NS-2 [16] uses the above description to simulate the reception of signal.

B. Conflict graph

In order to show which wireless links interfere with each other in the network we consider a conflict graph $G'(V', E')$ where V' is the vertex that represents each link in the connectivity graph G, and E' is the edge which represents the set of all possible relations between the vertices in V'.

Based on the protocol interference model described above, an edge can be drawn between two vertices l_{ij} and l_{pq} in G' if the links l_{ij} and l_{pq} may be active simultaneously. Such a condition is achieved if one of the two following conditions are true:

- $i \in R_I(q)$ or $p \in R_I(j)$.
- $i \in R_{CS}(p)$ or $p \in R_{CS}(i)$.

C. Multipath case

Our aim in this subsection is to show how the multipath routing reacts under the three ranges defined above. Namely how each node in each path will interact with other nodes in the other paths. Let have two paths from the source *S* and the sink *(a-b-c-d)* and *(e-f-g)* as mentioned in Fig.2.
In the first path the node *b* can only forward its data if the nodes *a* and *c* are not in the transmitting phase. The same observation can be expected for the node *c* and the nodes *b* and *d*. We notice that the transmission is done by a broadcast way due to the nature of radio device.
At the second path, if the node *g* in $R_I(c)$ starts transmission to the sink (if *d* and *c* do not transmit), then the receiving data at the node *c* from the node *b* will be disrupted. Also, if the node *f* starts forwarding, it will be in a competition with nodes *b* and *c* at the same time as it is located in the carrier sense range of the two nodes; which will cause delays and packet losses. If the node *a* sends packets to node *b*, this one will be able to successfully receive the packets without any potential interference caused by the node *f*.

IV. Simulation and Experimental Results

The aim of this simulation is to show how the same routing protocol performs in single path case and in the multipath

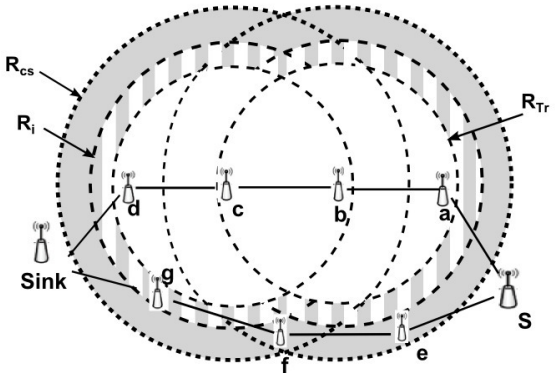

Fig. 2: Multipath study under the three ranges

case without considering the multipath effect. Also, we investigate how the carrier sense range can influence the routing results. We choose as routing protocol for this study our implementation [17] of the Two Phase geographical Greedy Forwarding (TPGF) as it has been one of the first protocol which introduces the concept of multi-paths in the field of WMSNs [18]. This algorithm focuses on the exploration and the establishment of a maximum number of best disjoint routes in terms of end-to-end delay. We evaluate the performance of the studied protocol under the delay metrics to measure the average end-to-end delay of successful received packets. And under the Packet Delivery Ratio (PDR) metrics to calculate the ratio between the number of correctly received packets at the destination and the number of packets sent by the source.

Working environment

Here we will describe our studied scenario. Each simulation scenario is presented as follows: **X** nodes are randomly located in an area of 1500*1500 m^2, where:

$$X=[\![100;150;200;250;300\ ]\!]$$

Data traffic is generated by a randomly source in the network to a sink. This one is located in the center of our experimentation area and has the last ID. The source node generates a constant bit rate sources (CBR) traffic with **Y** packets per second, where:

$$Y=[\![16;32;64;128;256\ ]\!]$$

The data packet size is 1000 bytes. The duration of communication is 40 seconds, an no mobility is supported in this scenario. For every value of **X** and **Y** 50 scenarios are generated and the average value of the results are calculated. Due to the lack of space we represent only the results in case of 64 packets per second.

Table I summarizes the parameters used for simulation.

Result analysis

From Fig. 3, we notice that for both multipath and single path cases, the average delay decreases as the network density grows, it is quite normal as we have only one source for each

TABLE I: Main configuration parametres

Parametres	value
link layer	LL
MAC layer	IEEE 802.11
radio propagation	two ray ground
interface queue	PriQueue
ifqlen	50
antenna	omni-antenna
$CPThreshold$ (Watt)	10
$CSThreshold$ (Watt)	$1.559 * 10^{-11}$
$RXThreshold$ (Watt)	$3.652 * 10^{-11}$
Pt (Watt)	0.2818

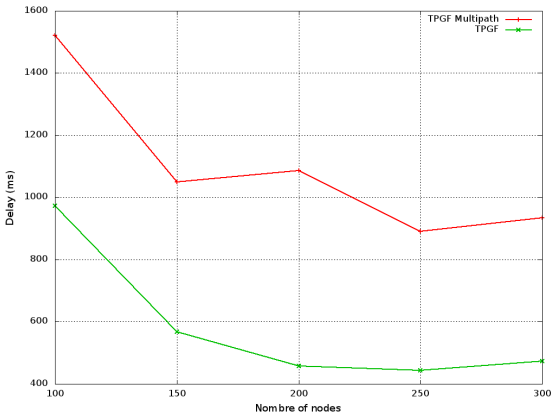

Fig. 3: Average delay vs network size

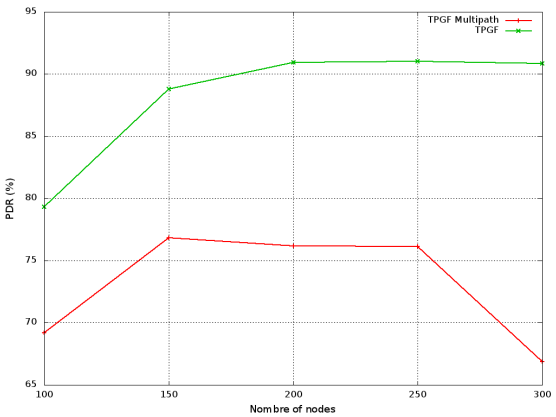

Fig. 4: Average PDR vs network size

scenario. Also, the main observation that Fig. 3 shows is the fact that the single path has the best average delay against the multipath case. The gain is approximately equal to 70%.

This result is expectable since the TPGF protocol does not take into account the interference problem. For Fig. 4 we can see also that the single path has the best average PDR against the multipath case. The gain is approximately equal to 20%.

This part of results confirms that using multipath routing

without taking into consideration interference and the carriers sense range effects makes the multipath solution less profitable than a single path one.

In order to show how the effect of the carrier sense range can influence performances of routing protocols, we discuss the following scenario. First of all, we modify the TPGF protocol in order to have two version. The first one represents the case where the different paths constructed from the source to the sink have at least a distance from each other equal to the transmission range. We denote this version by *RX-avoid*. The second version represents the case where the paths constructed from the source to the sink have at least a distance from each other equal to carrier sense range. We denote this version by *CS-avoid*. In this simulations, we have used a grid with 100 nodes spaced by a distance equal to 200 m. The area of the grid is 4000*2500 m^2. The source node is selected randomly and generatesa constant bit rate (CBR) traffic with **Y** packets per second, where:

$$Y=[\![16;32;64;80;128;256\ ]\!]$$

In this simulation we simply use two paths. We notice also that if there is no way to find the second path with the desired condition, we use only the first path. We repeat the simulations several times and we measure the average of delay sand PDRs.

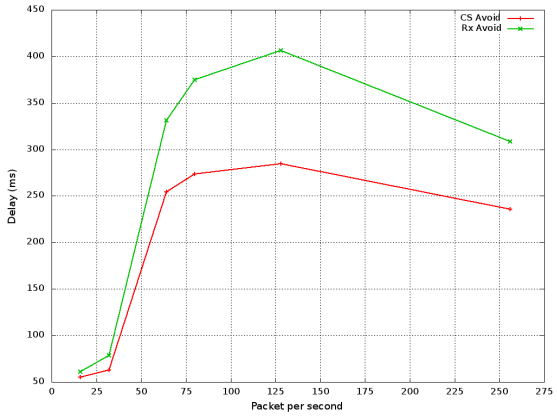

Fig. 5: Average delay vs Rate

From Fig. 5, we notice that for both *CS-avoid* and *RX-avoid* case the average delay increases as the rate grows espacialy from 16 to 128 packet per second. It is quite expected as more the rate is higher more the queue of intermediate nodes is filled. So each packet takes more time to reach destination. But the main observation that we can make from Fig. 5 is the fact that the *CS-avoid* case has the best average delay against the *RX-avoid* case.

As discussed in section III, the carrier sense range effect occurs when a node cannot transmit as an other node in its carrier sense range is already in transmitting phase. This is exactly the case here, in fact more the number of packets per second increases, more the need for channel access is higher. Therefore the nodes of the two paths deprive mutually the channel access since there is a competition between them. For

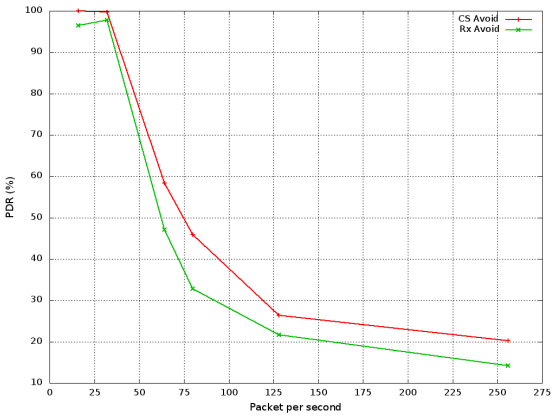

Fig. 6: Average PDR vs Rate

Fig. 6, we can see also that the multipath with the *CS-avoid* has the best average PDR against the *RX-avoid* case.

V. Conclusion and Future Work

Using the multipath routing in the WSN has many benefits such as aggregation of bandwidth, reducing the end to end delay, improving reliability. However, using the multipath routing scheme without considering the effect of the carrier sense range decreases the network performances instead of enhancing it.

We have presented in this paper how the carrier sense range can influence the performance of communication in wireless sensor networks. We show by analytical and experimental results that using multipath techniques can never overshoot the performances of a single path solution unless the carrier sense range effect is considered in the routing design.

We have performed a large number of simulations. Their results prove that multipath with the *CS-avoid* outperforms the multipath with *RX-avoid* for both metrics: delay and PDR. As a future work ,we intend to achieve much more simulations for large scale situations and will consider mobility feature. In addition, we need to experiment this protocol with realistic streams which model multimedia ones.

***Abstract*—Energy saving is one of the most important issues in Wireless Sensor Network (WSN) context. Since the communication task is the most power-consuming operation, it is quite important to achieve an energy efficient communication in order to increase the lifetime of the devices through an intelligent use of the power transmission. In this context, the integration of WSN nodes with switched-beam antennas is becoming more and more appealing due to the possibility to extend sensor node lifetime by optimizing the transmitted power.**

In this work a switched-beam antenna for WSNs nodes in the ISM band (2.4-2.4835 GHz) is proposed. The radiating structure consists of four identical antennas, composed of an array of two L-shaped quarter-wavelength slot antenna elements arranged in a compact and symmetrical planar structure. Thanks to a properly designed switching circuit which controls the feeding of the antenna elements, one among eight possible different radiation patterns in the azimuth plane can be selected on the basis of specific needs. Simulations and experimental results, referred to a prototype realized on a FR-4 substrate, demonstrate the appropriateness of the proposed switched-beam antenna system as hardware element enabling new power saving strategies in WSN contexts.

I. Introduction

GUARANTEEING adequate energy efficiency in Wireless Sensor Networks (WSN) contexts is still an open issue. Indeed, WSN nodes, hereafter referred as motes, are frequently placed in unpractical or hardly accessible places and it could be difficult, time-consuming and expensive to replace batteries. Therefore, both WSN devices and communication protocols must be carefully designed to maximize the motes lifetime, in order to reduce maintenance costs and outages. In such a context, it is well known that the data communication through the RF frontend represents the most power consuming task [1-3]. Just to give an idea, the power required by the mote processor to process thousands of operations is comparable to that the RF transceiver needs to transmit a single bit. Therefore, in the last years, many techniques aimed at minimizing the energy consumption have been proposed [4-6]. Such techniques are often based on specific protocols optimizing the data transmission, for instance by periodically turning motes into sleep mode or opportunely controlling the radio transceiver activation/deactivation.

In order to further increase the energy efficiency, thereby extending even more the motes lifetime, the use of opportunely controlled directional or switched-beam antennas could be a winning approach. Indeed, as already stated, motes are usually equipped with almost omnidirectional antennas and, consequently, only the power portion transmitted toward the proper mote is effectively used, whilst most of the power is wasted elsewhere. Vice versa, a mote provided with a switched-beam antenna could smartly reconfigure the antenna radiation pattern so to convey the power only toward the destination mote.

In this work a full planar and really compact switched-beam antenna particularly suitable for WSN applications in the ISM band is proposed. When connected to the wireless module of a mote, it works in place of the common omnidirectional antenna and its radiation properties can be controlled through a digital interface. The proposed solution consists of four identical radiating structures, each one composed of two L-shaped quarter-wavelength slot antenna elements, arranged in a compact and symmetrical planar structure. Eight switchable radiation patterns with remarkable gain can be obtained, covering symmetrically 360 degrees in the azimuth plane, in order to reduce the transmission power and consequently extend the lifetime of the mote.

The paper is structured as follows: in Section II the state of the art on switched beam antennas in WSN context is discussed, whilst in Section III both working principle and design of the proposed antenna are described; later on in Section IV simulated and experimental results are shown and discussed. Finally, conclusions are drawn in Section V.

II. Related Works

Over the last few years, a strong research effort has been dedicated to the design of more and more performing switched-beam antennas [7-14]. Nevertheless, their integration in WSN motes to reduce energy consumption and to extend motes lifetime, has not been exhaustively explored yet. In particular, a smart switched-beam directional antenna is proposed in [7]. It is composed of four planar patch antennas arranged in a box-like structure. It can switch among four radiation beams with a uniform coverage of the azimuth plane and a good radiation gain in the main lobe direction, but its very large size is not compatible with the integration in WSN nodes. A pattern reconfigurable antenna composed of microstrip parasitic array elements is proposed in [8]. It is

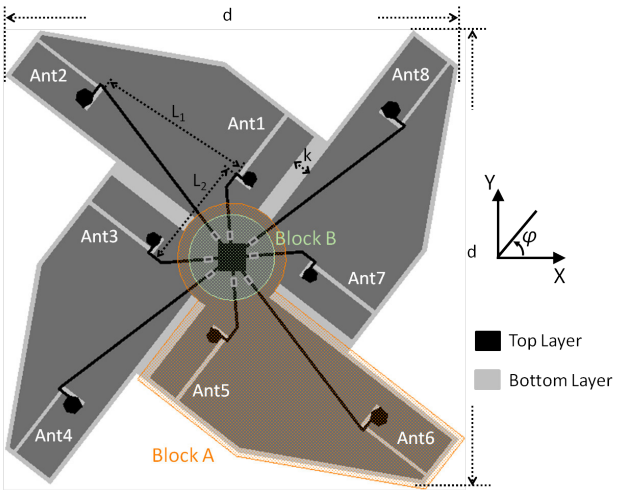

Fig 1. Structure of the proposed switched-beam antenna. The detailed structure of block A is shown in Fig. 2 and those of Block B in Fig. 3.

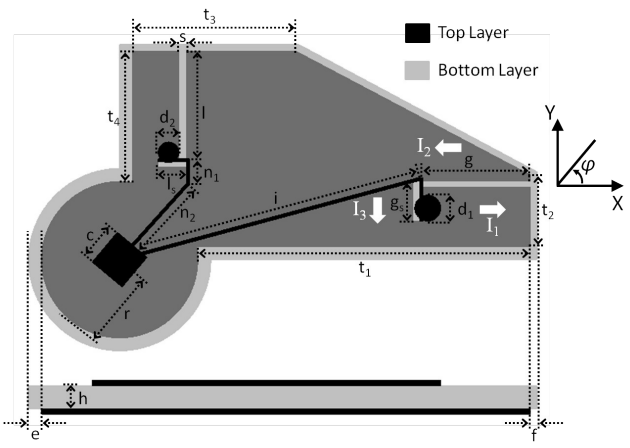

Fig 2. Geometry of the proposed array of two L-shaped quarter-wavelength slot antenna elements, corresponding to Block A in Fig. 1.

based on a simple and compact structure, but it does not ensure a 360-degree uniform coverage in the azimuth plane. Another interesting reconfigurable antenna for WSN sink nodes capable to switch between front-directional and conical beam pattern, is proposed in [9]. It is composed of an EBG ground plane and a power divider with a stub switched phase shifter. Despite the appreciable peak gain in the main lobe direction, it is rather cumbersome and presents no radiating beams in the azimuth plane. A reconfigurable angular diversity antenna using quad corners as reflector arrays and a switching control circuit is proposed in [10]. It presents a high radiation gain, but occupies a large volume and does not guarantee a uniform radiation patterns. On the contrary, a compact Switched-Beam Antenna composed of a four-element antenna array is presented in [11]. It shows eight switchable directional patterns and an omnidirectional one, thus ensuring an uniform coverage of the 360 degrees horizon. Moreover, it is both compact and inexpensive. Unfortunately, it exhibits an Half-Power Beam Width (HPBW) of a single beam of nearly 120 degrees, which causes a large overlapping area, thus not ensuring an optimized energy saving.

Finally, in our earlier work [12]-[14], a reconfigurable beam-steering antenna for WSN nodes is presented. It is composed of a vertical half-wavelength dipole antenna and eight microstrip antennas arranged in a 3D configuration. Thanks to a digital control circuit, it can switch among nine radiation patterns, one omnidirectional and eight directional with a HPBW of nearly 60 degrees in the azimuth plane. It guarantees a uniform coverage of the 360 degree horizon and a remarkable peak gain. The main issue is related to its integrability with real WSN nodes due to its 3D configuration.

In the following Sections, a new switched beam antenna controllable by and easily integrable into WSN nodes will be exhaustively presented along with simulated and measurement results.

III. Switched-Beam Antenna Design

The overall structure of the proposed switched-beam antenna is shown in Fig. 1. In order to explain the characteristics of the designed radiating structure, the geometry of the array of two L-shaped quarter-wavelength slot antenna elements is firstly introduced.

The geometry of the proposed array of two L-shaped quarter-wavelength slot antenna elements is shown in Fig. 2. As described in [11], [15]-[16], a conventional L-slot antenna is composed of two slots connected at their ends with an angle of 90 degrees, with a total slot length near to a quarter-wavelength at the reference frequency. The antenna is fed by a 50 Ω microstrip transmission line on the opposite side of the substrate (FR-4 in our case) with respect to the slot antenna. Such a feeding line configuration does not impact on weight and size of the entire system and it is suitable for the integration with electronic devices. As shown in Fig. 2, the total current on the ground plane can be decomposed in three parts; in particular, currents I_1 and I_2 have opposite directions and therefore their contribution vanishes, leaving only the contribution of current I_3. Therefore, the L-shaped slot antenna works as a small dipole oriented in the *y*-axis, with a bidirectional pattern in the *xy*-plane. Furthermore, due to the shape of the ground plane that has a larger area in the direction of the feed point, the antenna presents a directional pattern in *xy*-plane, with a main lobe direction oriented toward *x*-axis. Typically, the L-shaped slot antenna exhibits a gain in the maximum radiation direction similar to that of a dipole.

The proposed array consists of two L-shaped quarter-wavelength slot antenna elements, arranged at a distance of about a quarter of the wavelength at the reference frequency and perpendicular to each other. The resulting radiation pattern rotates of about 45 degrees from *x*-axis in the azimuth plane and the gain in the main lobe direction is about 5.09 dBi. The greater gain with respect to a dipole antenna gives the possibility to reduce the transmission power and hence extend the lifetime of a mote. The proposed array architec-

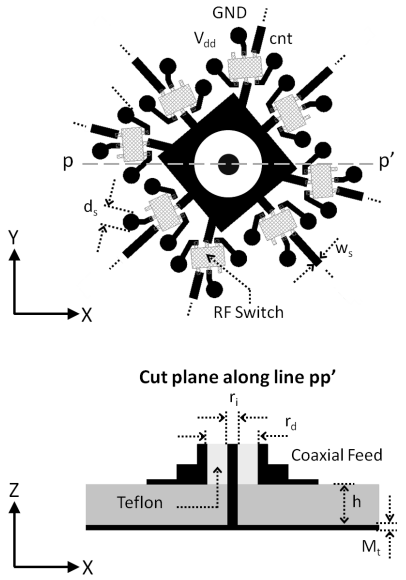

Fig 3. Detailed structure of the proposed switched-beam antenna, corresponding to Block B in Fig. 1.

ture is a good solution to increase energy efficiency or to reduce multipath effects, but it may deteriorate network performance if the signal comes from the directions of the nulls. For this reason, some arrays have been combined in order to have a uniform coverage of the 360 degrees in the azimuth plane.

The whole antenna structure is shown in Fig. 1 whilst the detailed parts, Block A and Block B, are depicted in Fig. 2 and 3 respectively. The antenna consists of four arrays of two L-shaped quarter-wavelength slot antenna elements arranged in a symmetrical planar structure. Basically, the array is replicated three times and rotated 90 degrees along the axis perpendicular to the *xy*-axis and passing through the center of the circumference with radius *r*. The radiating structure is fed by a 50 Ω SMA connector at the center of the antenna, so that the feeding point is sufficiently far from the radiating elements and does not interact with them. The eight microstrip transmission lines are interrupted by RF switches that control the feeding of the antenna elements. In Fig. 3, the structure of the feeding point and the digital circuit that controls the RF switches are shown. Powered through the lines V_{dd} and *GND*, the state of the RF switches is controlled by the signal *cnt*; when *cnt* is set to 3V, the microstrip line is connected and the relative antenna element radiates, otherwise when it is set to 0V the switch opens the line.

As described above, the array of two L-shaped quarter-wavelength slot antenna elements exhibits a directional radiation pattern with the main lobe direction oriented as the bisector of the angle identified by the two antenna elements. Thanks to the symmetrical replication of the array, the antenna can illuminate a specific direction that is $n\ \pi/2$ in the azimuth plane, where n = 0,...,3. Moreover, feeding two non-adjacent L-shaped elements (in particular Ant1-Ant3, Ant3-Ant5, Ant5-Ant-7 and Ant7-Ant1) other four patterns toward the directions $(1+2n)\ \pi/4$, where n = 0,...,3, can be obtained. Therefore, by carefully setting the *cnt* control line of the RF switches, the proposed antenna can switch among eight symmetrical radiation patterns spaced 45 degrees from each other.

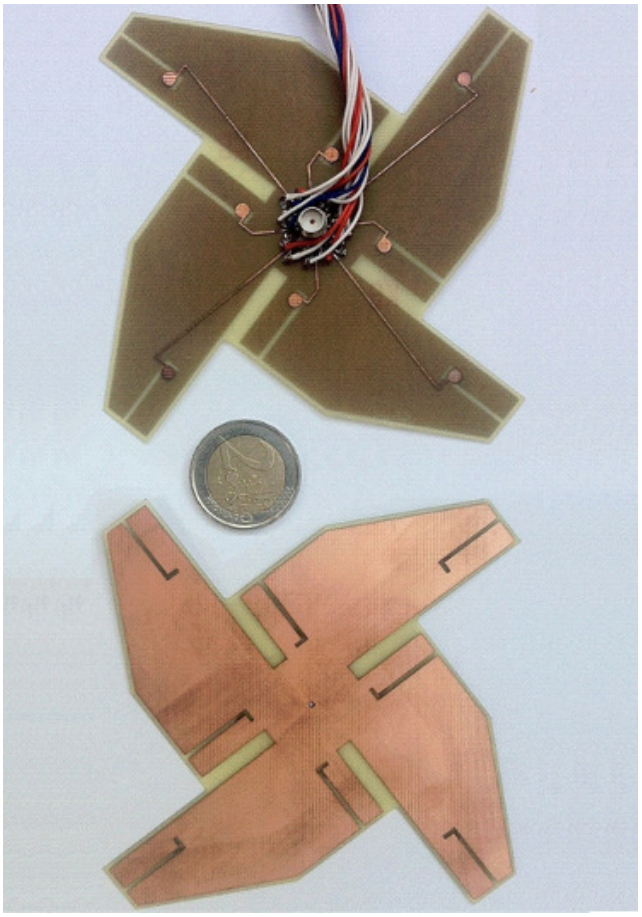

Fig 4. Proposed switched-beam antenna prototype (both sides).

IV. Simulated and Experimental Results

Several tests and measures have been performed in order to obtain an accurate characterization of the electromagnetic properties of the proposed antenna; for this purpose, a very cost-effective prototype of the switched-beam antenna with an overall size of 10 x 10 cm^2 has been fabricated through a technique described in [17]-[18], using an FR-4 substrate with thickness M_t = 0,8 *mm* and dielectric constant ε_r = 4,7 @ 2,45 *GHz* (see Fig. 4). The detailed design parameters of the proposed switched-beam antenna are listed in Table I. The used switches are the Peregrin PE4283 RF UltraCMOS switches with a single-pin CMOS logic control input, a 1.5 kV ESD tolerance, a low insertion loss of 0.65 dB at the reference frequency, an isolation of 33.5 dB between the output ports, a +3 V supply input and an operation band ranging from DC to 4GHz. The study of both radiation patterns and current consumption has been performed through the use of STM32W-EXT WSN boards with a 32 bit ARM micropro-

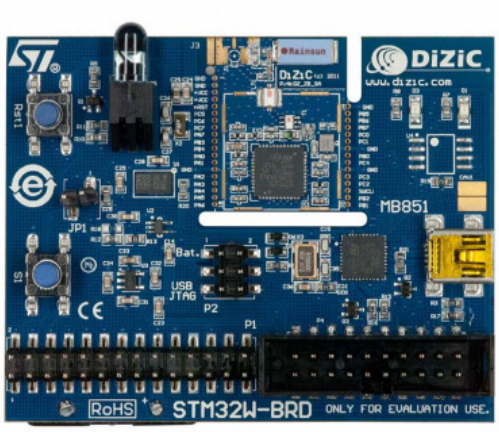

Fig 5. The STM32W-EXT WSN mote used for the experimental measurement.

cessor and an IEEE 802.15.4-compliant transceiver (see Fig. 5).

A. Antenna characterization

In order to characterize the antenna from an electromagnetic point of view, the reflection coefficient and the radiation pattern have been simulated and measured by varying the feeding configurations. In particular, the entire RF structure has been firstly modeled with the full-wave simulator CST- Microwave Studio [19] where the RF switches have been taken into account by means of proper equivalent circuits according to the datasheet. Return loss and radiation properties have been consequently calculated.

As described above, the proposed antenna presents eight switchable directional patterns, four of which, due to the feeding of Ant1-Ant2, Ant3-Ant4, Ant5-Ant6 and Ant7-Ant8 elements, are determined by the same feeding configuration (Conf 1) whereas the other four, due to the feeding of Ant1-Ant3, Ant3-Ant5, Ant5-Ant7 and Ant7-Ant1 elements, are determined by a different configuration (Conf 2). For such a reason, without loss of generality, only data referred to Conf 1 and Conf 2 will be discussed hereafter.

In Fig. 6 and Fig. 7, the measured return loss obtained through a Vector Network Analyzer (VNA) Agilent 3444/7 is compared with the simulated results showing a very good agreement. In particular, both Conf 1 and Conf 2 exhibit an appreciable impedance matching with an observed return loss smaller than -10 dB within the bandwidth of interest.

In Fig. 8 and Fig 9, the simulated radiation patterns in the azimuth ($\varphi = 0^o$), are reported in order to better appreciate the capability of the proposed antenna to correctly orientate the beam when varying the switch configuration. In particular, Fig. 8 is referred to the feeding of the L-shaped antenna element Ant1-Ant2 (belonging to Conf 1 scheme), and Fig. 9 to the feeding of Ant1-Ant3 (belonging to Conf 2 scheme), resulting in two adjacent radiation patterns separated by an angle of 30 degrees. The obtained main lobe magnitude for Conf 1 and Conf 2 are respectively 5.09 dBi and 4.85 dBi, the side lobe levels are respectively -15 dB and -14 dB and the cross-polarization levels are respectively -21 dB and -20 dB. Moreover the Half power beam width (HPBW) is nearly 70 degrees in the azimuth plane for both configurations, according to the proposed design specifications. As can be seen, the proper functioning of the proposed switched-beam antenna, in terms of overlapping area and beam width, are demonstrated.

TABLE I.
DETAILED PARAMETERS OF DESIGNED ANTENNA

Parameters	Value [mm]	Parameters	Value [mm]

r_i	1,3	r_d	4

As further validation, in order to accurately characterize the radiation properties of the proposed antenna, several tests with WSN nodes operating in the ISM band have been performed. In particular, two STM32W108B-KEXT devices have been used, one connected to the proposed antenna and statically positioned in the middle of a 50x50 m^2 area, and the other, with a standard omnidirectional configuration, used to measure the number of packets received in different points of the same area (see Fig. 10). For each radiator, the diagram individuating the portion of the area where more than 95% of the sent packets is correctly received corresponds to the related actually covered area. As shown in Fig. 11 the measurement points are disposed on concentric circumferences with a minimum radius of 10 m (R1) and a maximum radius of 45m (Rn) with an angular distance of 10°. In particular, Fig. 12 and 13 show the obtained diagrams for the two feeding configurations previously introduced (blue curve) and for the canonical dipole (green curve); black dots represent measurements points (see Fig. 11 for the experimental setup). In each case, the lower emitted power has been considered. As expected, it can be observed the proper functioning of the proposed switched-beam antenna, that guarantees a longer working range than the half-wavelength dipole, which is, as expected, substantially omnidirectional in the azimuth plane. Alternatively, a lower power could be radiated to guarantee the same working distance. Moreover, as desired, coverage areas associated to the two feeding configurations guarantee a suitable overlapping area and a beam width compatible with the simulated one. In fact, despite conceptually different, the behaviour of the radiation patterns of Figs. 8 and 9 can be com-

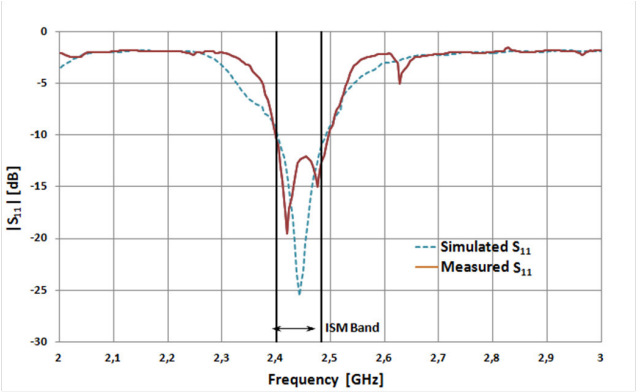

Fig 6. Simulated and measured reflection coefficient for the Conf 1 feeding configuration.

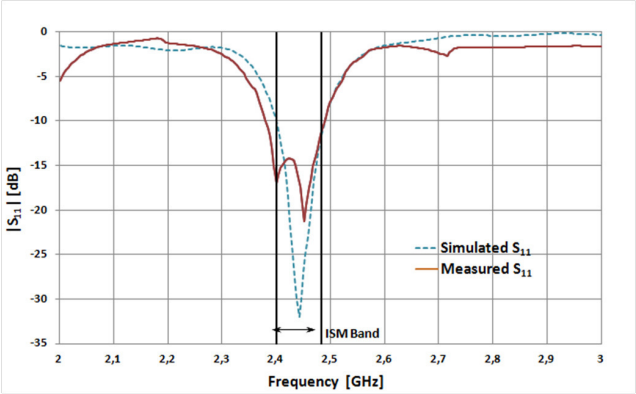

Fig 7. Simulated and measured reflection coefficient for the Conf 2 feeding configuration.

pared with those of the diagrams of Figs. 12 and 13. A substantial agreement can be observed for both feeding configurations previously introduced.

B. *Power consumption*

Several tests have been performed in order to accurately measure the power saving performance of the proposed antenna system. Similarly to the radiation patterns measurement, RSSI values estimated by STM32W-EXT WSN boards connected to the proposed antenna have been used also in this case. As previously explained, when the proposed antenna is used in place of the almost omnidirectional antenna of a mote, greater energy efficiency can be obtained. In order to estimate the power saving, the lower transmission power level P_{tl} to be set on the mote equipped with the proposed antenna, with respect to a canonical mote, must be calculated. For this purpose, a study on the received power varying the distance between the motes has been conducted. For such a purpose, it is considered that the most realistic way to correlate the RSSI to the distance is to use the Log-Normal Shadowing Model (LNSM) [20]-[22] which is able to predict the signal path loss in both indoor and outdoor conditions. This model is an extension particularly suitable for WSN context of the more general log-distance path loss

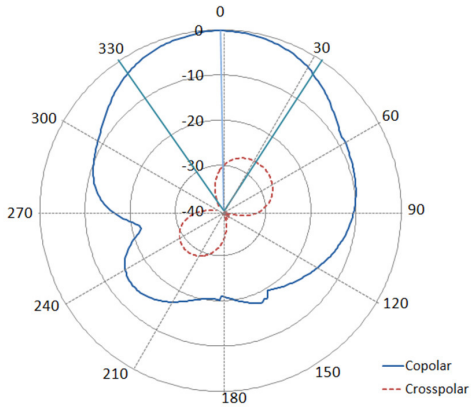

Fig 8. Simulated radiation patterns for the Conf 1 feeding configuration in the azimuth plane.

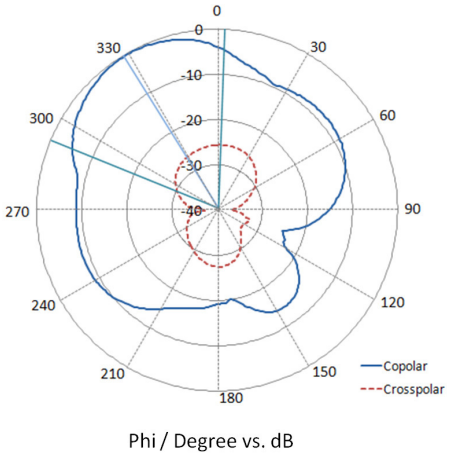

Fig 9. Simulated radiation patterns for the Conf 1 feeding configuration in the azimuth plane.

model described in [20]. Indeed, this last does not consider that the measured power values can be very different from the predicted average ones, as the reflections caused by irregularities of the surrounding environment result in a variance of the measured values. LNSM states that the path loss follows a log-normal distribution (normal in dB) due to the phenomenon called log-normal shadowing. Therefore the received power have a Gaussian distribution with zero mean and can be expressed as:

$$P_r(d) \sim N(\overline{P_r(d)}, \sigma^2)[dBm] \quad (1)$$

where $P_r(d)$ is the average received power and σ^2 is the variance related to the effects of reflections. According to LNSM the equation (1) can be rewritten as:

Fig 10. Measurement setup for the evaluation of the models and the diagrams of the average RSSI.

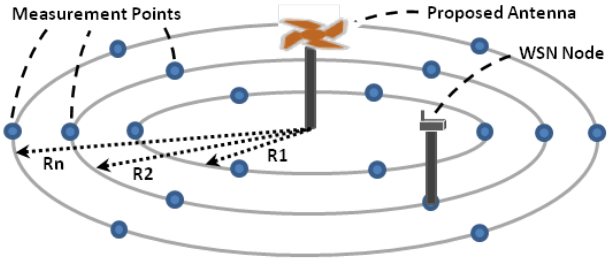

Fig 11. Experimental setup used for the evaluation of the diagrams of the coverage areas.

$$\overline{P_r(d)} = \overline{P_r(d_0)} - 10\, n\, \log_{10}\left(\frac{d}{d_0}\right) + X_\sigma \; [dBm] \quad (2)$$

where $P_r(d_0)$ is the power received at a reference distance d_0 that must be appropriate to the measurement context (in this case we selected a reference distance equal to 10 m), n is the path loss exponent that indicates how the received signal degrades in relation to the distance and depends on the electromagnetic characteristics of the surrounding environment, X_σ is a normal random variable with zero mean.

To obtain a relationship between the received power and the distance between motes, it is necessary to estimate n and X_σ; in practice, they are calculated from the measured power values at various distances, using the linear regression model:

$$\overline{P_r(d)} = \alpha + \beta \log_{10}(d) \; [dBm] \quad (3)$$

where $\alpha = P_r(10) + 10n + X_\sigma$ and $\beta = -10n$. The path loss model of equation (3) can be used to estimate the distance between the transmitting and receiving mote as follows:

$$d = 10^{\frac{\overline{P_r(d)} - \alpha}{\beta}} \; [dBm] \quad (4)$$

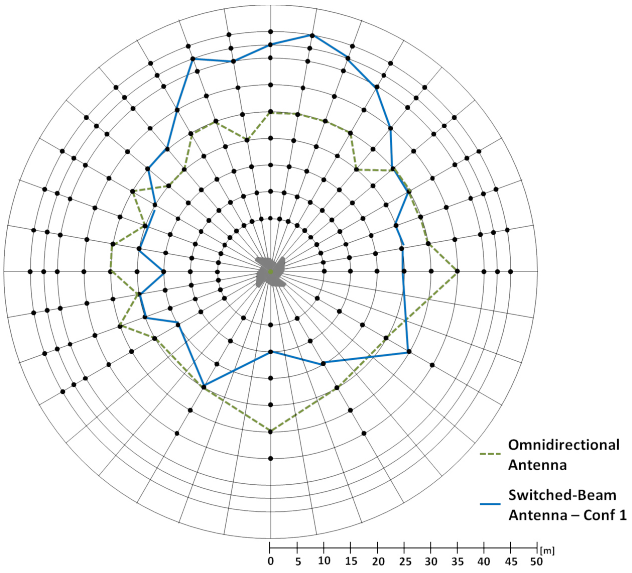

Fig 12. Diagram representing the regions where the WSN node in Conf 1 mode correctly receive more than 95% of packets.

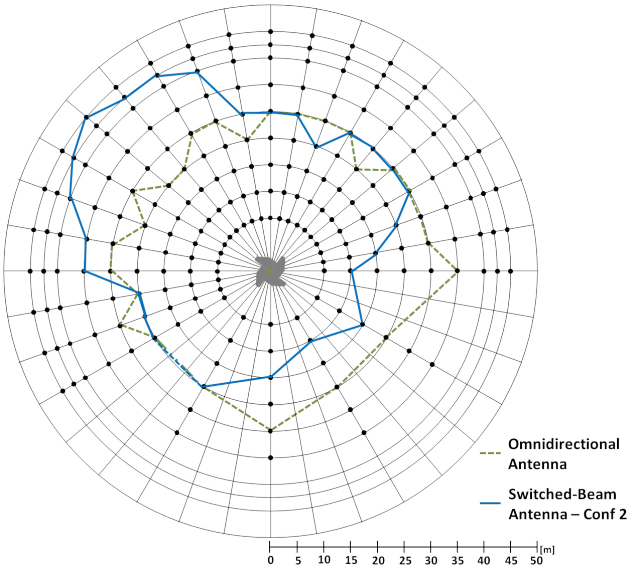

Fig 13. Diagram representing the regions where the WSN node in Conf 2 mode correctly receive more than 95% of packets.

In order to calculate the α and β parameters, and accordingly n and X_σ, several tests have been performed by varying both transmission power and distance and positioning the motes at an height of 1.5m. In particular, two kinds of tests have been performed in Line Of Sight (LOS) condition with surrounding obstacles. The former kind, named T1, has been performed using two motes equipped with a dipole antenna and setting the level P_{tl} to +3 dBm. Vice versa, the latter kind of tests, named T2, has been conducted using the proposed antenna and varying P_{tl}. In Fig. 14, the obtained results related to T1 and T2 tests, this last with P_{tl} to -3 dBm,

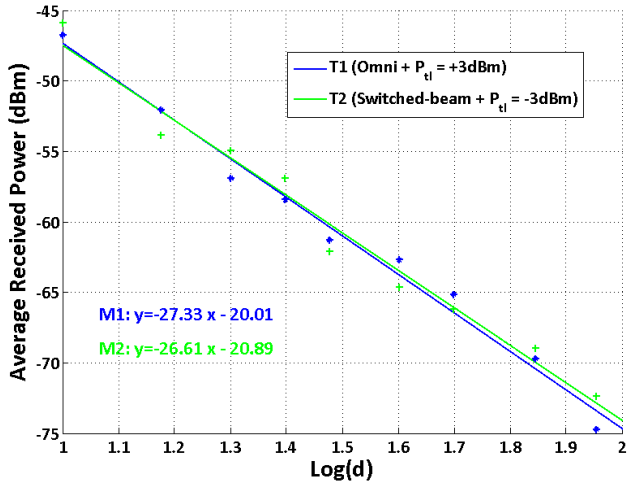

Fig 14. Average received power versus log(d) for the four tests performed.

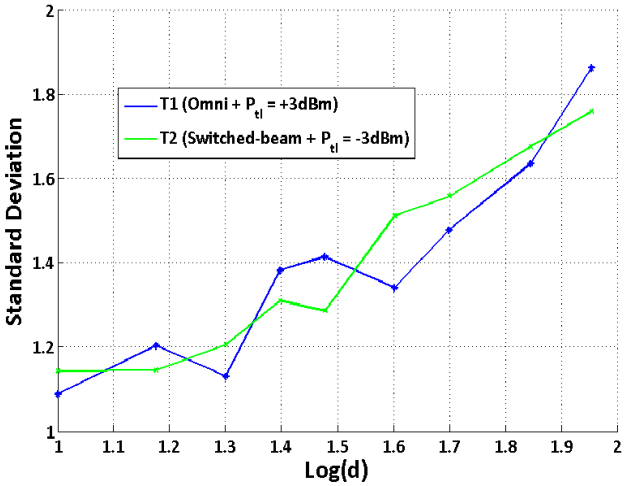

Fig 15. The standard deviations in RSSI measurements for T1 and T2

are reported. As can be seen, despite the strong difference in terms of emitted power, the two curves are in very good agreement; moreover, it is worth observing that measured RSSI values exhibits a linear dependence with log(d). By relating the linear regression model in equation (3) with the experimental measurements performed, the parameters n and X_σ have been determined and reported in Table II.

Fig. 15, shows the standard deviations in RSSI measurements at each distance for the T1 and T2 tests. As can be expected, the deviation in RSSI measurements increases with the distance between the nodes.

Once the parameters n and X_σ are known, α and β parameters can be straightforwardly be calculated and used in equation (4) to obtain the distance as a function of the received power. In Table 3 the estimated distance and the estimation error for the two tests considered are reported. In particular, Fig. 16 shows the comparison between the measured and estimated distances; the closeness of the curves proves the accuracy of the found models.

The presented results confirm the appropriateness of the proposed switched-beam antenna system as hardware element enabling new power-efficient WSNs. Indeed, as shown in Fig 14, the model M1 and model M2 are very similar. This is a crucial result because it allows a fair comparison in terms of power saving when the proposed antenna is used in place of the canonical dipole. Indeed, it is clear that, despite the different Ptl values, T1 and T2 configurations determine the same mote performance.

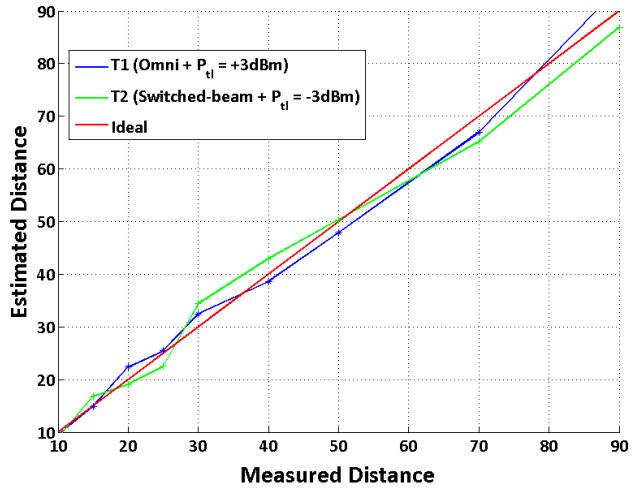

Fig 16. Measured versus estimated distance for the four models.

tests versus log(d).

V. Conclusions

This work proposes a switched-beam antenna particularly suitable for WSN applications. It is composed of four arrays of two L-shaped quarter-wavelength slot antenna elements arranged in a symmetrical planar structure. According to the context-dependent needs of the WSN, one among eight different radiation patterns can be selected by means of properly designed control lines. The antenna system has been rigorously characterized and has been then extensively tested in place of a canonical antenna mounted on a commercial WSN mote. The obtained and discussed results are really encouraging. Indeed, in spite of a very appreciable compactness and cost-effectiveness, the proposed switched-beam antenna guarantees a considerable power saving if compared with traditional and almost omnidirectional WSN mote antennas.

Information Technology for Management, Business & Society

IT4MBS is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to the disciplines of information technology and information systems. The IT4BMS area emphasizes the issues relevant to information technology and necessary for practical, everyday needs of business, other organizations and society at large. This area takes a sociotechnical view on information systems and relates also to ethical, social and political issues raised by information systems.

Events that constitute IT4BMS are:

- **ABICT'14** - 5th International Workshop on Advances in Business ICT
- **AITM'14** - 12th Conference on Advanced Information Technologies for Management
- **IT4L'14** - 3rd Workshop on Information Technologies for Logistics
- **KAM'14** - 20th Conference on Knowledge Acquisition and Management
- **SS4SI'14** - 1st International Symposium on Service Systems for Social Innovation

5th International Workshop on Advances in Business ICT

ABICT focuses on Advances in Business ICT approached from a multidisciplinary perspective. It will provide an international forum for scientists/experts from academia and industry to discuss and exchange current results, applications, new ideas of ongoing research and experience on all aspects of Business Intelligence. ABICT will be also an opportunity to demonstrate different ideas and tools for developing and supporting organizational creativity, as well as advances in decision support systems.

We kindly invite contributions originating from any area of computer science, information technology and computational solutions for different applications areas, data integration and organizational implementation of ABICT, as well as practical ABICT solutions.

Topics

Topics include (but are not limited to):

- Advanced technologies of data processing, content processing and information indexing
- Analytics as a service
- Big Data: benefits and challenges
- Business Analytics
- Business applications of social networks
- Business data mining and knowledge discovery
- Business Intelligence
- Business Rules
- Business-oriented time series data mining, analysis, and processing
- Cloud based Business Intelligence
- Creativity Support Tools
- Customer Relationship Management, social Customer Relationship Management
- Data driven marketing
- Data Warehousing
- Decision support
- Information forensics and security, information management, risk assessment and analysis
- ICT technologies in enterprise management
- Knowledge Management (for better Decision Support, Collaboration and Competitiveness)
- Legal text processing
- Semantic Web and Ontologies in Business ICT
- Virtual Enterprise
- Web 2.0 and Web 3.0 in fusing Business Intelligence systems and Decision Support Systems
- Web-Based Data Management Systems

***Abstract*—The paper presents some problems of logical coherence while reasoning temporally. It shows the importance of these problems in some application domains for temporal intelligent systems, e.g. in legal domain. It then presents Logos reasoning tool and its inference techniques, it also shows how Logos can handle temporal rules now, and it points out what should still be done in order to make the system resistant to temporal reasoning logical problems.**

I. Introduction

TIME indispensable representation in many artificial and temporal intelligence reasoning systems [1]. are It is so, because time is a basis for reasoning about change and actions. Many AI systems concern the currently changing economic environment (see e.g. [2]). Therefore, if the decisions taken on the basis of system's advice are to be correct, the system has to take into account the temporal dimension of information, the changes of information in time and has to be aware of the nature of those changes [1]. Therefore the need for representing temporal knowledge in artificial intelligence systems is nowadays obvious. Even intuitively, one can feel the need of capturing a temporal aspect of relationships between objects in AI systems.

Representation of knowledge changing in time and temporal reasoning have to be based on some formal foundations. One of such foundations is the language of logic, both the classical as the modal one (see e.g. [3], [4]). The shortest motivation for using the temporal logic may be found in [5], where it is concluded, that "in order to introduce temporal relationships (...) it is necessary to broaden the formal apparatus with the temporal logic" (p. 429).

The paper is organized as follows. In section 2 the general view of temporal knowledge is given. Section 3 contains a few examples of temporal knowledge engineering problems. Section 4 is devoted to the discussion on inference techniques already implemented in the Logos tool. The next section shows the importance of knowledge verification as important knowledge engineering process, and how it is handled by Logos. In section 6 we provide an example of temporal reasoning in the Logos system. The paper ends with summary and conclusions.

II. Knowledge Engineering Problems

The tasks for a temporal AI system encompass among others:

- maintaining temporal coherence,
- answering temporal queries,
- explanations,
- prediction, etc.

The most commonly known domains, in which there is a need for an explicit time notion, are: natural language processing (NLP), planning, robotics, image processing, medical diagnosis, and law [1], [2]. In all of the above mentioned domains, change has a primary meaning. Introducing time in an explicit way allows for reasoning about changing domains, also about the economic one. It also allows for a computer simulation of human reasoning process, because people reason about action and change [3]. In particular, there are described such notions, as change, causality or actions, therefore the proper representation of time and temporal reasoning are so important in (among others) artificial intelligence [1]. If an AI system is to simulate intelligent behavior, to adapt to changes in the environment, or to verify its beliefs, it has to be able not only to gain new knowledge, but also to keep its knowledge in an up to date state. Knowledge changes – due to two basic reasons. The first is simply the passage of time. The second reason is due to new information on objects, which possess temporal characteristics [4].

III. Knowledge Engineering Problems

There exist several problems which one has to overcome in some way to reason consistently about time and change. In the paper there will be mentioned three problematic issues: the TBS (Tossed Ball Scenario), the DIP (Divided Instant Problem), and finally the FP (Frame Problem).

Tossed Ball Scenario (TBS)

The problem called the Tossed Ball Scenario is connected with the question of temporal primitives in the ontology of time. As temporal primitives there can be chosen [1]:

- time points (also called instants) – as for example in McDermott's logic;
- time periods (also called intervals) – as for example in Allen's interval calculus;
- both primitives.

In logic systems using the notion of time points (instants), there is a question of modeling continuous change (e.g. in the environment). This is considered a problematic issue, because

978-83-60810-58-3/$25.00

to do it properly one must be able to describe fluents that hold at an instant, more precisely – an isolated instant.

Divided Instant Problem (DIP)

The problem is similar in its nucleus to the TBS. It consists of establishing logical value (truth-value) of a fluent f at an instant i, if f is true on period p1 and false on period p2, given that p1 ends at i and p2 begins at i. Of course we assume that we take instants and periods as temporal primitives. Let us discuss the problem using an example given by [5]. Consider fig. 1:

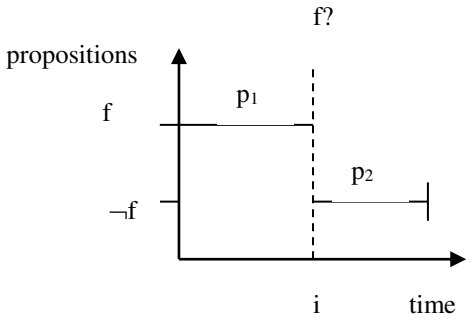

Fig. 1.: Divided Instant Problem [6]; "f" denotes fluent, "p1" and "p2" denote periods.

Vila gives an example concerning light. If fluent f means "the light is on", then on p_1 light is on and on p_2 light is off. Question: is the light on or off at i? More generally: what is a truth-value of the proposition at i?

Frame Problem (FP)

The frame problem is one of the central theoretical issues of artificial intelligence. The problem arises when logic is used to describe the effects of actions and events. The frame problem(s) appears in all approaches to reasoning about action and change [6].

In order to be historically correct, the first description of this problem has been done by McCarthy and Hayes in 1969 [7]. While working on situation calculus they noted that a problem occurs when there are several actions available, each of which changes certain features of the situation.

The classical examples of such problems are: 'Yale Shooting Problem' , 'Stolen Car Problem' and others [8]. Let's take a look on the first example. Given the sequence of events at times as denoted by the times of their assertion t(n):

t(0): I (now) pick up a loaded gun

t(1): I unload it

t(3): I point the gun at my head

t(4): I pull the trigger

The answers to the question: 'Am I alive?' should be negative as the representation did not contain the information that the gun was still unloaded (there is no information about the change of fact - gun is unloaded in t(3)).

There were already many attempts to solve the above enumerated logical problems, e.g. by [5] or by [9]. Especially the results obtained by Reiter are interesting, as he uses situation calculus. And this formalism or its mutation called Golog [10] are planned by us to be implemented in the intelligent system Logos. Therefore we hope Logos will be able not only to reason temporally, but to do it in a consistent way, that is the tool will be resistant to temporal logic inference problems. Some previous remarks on reasoning temporally about the legal domain in Logos were published in [11]. Logos now achieved the status of a research prototype and is treated as environment and reasoning engine for temporal knowledge bases experiments.

In the next section we will present currently implemented reasoning strategies in Logos, and we will show how the tool can now handle temporal rules.

IV. Inference in Logos

In present version of Logos system we successfully implemented four variants of inference:

1. Top-down inference using two-valued logic,
2. Top-down inference using Stanford Certainty Factor Algebra,
3. Bottom-up inference using two-valued logic,
4. Bottom-up inference using Stanford Certainty Factor Algebra.

Each of these methods of inference can operate in two modes: with askable or not askable conditions. The top down inference is goal-driven and is similar to that used in logic programs with backtracking mechanism which makes it possible to find all solutions to a given problem. Generally this method of inference is based on resolution principle developed by Robinson [12]. The whole process of inference starts with a given goal:

```
<- C1,..,Cm
```

In procedural interpretation each step of computation relies on matching of a given goal C_i with the head of any procedure in knowledge base. Procedure is Horn clause (rule) of the following form:

```
A <- B1,..,Bn
```

Where $\{C_1,..C_k,A, B_1,..,B_m\}$ are atomic formulas. In our implementation those atomic formulas take the form < O, A, V >, where O is identifier of object, A is identifier of attribute and V represents value. Value can be symbol (more generally any string), numeric constant or variable.

If the mentioned matching is not possible, we call it failure. If the matching of C_i is successful, then current goal is being reduced to the following form:

```
<- (C1,..,Ci-1, B1,..,Bn,Ci+1,..,Cm)Θ,
```

where Θ is called matching substitution, mainly concerned with assignment of temporary values to variables.

The inference process finishes when the goal is reduced to empty clause.

The bottom-up inference, as implemented in our system, starts from facts and using rules of knowledge base finishes with generation of set of conclusions.

While building inference module of Logos we assumed that in temporal knowledge base some parts of knowledge (facts or rules) can be to some degree uncertain, so we implemented

Stanford Certainty Factor Algebra. We chose this method because of the simplicity of its use and good practical verification. In this method for given rule R:

R: C if W with CF(R)

is assigned certainty factor CF(R) and its value is in the range <-1; 1>. The current CF for a conclusion of the rule R is dynamically computed in the following way:

$$CF(C) = CF(R) * CF(W).$$

If antecedent of a given rule consists of a set of conditions e.g. W_1 and W_2 joined by disjunction or conjunction its value is calculated as follows:

$$CF(W1 \wedge W2) = MIN \{ CF(W1), CF(W2) \}$$
$$CF(W1 \vee W2) = MAX \{ CF(W1), CF(W2) \}$$

During inference, especially using bottom-up (forward chaining) method it is possible that several rules add the same conclusion to the working memory of the knowledge base. In such situation the CF of the added conclusion have to be dynamically changed. Calculation of the new CF for two rules R_1 and R_2 is as follows:

$$CF(C) = CF(R1) + CF(R2) * (1 - CF(R1))$$
if $CF(R1) > 0$ and $CF(R2) > 0$

$$CF(C) = CF(R1) + CF(R2) * (1 + CF(R2))$$
if $CF(R1) < 0$ and $CF(R2) < 0$

$$CF(C) = (CF(R1) + CF(R2)) / (1 - MIN \{ |CF(R1)|, |CF(R2)| \}),$$

when the signs of $CF(R_1)$ and $CF(R_2)$ are different.

The next step of our empirical research will attempt to implement inference of temporal situation calculus method using reasoning schemes of already implemented methods. Problem of uncertainty will be important part of the temporal inference and knowledge representation language.

Logos inference engine is equipped with rich set of explanation facilities, among others:

- How explanations,
- Why explanations,
- Metaphors,
- What is explanations and
- Facts descriptions.

How explanations show the way the conclusion has been derived and can be used after the end of reasoning process. Why explanations explain the reason system asked a question during consultation. In this case Logos shows the current context of reasoning and shows in what way the answer will contribute to solving the problem. Metaphors enable knowledge engineer to attach more textual information about selected rules, what can be useful at initial stage of using the application. What is explanation provide more detailed, textual information about conclusions as well as some questions. It is also possible to attach some explanations to facts, in the form of facts descriptions, e.g.: source of information or availability of deeper/further How explanations (in the blackboard architecture) showing how the fact has been derived during consultation.

The mentioned explanations are equally important in usual knowledge bases and in the temporal ones.

V. Knowledge Verification as Important Knowledge Engineering Process

As it has been already mentioned, one of the main aims of our research is creation of temporal knowledge base using Logos system. To this end we started building special reasoning system called Logos which will be kind of experimental environment. One of our assumptions is that appropriate verification algorithms are necessary to provide solid foundation for temporal reasoning. At present we implemented broad range of knowledge base anomalies detection procedures, among others [13]:

1. Redundant rules,
2. Subsuming rules,
3. Contradictory rules,
4. Recursive rules (circular loop).

Ad. 1.

Two rules we call redundant if

$R_i \leftarrow C_{i1} \wedge \ldots \wedge C_{in}$ and $R_j \leftarrow C_{j1} \wedge \ldots \wedge C_{jn}$

where R_i and R_j are conclusions and C are conditions and $i \neq j$, holds: $\{ C_{i1}, \ldots, C_{in} \} = \{ C_{j1}, \ldots, C_{jn} \}$.

Ad. 2.

If for two different rules: $R_i \leftarrow C_{i1} \wedge \ldots \wedge C_{im}$ and $R_j \leftarrow C_{j1} \wedge \ldots \wedge C_{jn}$ and $i \neq j$,

holds $\{ C_{i1}, \ldots, C_{im} \} \subset \{ C_{j1}, \ldots, C_{jn} \}$, then we say that rule R_i subsumes rule R_j.

Ad. 3.

Two rules are regarded as contradictory if $R_i \leftarrow C_{i1} \wedge \ldots \wedge C_{in}$ and $R_j \leftarrow C_{j1} \wedge \ldots \wedge C_{jn}$ where $i \neq j$.

Ad. 4.

We distinguish in Logos two kinds of the recursion: direct and indirect. The notion of direct recursion is consistent with notion of circular rule set by Vermesan [14]: a rule set is circular iff the antecedents cannot be derived from any other rule except given rule consequent.

Typical situations are as follows:

$q \leftarrow q, p_1, .., p_n$

$q \leftarrow p_1, .., p_1, q, p_m, .., p_n$

$q \leftarrow p_1, .., p_n, q$

In practice the circular loop can be much more complicated and engage some set of rules (see fig. 2). Detection of such situation is more difficult but is necessary the knowledge base to function properly. Exemplification of this kind of indirect recursion can be as follows:

$q_1 \leftarrow p_{11} \wedge .. \wedge p_{1j} \wedge .. \wedge p_{1x}$

$q_i \leftarrow p_{i1} \wedge .. \wedge p_{il} \wedge .. \wedge p_{iy}$

$q_n \leftarrow p_{n1} \wedge .. \wedge p_{nm} \wedge .. \wedge p_{nz}$

where $p_{1j} = q_i$, $p_{il} = q_n$, $p_{nm} = q_1$.

where "=" has more general meaning and denotes beside equality/identity ability of instantiation and matching . Our system detects all levels of recursive interconnections between rules, what is important to guarantee correct behavior of knowledge base in practical use.

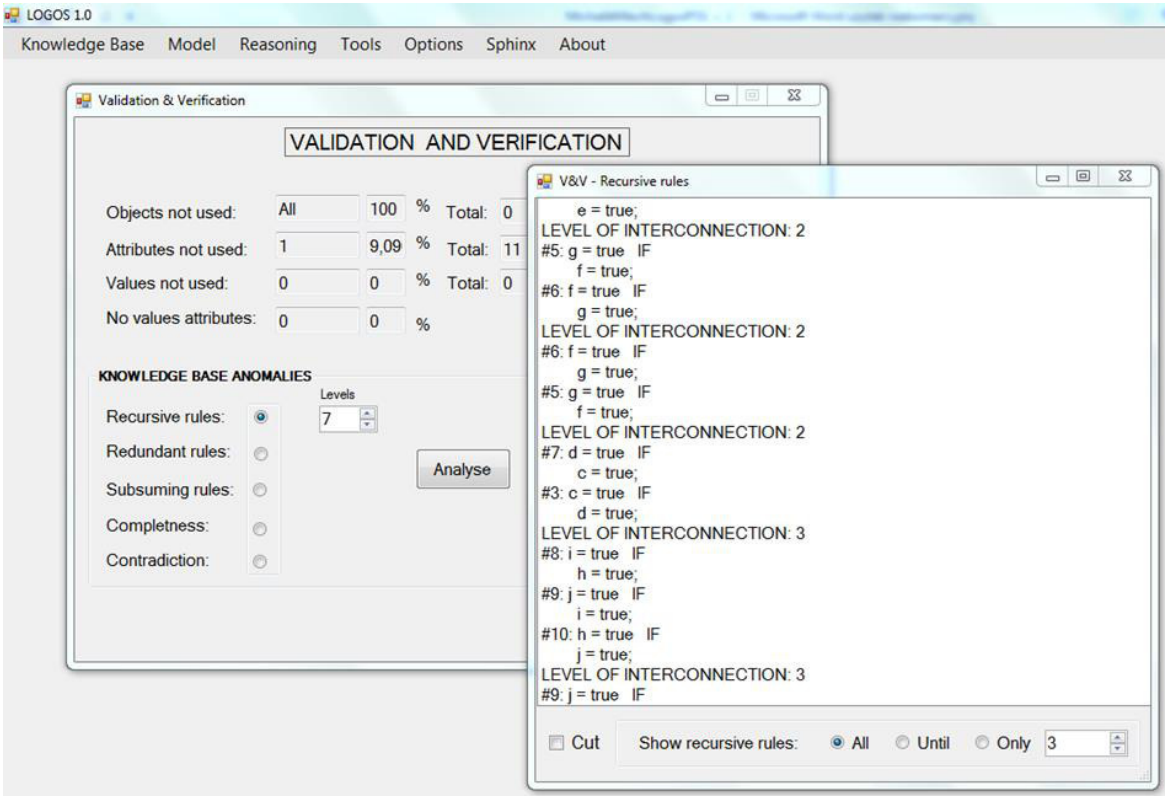

Fig. 2. Sample circular loop in Logos.

Source: own elaboration.

What is very important, we expect that full implementation of temporal knowledge base and temporal inference will require some specific verification algorithms in response to anomalies in temporal knowledge base. At this stage of our empirical research it is difficult to precisely point out these anomalies, it will be subject of further investigations.

VI. Temporal Reasoning in Logos

To show how Logos performs temporal reasoning, we have chosen an example arising from Polish act on economic activity. It concerns the obligation to obtain a license for certain economic activities: a certain enterprise wishes to perform an activity, that needs a license obtained from the state.

The act issued in 1988, that has been valid from January 1st 1989 till December 31st, 2000, stated, that "A license is given indefinitely"; while the act issued in 1999, valid from January 1st, 2001 till July 19th, 2004 stated: "A license is given for a specific period of time, not shorter than 2 years and not longer than 50 years". The actual act of July 2nd, 2004, which is valid from July 20th, 2004 till now, states that "A license is given for a specific period of time, not shorter than 5 years and not longer than 50 years".

While analyzing the above statements as a temporal legal knowledge, we can distinguish such temporal elements as events (an act of granting an enterprise a license), objects (a license), temporal relations (not shorter than, not longer than), temporal constants (2 years, 5 years, 50 years).

The basic temporal elements are points (e.g. the date when a license is granted) and intervals (e.g. the period for which a license is valid). We may also consider – in a broader perspective – an event consisting of "license withdrawal" which of course always happens before the period of license validity ends. Therefore while formalizing legal statements one should choose a formalism that keeps total linear order of time, with precedence relation. The formalism has to be a point-interval one, as we have both types of basic temporal elements to be taken into consideration. All the above conditions are fulfilled by the model of calendar time.

If we take into account the regulations coming from both acts, we immediately see two of the three temporal aspects of legal knowledge, discussed earlier. These are namely "law in time" (three periods of legal acts validity) and "time in law" (a period for which a license is granted) aspects. The third aspect – "transitional law" – will not be discussed here.

The above cited law articles of our example may be also written in the form of general rules:

If a license is issued, then it is valid indefinitely (Act of 1988)

If a license is issued, then it is valid for a period not shorter than 2 years and not longer than 50 years (Act of 1999)

If a license is issued, then it is valid for a period not shorter than 5 years and not longer than 50 years (Act of 2004)

The rules may be formalized e.g. in the Legal Temporal Representation (LTR) language [15], and they are as follows:

```
  Attributes(license,{who_issues,who_gets
})
  Attributes(is_issued, {what})
  Attributes(valid, {what},_,)
  Granularity(day)
```

Rules for the 1988 Act:
Rule 1:

```
  If TT1:license(issuing_authority,
enterprise)
     TT2: is_issued(TT1)
     Occurs(TT2)
  Then Occurs(valid(TT1), instant(TT2))
```

Rule 2:

```
  If TT2: valid(TT1)
     Occurs(TT2)
  Then Holds_on(valid(TT1), period(TT3))
    Period(TT3)   Equals   [instant(TT2),
+inf]
```

The above rules state, that if a certain enterprise has been granted a license issued by a certain authority and it happened in the point (day) stamped by token TT1, then the license is valid from this day, and for indefinite time (that is, over an interval from TT1 to infinity).

Rules for the 1999 Act:
Rule 3:

```
  If TT1:license(issuing_authority,
enterprise)
     TT2: is_issued(TT1)
     Occurs(TT2)
  Then Occurs(valid(TT1), instant(TT2))
```

Rule 4:

```
  If TT2: valid(TT1)
     Occurs(TT2)
  Then Holds_on(valid(TT1), period(TT3))
    Period(TT3) Equals [2y, 50y]
```

Rules for the 2004 Act:
Rule 5:

```
  If TT1:license(issuing_authority,
enterprise)
     TT2: is_issued(TT1)
     Occurs(TT2)
  Then Occurs(valid(TT1), instant(TT2))
```

Rule 6:

```
  If TT2: valid(TT1)
     Occurs(TT2)
  Then Holds_on(valid(TT1), period(TT3))
    Period(TT3) Equals [5y, 50y]
```

As it can be easily seen, rules 4 and 6 differ from rule 2 only in the length of a period over which a license is valid, while rules 1, 3 and 5 are identical. Example of the use of the discussed rules for the reasoning along with HOW explanations in the Logos system is shown in fig. 3.

VII. Summary and Conclusions

As it has been mentioned, in some areas, especially in the legal domain, temporal reasoning is natural part of problem solving. Therefore it should be taken into account while building real-life decision support systems in that domain. Our research is aimed to add temporality to knowledge representation of legal knowledge for building more adequate knowledge base. At present stage of our work we are trying to build temporal knowledge base using Logos reasoning system. Important part of any knowledge-based system should be module for automatic detection of all possible anomalies in the knowledge base, so we implemented wide range of special algorithms for that purpose. The next step it will be adding more temporal relations to our system, and to implement temporal reasoning in the Situation Calculus in order to overcome logical inference problems, pointed out in this paper. If we are succeed as far as building prototype temporal knowledge base, we will try to implement such application into practice.

***Abstract*—Modeling based on a graphical notation understandable for different specialists has become very popular. Within the area of business processes, the most common one is the Business Process Modeling and Notation (BPMN). BPMN is aimed at all business users who design, analyze, manage and monitor business processes. Most papers in this area focus on making use of the possibilities that BPMN makes available, but there is lack of papers analyzing possible errors and ways of detecting and eliminating them. Specification of a BPMN diagram is relatively precise, but it is only a descriptive form presented at some abstract, graphical level. Hence, the main focus of this article is an attempt to analyze the topic of the anomalies which are likely to occur when modeling with use of BPMN.**

I. Introduction

CURRENTLY, the approach to modeling based on a graphical notations understandable for different specialists has become very popular. In the are of business processes the most common one is the Business Process Modeling and Notation (BPMN). BPMN is a business process modeling standard developed by Business Process Management Initiative. At present, BPMN is supported by the *Object Management Group* (OMG) because the two organizations merged in 2005.

In March 2011 the most recent specification of BPMN (BPMN 2.0) was released. The purpose of BPMN was to create a uniform notation of business processes that would be generally understandable — from professional process analysts, through managers to ordinary workers. According to [1], BPMN 'a standard Business Process Model and Notation (BPMN) will provide businesses with the capability of understanding their internal business procedures in a graphical notation and will give organizations the ability to communicate these procedures in a standard manner. Furthermore, the graphical notation will facilitate the understanding of the performance collaborations and business transactions between the organizations'. The main aims of BPMN include the following:

- process visualization which uses a graphical presentation of a business process. This form of visualization is much more effective than a textual representation;
- documentation through specification of process features;
- communication — provides a set of simple, commonly understandable notations.

BPMN is aimed at all business users, from the analysts, who create the initial process drafts, through the technical developers, whose responsibility it is to implement the technology performing those processes, and finally, to the business people, who will manage and monitor the aforementioned processes. The notation is clearly identified by various groups of experts, not only those connected with the IT industry. Yet, in spite of numerous endeavors, problems with unambiguous interpretation still exist. This fact stems from lack of a satisfactory BPMN interpreter. In fact as a consequence no semantics of BPMN components and connection is provided. Hence, various devices can interpret BPMN differently. The fact that there is no formal semantics may lead to misinterpretations and errors.

Most papers in the business process area focus on making use of the possibilities that BPMN brings, but there is lack of papers analyzing errors and ways of eliminating them. BPMN specification is precise but it is only a descriptive, graphical form. Hence, the subject of this article is an attempt to analyze the topic of the anomalies which are likely to occur in BPMN.

This paper is a kind of survey on anomalies in BPMN. An attempt has been made at presenting a taxonomy of possible problems, both of static, structural and dynamic nature. The research is based on literature analysis and some limited experience with BPMN models.

The article has been divided into five sections. The first one covers the basic elements of BPMN, the second presents an overview of the literature on anomalies. The consequent part touches potential misinterpretations and errors; it is based on examples. The last section contains the summary and conclusions.

II. ELEMENTS OF BPMN

BPMN model consists of simple diagrams made up of a limited set of graphical elements. Simplification of activity flows and processes is clearer for business users and developers. There are four main elements of BPMN, namely: Flow Objects, Connecting Objects, Swimlanes and Artifacts.

A. Flow Objects

Flow objects are the key elements describing BPMN. They consist of three core elements: events, activities and gateways [2].

An Event is represented by a circle and means something that happens (compared to an Activity, which is something

978-83-60810-58-3/$25.00

An Event is represented by a circle and means something that happens (compared to an Activity, which is something that has been done). The circular figures differ depending on the type of Event. Events may have an impact on a business process. An event can be an external or internal one. As long as they can influence the process being modeled, they should be modeled.

In general, there are three types of Events: Start, Intermediate and End. Start Event works like a trigger to a process. It is important for every process to have a Start Event to show the beginning of the business process. It allows readers to locate in the BPMN diagram where the process begins, and under what conditions. End event is used to indicate where the business process finishes. It presents the outcome of the process. Intermediate Event represents what happens in the gap between Start Event and End Event. It is responsible for driving a business flow based on the event it specifies.

An Activity is represented by a rounded-corner rectangle and describes a type of work that has to be completed within a business process. There are two kinds of Activities: Tasks and Sub-processes. Task means a single unit of work which is not or cannot by divided in the next stage of business processes specification; in certain sense a task is of an *atomic* nature. On the other hand, sub-process is used for complex work which can be divided into smaller units. It is applied in order to cover or uncover additional specification levels of business processes.

Gateways are elements used to monitor the way in which some business process flows interact with the others. A Gateway is represented by a diamond shape. Some of the typical types of gateways are the following ones:

- **Data-Based Exclusive Gateway** — it is used to control process flow based on given process data.
- **Inclusive Gateway** can be used to create parallel paths. (Fig. 1).

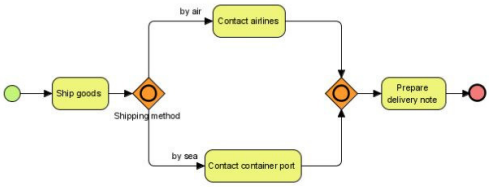

Fig. 1. Inclusive gateway

- **Parallel Gateway** — it is used to model the execution of parallel flows without the need of checking any conditions, all outgoing flows must be executed at the same time (Fig. 2).
- **Event-Based Gateway** — it is used to model alternative paths that are based on events (Fig. 3).

B. Connecting Objects

Flow objects are connected to each other using Connecting objects, which are of three types: sequences, messages, and associations [2]. Sequence Flow is used to show the order

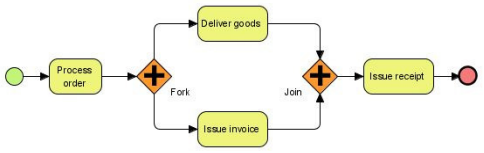

Fig. 2. Parallel gateway

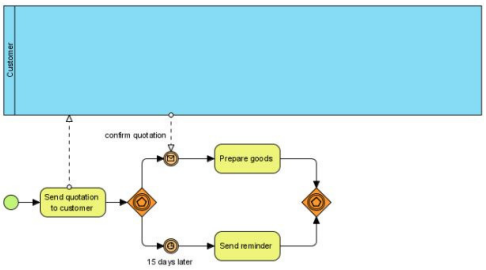

Fig. 3. Event-based gateway

in which particular activities will be performed in a process. Message Flow is used to show the flow of messages between two process participants entitled to send and receive them. Association is used to link information and artifacts to activities, events, gateways and flows.

C. Swimlanes

BPMN usually uses the concept of swimlanes in order to demonstrate what business function a particular activity is connected with or what system executes it. There are two types of swimlanes objects: lanes (sub-partition of pools) and pools (represent participants in a business process) [2].

Inside a pool, there are flow elements. It acts as a graphical container for partitioning a set of Activities from other Pools. Lanes can be used to represent specific objects or roles engaged in a process. They are used to organize and categorize activities in a pool, according to the function and role. They are represented by a rectangle extending either vertically or horizontally along the length of the pool. A lane contains flow objects, connecting objects and artifacts.

D. Artifacts

Artifacts are diagram elements used to display additional information relative to the process. They enable programmers to include more information in a model. In this way, the model becomes clearer. BPMN does not restrict the number of artifacts, though currently three have been defined [2]:

- *Data objects* are a mechanism whose aim is to show how data is prerequisite or result from activities. They are connected to activities though Associations.
- *Groups* can be used for analysis or documentation objectives but they do not affect the sequence flow.
- *Annotations* are a mechanism used in modeling to provide additional text information for the reader of BPD (Business Process Diagram).

III. THERMOSTAT: AN ILLUSTRATIVE EXAMPLE

[3].

In order to provide intuitions, the theoretical considerations will be illustrated with a simple example process. The process goal is to establish the so-called *set-point* temperature for a thermostat system [4]. The selection of the particular value depends on the season, whether it is a working day or not, and the time of the day. A BPMN diagram of the process is specified in Figure 4.

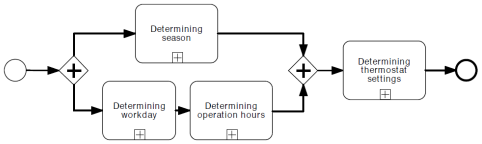

Fig. 4. An example BPMN diagram top-level specification of the thermostat system

After start, the process is split into two independent paths of activities. The upper path is aimed at determining the current season [1] *aSE*; it can take one of the values *sum, aut, win, spr*; the detailed specification is provided with rules 7-10. A visual specification of this activity with an appropriate set of rules is shown in Fig. 5.

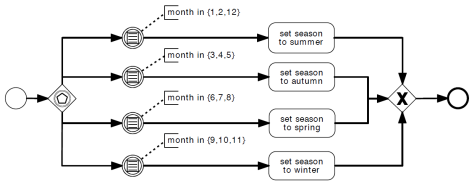

Fig. 5. An example BPMN diagram detailed specification a BPMN task

The lower path determines whether the day (*aDD*) is a workday (*aTD=wd*) or a weekend day (*aTD=wk*), both specifying the value of today (*aTD*); specification provided with rules 1 and 2, and then, taking into account the current time (*aTM*), whether the operation (*aOP*) is during business hours (*aOP=dbh*) or not (*aOP=ndbh*); the specification is provided with rules 3-6. This is illustrated with Fig. 5 and Fig. 6.

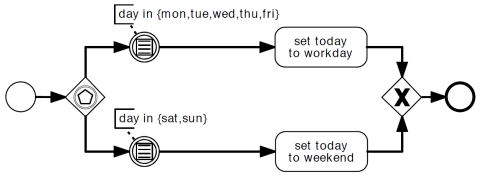

Fig. 6. An example BPMN diagram detailed specification of determining the day task

The whole process is formally specified with the following eighteen inference rules.

[1]For technical reasons all attribute names used in this example start with lower-case 'a'.

Rule 1:$\in \{,,,\} \longrightarrow = wd.$
Rule 2:$\in \{,\} \longrightarrow = wk.$
Rule 3:$= wd \wedge \in (9,17) \longrightarrow = dbh.$
Rule 4:$= wd \wedge \in (0,8) \longrightarrow = ndbh.$
Rule 5:$= wd \wedge \in (18,24) \longrightarrow = ndbh.$
Rule 6:$= wk \longrightarrow = ndbh.$
Rule 7:$\in \{,,\} \longrightarrow = sum.$
Rule 8:$\in \{,,\} \longrightarrow = aut.$
Rule 9:$\in \{,,\} \longrightarrow = win.$
Rule 10:$\in \{,,\} \longrightarrow = spr.$
Rule 11:$= spr \wedge = dbh \longrightarrow = 20.$
Rule 12:$= spr \wedge = ndbh \longrightarrow = 15.$
Rule 13:$= sum \wedge = dbh \longrightarrow = 24.$
Rule 14:$= sum \wedge = ndbh \longrightarrow = 17.$
Rule 15:$= aut \wedge = dbh \longrightarrow = 20.$
Rule 16:$= aut \wedge = ndbh \longrightarrow = 16.$
Rule 17:$= win \wedge = dbh \longrightarrow = 18.$
Rule 18:$= win \wedge = ndbh \longrightarrow = 14.$

Let us briefly explain these rules. The first two rules define if we have today (*aTD*) a workday (*wd*) or a weekend day (*wk*). Rules 3-6 define if the operation hours (*aOP*) are during business hours (*dbh*) or not during business hours (*ndbh*); they take into account the workday/weekend condition and the current time (*hour*). Rules 7-10 define the season (*aSE*) is summer (*sum*), autumn (*aut*), winter (*win*) or spring (*spr*).

Finally, the results are merged together, and the final activity consists in determining the thermostat settings (*aTHS*) for particular season (*aSE*) and time (*aTM*) (the specification is provided with rules 11-18).

This is illustrated with Fig. 7.

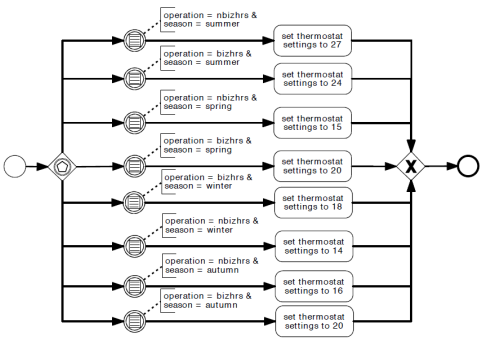

Fig. 7. An example BPMN diagram — detailed specification of the final thermostat setting task

Even in this simple example, answers to the following important questions are not obvious:

1) *Data flow correctness*: Is any of the four tasks/activities specified in a correct way? Will each task end with producing desired output for any admissible input data?
2) *Split consistency*: Will the workflow possibly explore all the paths after a split? Will it always explore at least one?
3) *Merge consistency*: Will it be always possible to merge knowledge coming from different sources at the merge node?
4) *Termination/completeness*: Does the specification assure that the system will always terminate producing some

temperature specification for *any* admissible input data?
5) *Determinism*: Will the output setting be determined in a unique way?

Note that we do not ask about *correctness* of the result; in fact, the rules embedded into a BPMN diagram provide a kind of *executable specification*, so there is no reference point to claim that final output is correct or not.

IV. Related work

There is a possibility of defining incoherent business logic specification and its interpretation. Even in basic processes anomalies are observed [5]. An improvement is required in the mechanism which provides cohesion in detecting anomalies in business processes [6]. Anomalies have been defined in numerous papers, yet a uniform definition was presented in [7] IEEE standard classification for Software Anomalies and it says: *"Each condition different from the expected is an anomaly"*.

In business logic an anomaly can be considered as every negative influence on modeling and models. There is a special kind of anomaly — a defect, which blocks the correct and efficient flow of objects completely.

A taxonomy of anomalies was created on the basis of literature. It concerns the flow control, bases and verification rules of data as well as flow accuracy. The taxonomy can make up a base for classification and research on anomaly possibilities.

The anomaly problem in BPMN is based on searching business logic for particular patterns. In [8], typical controls for anti-patterns are searched for by using a query language for BPMN. It is confirmed by deadlocks or livelock patterns which are used improperly. A similar thing happens in [9] where typical gateway constellations leading to problematic situations in the flow work diagram are presented. A comparable situation occurs in [10] as well, where an 'anomaly pattern' is used. This approach is based on detecting anti-patterns in the data flow. The whole thing is based on time logic using a real model control. By making use of different tools, position [11] is focused on various anomalies which stem from formalism or inadequacy of the tools. Yet another approach is a conception based on UML diagrams in development stages [12].

Control flow anomalies concern problems connected with flow control and gateways conditions [12]. In [13] , a problem was presented of control over many semantically identical connections between two work flow elements. This multiplicity complicates changes in the work flow, which is not desired.

Another element of flow control are gateways placed in the modeling center. It was stated in [14] that XOR-gateways with undefined gateway conditions can cause practical problems or even be a reason of an error. A similar thing happens when XOR-gateways conditions do not exclude each other and partly or fully overlap. What happens in flow control in case of lack of synchronization is multiple flow execution. For example, branches and some loop instruction cause such an anomaly [15].

Another situation is a flow deadlock. It is a situation in which the work flow is stopped in the current position of the path and cannot be accomplished. Another lock of flow is known as livelock. In [8] it is called an 'infinite loop'. Flow livelock keeps the operating work flow system in an infinite loop. The reason are bad modeling conditions, which prevent leaving the loop. Both cases — deadlock and livelock are described in [8], [15].

Rule-based anomalies are described in numerous papers [16], [17], [18], [19]. They involve mainly two problems connected with base rules. First, Rule-base Consistency are anomalies concerning coherence. Problems result from the set of rules, which have determined conditions but different outcomes at the same time. Rule-base livelocks, also called *circular rules* [17]. Rule-base livelocks and rule-base deadlocks describe a problem with creation rules, which are dependent on one another although they should not. This type of anomaly suggests that rule-base does not encompass the basic context in which it is used. Coverage anomalies concern the rules in which conditions can be fulfilled by the base context but conclusions are modeled in such a way that no effect will ever be seen. Another type of data flow anomaly is based on [20]. Such anomalies are influenced by those data elements which can be processed by workflow activities.

V. Anomalies in business processes

There are two kinds of business process anomalies which can occur while process modeling, namely [19]: Syntactic anomalies and Structural anomalies.

A. Syntactic Anomalies in Business Process

Analysis of Syntactic Business Process anomalies is important while designing a business process model. In this section examples of syntactic anomalies in business processes will be presented. A division into three groups has been made: **Incorrect usage of Flow Objects**, **Incorrect usage of Connecting Object** and **Incorrect usage of Swimlanes**.

B. Incorrect usage of Flow Object

The anomaly of this type result from improper use of the Event, Activity and Gateway.

Incorrect usage of Activities: Invalid use of Start Event or End Event. The BPMN specification defines the start and end events as optional. However, their usage is highly recommended, since each process starts and ends somewhere. Without explicitly using start and end events, a regular BPMN process might look the process in Fig. 8. This modeling

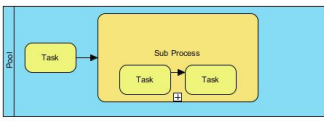

Fig. 8. Implicit process events

approach is undesirable and could lead to misinterpretations.

Depending on application, three anomalies can be distinguished. These are: Activities without Activation, Activities without Termination and Invalid use of Receive Task. Activities without Termination and Invalid use of Receive Task.

- **Activities without activation** If an activity is situated on a path that has no start, then this is an activity without activation. Even if a start of an event is used.
- **Activities without Termination**. An activity without termination happens when the activity cannot be brought to an end. Even if End Event is used.
- **Invalid use of receive task**. Receive Task Element is designed to wait for incoming messages from outside users in a business process.

Invalid use of Gateway. There are two groups of anomalies: invalid use of Data-Based XOR Gateway and invalid use of Event-Based XOR Gateway.

- **Invalid use of Data-Based XOR Gateway**. A data-based XOR Gateway relies on the arrival of a data token that has traversed the Process Flow. Data-based XOR Gateway must be date-based objects.
- **Event-Based XOR Gateway**. According to BPMN, the event-based gateway cannot be used as a merge gateway. It can only be used as a decision type gateway (multiple outputs).

Incorrect usage of Connecting Object. Anomalies concerning connecting objects stem from incorrect usage of their elements, that is message flow and sequence flow. As far as incorrect utilization of connecting objects is concerned, a few anomalies can be differentiated: the ones concerning incoming sequence flows, outgoing sequence flows, invalid use of conditional sequence flow. In this case there are two possible irregularities regarding the invalid use of a pool or lane [26].

C. Invalid use of Pool

When modeling multiple pools, a common mistake is that activities in a Pool are not connected with sequence flows. It is incorrect to use multiple pools as a single process and incorrectly interprets messages flows as way of indicating a sequence of activities (Fig. 9).

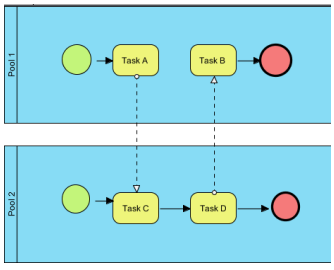

Fig. 9. Missing sequence flow

Another common problem when modeling multiple pools is the use of a set of pools as a single pool with multiple lanes. The end result will be an incorrect model (Fig. 10) that represents a single process that spreads over the boundaries of the pool.

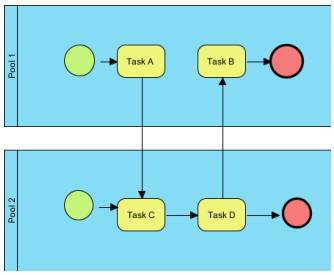

Fig. 10. A Sequence flow May not cross pools boundaries

D. Invalid use of Lane

Improper use of lane as a pool, thereby representing individual processes within separated lanes. This is wrong, because a lane is just a activity-classifying mechanism (Fig. 11).

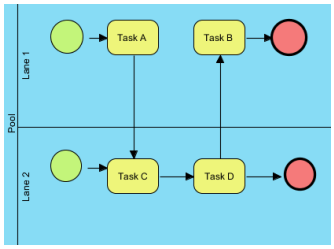

Fig. 11. Two Lances are used as two Pools

E. Structural Anomalies

Structural anomalies have been described in the literature [21], [22], [23], [24]; they are classified as four types: **Deadlock**, **Lack of synchronization**, **Dead Activity** and **Infinite Loop**.

Note that in fact all the above anomalies correspond to *wrong dynamic behavior*; all of them occur during execution of the process.

A process is sound [25] if and only if it is free of two control-flow errors: the deadlock and the lack of synchronization. First, deadlocks are blockings in the process model, which occur when gateways are used incorrectly. In this case, the links in the process where gateways were installed should be checked. Deadlocks occur when an exclusive gateway was picked for linking and this linkage was combined again with a parallel gateway. They may arise from added intermediate events or multiple exclusive start events, which should be checked again. There are two types of deadlocks: deterministic deadlock (Fig. 12) and non-deterministic deadlock (Fig. 13).

A deadlock is a reachable state of the process that contains a token on some Sequence Flow that cannot be removed in any possible future. A lack of synchronization (Fig. 14) is a reachable state of the process where there is more than one token on some Sequence Flow. To characterize the lack of synchronization, we follow the intuition that potentially

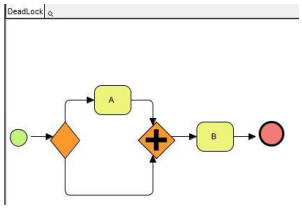

Fig. 12. Deterministic deadlock

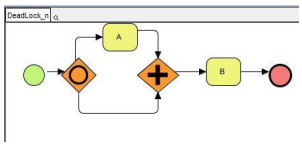

Fig. 13. Non-deterministic deadlock

concurrent paths, paths starting with an IOR-split or an AND-split, should not be joined by XOR-join. In the following, we formalize this characterization and show that such structure always leads to lack of synchronization in deadlocks free acyclic workflow graphs [24]. While *Dead Activities* are activities which will never be executed. A last type of anomaly is Infinite Loop [27] , also called *closed loop*. A closed loop is a cycle without any split. Tokens that enter a closed loop are forever lost to the rest of the workflow. In our model, this leads to a deadlock, because each token entering the closed loop will have a synchronization copy of itself placed on the incoming edge of the initial join that loops back from the cycle. It is hard to imagine a sensible real-world example that contains a closed loop (the BPMN standard document admits this). Banning closed loops from workflows is thus not a serious restriction, especially since infinitely looping cycles are still possible as long as they are not closed [25].

VI. Conclusion

BPMN is a popular business process modeling language. The ability of using it is very important in the modeling stage. Yet, despite its advantages, the problem of effective anomaly detection still remains. There is a lack of a proper tool that would automate the process of detecting anomalies in business process modeling.

Email: celina.olszak@ue.katowice.pl

Abstract—Although Business Intelligence (BI) is one of the most essential technologies to be purchased, the implementation of many BI applications fails. The reasons for this failure are not clear and still not well investigated. Resource-based View (RBV) and dynamic capability theory could help to overcome this gap and to provide an appropriate theoretical basis for future research in BI area. It is considered that BI capabilities may be critical functionalities that help organizations to improve their performance and adopt to environmental change. The research objectives for this study are: (1) conceptualization and discussion on BI dynamic capability, (2) building the comprehensive framework of BI capabilities. In order to address these objectives, the remainder of the paper is structured as follows: The first sections provide the theoretical foundations of BI, RBV and dynamic capability theory. Next, the BI capability was conceptualized. Finally, a model of BI as a dynamic capability, was proposed. The study was based mainly on: (1) a critical analysis of literature, (2) an observation of different BI initiatives undertaken in various organizations, as well as on (3) interviews with managers and experts in BI. The results of this study can be used by IT and business leaders as they plan and develop BI capabilities in their organizations.

I. Introduction

In order to gain competitive advantage, many organizations decide to use Business Intelligence (BI) systems. It is believed that BI enables organizations to better understand not only internal business processes, but also the competitive environment through the systematic acquisition, collation, analysis, interpretation and exploitation of information. BI allows for the identification of the opportunities and threats, which may occur on the market, while cooperating with customers, suppliers and competitors [1], [2], [3], [4], [5], [6], [7], [8].

It is worth mentioning, that in 2010, BI topped the list of the most important application and technology development in an annual survey of IT executives [9]. According to Gartner research and Forrester the BI market will grow from $8,5 billion in 2008 to $12 billion in 2014 [10]. Although BI is one of the most essential technologies to be purchased, many BI applications fail or the organizations do not achieve the appropriate benefits [11], [12], [13], [14], [15]. The reasons for this failure are not clear and still not well investigated. Resource-based View (RBV) and dynamic capability theory could help to overcome this gap and to provide an appropriate theoretical basis for future research in BI area.

This paper seeks to throw more light on the concept of BI by using a dynamic capabilities perspective. I consider that BI capabilities may be critical functionalities that help organizations to improve their performance and adopt to environmental change.

The research question I ask in this paper is: what new light contribute RBV and dynamics capabilities to BI area. Consequently, the research objectives for this study are: (1) conceptualization and discussion on BI dynamic capability (2) building a comprehensive framework of dynamic capabilities for BI.

In order to address these objectives, the remainder of the paper is structured as follows: The first sections provide the theoretical foundations of BI, RBV and dynamic capability theory. Next, the BI capability was conceptualized. Finally, a comprehensive framework of BI as a dynamic capability was proposed. The study was based mainly on: (1) a critical analysis of literature, (2) an observation of different BI initiatives undertaken in various organizations, as well as on (3) interviews with managers and experts in BI. The results of this study can be used by IT and business leaders as they plan and develop BI capabilities in their organizations.

II. Background on Business Intelligence and Dynamic Capabilities

A. Business Intelligence

Business Intelligence has become the significant research area in the domain of management information systems in the last years. The roots of BI originate from decision support systems, which first emerged in the early 1970s when managers used computer applications to model business decisions. Over the years, other applications, such as executive information systems (EIS), online analytical processing (OLAP), data warehousing, and data mining became important [5],[6], [7]. Today BI is compared to "an umbrella" that is commonly used to describe the technologies, applications, and processes for gathering, storing, accessing and analyzing data to help users to make better decisions [1], [16].

BI is comprised of both technical and organizational elements [17], [18], [19], [20], [21]. From technical point of view BI is an integrated set of tools, technologies and software products that are used to collect heterogenic data

978-83-60810-58-3/$25.00

from dispersed sources and then to integrate and analyze data to make them commonly available. The key BI technologies include: data warehousing, data mining and OLAP [22]. They are often called BI.1.0.

In the last years, new techniques, such as: web mining, opinion mining techniques, mobile mining techniques and semantic processing are applied in building BI systems They are focused on processing of semi-structured or un-structured data that originate mainly from Internet and social media. BI addressed for acquiring and processing data from web resources are named BI 2.0. In turn, BI 3.0 are responsible for collecting and analyzing data from various mobile devices [7], [24].

From organizational perspective, BI means a holistic and sophisticated approach to cross-organizational decision support [8], [11], [25]. Negash and Gray [3] argue that BI is responsible for transcription of data into information and knowledge. Also, it creates some environment for effective decision-making, business processes, strategic thinking, acting in organizations and taking the competitive advantage [26], [27], [28], [29], [30]. Many authors highlight that BI is predisposed to support decision-making on all levels of management [1], [3], [8], [31], [32]. On the strategic level, with the help of BI it is possible to set objectives precisely and follow the realization of such established objectives. BI allows for performing different comparative reports, e.g. on historical results, profitability of particular offers, effectiveness of distribution channels or forecasting future results on the basis of some assumptions. On the tactical level BI may provide some basis for decision-making within marketing, sales, finance, capital management etc. BI allows for optimizing future actions and modifying organizational, financial or technological aspects of company performance appropriately in order to help enterprises to realize their strategic objectives more effectively. In turn, on the operational level, BI systems are used to perform ad hoc analyses and answer questions related to departments' ongoing operations, up-to-date financial standing, sales and co-operation with suppliers, customers [22].

It is indicated that BI facilitates the realization of business objectives through reporting of data to analyse trends, creating predictive models for forecasting and optimizing process for enhanced performance. The value of BI systems for business is predominantly expressed in the fact that such systems cast some light on information that may serve as the basis for carrying out fundamental changes in a particular enterprise. It is stated that BI has become the critical component for the success of the contemporary organization [2], [15], [33], [34]. Wells [18] argues that BI is the "capability of an organization to explain, plan, predict, solve problems, think in an abstract way, understand, invent, and learn in order to increase organizational knowledge, provide information for the decision-making process, enable effective actions, and support establishing and achieving business goals".

It should be pointed that although, BI applications have become the most essential technologies to be purchased in the last years, the BI success is still questionable. It is reported that the practical benefits from BI are often unclear and some organizations fail completely in their BI approach or they do not achieve the appropriate benefits [11], [12], [13], [14], [15]. It is said that about 60 to 70% of business intelligence applications fail due to the technology, organizational, cultural and infrastructure issues [35], [36], [37], [38]. It is reported that the most important elements that decide on BI success in the organizations include: quality of data and used technologies, skills, sponsorship, alignment between BI and business, and BI use [35]. Other elements concern: organizational culture, information requirements, and politics. According to Olszak and Ziemba [38] the biggest barriers that the organizations encounter during the implementation of BI systems have a business and organizational character. Among the business barriers, the most frequently mentioned are: the lack of well defined business problem, not determining the expectation of BI and the lack of relations between business and BI vision system. Whereas as the key organizational barriers the enterprises enumerate: the lack of manager's supporting, the lack of knowledge about the BI system and its capabilities, exceeded the BI implementation budget, ineffective BI project management and complicated BI project, the lack of user training and support.

B. Resource-based View

RBV argues that about the success of organization's strategy decide the configuration of its resources and capabilities that are the basis to build key competences. Acquiring, configuration, reconfiguration and developing of available resources is critical factor for taking the competitive advantage and creating the value [39], [40], [41].

RBV was put forward by Wernerfelt [42] and subsequently popularized by Barney's work [39]. Many authors made significant contribution to its conceptual development [43], [44], [45].

According to RBV in order to provide sustainable competitive advantage, resources should be (VRIN): Valuable (enable an organization to implement a value-creating strategy), Rare (are in short supply), Inimitable (cannot be perfectly duplicated by rivals) and Non-substitutable (cannot be countered by a competitor with a substitute). In an extended approach of RBV resources imply intangible categories including organizational, human and networks [46]. This knowledge-based resource approach of RBV encourages organizations to obtain, access, and maintain intangible endowments because these resources are the ways in which firms combine and transform tangible input resources and assets [47]. It is reported that BI technology, as well others ICT, do not satisfy the VRIN criteria [48]. However, they may be synergistically combined with existing organizational resources, to form other VRIN resources [41], [49].

C. Dynamic capabilities theory

The concept of dynamic capabilities is rooted in the RBV of competitive advantage. RBV defines capability as the ability of a bundle of resources to perform an activity. It is a

way of combining assets, people and processes to transform inputs into output [50].

Teece et al. [50] define capabilities as "the key role of strategic management in appropriately adapting, integrating, and reconfiguring internal and external organizational skills, resources, and functional competences to match the requirements of a changing environment". Many authors, explaining the topic of capabilities, highlight some differences between competency, capability and capacity [51]. Competence is the quality or state of being functionally adequate or having sufficient knowledge, strength and skill. While capability is a feature, faculty or process that can be developed or improved. Capability is a collaborative process that can be deployed and through which individual competences can be applied and exploited. Capacity is the power to hold, receive or accommodate.

Hamel and Prahalad [52] coined the term core competence to distinguish those capabilities fundamental to a firm's performance and strategy. Core competencies are the activities that the firm performs especially well compared to competitors and through which the firm adds value to its goods and services over a long period of time. They emerge over time through an organizational process of accumulating and learning how to deploy organizational resources and capabilities.

The RBV conceptualizes organizational resources as static, neglecting changes due to turbulent environments. A stable resource configuration can not guarantee long-term competitive advantage as organizations have to adopt this configuration to the market environment [50]. This argument is even stronger in dynamic market environments where there is "rapid change in technology and market forces and feedback effects on firms [53]. Dynamic capabilities were conceptualized in response to this criticism [41], [44].

Teece et al. [50] identify dynamic capabilities as "the firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments". The notion of dynamic capabilities was subsequently refined and expanded [44], [45], [54]. Zollo and Winter [45] also distinguish dynamic capabilities from operational or ordinary capabilities. Operational capabilities enable firms to perform their every day living, "and while dynamic (as all processes are), they are used to maintain the status quo" [54]. By contrast, dynamic capabilities are those that enable a firm to constantly renew its operational capabilities and therefore achieve long-term competitive advantage.

It is worth noting, that RBV has been used extensively in IS (Information Systems) research to explain how IT (Information Technology) assets provide value and sustainable competitive advantage to organizations [41]. Some studies found a direct link between IT assets and value but most found that IS capabilities and the interaction of IT assets with other organizational resources, lead to business value [40], [41]. IS capabilities are created through combining IT assets with other resources including people, routines and processes. IS capabilities develop and mature over time as organizational learn [43]. Dynamic capabilities are the high-order capabilities and thus can be disaggregated into different capacities, such as the capacity for improving quality, the capacity for managing human resources and the capacity for utilizing technologies [55].

D. Conceptualization of dynamic Business Intelligence capabilities

Drawn from the concept of dynamic capabilities, BI capability may be defined as IT-enabled, analytical dynamic capability for improving decision making and firm's performance [55]. It is a specific and important type of IS capabilities. Different organizational characteristics and strategic goals may also require using different BI capabilities. According to Gartner Group BI capabilities relate to information access and analysis to decision-making style within an organization [11]. Isik, Jones and Sidorova [11] delineate information access and analysis capabilities and relate them to the overall BI success. Davenport and Harris [6] state that analytical capability is a key element of strategy for the business. Wixom, Watson and Werner [5] argue that BI capability is "a journey over long periods of time during which foundational competencies are developed".

According to Teece et al. [50] dynamic capabilities can be distinguished into three classes of activities including sensing, seizing, and transformation. In the context of Business Process Management [53] and also of BI, sensing refers mainly to identification of the need to change an organization's business processes, relations with customers and suppliers. Seizing means the exploration and selection of opportunities for change. Transformation concerns socio-technically implementation of changed business processes in the organization. Some authors argue that BI capabilities are critical functionalities of BI that help an organization to improve its adoption to change as well as to improve its performance [5], [11].

Organizations may develop two activities in order to build BI capability. The former concerns the widely understood data exploration, the latter, data exploitation [56]. Data exploration enables organization to overcome the bounder of actual knowledge and its capabilities. This may refer to new technical capabilities, market experiences and new relations with the environment. Also, the exploration is a conscious searching of new knowledge sources, enriching of existing resources, adoption of new behavioral orientations and acquisition of new competencies. It can be achieved through: advances data mining, text mining, web mining, intelligent agents, and search based application. In turn, data exploitation concerns the using of existing knowledge bases. It is limited to actual resources and refers to their detail analysis.

Davenport and Harris [6] distinguish five stages of analytical capability called: analytically impaired, localized analytics, analytical aspiration, analytical companies, and analytical competitors. The first stage means that "organizations have some desire to become more analytical, but thus far they lack both the will and the skill to do so". They face some substantial barriers – both human and

technical. They may also lack the hardware, software and skills to do substantial analysis. The second stage "localized analytics " is characterized by reporting with pockets of analytical activity. The organizations undertake the first analytical activities, but they have no intention of competing on it. BI activities produce economic benefits but not enough to affect the company competitive strategy. The third stage called "analytical aspirations" is triggered when BI activities gain executive sponsorship. The organizations build the plan of using BI. The primary focus in "analytical companies" stage is building word-class analytical capabilities at the enterprise level. The organizations implement the plan developed in previous stage, making considerable progress toward building the sponsorship, culture, skills, strategic insights, data and technology needed for analytical competition. At the last stage, analytics moves from being a very important capability for an organizations to the key to its strategy and competitive advantage. Executive managers trust in BI and all users are highly educated in BI.

For the purpose of this paper it is assumed that dynamic BI capability is the ability of an organization to integrate, build and reconfigure the information resources, as well as business processes to address rapidly changing environments.

III. RESEARCH METHODOLOGY

An interpretative philosophy and an inductive qualitative approach were applied to build a comprehensive, dynamic BI capabilities framework. The theories (from IS and management literature) and studies developed mainly by Davenport and Harris [6], Wixom, Watson, and Werner [5], Cosic, Shankes, and Maynard [41] were adopted and used to create the dynamic BI capabilities framework.

BI is regarded as an applied discipline and therefore practitioner, viewpoints and opinions were considered of high importance. Therefore, I have used the results from the survey that was conducted in 2012 among 20 purposefully selected firms (in Poland) that are considered to be advanced in BI [24]. They represented the service sector: telecommunications, consulting, banking, insurance, and marketing agencies. Interviews were held with executives, senior members of staff and ICT specialists. Interviewees were selected on their involvement in BI or on their ability to offer an insight based on experience in BI and related decision support systems. The research was of qualitative nature and used as a research technique of an in-depth interview. Types of core interviews questions relevant to this paper have included among others: (1) Does your organization have a defined BI strategy?, (2) Does your organization have defined business processes?, (3) Are you skilled enough in order to take advantage of BI systems?, (4) Are you motivated to use BI (how)?, (5) Do you use BI for analyzing customers, suppliers, competitors and other business partners?, (6) What kind of BI software do you use?, (7) Describe some successes/failures from using BI. This methodology is appropriate for the explorative objectives of this research as it aimed to build dynamic BI capabilities framework.

IV. FINDINGS AND DISCUSSION

Figure 1 provides an initial framework for dynamic BI capabilities. It includes six capabilities areas like: governance, culture, technology, people, processes, and change management & creativity. So far, these areas were presented separately and were used for different aims and tasks. In this study, I integrate them into one comprehensive model for dynamic BI capabilities. Below, I present the arguments for adopting them to create a dynamic BI capability.

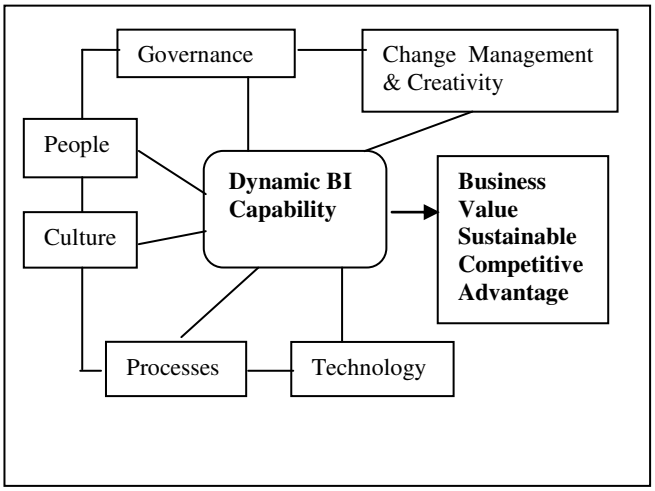

Fig. 1 Framework for BI capabilities

The governance is "the mechanism for managing the use of BI resources within an organizational and the assignment of BI initiatives with organizational objectives. It also involves continuously renewing BI resources and organizational capabilities in order to respond to changes in dynamic environments and mitigating resistance to change" [41].

Culture is often described as "personality of the organization" and comprises the assumptions, values, norms, and behavioral signs of organization/s members. They form over time and lead to systematic ways of gathering, analyzing and disseminating data. It influences the way decisions are made [41].

People refer to "all those individuals within organization who use BI as part of their job function. BI initiatives are considered to be knowledge intensive and require technical, business, managerial and entrepreneurial skills and knowledge" [41].

Technology refers "to the development and use of hardware, software and data within BI activities. It includes the management of an integrated and high quality data resources, the seamless integration of BI systems with other organizational information systems, the conversion of data into information through reporting and visualization systems and to use of more advanced statistical analysis tools to discover patterns, predict trends and optimize business process" [41].

Process constitutes of activities to gather, select, aggregate, analyze, and distribute information. Some of these activities are the responsibility of the BI staff, while others are the joint responsibility of the BI staff and the business units. Processes may be divided into categories: internal and external processes. The first group relates mainly to accounting, finance, manufacturing, and human resources. The second group concerns managing and responding to customer demand and supplier relationships [6].

Change management & creativity are organization's abilities to meet the requirements of dynamic environments. Organizations face rapid change like never before. Therefore, the ability to manage and adapt to organizational change is an essential ability required in the workplace today. Change management is an approach to transitioning individuals, teams, and organizations to a desired future state. BI requires permanent development and adaptation to new challenges and expectations of an organizations. While an organizational creativity is the firm's ability to generate new and useful ideas to address rapidly changing opportunities and threats by making timely and market-oriented decisions, and to frame breaking changes in its resource base.

The essentials analysis of the literature and the conducted interviews with various BI experts and managers allowed me to identify the detailed capabilities for each BI area (table 1). The number of the organizations that declared the possession of various BI capabilities and competences is presented in the last column of the table.

Table I.
BI CAPABILITIES AREA

BI Capabilities Area	Detailed BI capabilities	Number of organizations
Governance	Business vision and plan	10
	Business analysis planning and monitoring	11
	Strategic alignment BI and business strategy	5
	Decision rights (operational, tactical, strategic)	16
	BI solution assessment and validation	7
Culture	Executive leadership and support	6
	Flexibility and agility	8
	Establishing a fact-based and learning culture	7
Technology	Data management	16
	Systems integration and interaction with other systems	17
	Flexibility	17
	Reporting and visualization technology	20
	Advanced BI technology (OLAP, data warehousing, data mining, predictive analysis)	16
People	Securing and building technology skills	7
	Mathematical and statistical skills	5
	Organizational skills	7
	Organizational knowledge, knowledge sharing	5
	Managing analytical people	6
	Business interpersonal communication	12
	Entrepreneurship and innovation	5
	Trustworthiness	6
Process	Holistic overview business process/ knowledge processes	14/7
	Business process/knowledge/ modeling and orchestration	16/6
	Process redesign and integration	16
Change & Creativity	Monitoring of competitors, customers and current trends in the marketplace	9
	Introducing new business models oriented on change management, knowledge management and customer relationship management	7
	Generation of new and useful products, services, ideas, procedures, and processes	7

In the next step of my research, five detailed BI capabilities areas were mapped onto Davenport and Harris model. As a the result, a BI capabilities maturity matrix was created (table 2).

The analysis of the literature and the conducted survey allow me to state that the dynamic BI capabilities do not go hand in hand with the possibilities offered by BI technologies. Most organizations need to raise their "analytical erudition." Managers do not always know how such sources can be used in making decisions. The most of the organizations do not think creatively about the potential of data sources. They have a relatively high level of the technical competences. Unfortunately, they do not correspond with another BI capabilities (e.g., strategic alignment BI and business strategy, establishing a fact-based and learning culture, entrepreneurship and innovation, change management, and creativity).

BI is still treated as a technology or tool to acquire and analyze data and not as a trigger for making more effective decisions, improving business processes and business performance, as well as doing new business or creating new ideas and procedures. The organizations still underestimate the soft competences and skills needed for BI (e.g., culture-based on facts and knowledge, trust, human resources management, managing analytical/creativity people). Worried, that BI and business strategy are not aligned in many organizations.

Table II.
BI CAPABILITIES MATURITY MATRIX

BI capabilities area	Analytically impaired	Localized analytics	Analytical aspiration	Analytical companies	Analytical competitors
Governance	Lack of vision and plan	Businesses plans for limited departments	Integrated business strategy	Have an enterprise BI strategy	BI strategy oriented on customers, suppliers etc.
Culture	No flexibility and agility	Low support from senior executives	Users are encouraged to collect, process analyze and share information	Establishing a fact-based and learning culture, skill training in BI	Learning from customers, suppliers, communities of practice, social media
Technology	Missing/poor data, Unintegrated systems	Missing important data, Isolated BI efforts	Proliferation of BI tools	High- quality of data, integrated knowledge repositories	Enterprise-wide BI architecture largely implemented
People	Users do not know their own data requirements or how to use them	The users take the first BI initiatives	Users try to optimize the efficiency of individual departments by BI	Users have high BI capabilities, but often not aligned with right role	Users have capabilities and time to use BI
Processes	Users do not know business processes	Identification of basic business processes	Standardization of business processes, and building best practices in BI	Business process management based on facts	Broadly supported, process-oriented culture based on facts
Change & Creativity	Fear of change, no creativity	Risk management for selected business process, poor and limited creativity	Building the best practices for change management, individual and team creativity	Integrated risk management, team and organizational creativity	Cooperation with competition, organizational creativity, creative environment

In order to reach a comprehensive, dynamic BI capability, organizations should simultaneously build and developed a whole bundle of various BI capabilities. Undoubtedly, it is a long journey and developed over long periods of time. I think, that organizations should not start from building technical competences, structures (data bases, data warehouses etc.), without prior the implementation of knowledge-based organization, change management, and organizational creativity.

Concluding, I consider that organizations should simultaneously develop different BI capabilities in order to achieve high BI maturity. These capabilities may be focused on data exploration and data exploitation. As mentioned earlier, data exploration enables organization to overcome the bounder of actual knowledge and its capabilities. In contrast, data exploitation concerns the using of existing knowledge bases. It is limited to actual resources and refers to their detail analysis. The adequate linking capabilities concerning exploration and exploitation of the knowledge are useful solution for organizations. This results from the rapid obsolescence of knowledge, shortening life cycle of many products and services. Therefore, it is important for the survival and success of the organization to maintain some balance between these activities.

V. CONCLUSIONS

The research propose of this study was to investigate how Resource-based View and dynamic capability theory may be adopted and used in BI area. It was illustrated that they through more light on our BI understanding. I have proposed a comprehensive, dynamic BI capabilities framework that reflects six BI capabilities areas: governance, culture, technology, people, processes and change & creativity. This dynamic capability framework suggests that the abilities needed depend highly on the dynamics of the environment.

The conducted survey has shown that BI is still treated as a technology or tool to acquire and analyze data and not as a trigger for making more effective decisions, improving business processes and business performance, as well as doing new business or creating new ideas and procedures. The organizations still underestimate the soft competences and skills needed for BI (e.g., culture-based on facts and knowledge, trust, human resources management, managing analytical/creativity people). Worried, that BI and business strategy are not aligned in many organizations.

I consider that the father development of BI in organizations will depend on how they will focus on strategic alignment BI and business strategy, establishing a fact-based and learning culture, entrepreneurship and innovation, change management, and creativity. The time of technical BI competences is over. Organizations should build a whole bundle of more soft BI capabilities.

Future research might take some of the following directions. It would be valuable to build holistic approach for building the dynamic BI capabilities. Further research might explore the detailed BI capabilities areas. Some empirical investigations and precise validations would be useful to explore the associations between BI capabilities and strategic orientations of the organizations.

***Abstract*—Simulation models of real-world distributed systems depend both on the accuracy of the underlying model and the interaction between user and system. The user interaction is typically modeled as stochastic process depending on parameters and distributions describing the actual usage. Accurate data is often not available and (manual) assumptions are necessary. Taking an existing large-scale simulation model of the German tolling system we discuss the use of a genetic optimization algorithm for calibrating the simulation model.**

I. Introduction

DISTRIBUTED software-intensive systems become a part of everyday life. The engineering and operations of these systems is not yet well established: Most techniques in use focus on standalone systems [1] and even there successful implementations are not guaranteed [2]. Instead of the engineering aspects one can rather argue [3] that the integration of subsystems into a functioning system-of-systems becomes a core strategic business capability. Whether it is the engineering, integration or the subsequent operation of a highly automated software-intensive system – many dynamic aspects depend on its usage and often unknown user behavior.

Taking the example of the German automatic toll system for heavy goods vehicles (HGVs) – a typical example of a modern toll system based on global navigation satellite systems (GNSS) [4] – we complement the system operations and system design through simulations [5]. Having a detailed, realistic simulation model at hand it is possible to predict the upcoming operational behavior (e.g. for fleet-wide updates) even for systems under design e.g. when a different system architecture is proposed. In both scenarios simulation results yield numerical results to support decisions and to reduce the risk inherent in any software development process. Particularly in the latter case simulation models help to explore different solutions and to create exact specifications right from the start of a software development project.

"*Good models are essential for communication among project teams and to assure architectural soundness*" [6]. Yet the emphasis on communication (even in more formal methods as UML [6]) creates a source for misunderstandings and errors through the inexact verbalization of the requirements. To reduce the ambiguity we use executable models, i.e. implement the requirements in a model that can compiled and executed [7]. From the very beginning this allows verifying the system requirements by comparing the simulation results with the expected behavior. As the development of the system progresses the simulation models can progress as well (to give an accurate model at the level of abstraction available at that time) or remain at a reasonable level of detail sufficient e.g. to simulate the overall system dynamics. In the case of the German toll system we have established a simulation model of the automatic tolling process and used it both to predict the operational behavior of the existing system [8] and to aid the software development process to better scope proposed changes (e.g. [5]).

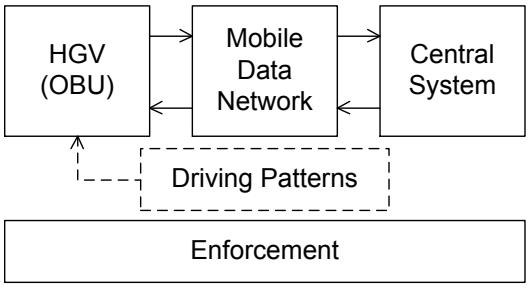

Fig. 1. High-level system design of a GNSS-based electronic tolling system and its dependency on the user interaction (driving patterns).

In the next section we introduce the simulation model of the German toll system. To get an executable system we need two models: A model of the technical system and a model of the user interaction. At present not much is known about the user interaction (due to technical restrictions and data protection regulation) and we started with a simple model that can be parametrized to fit the observed dynamic behavior of the toll system. Section IV uses a genetic algorithm (introduced as a separate model in section III) to find a set of parameters that best reproduces the actual system dynamics. The initial results are given in section V followed by a brief summary.

II. Simulation model of the German toll system

Starting with an existing model of the German toll system and a simple model of the user interaction [8] we take data observed in the real-world system to measure the accuracy of the simulation model. This section gives a brief overview of two models necessary to reproduce the dynamic behavior of the German toll system. In addition we need to address the

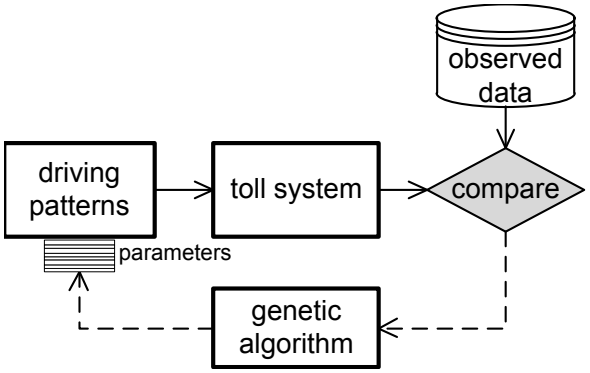

Fig. 2. The existing models for the driving patterns and the toll system are complemented by a dataset of the known dynamic behavior of the toll system. Adding a fitness functions allows comparing the simulation results with the observed data and the use of a genetic algorithm (again as a model) to choose the right parametrization.

term "accuracy" to define the appropriate in our context more clearly.

A. System model

The main model from the perspective of system operations or engineering is of course the model describing the (technical) toll system (Fig. 2). It is a discrete event simulation model of the German automatic toll system encompassing a fleet of almost 800 000 HGVs, each with an on-board unit and access to the central system via a mobile data network. The major processes at time scales of 1 second and above are included in the model (and some at considerably shorter time scales) including the network connection with their respective bandwidths and latencies (but not modeled on the level of the TCP/IP protocol). Simulating at a scale of 1:1 we do not introduce ambiguities due to scaling (especially since the system under consideration is in parts highly non-linear) but have achieve a high simulation speed. Looking at fleet-wide updates taking more than a month the model itself works with typical time scales of one second. All in all the typical simulation performance after a number of performance improvements [9] gives execution times of less than 10 hours for the simulating the whole fleet over half a year.

The model has been verified through software inspection [10] and validated through the comparison with the data observed in the real-world system. At present the biggest source of uncertainty is introduced by the driving patterns (our model of the user interaction).

B. "Driving patterns": A model of the user interaction

The model of the toll system depends on the external stimulus of the user interaction. With an emphasis on the fleet-wide propagation of updates we started with a simple model describing only the temporal behavior (fig. 3): The points in time when an HGV is powered on (or off) and when a toll event is created. Since we do not yet include any geographic information the toll events correspond to the HGV driving

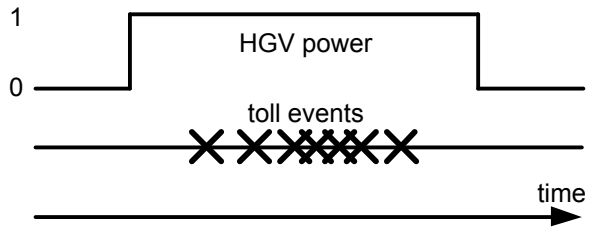

Fig. 3. The user interaction is modeled as the points in time where power-cycles or toll events are registered for a given HGV.

distance of 4.2 km (the average length of a toll segment) at an average speed of $\approx$ 80 km/h.

To achieve a realistic update behavior (taking several weeks to reach the whole fleet) we start with a probability distribution of "active weeks", i.e. the probability that a given HGV is powered-on (at least once) in N of M weeks and take data observed in the actual system and existing HGV-fleets used for testing (typically covering several hundred to a few thousand HGVs). This is in turn followed by probability distributions determining the number of "active days" within a week, the number and duration of power cycles per day and the time during the day when power-cycles take place (for details see [8]). The driving patterns are (manually) calibrated to reproduce the update behavior observed in the real-world system – i.e. looking at time scales of several weeks taking one sample per day.

However, in reality not much is known about the user interaction. Apart from small test fleets no data is available on the power-cycles of the HGVs (even the average speed is not known): Most often the data is not collected and even if data is available data protection regulation often prohibits its use [11]. Looking at the simulation results in more detail it is very difficult to manually adjust the parametrization as to reproduce the intra-day dynamic system behavior (see fig. 4). To make matters worse, some processes are deliberately made strongly non-linear (e.g. to favor updates during the night-time or to protect the central system when it is operating close to the specification limit).

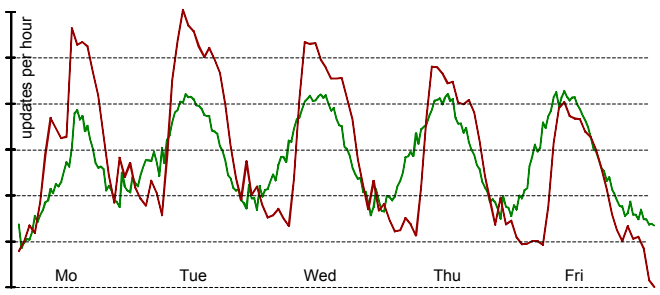

Fig. 4. Example of the simulation results (green line) in comparison to the observed data (red line) of the hourly update rate.

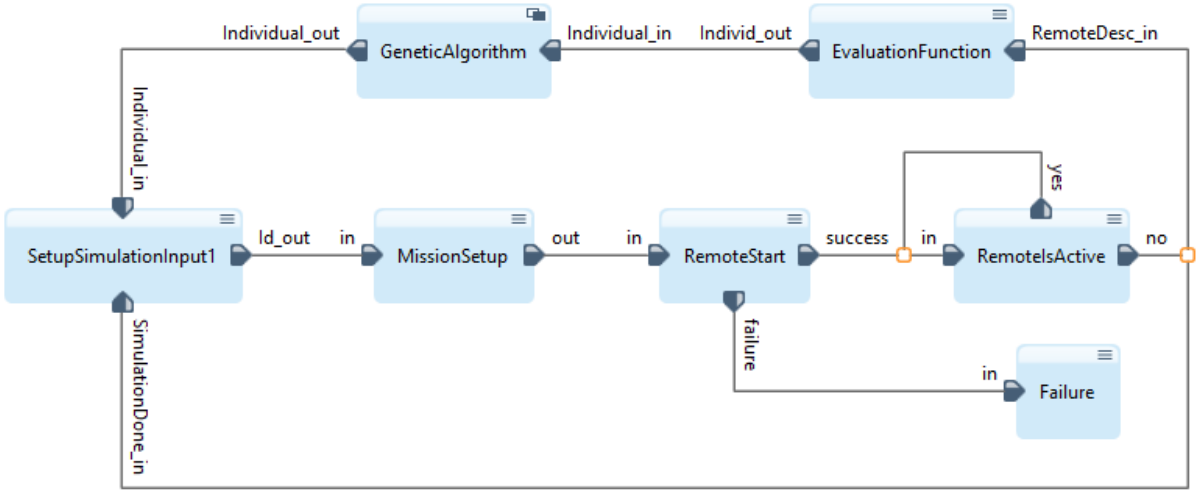

Fig. 5. MSArchitect model using the genetic algorithm to optimize the user interaction (driving patterns) model.

C. Measuring accuracy

To overcome these difficulties we started to let an optimization algorithm adjust the parameters to improve the simulation results. Keeping in mind the mantra "good enough" [12] we need to look at the context in which the simulation results are used:

- *Updates* take several weeks to propagate across the whole fleet. A comparison of the daily data is sufficient to measure the quality of the simulation results.
- *Utilization* of servers or data networks changes rapidly and a time resolution of an hour or less needs to be taken into account.

With the emphasis on fleet-wide updates we compute the fitness as rms-deviation using one data point per day. Depending on the use case this may include the one or several components that are updated: geo and tariff data and the OBU software. For the purpose of this article we take the OBU software as the only input to the fitness function and compute the rms-deviation only for the first weeks after the start of a software update. Only the first weeks of an update are influenced by the system simulation model (and its parametrization of the update rate), very soon the HGV activity is the limiting factor (i.e. a substantial part of the HGV fleet connects only rarely to the central system either because the HGV is constantly powered off or in a foreign country).

III. Simulation Model to Optimize the Driving Patterns

The limited knowledge of the actual user interaction (as mentioned above) combined with the difficulty of setting the parameters of the user interaction manually necessitates the use of an automatic optimization algorithm to calibrate the model with the data available. Consequently the model of the German toll system is connected to an optimization algorithm (see Fig. 2). To separate these tasks we introduce a second optimization model responsible for the optimization of the driving patterns (user interaction). Using a genetic algorithm the model iterates automatically over different parametrization improve the simulation results for the model of the German toll system.

To that extent the existing model of the German toll system needed only minor modifications: Any parameters intended for optimization were implemented as explicit parameters at the top-level of the model and exported to the optimization model. The existing models generating the driving patterns and simulating the tolling system are now integrated into one model and followed by a *fitness function* evaluating the deviation between the simulation results and real-world data (typically of the progress of fleet-wide updates computed as the rms of the daily version status).

The idea of using a separate model controlling the optimization process, including structural and parameter modifications as well as evaluation of the model to be optimized, is a basic concept of Simulation-Driven Design [7]: There it is called *Executable System Design Process*, defined as an automated series of design steps, which alter the Executable System Specifications (in our case the model to be optimized) in a formal, consistent, and self-contained manner to enable processing [13]. Three base types of components are differentiated:

- *Execution components* are responsible for the execution of the whole, of the parts or of abstractions of the embedded executable system specification as well as execution of associated systems.
- *Control components* implement the evaluation of constraints, rules and objective functions to control the execution of process components.
- *Generator components* generate, transform and extend executable models to comply with different purposes, abstraction levels, parameterizations and structural architectures.

Looking at the simulation model used for optimizing the driving patterns (Fig. 5) we recognize all three types of compo-

nents: Starting with the block instance `GeneticAlgorithm` we recognize a generator component responsible for generation of individuals with different genomes. The genome represents a parametrization of the toll system in the form of a parameter vector and is sufficient to execute the model of the toll system for the given individual. The value of each parameter is bound to a defined range and granularity (i.e. a bit representation of the value) – at present the parameters are the number of active weeks of domestic and foreign trucks (see section II). In the next step `GeneticAlgorithm` sends the representation of the individual via its output port and connection to the block instance `SetupSimulation` responsible for the preparation of the toll system model. `SetupSimulation` (obviously a generator component) creates the necessary environment e.g. the directory structure for simulation in- and output including the parameters and any necessary configuration files. In addition `SetupSimulation` checks the available resources and chooses the number of simulations to be executed in parallel (depending on the number of CPU cores available and the population size). However, the final setup of a simulation run is delegated to another generator component (`MissionSetup`). It generates a mission descriptor data structure, containing the command line parameters to setup and execute a simulation run. This data structure is in turn sent to the first execution component (`RemoteStart`) to execute the model on a specific CPU core. While the simulation run is ongoing two further execution components (`RemoteIsActive` and `Failure`) observe the simulation run and inform the subsequent block instances `SetupSimulation` and `EvaluationFunction` when the simulation run has finished: `SetupSimulation` prepares a new simulation run if necessary an `EvaluationFunction` evaluates the simulation results with respect to the fitness function (see section IV). Since block instance `EvaluationFunction` decides about continuing the optimization loop or not it is a control component.

IV. Applied Optimization Algorithm

To solve our optimization problem we decided to use a genetic algorithm. The straight-forward implementation of a parallelized genetic algorithm was the main reason to choose this optimization algorithm. A genetic algorithm is a search algorithm for optimization purposes based on the mechanics of natural selection and natural genetics. Genetic algorithms are able to avoid getting stuck in a local optimum in the search space, can be used in high-dimensional search spaces and are trivially parallelized ("embarrassingly parallel", [14]). They belong to the group of so called meta heuristics – search methods for approximate solutions [15].

Fig. 6 gives the generic flow chart of the genetic algorithm used: At the beginning an initial population of a fixed size is generated either randomly or using previously available individuals. To limit the search space we choose the parameters to be within pre-defined intervals. Next the fitness of all individuals in the population is computed (step 2 in Fig. 6) to yield the 'parent population'. In the third step the algorithm

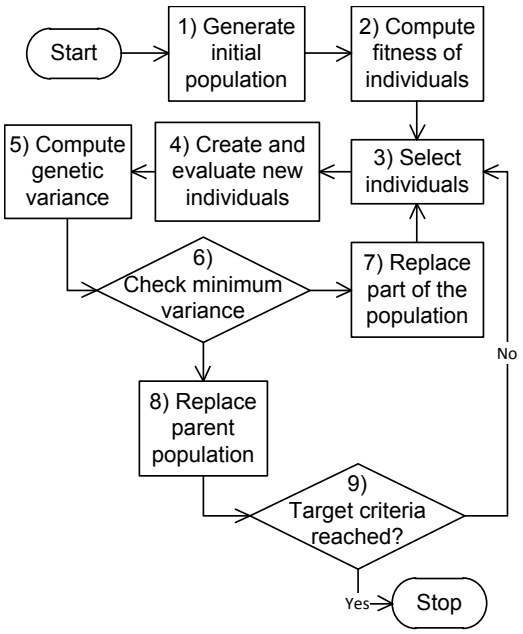

Fig. 6. General sequence of action of the genetic algorithm used (based on [16, 17]).

randomly selects two sets of parents in a *tournament selection* to choose those two parent individuals with the best fitness value.

Once two parent individuals are selected one child individual is created using uniform crossover without mutation (step 4 in Fig. 6). For crossover we select one part of the genome of the first parent individual and the complementary part from the second parent individual. In order to do this a crossover point is chosen randomly. At present we are not using mutation where parts of the genome of an individual are changed randomly to increase population diversity. From the perspective of optimization theory this method is used to overcome local optima [18] – which is implemented in our case by enforcing a minimum variance within the population (step 6 in Fig. 6).

When the child population is fully populated the optimization model starts to evaluate the fitness function by executing simulation runs of the toll system model (as described above). When the evaluation is finished the algorithm checks the genetic variance [19] inherent within the child population (step 5 in Fig. 6). If the variance becomes too small a part of the population is replaced by new randomly generated individuals (step 7 in Fig. 6) otherwise the child population replaces the parent population (step 8 in Fig. 6) and the optimization run continues until the target criteria are met (step 9 in Fig. 6). In addition we use step 6 to check whether the optimization run finds better solutions and again replace part of the population if the results did not improve within 6 generations.

In our case we use fairly small populations with 765 individuals i.e. at a scale of 1:1000 and a genome of 32 parameters each expressing the probability for an HGV of

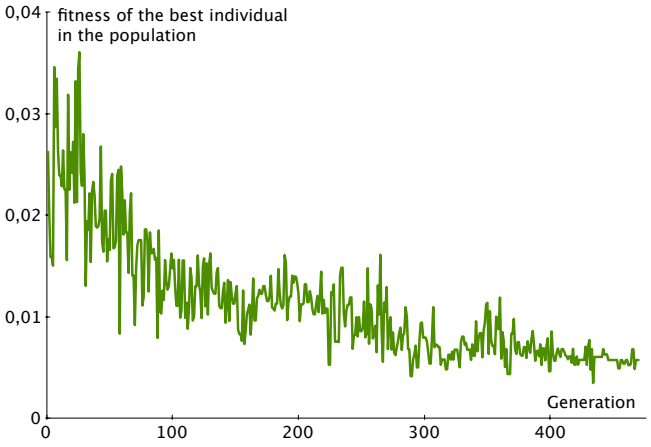

Fig. 7. Fitness of the best individual per generation over the optimization run.

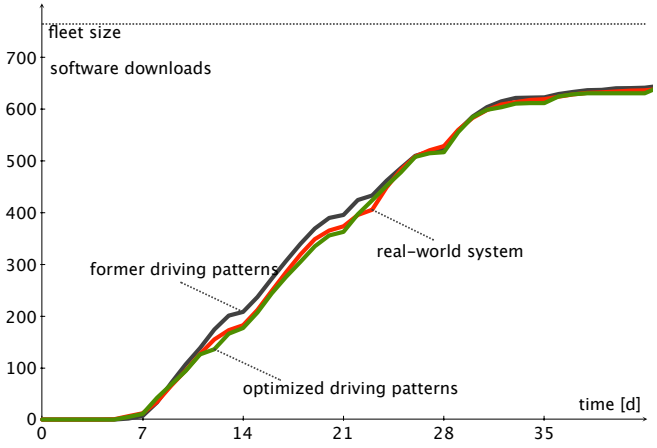

Fig. 8. Simulation results for a fleet-wide software update before and after optimization (red line: data observed in the real-world system, black line before optimization and green line after optimization).

being active (with at least one power cycle) a certain number of weeks within a 15 week period (once for German HGVs and foreign ones). The optimization algorithm starts with a given probability distribution based on historical data from the real-world system (or a previous optimization run). In the next step the fitness function (also called target or evaluation function) is evaluated to quantify the fitness of each individual. Since the evaluation of each individual is independent the algorithm is trivially parallel and we send each computation via the `Remote` component to a different CPU node (see section III) for execution, i.e. the model of the German toll system with the parameterization given by the individual is executed for each individual in parallel.

As an example we take a fleet-wide software update that was rolled out in spring 2012. Using fleet-wide timing parameters the roll-out was configured to spread over 6 weeks where a single update needed less than 10 minutes to download under optimal conditions. To achieve a reasonable number of function evaluations in the optimization we run the simulation model at a scale of 1:1000 resulting in an execution time of less than one minute for the time period of interest – 4 weeks before the start of the update and the first 10 weeks of the update. The simulation model itself is not modified from previous versions [5] and each instance works within its own subdirectory to read and write intermediate results as necessary. At the end of each simulation run the fitness function is evaluated expressing the quality of each individual as the square deviation between the simulated and the real world update roll-out curve (see section V).

V. Optimization Results

For the purpose of this discussion we choose a software update in 2012. Without access to the optimization algorithm the simulation model was parametrized using statistical data from the real-world system and subsequent minor manual adjustments. In comparison we give the results after performing an optimization run with the simulation model at a scale of 1:1000, a population size of 64 and some 400 generations.

Fig. 7 gives the evolution of the fittest individual per generation. The fitness gradually improves over run-time but from generation to generation it can give worse results since the algorithm creates a completely new population for each generation without keeping the best individual around.

Looking at the results (Fig. 8) the optimized driving patterns perform considerably better during the main update phase. The real-world system is configured to give an almost constant rate of updates during the first weeks (red line in Fig. 8) where the OBUs decide randomly when to download the update according to fleet-wide timing parameters. After a few weeks the update rate is determined mostly by those OBUs that are rarely active within the German mobile data networks and no longer depends on the download parameters. So far the previously existing user interaction model typically produces too many updates during the 2nd and 3rd week (black line in Fig. 8) even though the model uses statistical data gathered in the real-world system on Toll Collect test fleets.

To emphasize the time period where the algorithms of the toll system determine the download rate rather than rarely visiting HGVs we compute the fitness function only for the initial 6 weeks. This results in a marked improvement of the simulation results (green line in Fig. 8) for the time period shown. However, since the long-term activity pattern was in this case not subjected to optimization the optimized driving patterns give somewhat worse results for longer time periods (not shown). Taking the deviation from the data observed (Fig. 9) the improvement during the first two weeks of the software update are obvious.

Optimizing the probability distribution for the weekly activity pattern quickly improved the simulation results. However, deviations are still visible even when using a coarse time resolution of one day : Typically at the end of the workweek the difference is biggest and changes its sign with the coming week. This suggests that at least further parameters need

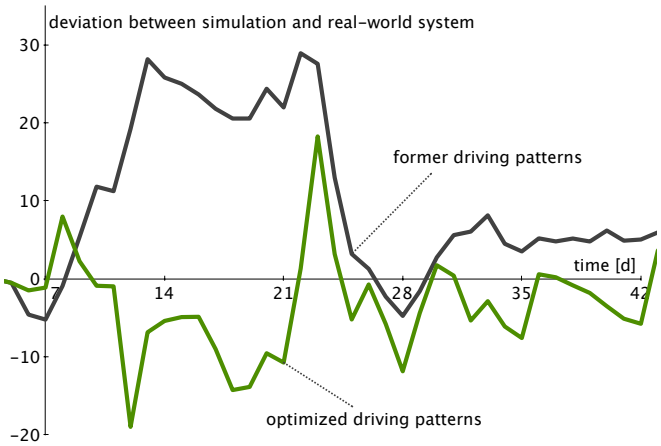

Fig. 9. Difference (in cumulated downloads) between the data observed in the real-world system and both simulation runs (black line before optimization, green line after optimization).

systematic optimization or even a different underlying model to create the driving patterns.

VI. Summary

Taking the example of the German automatic toll system we have discussed the challenge to model the user interaction. Even with a simple model many parameters (e.g. probability distributions) need to be adjusted so as to achieve "good enough" simulation results. The use of a genetic algorithm simplifies the optimization i.e. adjusts the parameters as good as possible starting from the limited data available. The sheer number of parameters available poses a significant challenge even to a parallelized genetic algorithm. To us this suggests that the model of the user interaction is not yet expressed in the right way. In addition, "good enough" models depend on the context. In our example, a better model of the user interaction is needed to reproduce the intra-day behavior – e.g. to use the simulation to monitor everyday operations of the toll system.

Looking back at fig. 2 this article discussed the recently added model of a genetic algorithm. In future work the model of the user interaction should be split in two parts: A generic, domain-independent model of stochastic processes and its domain-specific application to generate driving patterns.

***Abstract*—Project selection is a complex multi-criteria decision making process that is influenced by multiple and often conflicting objectives. The complexity of the project selection problem is mainly due to the high number of projects from which an appropriate collection (an effective portfolio) of investment projects must be selected. This paper presents a new conception of a hybrid framework for construction of an effective portfolio of investment projects. The parameters of the considered model are described using both probability distributions and fuzzy numbers (possibility distributions). The proposed framework enables to take into account stochastic dependencies between model parameters and economic dependencies between projects. As a result, a set of Pareto optimal solutions is obtained. The performance of the proposed method is illustrated using an example from metallurgical industry.**

I. Introduction

THE of estimation and selection of investment projects is often named in literature as ”capital budgeting”. An effective capital budget (a portfolio of investments) is a budget which provides the maximum NPV (Net Present Value) for an acceptable level of risk or the lowest level of risk for a given acceptable NPV of a portfolio. The choice of an appropriate method for risk assessment is associated, among others, with the problem of description of uncertainty in business activity.

For many years, probabilistic calculus was considered as the only appropriate way to mathematically describe and deal with uncertainty. However, in real problems of assessing risk in business activity, not only randomness, but also imprecise or incomplete data is an important source of information. For this reason, many researchers often use alternative ways of modelling of uncertainty, such as fuzzy sets or interval numbers. Also for the selection of investment portfolio, the most appropriate approach to risk assessment is to develop and use methods that allow different representations of uncertainty (e.g., by probability distributions, fuzzy numbers and intervals) to be processed according to their nature and only finally combine them into a synthetic easy-to-interpret risk measure.

Another important aspect of defining an effective portfolio of investment projects is the analysis of the dependency problem. There are two kinds of dependency. The dependency between parameters is usually described statistically and, therefore, is called “statistical dependency”; statistical dependency is typically modelled by fuzzy or probabilistic correlation or regression. The second type of dependency is projects’ interdependency, usually called “economic dependency”. It is used to describe an interaction between investment projects. Interdependency is especially challenging to model, due to the difficulties with its description.

This paper briefly presents a novel framework for the selection of an efficient portfolio of investment projects. The proposed framework integrates a non-linear programming with tools that enable to describe interdependency between projects in a situation when model parameters are described both using probability distributions and fuzzy numbers. The paper has the following structure. Section II outlines different ways of description of uncertainty. In Section III, the current state of art in the selection of a portfolio of investment project is presented. A novel framework for the selection of an effective portfolio of investment projects is suggested in Section IV. In Section V a numerical example is solved using the proposed framework to demonstrate the effectiveness of the latter.

II. Description of uncertainty in evaluation of investment projects

Most of models of the real-world investment projects contain a mixture of quantitative and qualitative data. Therefore, increasingly often alternative descriptions of uncertainty in the assessment of the efficiency of investment projects are applied. The most common situation is when some parameters are described by probability distributions (statistical data), while others are given in the form of possibility degrees (subjective assessments of phenomena made by experts [27], [4]), i.e., the available data is heterogeneous in nature. To sum up, one may say, after Baudrit *et al.* [4], that randomness and imprecise or missing information are two reasons of uncertainty, which have an impact on the analysis of economic efficiency. Therefore, in the process of the evaluation of investment projects (estimation of efficiency and risk of projects), it is inevitable to deal with uncertainty caused by vagueness intrinsic to human knowledge and imprecision or incompleteness resulting from the limit of human knowledge [13], [20]. Hence, it is necessary to use a scheme for representing and processing vague, imprecise, and incomplete information in conjunction with precise and statistical data [4], [8], [13].

978-83-60810-58-3/$25.00

There are hardly a few studies that describe the use of hybrid data [25], i.e., data partially described by probability distributions, and partially by possibility distributions. The use of such data allows to reflect more properly the knowledge on parameters of economic calculus. However, very often, in the assessment of efficiency of investment projects, no distinction is made between these two types of uncertainty, both being represented by means of probability distributions [27]-[13]. Whereas, as suggested by Ferson and Ginzburg [11], distinct methods are needed to adequately represent random variability ("objective uncertainty") and imprecision ("subjective uncertainty").

III. Methods for the selection of effective portfolios of investment projects

The problem of capital budgeting was for the first time formulated by Lorie and Savage [20]. Later on, it was solved using mathematical programming methods. First works on this subject date back to 1960s and 70s [6]-[2]. The problem of determining the capital budget was also solved using linear programming, linear programming with binary variables and multi-objective programming methods.

A lot of attention, especially in the recent years, is given to the risk of investment projects. A method for the construction of an effective portfolio of investment projects on the capital market was first presented by Markowitz [22]. Seitz has adopted the ideas of Markowitz for capital budgeting [26] by using the binary quadratic programming. Methods for the selection of an effective portfolio of investment projects are being constantly improved [7], [9], [1], [3], [24]. Probability distributions of selected parameters were used to describe the uncertainties in these models. In the literature, also presented are methods for the selection of a portfolio of investment projects in the case when uncertain parameters of efficiency calculus are described by means of fuzzy numbers. Such methods were proposed by Huang [15], [16] and Liu and Iwamura [19] and Kahraman [18].

Guyonnet *et al.* [13] has proposed a method which facilitates estimation of risk in the case when probability and possibility distributions are used simultaneously. This method was a modification of the method proposed previously by Cooper *et al.* [8]. Methods for processing hybrid data combine stochastic simulation with arithmetic of fuzzy numbers. As a result of processing of such data, Guyonnet *et al.* [13] define two cumulative distribution functions: optimistic and pessimistic. Similarly, Baudrit *et al.* [4] use probability and possibility distributions in risk analysis. As a result of processing of such data, authors obtain random fuzzy variable, which characterizes the examined phenomenon.

Dickinson *et al.* [10] presented a method for optimal scheduling of investment projects, which takes into account the fact that particular projects can be complementary or substitutive to each other. Santhanam and Kyparisis [29] presented a mathematical model for the selection of a portfolio from economically dependent investment projects associated with the development of information systems. Zuluaga *et al.* [31] presented a model that enables the selection and scheduling of economically dependent investment projects. However, the models of Dickson, Santhanam and Kyparisis and Zuluga do not take into account uncertainty of cash flows generated by investment projects and stochastic dependencies between projects. Medaglia *et al.* [23] proposed the usage of evolutionary algorithms for the selection of economically and stochastically dependent investment projects.

It must be, however, highlighted that there are no methods for the selection of effective investment portfolio, which could process hybrid data, e.g., data expressed in the form of fuzzy numbers and probability distributions. In most of the existing approaches, different ways of uncertainty representation are usually unified by transforming one form of uncertainty into another. Obviously, such transformation entails some problems. For example, transformation of a probability distribution into a possibility distribution causes the loss of information, whereas the opposite one requires additional information to be introduced. This leads to systematic errors in the estimation of efficiency. It is, therefore, necessary to elaborate a framework for representing and processing stochastic, vague, imprecise, and incomplete information in conjunction with precise data for selection of investment project portfolio. Such a framework should also be able to take into account stochastic and economic dependencies.

IV. A framework for the selection of investment project

The process of building an effective capital budget consists of three phases [14]: strategic consideration, individual project evaluation and portfolio selection. Because the approach proposed here focuses on interdependency between projects, the problem of building an effective capital budget is divided into two models – *portfolio selection model* (PSM) and *portfolio evaluation model* (PEM). The purpose of first model is to find selection of the investment projects to gain the best evaluation parameters. Second model is used to determine evaluation parameters for a given set of investment projects.

A. Projects interdependency in uncertain environment

PSM focuses on the selection of projects. Most of project portfolio optimization methods and tools treat each project in a portfolio as an isolated entity. This leads to systematic errors in the estimation of risk and efficiency, and usually produces large overestimation. In order to eliminate these deficiencies, the interdependency between project should be considered. Three types of projects interdependencies are recognized in the literature: benefit, resource and technical [12].

Resources interdependency occurs when the demand for resources to develop projects independently is greater than amount of resources required when all of projects are selected. *Benefit interdependency* occurs when the total advantage of at least two independent projects increases or decreases when these projects are treated as interrelated. *Technical interdependency* occurs when there is a set of exclusive projects such that only one of them may be selected.

There are five classes of project portfolio selection models [2]: ad hoc approaches (e.g., profiles), comparative approaches [28] (e.g., AHP), scoring models, portfolio matrices, and optimization models. PSM is multi criteria linear programming model, and PEM is non-linear programming model combined with stochastic simulation.

B. Portfolio selection model (PSM)

Let us consider a company which plans to launch m potential projects. Due to the changing environment, the company must select a proper subset of those projects. Let each project create new or modify existing primary process steps. A portfolio of investment projects is defined as $(x_1, \ldots, x_m)$ and $x_i = 1$ when project i is selected and 0 otherwise ($i \in I = \{1, \ldots, m\}$). Let b defines overall budget allocation for a selected portfolio, and c_i initial cost of implementation of i-th investment. Let $fin(x_1, \ldots, x_m)$ denote financial evaluation parameter for a given portfolio of investments. The performance of the selected portfolio is measured by two functions: $E(fin(x_1, \ldots, x_m)$ and $\sigma(fin(x_1, \ldots, x_m))$. Then, the selection of the portfolio of investments is defined as follows: find $(x_1, \ldots, x_m)$ that maximize of the expected value of $fin(x_1, \ldots, x_m)$ and minimize $\sigma(fin(x_1, \ldots, x_m))$ subject to:

- *portfolio selection constraints* – for each investment, the cost of implementation cannot exceed the overall budget $\sum_{i \in I} c_i * x_i \leqslant b$
- *integrability constraints*: $x_i \in \{0, 1\}, i \in I$

In order to solve PSO problem, for each portfolio of investments, PEM model must be invoked in order to compute evaluation parameters.

C. Portfolio evaluation model (PEM)

PEM computes evaluation parameters for a given set of investment projects $(x_1, \ldots, x_m)$. Since some of the model parameters are given as fuzzy numbers, thus, the value of the $fin()$ function is a fuzzy variable, which results from the simulation combined with non-linear programming.

In order to evaluate a portfolio of investments, a mathematical model of an enterprise is built. Mathematical model consists of two groups of equations. First group of equations includes balances of the enterprise manufacturing capacities and material balances. It allows to determine size of the total production and size of sale achieved by enterprise. It determines also conditions of the selection of projects to be implemented. These conditions result form manufacturing capacities balance, material balances and availability of capital allocated for investments. The second group of equations are financial equations.

- equations of manufacturing capacities balance for primary production departments

$$\sum_{i \in I} X_{ijw}^{t\tau} \leqslant v_{jw}^{\varsigma} \cdot \Delta_{jw}^{\tau}, \tag{1}$$

where $\tau = 0, \ldots, \bar{\tau}, \tau \leqslant t, j \in J, w \in W_j$ and $t = \tau, \ldots, \tau + \bar{t}_{jw}$.

$$X_{ijw}^{t\tau} \geqslant 0\,,\ \varsigma = t - \tau \tag{2}$$

$$\Delta_{jw}^{\tau} = \begin{cases} 1 & \text{for } w \in \bar{W} \\ 0 & \text{for } w \in W - \bar{W} \end{cases} \tag{3}$$

$$\kappa\left(\bar{W}\right) = 1, \tag{4}$$

$$\eta^{\tau}\left(\bar{W}\right) \leqslant \bar{\eta}^{\tau},\ \tau = 0, 1, \cdots, \bar{\tau} \tag{5}$$

- equations of the enterprise material balance

$$\sum_{j \in J} \sum_{w \in W_j} \sum_{\substack{\tau=1 \\ \tau \leqslant t}}^{\bar{\tau}} X_{ijw}^{t,\tau} - \sum_{j \in J} \sum_{w \in W_j} \sum_{z \in I} \sum_{\substack{\tau=1 \\ \tau \leqslant t}}^{\bar{\tau}} m_{izjw} X_{zjw}^{t,\tau} = G_i^t \tag{6}$$

$$G_i^t \leqslant \bar{g}_i^t\left(\bar{W}\right), \tag{7}$$

where:

- $X_{ijw}^{t\tau}$ - quantity of the gross output of product i produced in j department in t year, in case of qualifying to realization project w in τ year,
- G_i^t - size of sale of the product i in year t,
- KRK^t - value of short-term credit in year t,
- KRD^t - value of long-term credit in year t,
- ZB^t - gross profit in year t,
- I - set of product indexes,
- I_j - set of indexes of products produced in j department,
- W - set of project indexes,
- W_j - set of indexes of projects connected with j department,
- $\bar{W}$ - set of indexes of projects qualified to realization,
- J - set of primary production department indexes
- v_{jw}^{ς} - manufacturing capacity of the j department after realization of w project in ς year of the duration
- $\bar{\eta}^{\tau}$ - limit of investment outlays in the τ year,
- m_{izjw} - consumption per unit of the i product for producing the z product in the j department after realizing the w project,
- $\bar{t}_{jw}$ - duration of the w project being realized in j department
- c_i^t - selling price for product i in year t
- kz_{ijw}^{ς} - variable cost of processing the product i by department j after realization of w project in ς year of the duration
- r_d - long-term interest rate
- r_k - short-term interest rate
- $\bar{\kappa} : 2^W \rightarrow \{0, 1\}$ - function determining sets of projects being possible for realization, value 1 means a set possible to realization, value 0 means set impossible to realization,
- $\eta^{\tau} : 2^W \rightarrow R$ - function assigning to $\bar{W}$ set of the projects an investment outlay for realization of this set in τ year of capital budgeting period
- $\bar{g}_i^t : 2^W \rightarrow R$ - function assigning to $\bar{W}$ set of the projects possible sale of the product in the t year

The second set of equations of the model are financial equations. They are linear equations, which for all the

above-mentioned parameters determined by equations (1)-(7), determine specific items of the company's balance sheet, P&L account and cash flows (NCF) used to calculate the NPV. As an example, an equation for calculating a company's gross profit is presented below.

$$ZB^t = P - C_1 - C_2 - C_3, \tag{8}$$

where $i \in I;\ t = 0, 1, 2, \cdots, T$ and

$$P = \sum_{j \in J} \sum_{i \in I_j} c_i^t G_i^t \tag{9}$$

$$C_1 = \sum_{\tau=1, \tau \leqslant t}^{\bar{\tau}} \sum_{w \in W_j} \sum_{j \in J} \sum_{i \in I} k_{ijw}^{\varsigma} X_{ijw}^{t,\tau} \tag{10}$$

$$C_2 = r_k K R K^t + r_d K R D^t \tag{11}$$

$$C_3 = \chi^t \left(\bar{W}\right) - \xi^t \ \left(\bar{W}\right) \tag{12}$$

The remaining financial equations express commonly known dependencies. A detailed presentation on them would considerably increase the volume of the article. Therefore, it is omitted.

In the next step, an appropriate model of uncertainty is assigned for every parameters. In the proposed framework, material consumption and product cost are characterized by fuzzy numbers. Demand and selling prices are described by probability distributions. Then, fuzzy simulation is employed, which allows different representations of uncertainty to be processed according to their nature. Moreover, the proposed framework takes into account economic dependencies in the process of selection of an effective portfolio of investment projects. Statistical dependency is used for describing relation between model parameters. Dependency between parameters characterized by fuzzy numbers are described by interval regression. Interval regression is an extension of the classical (crisp) regression where regression parameters are bounded closed intervals. For probabilistic parameters their dependency is determined by the correlation matrix. To process them, a method presented by Yang [30] based on Cholesky decomposition of the correlation matrix is utilized.

D. Procedure of determining portfolio evaluation model

The proposed procedure of determining the effectiveness of investment portfolio consists of two stages. It combines the procedure of stochastic simulation with execution of arithmetic operations on interactive fuzzy numbers. To execute such arithmetic operations non-linear programming is used. Computation procedure in this case is the following. Random variable values are drawn from among mentioned above parameters expressed in the form of the probability distribution. The procedure of generation accounts statistical dependency between variables. These values and remaining parameters expressed in the form of fuzzy numbers allow to determine evaluation parameter as fuzzy number. The problem of determining the fuzzy number characterizing evaluation parameter may be written owing to use of the concept of α-levels of fuzzy sets. Thus, the variables y corresponding to the parameters that are expressed in the form of fuzzy numbers are introduced, and then the parameters are replaced for those variables. Additionally, the following constraints are imposed:

$$\inf\left(\tilde{Y}_i\right)_\alpha \leq y_i \leq \sup\left(\tilde{Y}_i\right)_\alpha \tag{13}$$

$$y_i \geq \inf\left(a_1^{iz}\right) \cdot y_z + \inf\left(a_2^{iz}\right) \tag{14}$$

$$y_i \leq \sup\left(a_1^{iz}\right) \cdot y_z + \sup\left(a_2^{iz}\right) \tag{15}$$

where

- $\inf\left(\tilde{Y}_i\right)_\alpha$, $\sup\left(\tilde{Y}_i\right)_\alpha$ - respectively lower and upper bounds of α-level of the fuzzy parameter $\tilde{Y}_i$
- $\sup\left(a_1^{iz}\right)$, $\inf\left(a_1^{iz}\right)$, $\sup\left(a_2^{iz}\right)$, $\inf\left(a_2^{iz}\right)$ - respectively lower and upper bounds of interval regression coefficients describing dependency between parameters $\tilde{Y}_z$ and $\tilde{Y}_i$

Next, in order to determine the lower and upper bounds of the respective α-level of the efficiency parameter, the following constrained optimization problems must be solved:

$$NPV_\alpha \longrightarrow \min \tag{16}$$

for the definition of the lower bound of the α-level of the NPV,

$$NPV_\alpha \longrightarrow \max \tag{17}$$

for the definition of the upper bound of the α-level of the NPV. Drawing probabilistic values and determining NPV is repeated $n_{\max}$ times. As result $n_{\max}$ fuzzy sets characterized by membership functions $(\mu_1^{NPV}, \ldots, \mu^{NPV})$ are obtained and thus NPV is represented by a random fuzzy variable. Based on the vector $(\mu_1^{NPV}, \ldots, \mu^{NPV})$, the mean value, standard deviation as well as lower and upper cumulative distributions for the NPV are calculated. The hybrid procedure which implements the described approach is presented in the following algorithm.

Algorithm 1 Procedure of determining evaluation model

$n \leftarrow 1$;
2: Randomly generate vector probabilistic variables taking into account the correlation between them
$\alpha = 0$;
4: Define α-levels for fuzzy variables defining efficiency parameter
Calculate (sup) and (inf) for defined α-levels by finding: $eff_\alpha \leftarrow \min$ and $eff_\alpha \leftarrow \max$ under the problem constrains specified by constraints
6: $\alpha = \alpha + \phi$
If $\alpha \leqslant 1$ goto **STEP 4** else $n = n + 1$
8: if $n \leqslant n_{\max}$ goto **STEP 2**
Calculate mean value, standard deviation, and lower and upper cumulative distributions of the NPV.

V. NUMERICAL EXAMPLE

The capital budget was determined for the production process presented on the fig. 1. This setup includes the production cycle in steel industry, from production of the pig iron, production of steel, hot rolling products to production products coated with metal and plastics.

We take into consideration five investment projects: steel making plant, hot rolled sheet mill, cold-rolled sheet mill, hot-dip galvanizing sheet plant, sheet organic

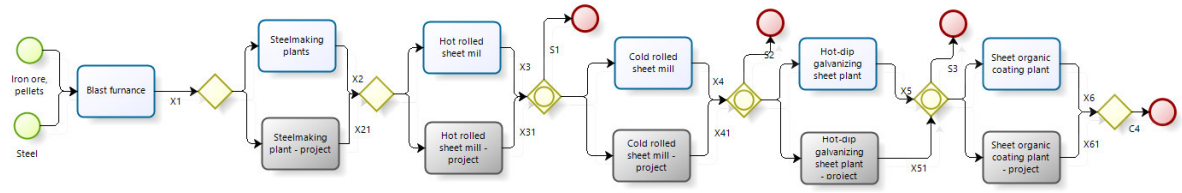

Fig. 1. Diagram of the analyzed technological setup

coating plant. Those investments are highlighted in gray. Decisive variables for the estimation of efficiency and the risk of investment projects in case of the investment in iron metallurgy are: quantity and selling prices, costs of materials and quantity of investment outlays. It was recognized also from here, that in the simulation experiment is necessary to take into consideration the uncertainty of the possible quantity of sale for each of products ranges being produced by the company, prices of these products, prices of metallurgic raw materials (prices of iron ores and the pellets), consumption per unit indexes, quantity of investment outlays. It was assumed, that remaining parameters of the efficiency calculus were determined. Prices of individual assortments of metallurgic products and metallurgic raw materials are correlated strongly. Similarly, sale quantities of each assortment of metallurgic products are correlated. This fact was taken into consideration when processing the values of efficiency calculus uncertain parameters.

In the computational experiment it was taken into consideration the uncertainty of the possible quantity of sales for each of products ranges being produced by the company, prices of these products, prices of semi-finished steel (prices of continuous casting stands), investment outlay for projects, construction period for investment projects and consumption per unit indexes for all products. Sales and possible quantity of sale for each product are described be probability distribution (in this case normal distribution). Rest of parameters were presented as a triangular fuzzy numbers.

In numerical example, we identify two types of dependencies. Prices of individual assortments of metallurgic products and metallurgic raw materials are correlated. Also sale quantities of each assortment of metallurgic products are correlated. Those parameters are using to describe benefit interdependency. Equations of manufacturing capacity balance are using for describing resource dependency and technical dependency.

The following new investment projects are considered: steel mill, rolling mill of cold milled steel sheets, hot dip galvanized coating, organic coating, rolling mill of hot milled steel sheets. Material consumption as well as product and half-product prices are given in the form of fuzzy numbers. They are presented, respectively, in Table I and Table II.

Sale parameters are given by normal probability distributions given in Table III.

TABLE I
TRAPEZOIDAL FUZZY NUMBERS (TFN) INDICATING MATERIAL CONSUMPTION

Material consumption	**TFN**
steel half-products – molten iron	$(0.855, 0.860, 0.870, 0.875)$
half-products – hot rolled steel sheets	$(1.058, 1.064, 1.075, 1.078)$
hot rolled steel sheets – cold rolled sheets	$(1.105, 1.111, 1.124, 1.130)$
cold rolled sheets – dip galvanized sheets	$(1.010, 1.020, 1.026, 1.031)$
dip galvanized sheets – organic coated sheets	$(0.998, 0.999, 1.000, 1.001)$

TABLE II
TRAPEZOIDAL FUZZY NUMBERS (TFN) FOR PRICES

Price	**TFN (USD/t)**
iron ore	$(335, 360, 400, 425)$
lumps	$(375, 400, 440, 470)$
steel scrap	$(940, 960, 1010, 1035)$
hot rolled sheets	$(2040, 2080.8, 2177.7, 2228.7)$
cold rolled sheets	$(2220.08, 2266.65, 2370.15, 2427.08)$
hot dip galvanized sheets and strips	$(2535.75, 2588.25, 2709, 2772)$
organic coated sheets and tapes	$(3450.6, 3519.82, 3684.9, 3754.13)$

TABLE III
PROBABILITY DISTRIBUTIONS INDICATING SALE PARAMETERS

Sale	**Mean value**	**Std. dev.**
hot rolled sheets	4704.0	117.5
cold rolled sheets	2750.0	51.4
hot dip galvanized – sheets and tapes	1147.9	52.4
organic coated – sheets and tapes	708.4	30.8

The Cholesky matrix which describes the dependencies between sale parameters is given by the equation (18).

$$\begin{pmatrix} 1.00000 & 0.87786 & 0.91142 & 0.86321 \\ 0.00000 & 0.47891 & 0.24007 & 0.27276 \\ 0.00000 & 0.00000 & 0.33418 & 0.34165 \\ 0.00000 & 0.00000 & 0.00000 & 0.25249 \end{pmatrix} \tag{18}$$

For the computational example, the α-level for fuzzy variables are set at 10 and the number of simulation are set to 100. The result for the computational example is shown in Fig. 2.

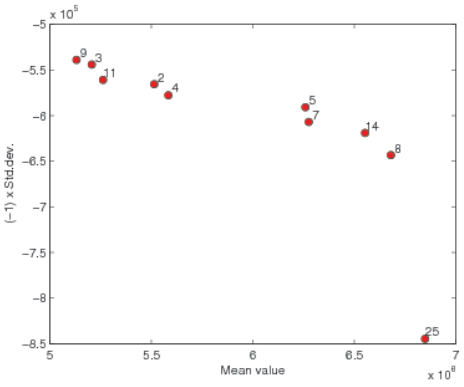

Fig. 2. Pareto optimal solutions for the problem of selection of an efficient portfolio of investment projects

VI. Conclusions

Above, the new method of choice of the effective portfolio of investment projects was presented. Presented concept of the mathematical model and the algorithm elaborated are making it possible to generate the set of Pareto-optimal solutions. The method is allowing for flexible formulating of dependence between projects. It concerns to dependencies with the technical character, how for example mutual excluding of projects. The structure of the model is causing, that dependencies with the economic character are also taken into account, it means, that projects are substitutionary or complementary in relation to themselves. Elaborated model has been utilized for selection of projects for the chosen production setup. The model is generating the set of Pareto-optimal solutions, which may to be the subject of the further analysis with taking extra criteria of quality into account.

***Abstract*—A significant volume of Web traffic nowadays can be attributed to robots. Although some of them, e.g., search-engine crawlers, perform useful tasks on a website, others may be malicious and should be banned. Consequently, there is a growing need to identify bots and to characterize their behavior. This paper investigates the share of bot-generated traffic on an e-commerce site and studies differences in bots' and humans' session-based traffic by analyzing data recorded in Web server log files. Results show that both kinds of sessions reveal different characteristics, including the session duration, the number of pages visited in session, the number of requests, the volume of data transferred, the mean time per page, the number of images per page, and the percentage of pages with unassigned referrers.**

I. Introduction

ALONG with the growing popularity of search engines and other Web-based applications there has been the growing need to develop advanced tools for retrieving information on the Web content, structure, and usage. Such tools are Web bots (also called Web robots, spiders, or crawlers). They can traverse the Web autonomously by following the structure of hyperlinks, collect different kinds of information, and perform specific tasks on websites.

The most common bots are search engine crawlers, which visit Web pages on a regular basis to build and maintain huge search indexes [1], [2]. Popular bots visiting e-commerce sites are shopping bots, which collect information on products in various Web stores on behalf of product search engines or price comparison services. SEO spybots and content scrapers can expeditiously scrape from websites large amounts of information which may be valuable for SEO professionals or competitive e-business companies [3]. Other examples of robots include resource archivers, link checkers, e-mail harvesters, chat bots [4], spambots [5], hacking bots, artificial actors in e-dating [6], or automatic online game players [7].

Robot traffic on a website should be identified and sometimes also banned for several reasons. The most obvious ones are connected with potential threats of malicious bot activities [8], [9], [10]. Bot-generated click frauds in pay-per-click advertising result in higher fees paid by the advertisers [11]. Content-stealing bots may gather valuable business intelligence knowledge from websites and thus indirectly harm e-business competitiveness. High bot activity may also negatively affect the position of a website in search-engine rankings. Besides, bots consume network bandwidth and server resources; thus, they may cause degradation of the server performance and the quality of service offered to human users. Especially dangerous are automated DoS (Denial of Service) attacks, which may even make the server stall or crash [9]. Lastly, identification of robot traffic is essential when analyzing behavior of human users, who are characterized by different navigational patterns than bots [1], [8], [9], [12], [13], [14], [15].

Although some studies have addressed the problem of robot traffic characterization based on Web server logs, very little research has been done for e-commerce sites ([16], [17], [18]). Our study aims to partially fill this gap by comparing key characteristics of bot- and human-generated traffic on a Web bookstore site. This issue is crucial for e-commerce sites where human users are potential buyers and their activity on the site is directly related to the profitability of the online store.

The paper is organized as follows. Section II presents Web server log data underlying our research and the research methodology. Section III discusses the share of bots in the analyzed Web traffic, whereas Section IV compares key characteristics of bot and human sessions. Section V concludes the paper and suggests prospective future work.

II. Research Methodology

A. Web Server Log Data Description

When an Internet user visits a website, their Web browser (which is a Web client, in fact) communicates via the HTTP protocol with the server hosting the site. For each Web page requested by the user, their client typically issues a series of HTTP requests to the server: one request for a page description file and the following requests for objects embedded in the page, such as images or video files. After

978-83-60810-58-3/$25.00

receiving HTTP responses the client assembles the page and displays it in a browser window. A Web client may represent not only a human user but it may also be a computer program, i.e. a Web bot.

Data concerning each incoming HTTP request is recorded in the access log file stored at the Web server. That data includes some client data (a client IP address, a client identifier, a user agent field, a user identifier, a referrer field), the requested resource data (an URI identifying the requested server resource, a transfer size), the HTTP-related data (a method, a protocol version, a status code), and a timestamp. As an example, let us consider the following log entry, representing one HTTP request:

```
66.249.66.52 - - [03/Dec/2013:08:55:59 +0100] "GET shopping/images/pict21.jpg HTTP/1.1" 200 242 "-" "Mozilla/5.0 (compatible;Googlebot/2.1;+http://www.google.com/bot.html)".
```

This line describes a request sent by a Web client with the IP address 66.249.66.52, whose user identifier is not available. The request was served 3 December 2013 at 8:55:59 (according to Central European Time) and it concerned downloading (by using the GET method) an image file identified by URI "shopping/images/pict21.jpg". The request was successfully served (a status code is 200) and the server sent to the client 242 bytes in response. A referrer field is unassigned. The client was Mozilla 5.0 which used the protocol HTTP/1.1. One can notice that the user was not a human but Google's web crawling bot (the user agent field contains the bot's name, "Googlebot").

Our analysis was based on access logs for an online store (the store name is not given in the paper due to a non-disclosure agreement). The data covered the period of one month, December 2013.

A dedicated computer program was used to read, preprocess, clean, and analyze the data. The program was implemented in C++ using MS Visual Studio. Its most important modules include:

- Input/Output Module containing functions for reading raw data from the input log files and saving the results to the output files;
- Basic Functions Module with functions for parsing each HTTP request's line in order to distinguish individual data describing the request and transform it to the format suitable for the analysis;
- Request Module for managing and processing HTTP requests, e.g., checking whether a request was generated by bot;
- Session Module for reconstructing and processing user sessions;
- Robot Module for identifying and processing sessions generated by bots;
- Statistics Module containing functions for computing all the necessary statistics;
- other modules implementing the operation of visual forms.

B. Reconstruction and Characterization of User Sessions

Based on HTTP requests user sessions were reconstructed. A `user session` means a sequence of requests issued by a Web client during the single visit to the Web store. Each individual user was identified based on two data fields describing HTTP requests: the client IP address and the user agent field. Consecutive user sessions were reconstructed based on the requests' timestamps, assuming a minimum 30-minute interval between two subsequent sessions of a given user (the value of 30 minutes has been commonly applied in previous Web traffic analyses, e.g. in [9], [19]).

Afterwards, each user session was described with a number of attributes:

- session length – the number of pages visited in session;
- session duration – time interval (in seconds) between the times of the last and the first requests in session (session duration is shorter than the actual time of the user-site interaction because the time of browsing the last page in session by the user in unknown at the server side; for the same reason this attribute cannot be determined for sessions containing only one page);
- mean time per page – the average time (in seconds) the user browsed a single page in session (this attribute may be derived only for sessions containing more than one page);
- volume of data transferred to the Web client (in MB);
- number of HTTP requests;
- image-to-page ratio – the average number of image file requests over the number of page requests in session;
- percentage of pages with unassigned referrers – the percentage of page requests with unassigned or blank referrer fields;
- percentage of requests with unassigned referrers – the percentage of HTTP requests with unassigned or blank referrer fields;
- percentage of requests of type HEAD – the percentage of HTTP requests with HEAD method;
- percentage of 4xx responses – the percentage of erroneous HTTP requests in session (i.e. requests with status codes starting with "4").

We decided to compute the aforementioned attributes because some previous user session analyses for non-e-commerce environments reported that these session features may be useful in distinguishing Web robots from human users [1], [8], [9].

Some sessions contained no Web page request and only one request for an image file (such a situation is often connected with displaying a banner advertisement of the store on another Web page). As these sessions cannot be regarded as intended visits to the store, we did not take them into consideration in our analysis.

C. Identification of Bot Sessions

There are a few ways to identify at least some part of user sessions issued by Web robots.

First, one should check if the file "robots.txt" was accessed in a session. Cooperative robots should request this file at the beginning of each visit to a site in order to read which parts of the site they can access.

Second, "ethical" bots should inform a Web server about their identities via their user agent fields, containing the name of the robot. We implemented a function verifying HTTP requests' user agent fields for compliance with user agents of known robots, available on online databases [20] and [21]. Moreover, some robots not included in these databases were identified based on keywords contained in user agent fields ("bot", "spider", "crawler", "worm", "search", "track", "harvest", "dig", "hack", "trap", "archive", or "scrap"), as well as through a semi-automatic inspection of user agent fields.

In practice, not all robots access the file "robots.txt" or declare their identities in user agent fields. However, some of such bots may be still identified based on the character of their interaction with the site, which proceeds differently from the interaction of human users. Humans usually communicate with the site via the Web interface and follow navigation paths according to the site topology. Each Web page request is typically followed by a group of requests for embedded objects (usually images). Moreover, the successive page requests are separated with some time intervals called "user think times". In contrast, robots tend to reveal navigational patterns incompatible with the site topology and have unintuitive session characteristics, e.g., the extremely low mean time per page. We assumed the following three groups of session characteristics that indicate Web robots:

- the mean time per page shorter than 0.5 second;
- an unassigned referrer field in the first request in session, the percentage of pages or requests with unassigned referrers equal to 100, and the percentage of requests of type HEAD equal to 100;
- an unassigned referrer field in the first request in session, the percentage of pages or requests with unassigned referrers equal to 100, the percentage of 4xx responses equal to 100, and the image-to-page ratio equal to 0.

All sessions which were not classified as performed by robots, after excluding sessions connected with executing administrative tasks on the site, were assumed to be performed by human users.

III. Bot Share in Overall Web Server Traffic

According to the results of earlier analyses for e-business workloads the share of robot requests has differed from several (3.2% in [17]) to a dozen or so (15% in [22], 16% in [23]) percent. In our data set 22.3% of all HTTP requests were identified as generated by bots (Fig. 1). However, as regards the number of user sessions, as many as 79.3% were performed by bots. Bot sessions seem to contain on average less requests and consume less server resources than human sessions (the volume of data transferred to bot clients comprised 38% of the overall data transfer).

In regards to known bots, possible to recognize by checking requests' user agent fields, 76 different robots were identified. The most active of them were popular search engine crawlers (Bingbot, MJ12bot, Googlebot, Google AdsBot, Yandex bot, MSNBot, Baidu spider). Large part of bot traffic was also generated by SEO and e-commerce crawlers (AhrefsBot, ShopWiki, WillyBot), link checkers (SEOkicks robot, SpBot), and social media agent FacebookExternalHit.

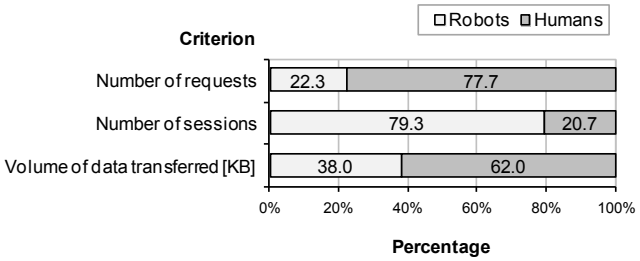

Fig. 1 Percentage breakdown of robots' and humans' data

It is worth noting that only 11% of all bot sessions (including 22.7% of known bots' sessions) accessed the file "robots.txt".

IV. Comparison of Bot and Human Sessions

An insight into the session characteristics revealed that a large number of all user sessions contained only one page and/or lasted only one second. One of the justifications of such user behavior may be that some users were referred to the store site by following a search engine link or by clicking a store advertisement placed on another site but the content of the store website was not what they had searched for. Such users left the site immediately after entering it. We decided to exclude from the statistical analysis sessions containing only one page and sessions lasting only one second.

Furthermore, using the graphical method, we excluded from the analysis a few outlying sessions which were extremely long and lasted for an extremely long time compared to other sessions. The outliers were two human sessions (containing 202 and 312 pages) and eight bot sessions (containing from 1 453 to 6 029 pages and/or lasting longer than 48 hours) – the reason for the exclusion of these several sessions was that they strongly distorted the statistical results for all human and bot sessions, respectively. Finally, only 27% of sessions were left in our dataset.

A. Session Length

An important aspect of user session characterization in the context of distinguishing bots from humans is the session length in the number of pages visited in session. Intuitively, there is some upper limit on the maximum number of human user's clicks, i.e. the number of pages a human user can open and browse during a single visit to a website. This limitation does not apply to automatic computer programs, such as bots, which are able to automatically traverse all pages belonging to a site in a relatively short time. For the same reasons the maximum time of a human-website interaction is limited as well, so bot-generated sessions tend to last much longer than human ones.

Our results achieved for the e-commerce site confirm these observations. Session length statistics presented in Table I show that robots requested on average above four times more pages in session than humans and the maximum session length was an order of magnitude higher for bots than for humans. (Taking into consideration the outlying sessions excluded from the analysis one can notice that the longest human session contained 312 pages whereas the longest bot session contained as many as 6 029 pages.) However, session length distributions presented in Fig. 2 are similar for robots and humans: both histograms illustrate a strong right-skew of session length distribution. Over 95% of human users opened less than 26 pages during their visits in the store and 97% of bots requested less than 176 pages.

B. Session Duration

Session duration statistics presented in Table II show that Web bots tend to spend much more time on the website than human users. The mean session duration is fifteen times longer for bots than for humans. The maximum session duration for bots is 39 hours (and up to 181 hours taking into consideration the excluded outlying bot sessions!) whereas for humans it is less than two hours. Distributions of session durations, shown in Fig. 3, are very similar to the distributions of session lengths in Fig. 2. For both kinds of sessions they are strongly right-skewed and heavy-tailed.

Intuitively, bigger numbers of pages in session should correspond to longer session durations so it is worth graphically examining this relationship. Fig. 4 presents a two-dimensional scatter plot of the session duration against the session length (to improve the graph readability robot sessions with lengths exceeding 800 pages were not shown in the figure). One can see the correlation between the number of pages visited in session and the duration of a visit for both kinds of session: as the session length increases, the session duration tends to increase as well. Human sessions form a quite well-knit group in the two-dimensional area whereas robot sessions are rather dispersed and seem to form a few (at least five) separate clusters. Fig. 4 suggests that different kinds of bots may reveal different behavior so it would make sense to separately characterize behavior of various bots (search engine crawlers, image indexers, link checkers, e-

mail collectors, etc.). One could also apply classification or clustering methods to determine classes or clusters of robot sessions. We leave these issues for our future work.

C. Mean Time per Page

Based on the session length and the session duration one can determine the mean time per page for each user session containing more than one page. The mean time per page in session was computed according to the formula:

$$\bar{d}_s = \frac{d_s}{l_s - 1} \quad (1)$$

where d_s is the session duration (in seconds) and l_s is the session length (in number of pages), $l_s > 1$. Unlike the session duration, which does not include the time for the last page visited in session, the mean time per page is not underrepresented as it is computed for all visited pages except one.

Mean time per page statistics, presented in Table III, show significant differences between bot and human sessions. It may be surprising that bots spend more time analyzing Web pages than human users and the average is equal to as much as 5.3 minutes. However, the median equal to 1.9 minute and the mode equal to 2 seconds are much lower. Besides, a relatively high value of the standard deviation, 8 minutes, indicates that the mean time per page is rather differentiated for bots. Histograms in Fig. 5 also show a bigger differentiation of mean times per page for bots than for humans. For robots the distribution of mean times per page is not so strongly right-skewed and does not include such a long tail as for human users. These results also indicate that it may be worth performing the statistical characterization of various kinds of robots visiting the Web store site.

D. Image-to-Page Ratio

Some previous studies reported that robots (especially crawlers) request mostly Web page files and ignore image files [8], [9], [24]. In contrast, human users navigate through the website following the structure of hyperlinks and when they open a new page, they usually download the page description file along with image files embedded in the page. Hence, such metrics as image-to-page ratio or percentage of image requests in session belong to strongly distinguishable characteristics between bots and humans. Image-to-page ratio statistics in Table IV, as well as histograms in Fig. 6 confirm these results. Humans request more than 22 images per page; the median is equal to 19 and the mode is equal to 36. In contrast, robot requests for image files are negligible: the mean number of images per page is only 0.3 and what is more, both the median and the mode are equal to 0. Among all robot sessions almost 50% did not request any image at all. Surprisingly, 0.6% of human sessions also contained no image request (it may indicate that some sessions considered as generated by humans were performed by bots, in fact).

Maximum	40.6	103.6

E. Volume of Data Transferred to Web Clients

We decided to examine if large numbers of image requests correspond to large volumes of data transferred to Web clients, i.e. whether data transfers are bigger for humans than for bots. Typically, a significant part of Web traffic concerns transmitting small files and messages (e.g. messages that the requested resource has not been modified or that resource could not be found on the server). In contrast, graphical and multimedia Web resources are relatively big files.

As can be seen in Table V, volumes of data transferred to human users tend to be much bigger than for robots. Although this metric in both cases ranges from 0 to over 14, distributions of data transfer volumes are quite different (Fig. 7). For robot sessions the histogram is extremely heavy-tailed. Average bot data transfer is 227 KB, however the median transfer is only 65 KB and the mode is merely 1 KB. For 98% of bot sessions the transmitted data did not exceed 1.7 MB. On the contrary, average data transfer for humans is 1.2 MB, the median is 765 KB and the mode is 263 KB. Data sent in 98% of human sessions were up to 5.1 MB.

It is interesting to observe that for both kinds of sessions the distributions of data transfer volumes (Fig. 7) correspond very accurately to the distributions of the numbers of HTTP requests in session (Fig. 8). Also the range of the numbers of HTTP requests in session is almost the same for bots and humans (Table VI).

F. Percentage of Pages with Unassigned Referrers

Users may reach the store website in many different ways, e.g. by following a search engine link (one of organic search engine results or sponsored links), or by clicking a banner ad on another website. In such cases an address of the referring

Minimum	2	2
Maximum	1 450	1 484

page is contained in the referrer field of the first HTTP request in session. Sometimes this field may be empty, e.g. when a user enters the site directly by typing the site address in a browser's address bar or clicking on a bookmarked page. However, as a human user navigates through the website, each newly opened Web page request will contain in its referrer field the address of the previously browsed page. On the contrary, the vast majority of Web robots initiate their sessions (or even all HTTP requests in session) with unassigned referrer fields, so it may be a good indicator of a bot-generated session. This was confirmed in previous Web characterization studies, e.g. in [10] and [25].

We computed the percentage of page requests with unassigned referrer fields in each session. Our results, presented in Fig. 9 and Table VIII, are similar to observations reported in earlier studies. In fact, 98.4% of all robot sessions had all pages with unassigned referrers. For comparison, among human sessions there were only 2.1% of such sessions (it is very likely that they were actually unidentified bot-generated sessions).

G. Percentage of Requests of Type HEAD

The most common HTTP method is GET, which is used do download contents from Web servers. By default, when a human user browses a website via a browser, requests sent to the server by the browser will be of type GET. Other possible HTTP method is HEAD, used to retrieve only Web metadata. In contrast to humans, robots are expected to use HEAD method instead of GET when possible (e.g. to download only recently updated contents) in order to reduce the amount of data downloaded from servers and to minimize the consumption of server resources.

Some previous workload characterization studies showed that the percentage of requests of type HEAD is higher for bots than for humans [25]. Other studies reported that nearly all crawler requests were of type GET [24]. Our results signalize an advantage of bots over humans in this respect, however the percentage of requests of type HEAD for bot sessions was not very high (Table VII). Only 0.4% of bot sessions had some requests of type HEAD, compared to 0.1% of human sessions. After taking into consideration all robot sessions (even those containing only one request, excluded from our statistical analysis), the mean percentage of HEAD requests for bots increases to 0.8 and 0.9% of bots sessions contain only HEAD requests.

Fig. 10 Histogram of percentages of 4xx responses: (left) for humans, (right) for bots

H. Percentage of 4xx Responses

Web robots tend to have a higher rate of erroneous requests (i.e. requests with status codes of type 4xx), because it is more likely that they request outdated or deleted files [1], [24], [25]. However, we observed that for our data set the rate of erroneous requests was a little bit higher for human sessions (the mean equal to 5) than for bot ones (the mean equal to 4.9) (Table IX). For robots the mean is a bit lower but more variable. Moreover, 2.8% of bot sessions had 100% of erroneous responses (compared to 0% of such human sessions). After taking into consideration also sessions containing only one request, the statistics for humans increase insignificantly whereas for bots they increase notably: the mean is equal to 10.8, the standard deviation is equal to 22.5, and 3.8% of bot sessions have 100% of erroneous responses.

V. Conclusion

The paper discusses key characteristics of sessions realized by Web robots and human users on the e-commerce site. Our results confirm some earlier findings of Web workload analyses, concerning differences between bots and humans in the following session characteristics: the session duration, the number of pages visited in session, the number of HTTP requests in session, the volume of data transferred, the percentage of pages with unassigned referrers, and the number of images per page. However, such characteristics as the percentage of requests of type HEAD and the percentage of erroneous responses turned out not to be as good indicators of bot sessions as reported in previous studies.

The analysis was done for the aggregated Web robot traffic. However, our observations suggest that the behavior of bots is not homogenous and various kinds of bots may reveal different navigational patterns. In our future work we plan to address this issue. We also plan to extend our research to another Web stores of different sizes and branches to verify the reliability of our conclusions for other e-commerce scenarios. Our findings may be applied in classification and segmentation methods aiming at identifying sessions of unknown bots on the e-commerce website.

12th Conference on Advanced Information Technologies for Management

We are pleased to invite you to participate in the 10th edition of Conference on "Advanced Information Technologies for Management AITM'2012". The main purpose of the conference is to provide a forum for researchers and practitioners to present and discuss the current issues of IT in business applications. There will be also the opportunity to demonstrate by the software houses and firms their solutions as well as achievements in management information systems.

Topics

The topics of interest include but are not limited to:

- Concepts and methods of business informatics
- Business Process Management and Management Systems (BPM and BPMS)
- Management Information Systems (MIS)
- Enterprise information systems (ERP, CRM, SCM, etc.)
- Business Intelligence methods and tools
- Strategies and methodologies of IT implementation
- IT projects & IT projects management
- IT governance, efficiency and effectiveness
- Decision Support Systems and data mining
- Intelligence and mobile IT
- Cloud computing, SOA, Web services
- Agent-based systems
- Business-oriented ontologies, topic maps
- Knowledge-based and intelligent systems in management

Towards Semantic-based Process-oriented Control in Digital Home

Tatiana Atanasova
Institute of Information and
Communication Technologies-BAS
Acad. G. Bonchev 2, 1113
Sofia, Bulgaria
Email: atanasova@iit.bas.bg

***Abstract*—The purpose of this work is to investigate the specifics in the development of technologies for heterogeneous data and process integration in digital home and to show possible solutions during design of integrated applications. The analysis of the integrated data can be useful for the development of improved algorithms for monitoring and control of digital networked home.**

I. Introduction

THE tendency for bringing more intelligence into building automation can be seen. It is observed that smart environments have growing demand. The technology development provides a new kind of lifestyle and designing of smart environment attracts attention of researches, home techniques manufacturers, mobile operators, civil engineers and other organizations. The scope of arising problems in digital networked homes is very wide and covers different scientific, technological and psychological aspects [8], [9], [13], [18], [20]. Difficulties results from rapid growing of heterogeneity of electronic devices and communications networks in modern buildings. Home appliances are evolving from purely components devices to complex systems that content processors, sensors and use interfaces. The complexity of the underlying infrastructure is increasing too. The broadband is widely available now in living environment, personal digital devices became very popular, local networks and wireless technologies get emergent interest.

Smart home digital systems have network functions and can be supplemented with connection to the Internet. Network access needs to be available on a range of devices over Wi-Fi and cellular links as well as wired connections. This gives a possibility to monitor and control various home appliances by network and to extend their capabilities through connections in the cloud. Thus home networked system transfers significant functionality from it to the cloud and allows simplifying its design and integration with other systems and services.

The research work reported in the paper is partly supported by the project AComIn "Advanced Computing for Innovation", grant 316087, funded by the FP7 Capacity Programme (Research Potential of Convergence Regions).

Technologies themselves are rapidly changing. The next generation networks are moving to Software-Defined Networking (SDN) where the network's data layer is decoupling from the control layer. SDN is relatively new field in research and consider involving intelligent control methods in network management. This will contribute to a better communication between the various actors involved with various objectives. These new tendencies can be observed in digital networked home environment too – in intention to construct intelligent control and monitoring methods.

However, a lot of problems still have to be resolved, for example: how all these house's devices will communicate, how they will be managed, aggregated, and how the data will be distributed. Besides that, methods for automation in living environment are focused at present on the construction of relatively static structures, designed in advance.

Uniform technology and methods for integrated interoperation of heterogeneous digital systems in living environment that are orientated to optimal using of resources and ensuring of comfort conditions are not developed yet.

The investigation in this paper is focused on problem formulation and directions, in which methods and tools have to be developed for inter-operation of heterogeneous digital systems in smart living environment that have extendible functionality.

First some problems connected with heterogeneous data and information sources are outlined. After then we consider involving semantics into infrastructures. Finally some proposals for solutions are suggested. The extended functionality can be oriented to improving subjective perception of quality of life as well as optimal using of resources in digital homes.

II. Data and Processes Integration

A. Levels of integration

The integration of heterogeneous data and processes can be accomplished at several levels (fig. 1).

978-83-60810-58-3/$25.00

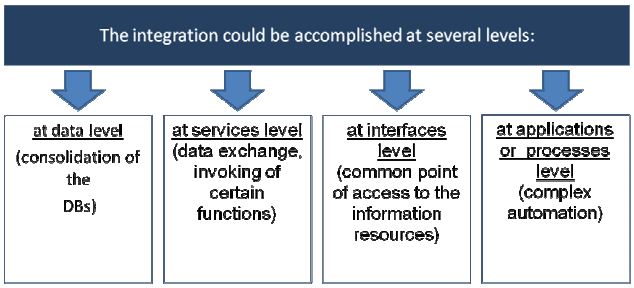

Fig. 1 Integration levels

The existing devices, systems and local networks in a digital house are usually realized with different technologies, regarding the volume of information that is transferred from the integrated devices. We have to take into consideration the heterogeneous data processes and the signals to be conveyed: Ethernet, RF TV and radio signals for wireless-end-connectivity [18] in the distributed building network and necessity of integration of various interfaces for different devices. When new objectives and tasks arise it may be hard to provide interaction between the diversity of the existing appliances.

Each device can be connected with a particular service or a set of services. Thus a multiservice network [12], [15] is established. The multiservice network gives a base for existence of multiple traffic types within the house.

The service may be shared between different devices and dynamically assigned to some of them depending on inhabitants' desires. For very simple example, music or video call may follow the indwellers everywhere in the house. The service can be transferred from one device to another with inference about possibilities for the transfer and service delivery.

Besides certain functionality, the data and process integration requires the construction of an infrastructure, providing safety and security.

B. Ontologies

The semantic description and realization of methods for semantic processing may be the key to achievement of common integration objectives. Several researches suggest an idea to enhance sensors and actuators with a semantic description of their capabilities [8], [9], [13], [20].

Ontologies as a core of semantics can be used for the purposes of information integration, sharing and reuse. The main components of ontology are concepts, relationship, rules and instances. Concept is a class of objects (entities) in the area. Relationships describe the interactions between concepts or properties; they can be in form of taxonomy or associative relationship. Taxonomies systematize concepts as a hierarchical tree, and the associative relationship disposals the concept on the tree.

Instances are specifications of concepts, together with the taxonomy and the relationships they form the knowledge domain. Axioms are used to restrict the values of classes or objects (examples).

Ontology may have logic inference, and then it is so-called formal ontology. Formal ontology must have axioms that restrict the possible interpretations of logical expressions. Web Ontology Language (OWL) can been used to describe each element in the ontology.

Ontologies are created in various forms - from lexicon to dictionary terms, or as first-order logic.

In a broad sense, they can be distributed over three categories: general, domain or applied ontology.

The domain ontology focuses on the refinement of a more narrow meaning of the terms used in a certain area, and may represent a basic reality, in this specific area, but independent of a specific task.

Applied ontology is a specific sub-ontology that contains concepts and relationships which are relevant only to the definite task, such as thesauri, which are semantic relations between lexical units. Usually they contain a small number of concepts with relationships and inference rules, which are defined in detail for solution of particular independent task.

The choice of an appropriate semantic model to represent ontology depends on the purpose for which the ontology is build and the underlying assumptions for achieving these goals.

As an ontology a symbolic system $\{C, T, P, F, A\}$ is considered, where

C is the set of concepts,

T - a thesaurus, or partial order on the set C, the hierarchy of relationships, "subclass" and "super-class";

P - the set of predicates (properties);

F - a function that assigns to each element of P an element from the set of C (considering them in T);

A -is a set of axioms of the ontology.

A hierarchy of concepts is represented as a graph $G = (N, E)$, N - the set of nodes, E - the set of branches, $N=\{n_1, n_2,\ldots n_n\}$, $E=\{e_1,e_2,\ldots e_m\}$.

The graph can be described using XML Schema Datatype (XSD).

At development time ontologies are used to provide ontology–driven development (for example, to describe a domain) or ontology–enabled development (to support developers with their activities).

At run time ontologies form ontology–based architectures (as part of the system architecture) or ontology–enabled architectures (to provide support to the users).

C. Process Ontology

Fundamental process ontologies are becoming more important in recent times [4], [6], [7]. For example, in [19] the idea is discussed that everything is a process and consists of the processes.

The basic postulates are:

- the world is represented as an interconnected system of large and small events;

- some of them are relatively stable;
- the events are always changing;
- the changes represent the actualization of certain features and disappearance of others.

The processes can be divided into:

- constant processes that are interpreted as *concepts*,
- processes which are interpreted as *events*, represent a finite set of four-dimensional space-time.

Thus, the world is built from events, i.e., ontologically, all consists of processes.

The consideration of processes includes:

- when a process should be initiated and finished;
- who participates in this process;
- how this process should be performed;
- which results must be examined, analyzed and taken into account.

The surrounding of a process in such a way consists of data, event, resources, goal and output as a result of a process (fig. 2).

The processes are divided in three main classes:

- *basic* processes;
- *composition* of basic processes and
- *external* processes.

Additionally, processes can be identified that determine the *trends* and directions of changing of basic processes, depending on the analysis and estimated data. The processes are available in the streams of data as implicit patterns. The data is contained in a multitude of sources R (data sensors, files, databases, external resources), $R = \{R_1, ..., R_q\}$.

Extracting knowledge from a specific domain can be considered as the construction of structural design pattern – that process ontology [19]. The objective is to identify processes that have brought to the particular event, and to predict future events based on the past experience.

The process ontology is the key for combining the device and system knowledge.

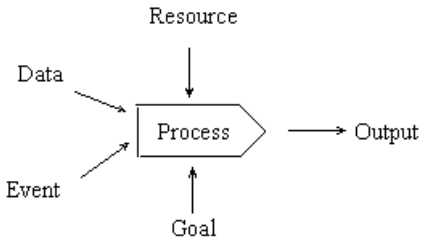

Fig. 2 Process surroundings

III. Proposed Trends and Solutions

The intelligent control methods in digital networked home aim to achieve three goals: semantic integration, providing interface to various devices and ensuring adaptation.

To supply resource control, interoperation and possibility for reconfiguration of digital systems we need to integrate the infrastructure with services.

The semantic and formal description of services and resources is relevant to digital home, where a large diversity of resources have to be described and managed in a highly dynamic way [14]. Services with different purposes can collaborate to offer new and more complex functionalities to the user transparently.

Buildings can be considered as a software problem. This problem addresses integration of information and resources, which are invisible in everyday life. One possible way is to develop operating system for buildings and drivers for every device enriched with semantics. Thus systems can be constructed that are connected to the Internet and are controlled automatically.

It is recognized that there are obstacles in extensive use of embedded devices with limited characteristics of mobility, computing resources and memory. Semantic description may be a way to overcome this large handicap.

Semantic description and modelling of services, together with constructing and using process ontologies provided to users is a key component to autonomic service management, service negotiation and configuration.

The full exploitation of semantics in user and device description has several benefits [21], [22]. The integration of knowledge representation features and reasoning techniques into standard home automation protocols can offer high-level services to users [7].

Current experiences suggest that trends from device-oriented to process-oriented control of home appliances can be seen.

Discovering process models from system event logs is definitely non-trivial. Within the analysis of event logs, process can be defined as the automated construction of structured process models. Each event is a part of the chain process.

The main goal is to suggest a model in which the decision support system provides solution on choosing the optimal set of services using the given network resources on the base of reasoning on process ontologies.

Decision support system (fig. 3) is a coordination unit that integrates heterogeneous data. It is on the top layer of the data processing and provides semantic reasoning. Middle layer realize control, monitoring and visualization functions by event processing, as each device is enhanced with metadata and it is associated with service. This allows discovering functionalities and request services from other devices. Services are discovered by semantic matching. It has to be developed a logic-based ranking of approximated matches allowing to choose resources/services best satisfying a request, also taking user preferences and context into account.

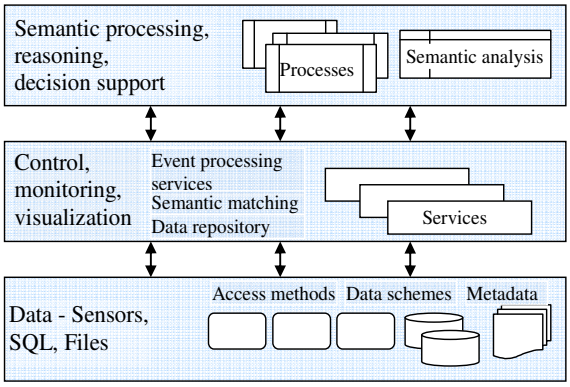

Fig. 3 Layers of data processing

In this framework ontologies are used twofold: for data integration from several sources and for intelligent systems operations.

The system evaluates and classifies records by the use of the process ontology. The ontology of processes will determine what information to extract and how to accelerate the semantic search.

The process-ontology will provide an appropriate philosophical foundation to integration problems. They will give a common conceptual framework for the researches as well as for the practice; it gives a possibility to compare different process-models and concepts and to interpret the dependencies between different models.

IV. Related Work

The development of ontologies in centralized settings is well studied and there are established methodologies. However, current experiences suggest, that ontology engineering should be subject to continuous improvement rather than a onetime effort and that ontologies promise the most benefits in decentralized rather than centralized systems [7].

Using ontologies for telecommunication is proposed by recently [1]-[3], [5]. The approach proposed in [1] discusses using ontologies to capture networking information as well as the domain and expert knowledge needed for network configuration tasks. By semantic description and the use of formal ontologies it is shown how task complexity can be reduced.

Collaborative mechanisms between services are a crucial aspect in the development of pervasive computing systems based on the paradigm of service-oriented architecture [15]. The current network can only provide syntax-layer services and not provide semantic-layer services [5].

The investigation in [20] describes a model of services composition based on a directed acyclic graph used in a service middleware for home-automation, in which loosely coupled services-oriented systems is suggested over the peer-to-peer technology.

The use of semantics (including the integration of ontologies with rule-based systems) has been proposed in early works on context-awareness in the home environment [23]-[26].

The presented in [8] approach proposes use of semantic description that can potentially make the digital networked home more adaptable, agile, sustainable, and dependable given the requirements of changing environment.

The development of multi-service model is discussed in [15] and it is concluded that is still at an early phase.

V. Conclusion

The upward trend in ubiquity and heterogeneity of networked home services and resources demands for a formal and systematic approach to home management tasks.

Current solutions of automated control systems in digital networked homes poorly support dynamic scenarios and context-awareness. Ongoing research covers sensors and how to include the description of these sensors in the control system for smart living environment [9].

In this work it is shown that:

- The primary aim to use of ontologies is to integrate different applications;
- Ontology is proposed to model the relations between events and to manage process configurations.

The rapid development and emerging demands for process automation and interoperability requires systematic modelling methodology and increased semantic information.

The work outlined some solutions for the hard problems during integration of heterogeneous data and processes and shows trends to overcome the lack of standard methods for integration of the information resources and processes that hampers the supply and the efficient use of the information by the users. Process ontologies are a base for providing the whole functionality of the digital networked home in a coordinated and controllable manner.

The future living environment will need to be more intelligent and adaptive, optimizing continuously the use of its resources without any impact on the demanding services.

An effective way to acquire knowledge and share it internally and with outside strategic sources is needed. It is still a challenge to provide a robust and acceptable solution for knowledge capture from different sources.

Methods that ensure integration between the various subsystems automatically and in real time have to be designed. It is hoped that the proposed model will invite further work on integrated framework and shall become reality in the near future.

Komandorska 118-120,
53-345 Wroclaw, Poland
Email: pawel.chrobak@ue.wroc.pl

***Abstrac*—The article describes the causes of the economic and organizational case for implementing VDI solutions in the learning centers of Academic Centers.**

The analysis laboratory infrastructure allows to better understand the broad ability to adapt to VDI and range of benefits they receive, administrators and staff research and teaching. Described implementation is based on VMware Horizon View 5.

The author was the originator of the concept of VDI implementation at the University of Economics in Wroclaw and participant of the project team.

I. Introduction

THE increasing popularization of centralized computing centers popularly referred to as the clouds [5] caused the Universities of Poland to begin building their own private clouds, not only to support their internal processes, but also to provide the students with the virtualized workstation model DaS (Desktop as a Service) [7].

The concept of DaS is to use a VDI environment to offer customers a persistent, highly available desktop that can be accessed from all of their mobile devices. This is significant because right now there are no services available that offer those services. The idea is to take the burden off of the customer by removing the tedious upkeep that the facilities must regularly go through. Desktop as a Service, or DaaS, is used in enterprises for a similar reason. The employees no longer have to worry about maintaining a PC, since the operating system would be centrally managed. The idea is to reduce complexity by centralizing management, which leads to a more productive and efficient IT organization.

This is significant because as the times change consumers are looking for different, innovative solutions to their problems. One problem that consumers have is that they have to regularly maintain their data and hardware. Consumer DaaS would provide a turnkey solution for consumers looking for a simpler computer experience [10].

The Article omits the description of Virtualization as it is generally known. Instead, after a brief description of the VDI we will focus on the analysis of the suitability and potential benefits for virtualization of student laboratory.

The author is an employee of one of the first universities in Poland (University of Economics in Wroclaw) which implemented this solution on a massive scale in their teaching process. In this article, we describe some of the benefits and other experiences gained from the implementation of this project.

The subject of this study are student academic laboratories, although the content contained herein also refers to any type of training centers and educational solutions in schools or centers of learning.

II. Desktop Virtualization (VDI)

For high end graphics workstations, consolidation seeks to migrate the processing load from multiple high end workstations to enterprise class servers in the data center. The primary goal is to offload the work from the local station and provide a desktop environment to users remotely. Rather than stack up a collection of workstations in the data center and provide remote access on a one-to-one basis, desktop virtualization utilizes virtualization techniques to consolidate multiple desktop workstations onto a single server. VMware, an industry leader in virtualization technologies, has created an alliance of vendors and service providers that support what they have coined the Virtual Desktop Infrastructure (VDI). Basically VDI is a server-based computing offering that provides desktop environments as an enterprise hosted service [19]. The core of the VDI initiative can be VMware's ESX server (or other virtualization solution) technology which provides hardware virtualization. Multiple separate operating system images and associated software packages share a single hardware server. Each instance is called a virtual machine (VM). For example, a VMware ESX server might host Microsoft Windows XP, Microsoft Windows Server family, Windows 7/8, and Linux virtual machines at the same time. In its simplest form, each user can connect to a specific virtual machine using some kind of remote desktop protocol. However, having a

978-83-60810-58-3/$25.00

dedicated virtual machine for each user is often impractical, unnecessary and cumbersome. Therefore, VDI solutions normally include some kind of connection broker to connect users to available VM's. Connection brokers are a part of a rapidly developing suite of management tools that can help minimize the support overhead of a VDI solution. Management tools may include services to connect users to the correct pool of VM's, determine which VM's are in use, locate active users, automatically reconnect disconnected remote sessions, provision additional VM's on demand, take VM's offline for testing, updating or troubleshooting, remotely relocate, reboot and reset running and offline VM's, anticipate performance issues or equipment failures, monitor performance, and perform load balancing. It is helpful to compare and contrast VDI with previous generations of remote desktop solutions. Server Based Computing (SBC) is one solution that has developed over the last 10 years, providing applications and desktops to users. Users connect to a remote server, sharing a single instance of an operating system and applications. The application access is increasingly seamless, providing users an illusion that they are working on the application locally even though it is executing on the remote server. Rather than each user getting a VM to themselves, users share connections to the server operating system and installed applications. Citrix Systems has coined the Dynamic Desktop Initiative (DDI) to contrast VMware's VDI. DDI is a Windows based desktop that's delivered over any network and optimized for office … tasks – from simple to complex. DDI is a developing initiative that builds on current solutions. Desktop virtualization is a term that can apply to other types of virtualization strategies. For example, a desktop workstation can be utilizing a desktop virtualization product to allow several operating systems to run simultaneously on one local desktop machine. One common example of this type of desktop virtualization is in the software development life cycles, where it is helpful to have a virtualized production environment available to the developer immediately. This is particularly useful in software development test-bed scenarios. Other desktop virtualization strategies focus on getting a standardized application or operating system image out to local workstations, streaming applications or operating systems out to office computers or unsecured terminals. In these scenarios, the local workstation hardware runs the operating system and/or software that are being provided from a remote source. Note that this does not match our scenario. In both notebook computer desktop virtualization and high end graphic workstation consolidation, the applications and operating system will be running on the remote servers. VDI and DDI approaches each have their strengths and weaknesses. For instance, due to lower overhead, Citrix Presentation Server can support more users per server. However, the applications run in the server operating system environment, rather than the Windows XP professional as they could in a VDI solution. This poses some challenges for us because the applications our users employ are created for use in desktop level operating systems such as Windows XP. They are often not well tested and qualified in the Windows Server environment. How would the developing VDI (VMware) and DDI (Citrix) solutions meet the desktop virtualization challenges presented by Ringling College? Only hands on testing would tell[8].

III. General benefits of implementation of VDI solutions

Computer labs students are usually characterized by low utilization of resources at a fairly fast computer purchased to laboratories. The low utilization statistics indicate that workstation consolidation could achieve great savings in infrastructure, networking, power consumption, and maintenance costs. In addition, we would spend less time in deployment, security, and fault isolation without compromising performance.

With the ever increasing prices of upgrading desktop computers, virtualization of the desktop is becoming very appealing. Here are some of the benefits of virtual desktop infrastructure (VDI).

- **Management** - In a typical corporate infrastructure, you manage desktops using remote software technology such as Altiris or some other push technology. It is really hard to man-age hundreds of desktops as you are well aware if you administer desktops in your corporate infrastructure. Using technology such as virtual desktop infrastructure (VDI) allows you to have central management of all your desktops and really control what is being installed and used on the desktops. Deployment of virtual desktops is lightning fast as opposed to using imaging technology such as Norton or other antiquated technologies. Would you like to manage 500 desktops all over the United States or Europe or manage them from one data center?
- **Security** - Security is a key factor in rolling out VDI. With VDI, you have greater control of how you secure your desktop. You can lock down the image from external devices or pre-vent copying data from the image to your local machine; I'm a big fan of this feature of VDI. Remote users or road warriors also benefit as sensitive data is stored on the server in the data center and not the device. If the device is stolen, the information is protected.
- **OS migrations** - Let's say you want to roll out Windows Vista to a select few managers. Prior to VDI, you would have to look at their equipment and most likely upgrade hardware, memory, disk space, etc. With VDI, you can just push out a Windows Vista image from a central location to the group of managers.
- **VDI image** - We can create a library of VDI images to meet all of your company needs. If your company is seasonal, you can have extra images to handle the increased employee traffic. If you use third-party vendors/contractors/consultants, you can use secure/encrypted locked down images to allow them to work in your environment.

• **Snapshot technology** - With VDI, you have the ability to roll back desktops to different states. This is a great feature, and it allows you to give a lot of flexibility to your end users.

• **Go green** - A thin client VDI session will use less electricity than a desktop computer. Using VDI is a way to reduce your carbon footprint on our planet and save your company money in power costs.

• **Independence** - With VDI, who cares what device you use? A thin client, a PC, Apple, Linux, etc. As long as you can connect to your VDI with ICA or RDP, you are golden[11].

IV. Economic and organizational causes of implementation of VDI in academic environment

Universities have a few reasons for deploying VDI in teaching laboratories: economic, organizational, technological or marketing. In fact almost all aspects have also the implied economic savings (redundancies, etc.), so in the characteristics below will focus on the economic and organizational aspects.

The reality was that desktop support had focused on bringing broken machines back from the dead and not on discovering new tools or ways in which they could be used. Desktop and laptop computer users were supporting themselves in regard to using software and the number of trouble tickets handled clearly indicated that it wasn't about the user. IT wasn't supporting the user of the desktop but instead the computer that was on the desktop. To improve customer service and deliver better support, this paradigm had to change and the only way to change it was to substitute the need for hardware fixes with the ability to apply user fixes. Solving the problems that the user had required extending the knowledge base to them and eliminating the break fix endless loop that existed [9].

V. Characteristics of student's laboratories

Computer workstations in the student laboratories have their own characteristics, the analysis and understanding of them allow us to understand the ability to adapt to VDI in such an environment. Let's try to describe these specifics:

1 For most classes are using the same software configuration of work stations (package Office + software specific to the various classes as Mathematica, Visual Studio package, graphics packages, etc.)

2 For some of the more advanced subjects a specific configuration is needed (usually requiring a more powerful computers) mainly in the case of configurations where the database is locally installed. Mostly these are the classes related to databases, ERP software (eg SAP with local database or computer networks (another network configuration or other elements of the local virtualization). This situation often is solved by separating the specialized laboratories or the ability to run different systems during take-off of systems (separate systems with different configuration on different disk partitions)

3 It is desirable that every student joining the course has a "clean machine " with no files or configuration changes that could leave the previous student

4 The key principle is that all the computers in the lab have exactly the same software configuration

5 One of the main problem of the administrators are configuration changes caused by students. The complexity of Windows causes that despite imposing further restrictions on student accounts, receiving permission to install there are still a lot of gaps, that clever students use to show their abilities (eg changing of desktop background, install add-ons to the browser, vulnerability installation malware). On the other hand, revoking causes problems with the software update, drivers (eg drivers for USB sticks), which handicap the life of students and teachers.

6 Most students perform simple tasks (eg working in Excel) by which the CPU utilization remains at 5-10% for 90 % of the time.

So we summarize some of the implications arising from these observations:

Very time consuming and tedious for administrators is to maintain a number of such labs (in the form of a PC) and the continuous outgoing students of ingenuity who more or less deliberately modify the standard configurations of the operating system or application. Of course, this time consumption expresses the amount of administrators posts, who spend half of their time to perform the same, often unnecessary tasks. Of course there are administrative tools which allow you to automate part of the action (Active Directory, automation software installation and other), but here are new difficulties arising:

• not always administrators working on Colleges are proficient in implementing of new solutions (which implicitly from the earnings on such positions in the Colleges)

• tools to automate software deployment often require administrators to take the time to be able to perform this process. (not all programs can be automatically installed or require a rewrite to version installation "msi"

In addition, there are a number of activities which cannot be automated and require intervention as system recovery, repair damaged units etc.

We also need to take a minute to analyze the second point of described characteristic. Both of described variants are inefficient and cumbersome in practice. Creating specialized laboratories causes the difficulties in allocating and scheduling classes and must lead to not optimal time

management of use of these laboratories or problems with their availability, especially if there are more. Often used on colleges the second option (multi - system configurations) is more efficient but requires a restart of computer before classes which practically can take up to 5 minutes and then require another restart (at the end or at the beginning of successive classes).

VI. Economy benefits of a VDI implementation in student's labs

From the analysis in the previous section is emerging organizational model of the optimal solution: ideally it would be if the student at the beginning of classes receives a computer with a freshly installed operating system and needed him during the classes applications and could do on it what he wants (and even in some cases have administrative privileges) and after completing the course, such a system were completely erased and in its place would be substituted entirely new.

Exactly this possibility gives the replacement of traditional PC by VDI architecture and terminal devices class "zero client".

However, all these considerations are only an introduction to change of the organizational model of maintaining laboratories, further we focus on the economic benefits and we will show savings that will allow institutions to manage more effectively its budget in the IT area :

• **Expenses of maintaining administration** - the implementation of the VDI architecture can significantly simplify the process of administration and maintaining laboratories and0 computer workstations. In the corporate environment in the 90s were taking that one administrative post covered support of about 50 workstations. With the passage of time and the expanding range of tools to automate administrative processes today it is assumed that one administrator (1 full time post) sufficient to support about 500 or more workstations. However in academicals environment (especially in the state Colleges) because of different not essential reasons, that go beyond this elaboration, development of increasing employment is observed in this segment. VDI specification itself causes that whether you have 100 or 500 workstations - for maintenance of laboratories and implementation of demand from the leading ½ of the post is enough. The method of its distribution and scheduling is already in the hands of the management of the institution.

• **Operating costs** - a typical terminal integrated with LED monitor made with "zero client" technology consumes in average 40-50W of electricity which is 4 times less consumption of a typical workstation (which consumes about 200W with the monitor). Of course the VDI infrastructure includes also a set of servers and disk array, so averaging the results for a typical example of ten 30 - bench laboratories we can assume electricity savings of 50%

• **Costs of equipment replacement** - assumed average amortization time of workstation to be three years, and in the university practice this time is estimated at 5 years. VDI equipment manufacturers as one of the advantages of VDI indicate twice as long amortization period of VDI client compare to typical workstation. The key is the fact that the VDI terminal has not in itself any components that determine aging hardware. So there is no processor or graphics card that will be too slow, disc you can drive crash, ending RAM, etc.. All of these components are found in servers, so long as the terminal does not break down naturally in the aging process of electronics or display - no need to replace it. VDI terminals have no mechanical parts including the lack of fans, so MTBF indicators (Mean Time between Failures) is for them around 70 000 hours which is a value more than twice that of a typical workstation (MTBF - 30 000 hours).

It should be noted, that alone cost of VDI terminal is about ¼ cheaper than the average computer set to the lab.

VII. Technical benefits of a VDI implementations

Further description of the functionality is based on the author's experience with VMware Horizon View [16], however, Microsoft's [17] solution offers similar functionality. Of course solutions based on VMware is currently considered the most technologically advanced, however, keep in mind that this solution is most expensive and, if in addition the University has the ability of implementation licensed under the MSDN Academic Alliance [18] (or another program) Microsoft solution can significantly reduce licensing costs and thus the entire implementation.

Philosophy and VDI infrastructure give administrators of the University efficient and stable management environment for teaching laboratories, automating many processes and increasing the reliability of the entire solution. The main aspects that empower administrators :

Central deployment and maintenance of virtual systems - the administrator prepares a single system image, so called " Gold Image " which will be available in read-only option then cloning of each image and creating a virtual system does not copy the entire image. The system reads the data from the golden image and all the changes that are implemented in the virtual system are stored in so called paintings " Linked Clone " This process is visualized in the figure below. We compared here the volume of disk space for five virtual desktops, providing that each prospective of the images saved 1 GB of data for its own needs, while the volume of the golden image is 20 GB (see fig. 1). Of course, space images "Linked Clone" will be automatically increased while writing new data until achieving maximum value (defined by the administrator) [3].

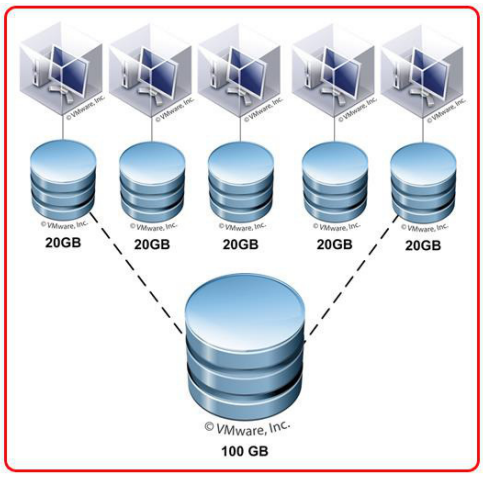

Fig 1. Compare disk space allocation.

For given example a space – saving (average) is 75 % and in the process of increasing the number of working stations factor will still grow. Of course, this technique requires a sufficiently fast disk to store the golden image. It should be stored on disks SSD or disk data should be cached, preferably also using the SSD. Using such technology also gives you another key benefit for our case and laboratories namely fast refresh of virtual systems.

Technology "link cloned 'is particularly useful in these environments. We have here a lot in the exact same virtual machines allowing large savings relate the space of disk. For example, with 100 of the same virtual machine where each would take a 20GB and "link clone" would be at the level of savings we achieve 1GB we can save almost 18 times more space on hard drives. (20GB x100 machines = 2TB and 100 x 1GB + 20GB = 120GB). Estimate the space required (for similar parameters 20GB - used space and 1GB of "link cloned" is shown in Figure 2. The figure shows estimated disk storage capacity requirements (in GB) depending on the amount of the same virtual systems.

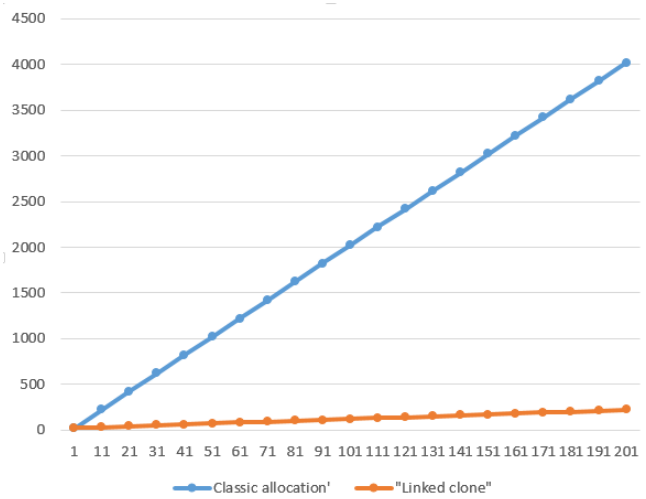

Fig 2. Estimated space required for virtual systems (in GB)

Instant Refreshing virtual systems - one of the implications of the golden images is the fact that if a virtual operating system only reads data from the golden image (without the possibility of writing anything on it) and all the changes differential writes on "Linked Clone", is to delete the data in this place immediately restore the clean image of the system (see fig. 3). The system automatically disconnects the user after 15 minutes of inactivity and instantly refreshes the image of the virtual system, which restores it to its original state (this process takes about five seconds for each system) [6][4].

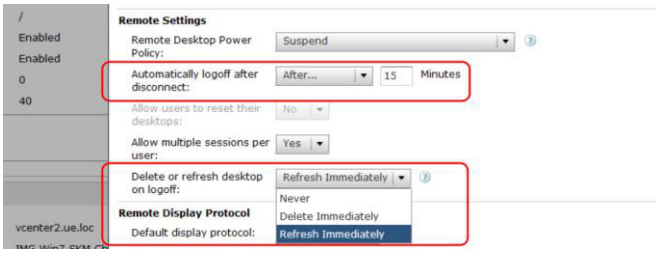

Fig 3. Refreshing virtual OS configuration

Business continuity of laboratory - User cannot spoil anything - unless he physically damages the terminal. Since the virtual system which works will be cleared immediately after work no matter how much he can reconfigure it, disorder or virused by student.

Security policy - depending on the philosophy adopted by the security administrators can be installed one central antivirus program with agents for individual virtual systems, or even resign from anti-virus software on workstations based on the assumption that even if the student hacked the computer, or even computers in the vicinity of this, anyway they will not exist after classes.

In addition, the VDI environment offers many useful additional features that allow you to: load balancing (moving virtual systems to the other servers in the cluster), shutdown of servers with lighter loads snapshots and much more.

Prior to the implementation, it is necessary, of course to

ensure the layout of server resources necessary to ensure adequate performance - the next section describes an example configuration and load up to 300 images, on pages could be found relevant calculators to calculate the parameters of the environment.

VIII. The limitation of VDI technology

Although the systems used for laboratories are not especially graphically demanding (not taking in consideration specific graphics applications) you should be aware that the real-time transmission of multiple video streams can cause performance problems of the entire ecosystem of VDI. These problems are growing not only with an increase of the amount of terminals but also with an increase in resolution of displayed images (which begins to be particularly important in Full HD resolutions and larger).

The specificity of VDI[12] and streaming overshadowing many virtual desktops through a common internet network, the servers even when you start Youtube are very heavily loaded for two reasons:

FIRST REASON - PCoIP stream is encoded in the default workstation and sent to the LAN. While decoding the entire image (especially for the Full HD resolution and larger), it turns out that the process of decoding the stream can take as many as 50-60 % of the two- core virtual processor. To remedy this server can be equipped with a special card decoding hardware PCoIP streams. (Card Teradici Apex 2800 [15]. Application card offloads streaming process several times. One card is able to decode at the same time 40 HD streams or 25 streams of 2560x1600.

SECOND REASON - problem with such high resolutions: default graphics 2/3D is emulated by VMware as for the desktop becomes a bottleneck (especially using newer Windows systems, even with off AERO). The solution to this problem is the use of specialized graphics cards designed for VDI environments - (eg Nvidia Nvidia Grid K1 or K2 Grid)[13] which can be used SVGA (shared VGA) graphics card that is shared for multiple virtual systems. Although the power of the card (and the price as well) seems to be huge in the case of dividing its power for 20-30 virtual machines, can barely support the basic graphical operations.

• Both of the above measures cannot be applied in Blade servers, though the HP Blade Gen8 solutions it is possible to use a miniaturized version of the card. Projecting such solutions for large format displays, should mount them on traditional servers (like dell R720) [14].

IX. Examples of implementations of VDI in University Of Economy in Wroclaw

The concept of rebuilding IT Infrastructure on University of Economics and building its own private cloud began to emerge in mid-2010 and after passaging of all the procedures, fixing concept and finding financing of the project, in September 2011 begin the process of public procurement and project was run in early 2012. The University of Economics was the first university in Poland, which has implemented such solutions on such a large scale.

On the university are working more than 240 terminals (mainly Samsung NC240), more than 400 virtual systems and students can connect to one of 5 available images, depending on the classes and necessary configuration. For the purposes of VDI six 2-processor servers are dedicated, giving a total of 1.2 TB of RAM. Disk array and some servers are equipped with cache memory for SSD -based. One of the servers is equipped with an nVidia card GRID K1 and streaming card supporting hardware PCoIP (Apex 2800).

As storage is used EMC disk array with a total of 20 Tb working gross capacity.

X. Analysis of system performance VDI in practical example

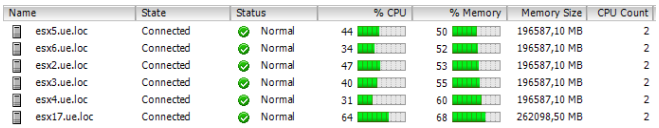
Instead of carrying out theoretical calculations functioning VDI performance will show a practical example of the above-described example, the our University (University of Economy in Wroclaw).

As we mentioned we use a few images of virtual system and the main virtual computers are:

1. **Windows XP** - with 1,5Gb RAM and one core processor, 60Gb provisioned disk and emulated graphics card by vmWare system. Most uses for office and economics applications.
2. **Windows XP with Oracle local database** - with 2GB RAM, two cores, 40Gb provisioned disk, shared graphics card like Nvidia Grid K1 and PcoIP accretion card (Apex 2800). This system is used for classes of databases
3. **Windows 7** – with 3 Gb RAM, two cores, 50Gb provisioned disk and shared graphics shared graphics card like Nvidia Grid K1 and PcoIP accretion card (Apex 2800). This system has software for computer networks and some graphics and business applications.

Below we present some examples of server load these virtual systems in a typical working day. The fig. 4 shows typical load the entire cluster. The cluster consists of:

- Five two-processors Xeon E5645 – 2,4GHz (16 logical cores) servers (Dell M710HD) with 196Gb RAM each –described as ESX2 – ESX6 on the figs.
- One two-processors Xeon E5-2630 – 2,3GHz (24 logical cores) server (Dell R720) with 262Gb RAM each, with NVIdia Grid K1 Video Card and Hardware Acceleration PcoIP Card (Apex 2800) –described as ESX17 on the figs.



Name	State	Status	% CPU	% Memory	Memory Size	CPU Count

IMG3-96	Powered On	Normal	esx2.ue.loc	111,79 GB	52,71 GB	23	1601	1
IMG3-95	Powered On	Normal	esx2.ue.loc	111,79 GB	52,81 GB	23	1609	2
IMG3-94	Powered On	Normal	esx3.ue.loc	111,79 GB	52,69 GB	0	1563	0
IMG3-93	Powered On	Normal	esx4.ue.loc	111,79 GB	52,76 GB	23	1606	4
IMG3-92	Powered On	Normal	esx4.ue.loc	111,79 GB	52,69 GB	167	1598	23
IMG3-91	Powered On	Normal	esx3.ue.loc	111,79 GB	52,70 GB	0	1563	1

Fig 6. Typically loaded Windows XP with emulated graphics cards

Of course the Windows XP is the best system for virtualization because of low demand for computing power and RAM size as we can see on fig. 7.

XI. Conclusion

After 2 years from implementing VDI on owner University (UE in Wroclaw) we know that VDI promises more efficient use of the university's resources, and could offer students the convenience of accessing specialty software from any device, at any time, from anywhere. Now we do not provide access from anywhere for students (just for teachers and some students involved in student's organization) but I's the next planned step.

ACKNOWLEDGMENT

Special thanks to other employees University of Economy in Wroclaw (administrators and the IT department of managers, employees of the Institute of Business Informatics, IT staff procurement and other departments involved in the project implementation and technology private cloud vdi on our University.

Abstract — The article presents an approach to evaluate the Decision Support System applied in the InKoM project. The evaluation method is based on a scorecard framework, oriented towards Business Intelligence (BI) systems and projects dedicated to the management supporting of small and medium enterprises (SME). To design the method, known existing commercial and no-commercial BI maturity models, usability standards, and scorecard frameworks have been analyzed and adapted to SMEs area. Notably, the scorecard framework was extended to the new evaluation criteria associated with innovative knowledge-based functions created in the InKoM project, especially such as ontologies of economic and financial knowledge, and visual navigation and exploratory interface based on topic maps. The main elements of the scorecard framework and usage in InKoM of multi-criteria evaluation are illustrated and discussed in this paper.

I. Introduction

The current economic situation forces the decision-makers of small and medium enterprises (SMEs) to have at their disposal current and appropriate knowledge about the economic and financial situation of the enterprise and its environment. Because of that, decision-makers must have the efficient methods and tools to identify and analyze key performance indicators that have an impact on the operations of the enterprise. Analysis and interpretation of information in the traditional way becomes very difficult, sometimes even impossible. Discovering all dependences between various financial ratios is necessary, because they alert managers about anomalies and dangers (see [23]). Decision-makers in these enterprises, in comparison to managers of big companies, may not have access to all essential strategic information. Usually financial expertise is either not available or too expensive. Big companies have at their disposal strategic consultation and possess standard procedures to solve problems in the case of essential changes in the business environment. For financial and personnel reasons most SMEs cannot afford these types of facilities. It should be noted that SMEs operate in a definitely more uncertain and risky environment than big enterprises, because of a complex and dynamic market that has a much more important impact on SMEs' financial situation than on big companies'. Tolerance of mistakes is narrower (see among others [11, pp. 74–91]). In these circumstances, SMEs' decision-makers often act intuitively and as a result, the rationality of their decisions is significantly weaker. Moreover, SMEs' decision-makers often do not have a solid knowledge of economics and finance.

In general, most existing Business Intelligence (BI) and Executive Information Systems (EIS) provide the functionality of data aggregation and visualization (see among others [26], [31]). Many reports and papers in this domain underline the fact that decision makers expect new ICT solutions to interactively provide not only relevant and up-to-date information on the economic and financial situation of their companies, but also explanations taking into account the contextual relationships.

The aim of this article is to present the approach to multi-criteria evaluation of BI innovative functions created and used in the Intelligent Dashboard for Managers (further referred to as InKoM). The InKoM system has been developed by the consortium consisting of the Wroclaw University of Economics (WUE), which is the leader, and a company UNIT4 TETA BI Center Ltd. (TETA BIC). Credit Agricole Bank Polska S.A. also participates in the project.

Figure 1 presents the main components of the InKoM: a comprehensive description of the TETA BI system with examples of its application is available on the website: [27] (see also UNIT4 TETA presentations [1], [29] and other papers published by the authors; see among others [17], [18], [19], [20]). It can be seen that the InKoM uses TETA BI mechanisms for extracting source data from ERP and non-ERP transactional systems internally (ETL), its data warehouse, and analytical database. However, the available solutions – in particular the standard analyses, reports and analytical statements generated by the system – are complemented by economic and financial knowledge – most

This work has been supported by the National Research and Development Centre within the Innotech program (track In-Tech), grant agreement INNOTECH-K1/IN1/34/153437/NCBR/12.

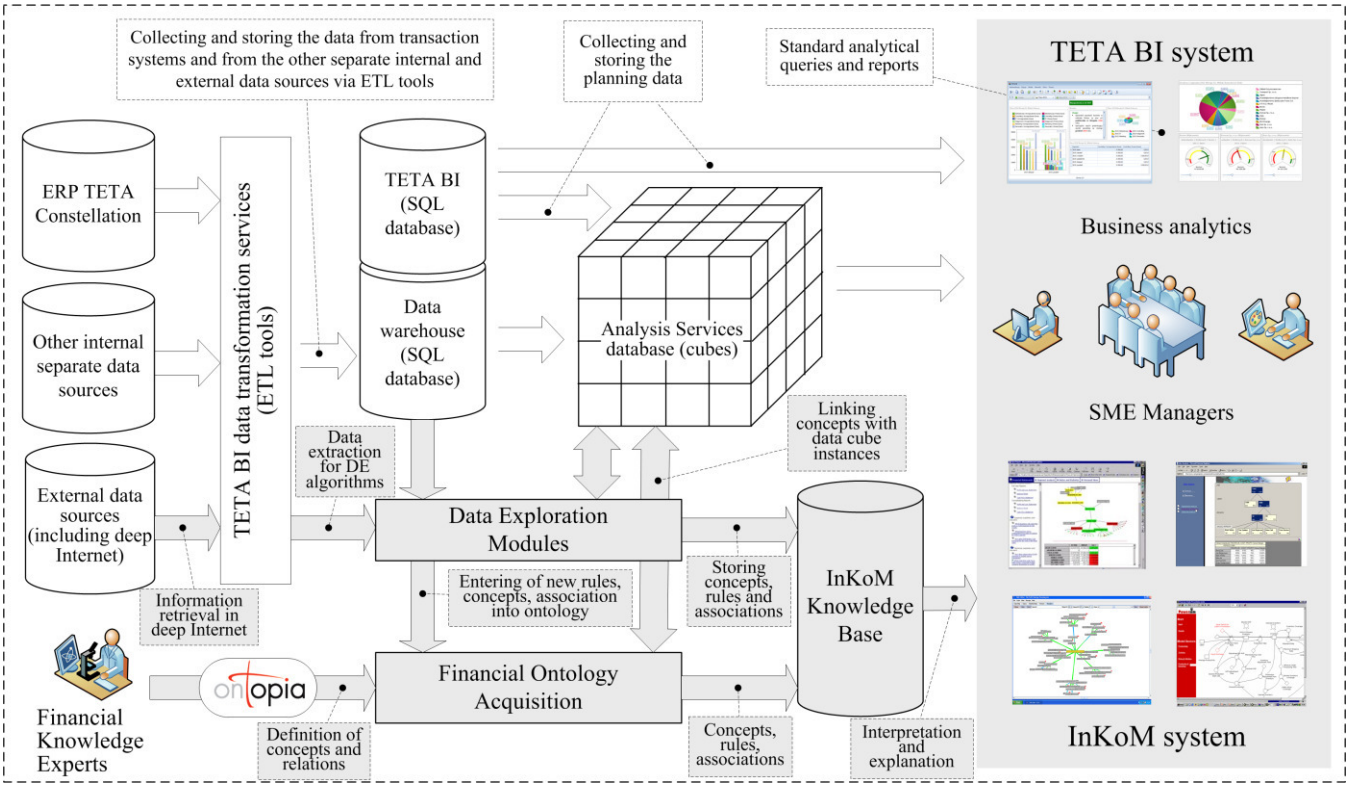

Fig. 1. Components of the Intelligent Dashboard for Managers and their location in the TETA BI system (The InKoM components are shaded in grey)

importantly ontologies and topic maps – and financial data mining algorithms, including mechanisms for extracting business knowledge from the deep Web (indicated as gray color boxes). This enables a dynamic, on-line, interactive analysis of key business indicators.

The transactional data obtained from external sources, supplemented with planning data, e.g., budgets in the form of multidimensional data structures, or cubes, which are stored in a TETA BI Analysis Services database and provide a basis for the on-line, interactive creation of standard analytical queries and/or reports. The InKoM system complements and extends these processes[1]. By providing economic and financial knowledge stored in ontologies and presented in the form of topic maps to facilitate the perception of concepts, InKoM can make the analysis more comprehensive and simpler. This is particularly important for users who are not specialists in the analysis and interpretation of economics and finance.

The structure of the paper is the following: In the next section the overview of approaches to evaluation BI systems and projects evaluation is briefly described. The third section presents the discussion about extension of criteria of evaluation for BI functions oriented on SMEs. To illustrate the use of the extended scorecard framework, a case study of the InKoM Dashboard evaluation is characterized in the fourth section. The last section summarizes the work already carried out and points out the most important conclusions.

II. AN OVERVIEW OF APPROACHES TO BI SYSTEMS AND PROJECTS EVALUATION.

The main goal of any BI system is to access the right data at the right time to allow proactive decision-making (see among others [6], [34]). The users of BI systems expect access to useful information and knowledge through an interface easy to understand and use[2]. However, most of existing BI solutions are designed primarily for users who are able to understand the business data models and semantic and/or algorithmic relationships between financial and economic objects/concepts (data, information, measure, key performance indicator, gauge etc.) used in analytical processes. Today the development of new BI systems is oriented towards BI 2.0 (using semantic search) and 3.0, Service Oriented Architecture (SOA), Software as a Service (SaaS), mobile BI, Big Data technologies using BI etc. (see among others [14], [23], [26], [32]). The typical features of the systems include: proactive alerts and notifications, event driven (real time) access to information, advanced and predictive analytics, mobile and ubiquitous access, improved visualization, and semantic search information.

[1] The InKoM architecture and functionalities have been presented in [17], [18], [19], [20].

[2] Generally the BI system interface should allow users to do: *"find what* they need, understand what they find, and act appropriately, within the *limits of time and effort that they consider adequate for the task"* (http://www.dataprix.com/en/bi-usability-evolution-and-tendencies).

But no matter what BI applications we implement, they should always meet the expectations and needs of their business users. Helpful in achieving these goals can be the systematic, continuous and multi-criteria evaluation of BI systems and projects based on formalized and verified in practice approaches to BI evaluation process [8]. The most important of these are:

1. BI Maturity Models,
2. BI commercial and non-commercial frameworks used to compare BI systems, projects and/or vendors,
3. BI scorecards,
4. Standards of BI systems and/or projects usability and quality,
5. Methods and tools dedicated for evaluation of economic efficiency of BI systems and/or projects.

There are many Business Intelligence Maturity Models (BI MM) developed by different authors such as Business intelligence Development Model (BIDM), TDWI's maturity model, Business Intelligence Maturity Hierarchy, Hewlett Package Business Intelligence Maturity Model, Gartner's Maturity Models, Business Information Maturity Model, AMR Research's Business Intelligence and Performance Management Maturity Model, Infrastructure Optimization Maturity Model, Ladder of Business Intelligence (LOBI) etc. All of these models and case studies of their use are widely described and compared in the available literature and on the websites of their owners, vendors and/or consulting firms applying them (see among others [3], [7], [8], [9], [15], [21], [22], [24], [25]). Because BI Maturity Models primarily assess the maturity of BI solutions used in decision-making processes, BI frameworks are more useful for the evaluation of development projects of the BI application.

BI frameworks are used to compare BI applications, projects and/or vendors. Examples of selected frameworks to the evaluation of BI systems are presented in table 1.

Generally, BI frameworks define the people, processes, platforms and technologies that need to be integrated and aligned to take a more strategic approach to business intelligence, analytics and performance management initiatives [2, p. 1]. There is no single or right instantiation of the BI frameworks. Different configurations can be supported by the framework based on business objectives and constraints.

Often BI frameworks owners as consulting companies create and provide BI evaluation scorecards. A good example is the BI Scorecard® (table 1). The BI evaluation scorecard is a tool to support the evaluation process based on the multi-level pre-defined breakdown structure of the evaluation criteria and scoring technique. The changes of the scoring evaluation of BI system/project from the "as-was" to "as-is" and/or "to-be" status can be monitored and visualized and then can be used for the continuous improvement of BI initiatives. The structure and the few elements of BI Scorecard® used to evaluate the InKoM system are described in Section IV.

The two last, but not the least, "sources of knowledge" need to create a system of evaluation that – as we noted above – use standards of BI usability/quality and methods/tools dedicated for measurement of economic efficiency of BI systems and/or projects.

In the first area the most important are ISO (IEEE, BSI) standards for software/systems usability/quality evaluation such as "the old" ISO/IEC 9126 (usability), "the new"

SQuaRE (Systems and software Quality Requirements and Evaluation) ISO/IEC 25000:2014, 25010:2011, 25051:2014 and ISO 9241-171:2008 (ergonomics of human-system interaction). The ISO standards defined usability as the software's capacity to be understood, learned, used, and to be attractive to the user in specific use conditions. ISO also establishes four basic principles on which usability is based: ease of learning, ease of use, flexibility, and robustness. These principles were used in the heuristic evaluation of user interface (e.g. dashboards) based on topic maps and visual navigation as a part of the InKoM system usability evaluation [5, pp. 50-58].

The important part of the BI evaluation framework concerns the economic efficiency/effectiveness of BI systems and/or projects (see among others [10], [30]). From this point of view, the evaluation of a given solution represents a process of analysis of costs, benefits and risks, of BI solution, which must be done by a team of both business and IT personnel. The initial evaluation is followed by a series of analyses made before the start of the project (a priori) and after each year of use in order to verify the initial estimation and to adjust the BI solutions.

The main problem that confronts the current frameworks for the measurement of BI solutions is the fact that much of the benefits are strategic benefits, hard to quantify and only appearing several years after the implementation of the solution. Thus, many of the effects of the BI solution are nonfinancial, sometimes intangible effects that lead to financial results after a certain period of time. These benefits come from improved decision-making, and increased quality of information, and often are not financial incomes directly quantifiable (see among others [10], [12], [30]).

There are different methods to evaluate an investment into IT (including BI) solutions. The most important of these is the Cost-Benefits Analysis (CBA) method based on discounted cash flows. CBA used well-known and widely recommended detailed measures and indicators such as IRR (Internal Rate of Return), MIRR (Modified Internal Rate of Return), NPV (Net Present Value) and ROI (Return On Investment). CBA can be extended by the TCO (total cost of ownership) analysis, where TCO/ROI calculators can be used. A good example of such a tool is TDWI Business Intelligence ROI Calculator (www.tdwi.org).

All of these presented "sources of knowledge" are very useful to design multi-criteria evaluation of BI systems and projects. But as a lot of works have noted, most of them are available for large or mid large companies (see among others [9], [23]). However, none of these tools address the project of designing and implementing BI systems in SMEs specifically. Also, there is a lack of guidelines informing how to create BI systems that might be used as reference examples for SMEs.

There is a very important need, because of the role of SMEs as catalysts for the EU (and also Polish) economy, to accelerate SMEs' growth and to improve their competitiveness. This is recognized by the European Commission, which has developed the set of 10 principles to guide the design and implementation of policies both at EU and Member State level, called "Small Business Act" (SBA). The VIII principle of SBA specifies that "The EU and Member States should promote the upgrading of skills in SMEs and all forms of innovation. They should encourage investment in research by SMEs and their participation in R&D support programmes, transnational research, clustering and active intellectual property management by SMEs" [28].

Therefore in the next section we discuss the extension criteria of BI evaluation frameworks for BI functions oriented on SMEs.

III. THE INKOM PROJECT AND THE EXTENSION CRITERIA OF BI EVALUATION FRAMEWORKS FOR FUNCTIONS ORIENTED ON SMES

SMEs may differ from larger companies by a number of key characteristics, e.g. resource and knowledge limitations, lack of money, reliance on a small number of customers, and need for multi-skilled employees. Some of the above-mentioned characteristics are putting a greater strain on the SMEs, causing the successful implementation of BI to be possibly more challenging in this context.

SMEs are socially and economically important and need tools and solutions to preserve their competitiveness in challenging environments, particularly because they operate in highly competitive, turbulent and uncertain markets**.** Usually they do not have control or influence over the market and thus they need to adopt a reactive approach and adapt to market changes.

Scarcity of resources is one of the main problems and a typical characteristic of SMEs. In addition also skills are limited, not only among staff**,** but also owner-managers often do not have enough managerial expertise or organizational capabilities, and this implies poor strategic business planning and human resource management.

Some of the research has mentioned that for a successful BI project implementation and to bring tangible business benefits to SMEs in the future, it is necessary to meet the following critical success factors: well defined business problem and processes, well defined users' expectations, adjusting the BI solution to users' business expectations, integration between the BI system and other systems, data quality and the flexibility and responsiveness of BI on users' requirements, appropriate technology and tools, and "user friendly"/usability of BI system (see among others [9], [23]).

The analyses presented in the report "Small and Mid-Sized Enterprise Business Intelligence Market Study" specified that "making better decisions" was the most-sought outcome of BI, but SMEs show an even higher regard for revenue growth and competitive advantage stemming from Business Intelligence than their larger peers

[33, p. 15]. The technology priority changes among SMEs 2012-2013. Only three technologies related to BI increased in importance over 2012: Software-as-a-Service (Cloud BI), Dashboards, and Mobile Device Support [33, p. 25]. For 2013, top technologies related to BI in SMEs included: Dashboards, End User "Self-Service", Advanced Visualization and Data Warehousing. [33, p. 35-36]. The same survey noted that at SMEs, Executive Management, Sales, Finance, and Strategic Planning are most likely to drive BI initiatives and projects. Small Enterprises of one to 100 employees are the most likely of all to see Business Intelligence driven by Executive Management (which might describe CEO, CFO, COO or other titles) and are more likely to be driven from the Sales function [33, p. 26].

Features of SMEs and analysis of the BI market for SMEs indicate the directions of the development of modern BI systems. These directions are included in the InKoM project. In the development of InKoM, many new features are integrated, such as domain ontology covering key concepts of corporate finance and economics, knowledge discovery algorithms, semantic search mechanisms, explanation facilities, and tools for visual navigation in domain knowledge.

One of the main parts of modern BI systems is the ontology. In general, the ontology is used to define the necessary knowledge (see [19], [20]).

In the InKoM project, six ontologies were built, covering economic and financial areas: Cash Flow at Risk, Comprehensive Risk Measurement, Early Warning Models, Credit Scoring, the Financial Market, and General Financial Knowledge. Integration of these ontologies into the BI systems assures:

– support for the definition of business rules in order to get proactive information and advice in decision-making;
– a semantic layer describing relationships between the concepts and indicators;
– relevant information according to the different kinds of users that can be found in an organization;
– effective usage of existing data sources and data warehouse structure [20].

All of these benefits require the extension of the evaluation criteria of BI systems for domain-ontologies category.

The knowledge representation layer is the most critical aspect of a BI system, since it broadly shapes the core understanding of the information displayed on their screen [34]. In InKoM design, the basic assumption of navigation was that managers should be able to view focus and context areas at the same time to present the relevant knowledge structure.

Visual exploration in InKoM (see figure 2) is based on a standard Topic Map (TM – ISO/IEC 13250:2003). TM enables the representation of complex structures of knowledge bases and the delivery of a useful model of knowledge representation, where multiple contextual indexing can be used. Developed topic maps for analysis of economic indicators (see among others [5], [6], [16], [19], [20]) have demonstrated that the system [4]:

– can be easily used for the representation of economic knowledge about economic and financial measures,
– can express the organizational structure,
– can be adapted to new applications and managers' needs,
– can be supportive of the managerial staff by facilitating access to a wide range of relevant data resources,
– can assure a semantic information search and interpretation for non-technically-minded users,
– can visualize different connections between indicators that make possible the discovery of new relations between economic ratios constituting knowledge still unknown in this area,
– can improve the process of data analysis and reporting by facilitating the obtaining of data from different databases in an enterprise, and finally
– can be easily extended by users who are not IT specialists, e.g. by experts in economic analysis (using tools for creating a topic map application).

In turn, this group of features and benefits requires the extension of the evaluation criteria of BI on visual navigation and a data exploration interface based on standard topic maps categories.

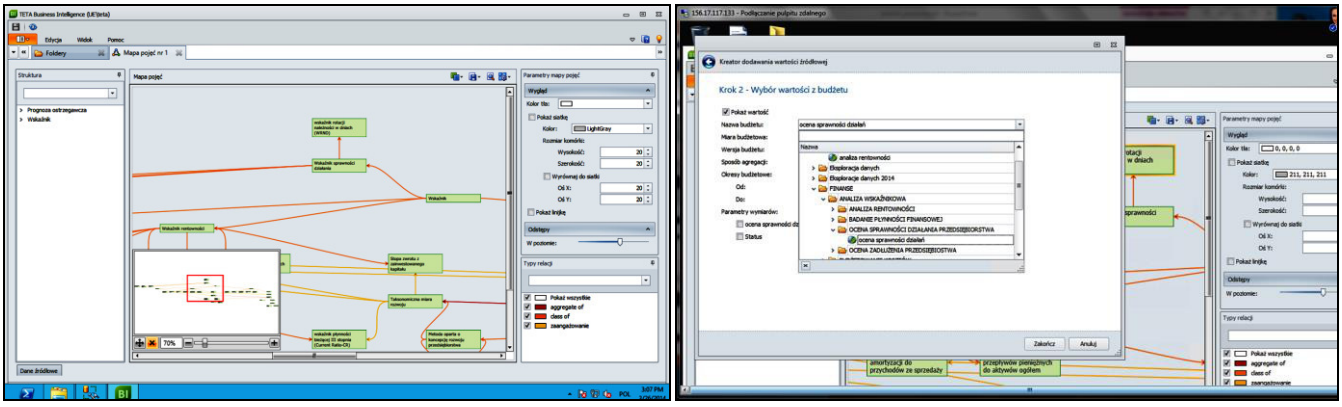

Fig. 2. The visual navigation and data exploration interface of the InKoM system based on topic maps with additional tools and wizards

This is very important in the case of SMEs, where a company does not employ experts in economic-financial analysis and using external consulting is too costly. Reproducing knowledge with the use of a topic map contributes inter alia to a better understanding of economic concepts and the interpretation of specific economic and financial indicators.

Data exploration algorithms (such as classification trees, association rules methods, clustering) have been integrated with topic maps (i.e. semantic search and visual data exploration). In general, data mining tools currently available on the market contain many knowledge extraction algorithms, but a lot of them are not applicable for SMEs. Moreover some of them are too complex and their usage requires costly expert support.

The data exploration module in InKoM not only is integrated with topic maps/ontologies and contains data exploration methods and algorithms dedicated for SMEs, but also is simple to use for non-analysts. Managers in the data exploration process use the built-in wizards to build step by step data mining models (see figure 3).

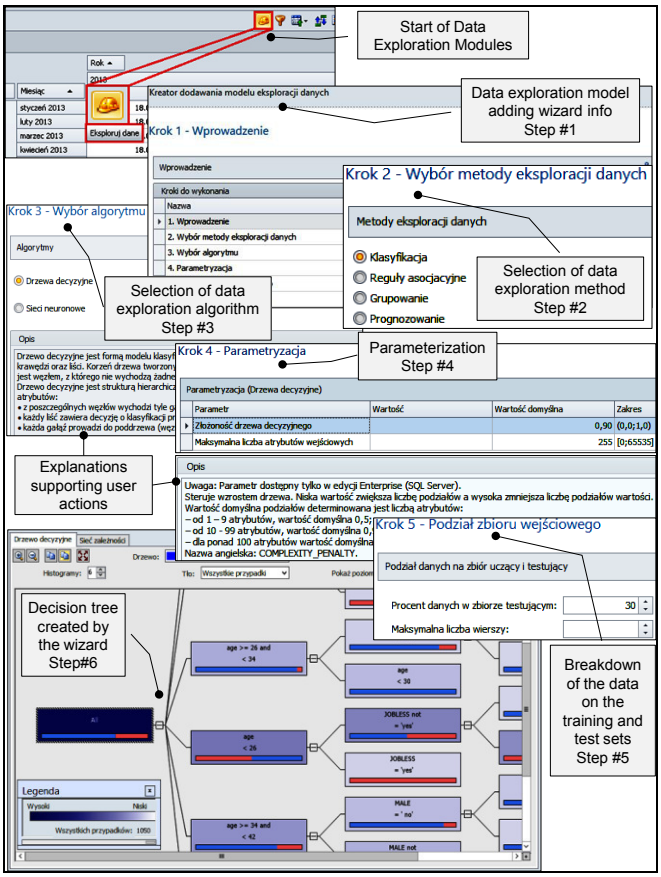

Fig. 3. Data exploration module wizard

These features require the extension of the evaluation criteria of BI related to topic maps/ontologies, dedicated to SMEs' exploration methods and built-in wizards.

IV. Case Study – Evaluation of Innovative Functions of the InKoM Dashboard

Evaluation of the InKoM Dashboard based on categories and subcategories used in BI Scorecard® with extensions was defined in the section III. All ratings were exposed using an approach based on the Delphi method. "As-was" assessment was issued on the basis of self-assessment by TETA BIC specialists. In turn, "as-is" assessment was prepared on the basis of internal expertise (developed by InKoM project teams from TETA BIC and WUE) and external expertise (developed by experts from universities and/or research centers and SME's managers). The results of the evaluation are presented in figures: 4 (business query and reporting category), 5 (delivery and exploration category), 6 (information delivery & BI reach category) and 7 (dashboard category). The detailed requirements for dashboard evaluation are reported in the tables 2÷10, namely:

- the dashboard layout category evaluation (table 2),
- the dashboard design category evaluation (table 3),
- the presentation category evaluation (table 4),
- the alerting category evaluation (table 5),
- the analysis category evaluation (table 6),
- the KPIs / metrics category evaluation (table 7),
- the dashboard interactivity category evaluation (table 8),
- the architecture category evaluation (table 9),
- the delivery and other category evaluation (table 10).

Table 2.
THE DASHBOARD LAYOUT CATEGORY EVALUATION
DETAILED REQUIREMENTS

Dashboard Layout - detailed requirements	as-was	as-is
Multiple objects on a page/display	2	3
Ability to resize portal objects independently	2	2
User defined dashboard layout, in addition to centrally built by IT	2	3
Multiple data sources within dashboard presentation	2	3
Average value	**2,00**	**2,75**

Table 3.
THE DASHBOARD DESIGN CATEGORY EVALUATION
DETAILED REQUIREMENTS

Dashboard Design - detailed requirements	as-was	as-is
Formatting templates for consistent look	0	1
WYSIWYG design mode	2	2
Structure mode for faster design without all data	1	2
Record limit in design mode	2	2
Undo	0	1
Java development environment or Visual Studio or SDK for embedding	2	2
Developer-defined calcs for data not in data warehouse	0	1
Elements re-usable in multiple dashboards	2	3
Web-based design environment	0	1
Ease of design and maintenance aspects	2	3
Average value	**1,10**	**1,80**

Table 4.
THE PRESENTATION CATEGORY EVALUATION
DETAILED REQUIREMENTS

Presentation - detailed requirements	as-was	as-is
Conditional formatting - traffic lights, trend arrows, highlighting of exceptions and variances within tabular display	2	3
Charts Overall	2	2
Hi/Lo Chart	2	2
Gauge Chart	2	2
Bullet Graphs	0	0
Spark Lines	0	1
Maps	1	2
Ability to create own visualizations	1	2
Average value	**1,25**	**1,75**

Table 5.
THE ALERTING CATEGORY EVALUATION
DETAILED REQUIREMENTS

Alerting - detailed requirements	as-was	as-is
Alerts - Visual display of exception values or text	2	3
Alerts - Email notification	2	2
Alerts - user defined in addition to centrally defined	2	3
Alert as RSS feed or textual display within dashboard	0	0
Average value	**1,50**	**2,00**

Table 6.
THE ANALYSIS CATEGORY EVALUATION
DETAILED REQUIREMENTS

Analysis - detailed requirements	as-was	as-is
This Year/Last Year analysis	2	3
Top 10 ranking	2	2
Asymmetrical reporting (expand Q4, collapse Q1-Q3)	1	2
Predictive analysis / what if	0	2
Advanced analysis (based on data exploration)	0	2

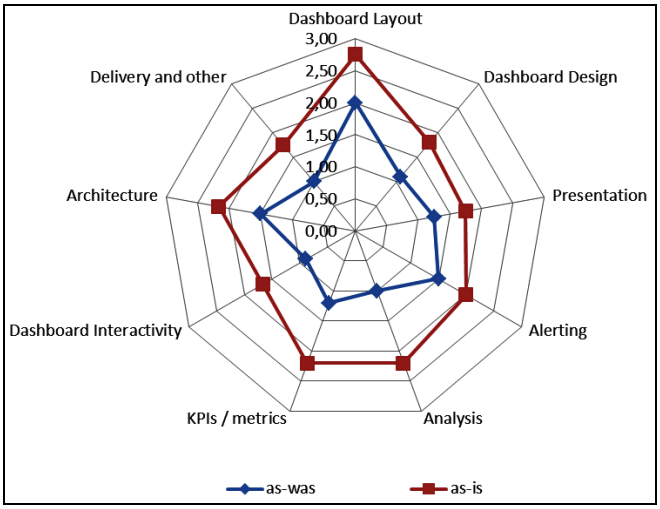

Fig. 7. The results of Dashboard category evaluation of the InKoM project. Average value of detailed requirements (see tables 2÷10) of scoring changes from the TETA BI system (as-was) to TETA BI with InKoM functionalities (as-is)

The evaluation of the InKoM system, especially the dashboard categories and subcategories (see the "greyed" cells), shows necessities for improvement of the BI evaluation frameworks and their customization to SMEs solutions and new innovative technologies and concepts.

V. SUMMARY AND FUTURE WORKS

In this paper, the multi-criteria evaluation of the Intelligent Dashboard for SME Managers used in the InKoM project environment was presented. Further studies will be conducted on empirical verification of the created framework in "real" SMEs, extension of the evaluation categories to support CBA analysis and measurement of ROI/TCO, and creation of a community of experts to continuously extend and update the evaluation tools.

***Abstract*—This article presents the problem of knowledge conflicts identification in the architecture of cognitive agents. The agents operate at the decision support systems. The types and the sample of cognitive agents architecture was characterized in the first part of article. Next, the causes of knowledge conflicts was indicated. The final part of article contains the analysis of sources of knowledge conflicts and their examples related to decision-making process.**

I. Introduction

A DECISION-MAKING process may be supported by the use of tools of various kind, in particular IT systems. Currently used IT tools (systems) support decision-making mainly at an operational and tactical level but they become insufficient at a strategic level. They only enable the analysis of the form of information, the links between economic values and they are unable to analyse their meaning. Thus these tools mainly serve the conversion of the gathered data (mostly disordered and unstructured) into information - useful, legible and easily interpretable and thus more suitable to a decision-maker. However, for the definition of meaning of information, a human mind is necessary, and the change of knowledge into wisdom (necessary to take a good decision) - requires not only human intellect but even human genius [19]. Therefore, it seems justified to use the tools which perform cognitive and decision-making functions, the ones that take place in the human brain and owing to this are capable of understanding the real meaning of the observed phenomena and economic processes taking place in the organization environment. These tools include cognitive agents which often cooperate within the framework of a multi-agent system [e.g. 21] in order to effectively reach a set goal.

The architectures of cognitive agents are complex and their functioning is of asynchronous nature, which may be the reason for the occurrence of knowledge conflicts and have a negative impact on the results of cognitive and decision-making functions, which in turn may hinder supporting a decision-making process.

Previous research related to the issues of knowledge conflicts, and in particular with defining their sources [e.g. 10, 20] relate mostly to multi-agent systems composed of reactive agents, so the ones which are capable of drawing conclusions and adequately react to stimuli from the environment however do not have the cognitive function and have limited learning skills. With respect to the agents of this kind, knowledge conflicts occur in situations of opposition or in-coherence of the knowledge held by the agent [7, 14, 15, 18]. However, works concerning the sources of knowledge conflicts with respect to cognitive agent [e.g. 12, 16] are limited to very general approaches, and they do not take into consideration modules of agent's architecture. This may result from the fact that the implementation of various architectures of cognitive agents is currently mainly at a prototype stage and few of them function in commercial solutions and thus the problem of occurrence of knowledge conflicts is not raised. The work [13], for example, presents using intelligent technologies, such as Bayesian Network Case-Based Reasoning, Expert System, Fuzzy System, Genetic Algorithms and Ontology Based techniques for resolving different types of conflicts both reactive and cognitive agents, however they are not related to agents architecture. The work [3] presents cognitive agents resolving methods only on the development stage (design time, programming), the knowledge conflicts at the runtime are not taking into consideration.

However, more intensive development of cognitive agent is noticeable, which may lead to a situation in which the knowledge of these agents will be so extensive that the issue of defining the sources of knowledge conflicts as well as the methods of their solving will become very significant both from a theoretical point of view and from the point of view of persons dealing with designing cognitive agents and multi-agent systems made of them. An automatic solution to the knowledge conflict, as stated in the study [8], is a key element of the functioning of multi-agent systems.

Thus the purpose of this article is to analyse the sources of knowledge conflicts occurring in the architecture of cognitive agent supporting a decision-making process.

II. The Modules Of Cognitive Agent's Architecture As A Potential Places Of Knowledge Conflicts Sources

The most important features of all cognitive agents' architectures include the way of their memory organization and learning mechanisms. The memory is the repository of the knowledge about the world and oneself, the objectives and

978-83-60810-58-3/$25.00

current actions. The role of memory is understood differently by the authors [5, 6, 8, 9, 12]. The organization of the memory depends on the manner of knowledge representation. Learning is a process which transforms the remembered knowledge and the manner of its use. In the study [4] considering the taxonomy of cognitive agent architectures with respect to two above mentioned features, three main groups of the architectures were distinguished:

1. Symbolic architectures which use declarative knowledge included in relations recorded at the symbolic level, focusing on the use of this knowledge to solve problems. This group of architectures includes, among others: State, Operator And Result (SOAR), Executive Process Interactive Control (EPIC), Semantic Network Processing System (SNePS), CopyCat, Non-Axiomatic Reasoning System (NARS), Integrated Cognitive-Neuroscience Architectures for Understanding Sensemaking (ICARUS).
2. Emergent architectures using signal flows through the network of numerous, mutually interacting elements, in which emergent conditions occur, possible to be interpreted in a symbolic way. This group of architectures includes, among others: Neurally Organized Mobile Adaptive Device (NOMAD), Numenta Platform for Intelligent Computing (NuPIC) Cortronics, Brain-Emulating Cognition and Control Architecture (BECCA).
3. Hybrid architectures which are the combinations of the symbolic and emergent approach, combined in various ways. This group of architectures includes, among others: Adaptive Components of Thought-Rational (ACT-R),The Connectionist Learning Adaptive Rule Induction ON-line (CLARION), CogPrime, DUAL, Cortical Capacity-Constrained Concurrent Activation-based Production System (4CAPS), The Novamente AI Engine, Cognitive Agents Architecture (Cougaar), The Learning Intelligent Distribution Agent (LIDA).

It was decided to analyse in this article (due to its volume), with respect to the sources of knowledge conflicts, only the architectures of the LIDA cognitive agent, proposed by S. Franklin [11], presented in the Fig 1. This architecture is of emergent-symbolic nature, owing to which the processing of both structured (numerical and symbolic) knowledge and unstructured (recorded in the natural language) is possible. In addition, the Cognitive Computing Research Group established by S. Franklin, elaborated in 2011 the framework (in Java language) significantly facilitating the implementation of the cognitive agent. It should also be emphasized that the whole framework code is open, i.e. the developer has access to the definitions of all methods, as opposed to, for instance, Cougaar architecture framework software, in which the agent's software code constitutes the so-called "blackbox".

In the LIDA architecture, presented on Fig 1, it was adopted that the majority of basic operations are performed by the so-called codelets, namely specialized, mobile programmes processing in-formation in the model of global workspace. The functioning of the cognitive agent is performed within the framework of the cognitive cycle and it is divided into three phases: the understanding phase, the consciousness phase and the selection of actions and learning phase. At the beginning of the understanding phase the stimuli received from the environment activate the codelets of the low level features in the *sensory memory* [11]. The outlets of these codelets activate the *perceptual memory*, where high level feature codelets supply more abstract things such as objects, categories, actions or events. The perception results are transferred to *workspace* and on the basis of *episodic and declarative memory* local links are created and then, with the use of the occurrences of *perceptual memory*, a current situational model is generated; it other words the agent understands what phenomena are occurring in the environment of the organization. The consciousness phase starts with forming of the coalition of the most significant elements of the situational model, which then compete for attention so the place in the *workspace*, by using *attentional codelets*. The contents of the *workspace* module is then transferred to the *global workspace* (the so-called "broadcasting" is taking place), simultaneously initializing the phase of action selection. At this phase possible action schemes are taken from *procedural memory* and sent to the *action selection* module, where there compete for the selection in a given cycle. The selected actions activate *sensory-motor memory* for the purpose of creating an appropriate algorithm of their performance, which is the final stage of the cognitive cycle [1]. The cognitive cycle is repeated with the frequency of 5 - 10 times per second.

Parallelly with the previous actions the agent's learning is performed (Fig 1), which is divided into *perceptual learning* concerning the recognition of new objects, categories, relations; *episodic learning* which means remembering specific events: what, where, when, occurring in the working memory and thus available in the awareness; *procedural learning*, namely learning new actions and action sequences needed for solving the problems set; *conscious learning* relates to learning new, conscious behaviours or strengthening the existing conscious behaviours, which occurs when a given element of the situational model is often in the *workspace*. The agent's learning may be performed as learning with or without a teacher.

It is worth emphasizing that each cognitive agent supporting decision-making must have the ability of grounding the symbols, namely assign relevant real world objects to specific symbols of the natural language. This is necessary to correctly process unstructured knowledge saved mainly by means of the natural language and thus, for instance, the clients' opinions on products. The knowledge of this type is currently becoming more and more significant for a company because it may have impact on its competitiveness level. For instance analysing the clients' opinions on a given product, the sales volume of a given product in the future may be estimated (of course with a certain level of probability).

Taking into consideration:

- the complexity of the cognitive agent's architecture (Fig 1) and functionality,

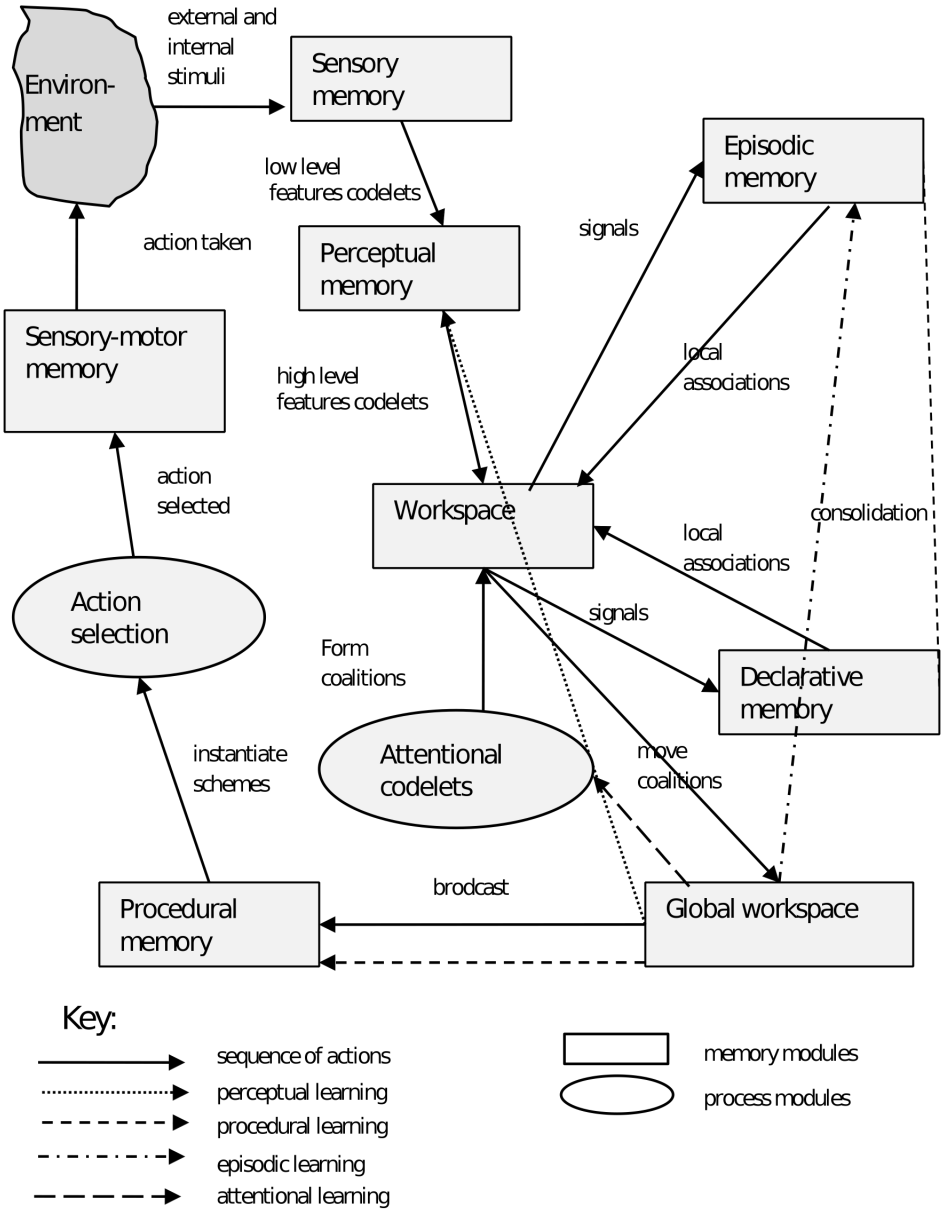

Fig. 1 The architecture of LIDA cognitive agent.
Source: Own work on the basis of [1, 2]

- asynchronous nature of the cognitive cycle (5-10 cycles per second) having impact on the contents of particular architecture models,

it may be concluded that they may constitute the reasons for the occurrence of knowledge conflicts. Potential places of these conflicts' sources may occur in the modules of the cognitive agent's architecture and be connected with:

- the domain of the value of objects stored in memory,
- the results of phenomena interpretation,
- events,
- rules,
- the perception of the current state of the environment (objects and links between them),
- the results of algorithm operation,
- the selection of the agent's actions.

Further in the article the sources of knowledge conflicts will be presented, illustrated with specific examples, connected with supporting the company decision-making process.

III. Sources of Knowledge Conflicts Connected With Supporting The Decision-Making Process

The environment of the functioning of cognitive agents supporting decision-making process, constitutes the company and its environment. The occurrence of knowledge conflicts is related to a situation when various values are assigned to the same objects, links between them, features, phenomena events and actions occurring in the environment of the party to a conflict. Generating various decisions by agents, at the same time, may serve as an example [17].

For the needs of considerations made in the article, the sources of the conflicts of knowledge will be presented at the example of an agent, the objective of which is customer relation management. This agent constantly obtains stimuli from the environment which relate to the characteristics of sales such as sales dynamics indexes in break-up into particular clients (delivered for instance from the agent/agents supporting logistic processes), the clients' opinions of products (being for instance in the company on-line store database), characteristics of products offered by the competition, actions taken by the competition (delivered for instance by the agent monitoring competition). The further part of article describes modules of agent's architecture from the point of view of the occurrence of conflicts of knowledge.

A. Sensory memory

As sales characteristics are stored, on regular basis, in the agent's sensor memory, the contents of this memory may constitute the source of knowledge conflict. These conflicts are mainly connected with the domain of the value of objects stored in the memory. For instance, if it was adopted in the solution that the memory should include the users' opinions recorded in the text form, however there occurs a situation in which the opinion contains graphic elements, their interpretation may be difficult or even impossible. As a consequence, the cognitive agent may incorrectly perceive the current state of the environment.

B. Perceptual memory

Sales characteristics are sent further to the perceptual memory where they are interpreted, for instance determining whether the clients' opinions are positive or negative or determining the difference between the characteristics of products offered by the company in question and the characteristics of products offered by the competition. The knowledge conflicts occurring in the perceptive memory are thus connected with the results of its contents interpretation. For example, if an opinion contains only the product characteristics such as the color, dimensions, the function, it is difficult to determine the polarity of the opinion (state whether the opinion is positive or negative).

C. Workspace, episodic memory and declarative memory

The perception results in the form of objects or events are sent to the workspace in which knowledge conflicts relate to the perception of the current state of the environment and are connected with the creation of local links with the use of events stored in the episodic memory and the rules stored in the declarative memory. Knowledge conflicts connected with the contents of episodic memory mainly relate to contradictory events which occurred as a result of the earlier event. For example, the earlier event recorded in the episodic memory is: "two years before the competition launched two products (which are also manufactured by the company in question) with better characteristics (product 1 and product 2) and later events recorded in the episodic memory include: "in the previous year the sales of product 1 decreased" and "in the previous year the sales of product 2 increased)" The knowledge conflicts occurring in the declarative memory are connected with the occurrence of the contradiction of rules (for instance "if the users' opinions are negative, the decrease in sales will take place", and "if users' opinions are negative, the sales will remain at the same level").

Based on episodic and declarative memory a current situational model is generated, in the workspace, in the form of objects (for example sales characteristics), events (for example the actions of the competition) and links among them (for example: the competition offered a product with better characteristics and in our company a decrease in sales is observed"). Knowledge conflicts occurring in the workspace take place as a result of conflicts occurring in the episodic and declarative memory - the current situational model may contain incorrect objects or incorrect links between them.

D. Attentional codelets

In the attentional codelets module, there are significant elements of the situational model (the agent "rejects" insignificant elements of the situational model such as for instance "the drop of sales of products to the client X occurred because this client liquidated business" - this element is insignificant as no marketing actions can be taken with respect to client X any more). The conflict of knowledge in this module relates to the results of algorithm actions determining which elements of the current situational model are insignificant.

E. Procedural memory

The procedural memory, in turn, contains specific action schemes - for instance "improving the product characteristics", "lowering the product price", "launching the new product meeting the clients' expectations on the market". The conflict of knowledge relates to algorithms implemented as an action scheme, for instance determining what measures should be taken to launch a new product on the market.

F. Action selection module

The knowledge conflict in the action selection module relates to decisions which should be taken, for instance whether the action: "lowering the product price" or "launching a new product meeting the clients' expectations" should be chosen.

G. Global workspace and sensory-motor memory

In the cognitive agent's architecture there are also modules in which the sources of knowledge conflicts do not oc-

cur. They include: the global workspace (sources of knowledge conflicts do not occur in this module because there are significant elements of the situational model transferred from the module of current awareness for the purpose of initiating the phase of action selection) and sensory-motor memory (the sources of knowledge conflicts do not occur in this memory because it is a working module).

H. Discussion

It should be noticed that the occurrence of the conflict results in restrictions in the agent's learning process. For instance, implementing perceptual learning, the agent may learn the interpretation of unknown economic indexes (for instance looking for their interpretation on the Internet - learning without a teacher or using human assistance - learning with a teacher). If, however, the index interpretations found are contradictory, the process of perceptive learning is disturbed.

And implementing procedural learning (learning without a teacher may be applied here as well (the agent may use the actions defined in its own perceptive memory and assigned so far to other elements of the situational model), with a critic (for example the agent may assign particular actions implemented in connection with the decrease in the sales dynamics and a person defines whether the actions are correct) or with a teacher, (the agent may for instance learn what actions should be taken in a situation when sales is dropping in a company and the competition is launching a new product). If the action algorithms are different (a knowledge conflict occurs), the learning process will be disturbed as well.

Knowledge conflicts occurring in the episodic memory have, in turn, a negative impact on episodic learning (performed without a teacher) consisting in remembering all events occurring in the environment.

Conscious learning (performed without a teacher), on the other hand, consisting in determining which elements of a situational model are significant, may be limited by knowledge conflicts occurring both in the workspace and in the attentional codelets module.

It should be also emphasized that the sources of knowledge conflicts may occur in other symbolic, emergent and hybrid architectures of cognitive agents. As similarly as LIDA architecture, their structure consists of many modules.

IV. CONCLUSION

The use of cognitive agent for the purpose of supporting decision-making allows for the implementation of actions performed in a company by a human being so far, starting with the operation of work stations, through the diagnosis of the current economic situation to automatic decision-taking, both at the operational, tactical and strategic level. This is connected with the agents' skills in the scope of correct interpretation and associating of facts, discovering links between the objects and phenomena of the real world, learning and having experience.

For cognitive agent to be able to effectively perform their tasks, they should be created upon conducting the analysis of particular modules, with respect to knowledge conflicts. Thus the identification of the sources of knowledge conflicts, presented in the article, and its consideration at designing the decision-making process support systems will allow for automatic detection of conflicts of this kind and, as a consequence, their solving. These actions are extremely significant because, as has already been emphasized, they have a positive influence on the effectiveness of processes performed by an agent, and, in turn, the effectiveness of decisions taking place in a company.

This results in the need to perform further research works connected with, among others, the elaboration of the formal model of conflict solving and the creation of the prototype of cognitive decision-support system.

Abstract—**The use of auctions in procurement results in price reduction as well as the reduction in the cost and the time required to complete transactions. In many situations, price-only auctions resulted in the violation of the contracts or even contractors' bankruptcies. This is one reason for the introduction of multi-attribute auctions as well as auctions-followed-by negotiations. Auction theory is based on two assumptions which assure that auctions are efficient mechanisms, guarantee efficient solutions, and produce the best possible results for bid-takers. In practice these assumptions are often violated. The contribution of this paper is to propose a procedure for auctions-followed-by negotiations which retains important auction features such as process transparency and efficiency while allowing for increased social welfare. The unique feature of the procedure is the introduction of the win-win phase in which the market participants may attempt to make joint improvements to efficient solutions obtained from auctions.**

I. Introduction

Government-to-business (G2B) and business-to-business (B2B) online revers auctions have been introduced in mid-1990s to complement the paper-based submissions. They have become a popular way to source products and services - a few years after their introduction, 25% of total purchasing was done using these auctions [1]. Their use resulted in price reduction as well as the reduction in costs and time required to complete transactions. Other benefits attributed to these auctions include the creation of new markets, increased participation of suppliers, increased transaction transparency and price visibility, and increased standardization and efficiency of purchasing [2, 3]. These advantages have been contrasted with such disadvantages as collusion, opportunism and coercion [4]. However, these drawbacks are not limited to the auction mechanisms. Catalogues and negotiations have been also found prone to collusion, coercion and opportunism as well as deceit and threats.

Many of the negative, often illegal, aspects of market mechanisms can be addressed through the imposition of organizational and legal frameworks. Organizational framework may be used to enforce transparency, information disclosure, and standardization. Laws can be used to make collusion and coercion difficult as investigations uncover criminal behavior, for example such as bids rigged by Montreal Mafia, which controlled most of road contracts [5].

The underlying theory of the exchange mechanisms appears to favor auctions. Bulow and Klemperer [6] in one of the first comparative studies of auctions and negotiations prove that given a choice between auctions with n+1 bid-makers and negotiations with n negotiators the bid-maker should always choose an auction. This implies that the value of increased competition in auctions exceeds the negotiator's skill and prowess.

There are three key conditions which need to be met in order for the exchange mechanisms to be considered efficient, namely:

1. MAE: *Mechanism allocative efficiency*: the requirement that the mechanism maximizes social welfare. This condition assures that the use of the mechanism is optimal in the sense that its use does not result in social welfare loss;
2. SOE: *Solution efficiency*: the requirement that the solution that is the result of the mechanism usage is efficient. This condition is the specific instance of the allocative efficiency; and
3. OCM: *The owner's criterion maximization*: the requirement that the mechanism results in the solution that is the best possible for the owner, namely the organizations that set the mechanism up and invites others to voluntarily use it in an exchange process. This condition means that the mechanism's users have incentives that lead them to propose solutions that favor the owner leading to the final (winning) solution that is the best the owner could achieve in the particular circumstances.

Auctions in which the sole criterion is price or any other single and linear measure may meet the above conditions providing that the participants are risk-neutral. However, in many B2B and G2B auctions over production goods and services the evaluation criteria are more complex. These criteria include multiple attributes, which may be different for the

This work has been supported by the grants from the Natural Sciences and Engineering Research Council of Canada (NSERC) and Concordia University.

bid-taker and the bid-makers. In fact, surveys of procurement managers as well as field studies find that procured goods (i.e., products and services) are described by price as well as non-price attributes, which range from 2 to 30 [7-10]. In addition, one may argue that in procurement undertaken by public organizations attributes which describe changes in the society's well-being caused by contracting and its implementation should be considered. An example of such a consideration is A+B bidding discussed in Section 2.

The use of multiple attributes does not necessarily imply that price-only auctions cannot be effectively used in B2B and G2B auctions. It does however, raises a question about their appropriateness, in particular, about auctions being able to meet the above key conditions: MAE, SOC and MOC. Given that auctions are used in transactions amounting to billions, their potential inefficiency is of great importance to public and private organizations.

The purpose of this work is to discuss single and multi-attribute auctions conducted in B2G and G2B exchanges and to show that in many situations auctions may result in the winning bid which is an efficient solution (SOE condition) but they are allocative inefficient mechanisms (i.e., they violate AEM condition). Furthermore, we show that if the two assumptions underlying—which is likely in real-life situations—then the winning bid may be replaced with a solution which improves both the bid-taker's and the bid-maker's criteria.

There are three more sections in the paper. In Section 2 we formulate formal conditions that are required for multi-attribute auctions to produce better results than one-attribute auctions. In Section 3 the discussion of two underlying assumptions of auction theory is contrasted with the assumptions' implications and their limitations in real-life auctions. Section 4 concludes with a brief discussion of a process that can be used to transform auctions to hybrid mechanisms which would yield higher utility for the bid-takers (owners) and higher social welfare.

II. One-, two-, and many-attribute auctions

In many auctions, including procurement auctions, bidders submit only price. There are also auctions in which bids are vectors of multiple attributes. In this section price-only auctions are briefly discussed followed by a discussion on two- and more-attribute auctions. Two-attribute auctions are distinguished because they are simple to use and seemingly assure bid-takers that they obtain goods at the lowest price.

A. Bidding on price

Many procurement contracts are awarded to qualified bid-makers who offer the lowest price and who can meet the delivery time and other pre-specified conditions. There are also many auctions which do not result in a contract. These auctions are used to determine price and are followed by negotiations [11]. The reason for the auction-followed-by-negotiation mechanism and buyer-determined auctions is that the auction theory and the results from the experimental economics are difficult to implement in procurement [12].

Nelken [13], a spokesperson for the Polish General Directorate of National Roads and Motorways (GDNRM) observes: "If all conditions stated in the contract are met, the price is the best criterion for contractor selection." This is the case if the bid-taker uses only price as the criterion for the good's assessment. In reality, often the attributes which values are given to the bid-makers are criteria rather than bounds. For example, GDNRM prefers shorter road completion time than longer and longer warranty period than shorter. The use of price-only auction in which bidders must observe the conditions does not allow the bid-makers to compete on non-price attributes.

If there are more than one attributes that the bid-taker uses, then the imposition of constraints on the good's attributes, other than price, is insufficient to claim that the winning bid-maker offers the best contract.

B. Two-attribute auctions

Two attribute auctions increase the exchange flexibility because the bid-makers can tradeoff value of one attribute against the second attribute value. They may also be necessary when the bid-taker is obliged to or wants to obtain a contract which optimizes two rather than one criteria. In order to show that in this case two-attribute may produce results that are superior to a single attribute auction.

Let:

$x_1 \geq 0$ be the price attribute and $x_2 \geq 0$ – the second (non-price) attribute;

$u_b(\boldsymbol{x})$ (where $\boldsymbol{x} = [x_1, x_2]$) be the assessment function of the bid-taker b which b wants to minimize, i.e., it is preferable that both x_1 and x_2 take low values.

In real-life auctions $u(x)$ is often a linear function, i.e.,

$$u(\boldsymbol{x}) = x_1 + a \cdot x_2, \ (a > 0). \tag{1}$$

Let's now consider two bid-makers $s1$ and $s2$ who have different capabilities. Assume that the best bid of s_1 is $(x_1^{s1}; x_2^{s1})$ and s_2's best bid is $(x_1^{s2}; x_2^{s2})$, and $x_1^{s1} < x_1^{s2}$. Bid-maker s_1 wins the price-only auction. If

$$x_1^{s1} + a \cdot x_2^{s1} > x_1^{s2} + a \cdot x_2^{s2},$$

then s_2 wins the two-attribute auction. This means that the higher price offered by s_2 is offset by the lower value of the second attribute weighted by a, i.e.,

$$x_1^{s1} - x_1^{s2} > a \cdot (x_2^{s2} - x_2^{s1}).$$

Condition (1) corresponds to a well-known and observed in practice situation when price leaders may be unable to provide goods or deliver them in a shorter time than suppliers who charge higher price.

The gains for the bid-taker in two-attribute auctions over the price-only auctions have been confirmed experimentally [14]. Although in experimental settings these gains were found to be modest, in the comparison of real-life auctions these gains have been found significant. Lewis and Bajari [15] studied over 1300 hundred contracts awarded by the California Department of Transportation, through one- and two-attribute auctions. The two-attribute auctions where of the A+B

type, where A represents price and B represents the total number of days required to complete the contract weighted by the user cost, which is the cost incurred by the road users who have to take alternative routes. Lewis and Bajari used structural analysis to estimate the counterfactual welfare gain from switching from A (price-only) to A+B (price and social costs). They report that this gain represents almost 22% of the total contract value of $1.14 billion. In addition, the contracts were completed 30-40% faster. These are significant savings for the bid-takers; as of 2003, 38 U.S. states were using auctions with scoring functions for large projects [16].

Lewis and Bajari [15] made another important observation. In both one- and two-attribute auctions the same businesses participated and many of them won both types of auctions. Although the winners were paid about 7% more in two-attribute as opposed to one-attribute auctions, the bid-takers' savings greatly exceeded these additional costs. Another observation is that the contractors (bid-makers) are able to be significantly more efficient when they have an incentive to do so. From the social perspective this is a significant result because in this way public organizations can not only reduce their total costs but they can contribute to the overall efficiency increase of the industry.

C. Multi-attribute auctions

The superiority of the results obtained through two-attribute rather than one-attribute auctions can be extended to exchanges characterized by multiple attributes. Several multi-attribute auctions are discussed in literature. Hohner, Rich et al. [17] discuss an electronic private exchange established by Mars Inc., in which volume discount bidding and multi-attribute bidding were used most often.

The attributes that were used in the auctions included payment terms (e.g., pre-payment, payment date, and discount) as well as turnaround time, delivery schedule, product quality, type of material, and color.

Trade Extensions (TradeExtensions.com) offers a procurement software platform which includes reverse auctions. A review of four procurement case studies (i.e., Ineos, Road resurfacing, Elderly Care Services, and Cleaning Services) shows that Trade Extension's uses a full costing process in which all attributes must be expressed in monetary terms. The focus is on the minimization of the costs of procured services subject to constraints imposed on the attributes and their combinations.

It has been recognized recently that public organizations ought to base their procurement decisions on multiple attributes and that this should be made explicit to their suppliers. The European Union has adopted a new public procurement directive, which requires that the procurement authority publish ex ante relative weighting of each criterion. The E.U. directives (Article 55 in 2004/17/EC or Article 53 in 2004/18/EC) require that public contracts be allocated by competitive bidding. The buyer has to either use a scoring function, in which price and other attributes and their weights are given, or a lexicographically ordered list of attributes. In Poland, some of the road construction auctions are still awarded solely based on price [13] but many of these auctions resulted in contractors' bankruptcy [18]. This may be one reason for the introduction attributes additional to price, such as completion time and warranty period [19].

III. THREE CRITERIA

All cases discussed in the preceding sections concern products and services that will be produced and delivered in the future. This characteristic must be contrasted with situations in which auctions are over earlier produced goods. The difference is that in post-auction, manufactured products and services can be customized to meet specific needs of the bid-takers. This can be exemplified with the A+B auctions discussed in Section 2.2 in which bid-makers increased price on average by 7% in exchange for the reduction of the contract fulfilment time. This may be seen as a standard business practice as it brings increase of quality, shortening of delivery time, and addition of more features, however, production costs are increased and thus the tree conditions formulated in Section 1 are violated.

A. Two assumptions and their implications

In Section 1 the three key conditions (i.e., MAE, SOC and OCM) for efficient exchange mechanisms were formulated. Auctions meet all the conditions if the following two assumptions about the bid-makers and bid-takers are met [20, 21]:

1. The bid-maker and the bid-takers are risk neutral; and
2. The bid-maker and the bid-takers employ an evaluation functions (e.g., utility, profit, and value functions) which are quasi-linear.

Attitude towards risk influences, among others, the way payoffs are considered. For a risk-neutral person every unit of money has the same value (irrespectively if it is one unit more or less) as long as there is no difference in risk associated with getting more (less) of units. If both bid-takers and bid-makers are risk neutral, then they have the same assessment of the price. If however, their risk attitudes differ, then the same price level will be seen differently.

Violation of risk-neutrality causes that the market participants' utility is not quasi-linear however, this is not a sufficient condition. Quasi-linearity means that that the market participants' utility is the sum of price (i.e., the numeraire) and the valuation function of all non-price attributes. The valuation function is strictly convex and twice differentiable (Varian 2010). The implication of the quasi-linearity assumption is that the valuation function is can be expressed in monetary terms.

Attitude towards risk: and the price cannot be separated from valuation [21, pp. 32-41]. The assumption that participants are risk neutral is often unrealistic; risk aversion has been used to explain overbidding behavior [22]. In procurement auctions, sellers of timber and construction firms were found to be risk averse [23, 24]. Procurement managers in public organizations were found more risk averse than their counterparts in private organizations [25]. (The risk neutrality

assumption is required in both price-only and multi-attribute auctions.)

Buyers who base their purchasing decisions on the long-run price and other direct and indirect costs or on the total cost of ownership (TCO) model, consider many attributes. The middle- or long-term perspective lends itself to associating money with time, which includes future interest paid and various types of risk (e.g., delayed or not delayed payment, litigation, and change in interest). Because different participants are likely to have different financial, market and production constraints their preferences over money may also differ.

Quasi-linearity utilities: Quasi-linearity is a strong assumption and not particularly realistic [26, p. 63]. Ausubel and Milgrom [27, p. 24] note that the assumption is very restrictive and "requires that there is no effective budget limit to constrain the bidders and that the buyer, in procurement auction, does not have any overall limit on its costs of procurement. Although we have no data on how frequently these assumptions are satisfied, it appears that failures may be common in practice."

When market participants' utilities are quasi-linear, then the efficient transactions, i.e., these that lie on the contract curve of a bid-taker and a bid-maker differ in price value but not in the configuration of attribute values [28]. This may be difficult to accept when the auction is not over goods produced earlier (in which case their costs are fixed) but over goods that are produced only after the auction successfully concludes. Other limitations include such requirements as: (1) the preferential order of attribute values has to be opposite for the bid-taker and the bid-makers; there may not be constraints which bind efficient solutions; and (3) price has to be either a single attribute or a sum of price attributes with exactly the same weights for the bid-taker and the bid-makers [29].

B. Convex/concave utilities of buyers and/or sellers

Given the above, we may assume that many market participants' utilities are not quasi linear and that they are not risk-neutral. The implication of this assumption is that the auctions with risk seeking or risk averse participants do not meet at least one of the mechanism efficiency condition. One may argue that private businesses, who are bid-takers, may not be concerned with the condition violation as long as the OCM condition is met, i.e., the winning bid maximizes their utility. This argument may be questioned when the bid takers are public organizations which should be concerned with the efficient use of resources (SOE condition) and maximization of social welfare (MAE condition).

If the utilities are convex or quasi-convex or, more generally, if the efficient frontier for the bid-taker and the winning bid-maker is concave, then the OCM and MAE conditions may not be met. In such situation the winning bids may be efficient solutions but they can be improved for both the bid-taker and the winning bid-maker. This is because concave efficient solutions create an opportunity to introduce trade-offs which increase utility value of both of them. This potentially significant situation is illustrated in Figure 1.

Consider a winning bid (A); it is a winning bid for both quasi-linear utilities, its efficient frontier is shown by a broken line, and utilities for which the efficient frontier is concave. Let's assume that seller i is the winner and the winning bid is point A. If the preferences are quasi-linear, then A maximizes both the buyer's surplus and social welfare. If the efficient frontier is concave, then A does not maximize social welfare; both B and D yield a higher social welfare than A.

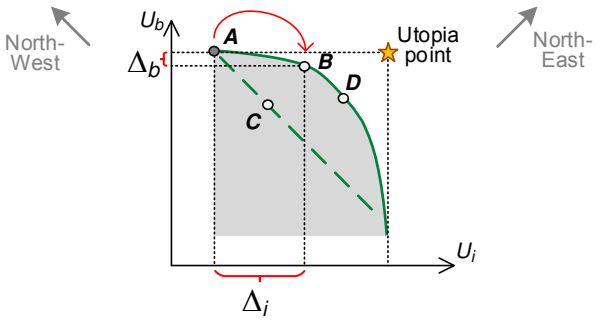

Figure 1. Improvement of the winning bid for concave efficient frontier

Market participants who want to maximize social welfare need to move in the North-East direction. Sellers, who are pushed by competition to increase the buyer's surplus, move in the North-West direction. Quasi-linear preferences together with the use of the sum of utilities as the measure of social welfare, remove the conflict in directions because the North-West moves do not change the distance from the Utopia point (max u_b; max u_i). However, market participants should be aware of the conflict as it arises when other types of preferences and/or other welfare measures are deemed more suitable.

The alternatives shown in Figure 1 have the following coordinates (u_b, u_i): A = (17; 3); B = (16; 11); C = (12; 7.5); and D = (13; 14.5). If we move from A to B, then social welfare increases from 20 to 27, i.e., by 35%. The maximum social welfare is 27.5 and it is reached at alternative D. This simple example illustrates that the difference in social welfare value may be significant.

Moreover, reaching a solution which is better than the winning bid may be possible. This, however, requires moving beyond the initial problem formulation. Let's assume that u_b and u_i are both expressed in monetary terms. We can see that the move from A to B results in buyer b's loss $(u_b(A) - u_b(B)) = \nabla_b$ = \$1 and seller i's gain $(u_i(B) - u_i(A)) = \nabla_i$ = \$8. If buyer b realizes the differences between the winning bid A and the alternative B, then she could suggest selecting alternative B under the condition that i pays her \$5 (or some other amount, which exceeds \$1).

When the utilities are not quasi-linear, then price transfer affects welfare. These utilities may also be assumed to be transferable (this assumption is often made in economics). If the amount to be transferred is positive, i.e., $\nabla_i - \nabla_b > 0$, then the winning bid A may be improved.

When the efficient frontier is concave, the move from the winning bid (*A* in Fig. 1) to a bid that increases social welfare (*B*) involves a transfer which is similar to price transfer when the frontier is linear with -1 slope, except for the following three differences:

1. Both price and configuration are included in the transfer and in social welfare calculation;
2. The transfer of value from the seller to the buyer requires a change of the configuration; and
3. The value transfer improves the buyer's and the seller's surplus as well as the social welfare.

Value θ that is transferred to the buyer has to be greater than the buyer's loss (i.e., $\theta > \nabla_b$). The difference between seller's *i* gain and buyer's *b* loss, i.e., $\nabla_i - \nabla_b > 0$, corresponds to the social welfare increase. Assuming that the concavity of the efficient frontiers for the pairs buyer$_b$-seller$_i$ ($i \in I$) is given and does not change, the size of the transferable value ($\nabla_i - \nabla_b$) can be viewed as the "value of competition". This is because the stronger the competition the greater the buyer's surplus, that is, the winning bid is further from the solution maximizing social welfare. To ascertain this let's denote the concave efficient frontier as function of u_i, i.e., $\upsilon_b(u_i)$ and assume that $\upsilon_b(u_i)$ is twice differentiable. We also assume that the buyer's utility produced by the winning bid is not smaller than the utility which maximizes social welfare.

Given concave efficient frontier, the greater the utility value of the buyer for the winning bid, the greater the transferable value ($\nabla_i - \nabla_b$). Function $\upsilon_b(u_i)$ is concave, therefore its second derivative is non-positive ($\upsilon''_b \le 0$). This means that the rate of increase of $\upsilon_b(u_i)$ decreases with the increase of u_i. Conversely, the rate of increase of $\upsilon_b(u_i)$ increases when u_i decreases. In other words, a small change in u_i causes an increasingly greater change in $\upsilon_b(u_i)$ as u_i gets smaller.

IV. Auctions and Multi-Bilateral Negotiations

A concave efficient frontier is the result of convex utilities. Also pairs of linear utilities defined over a convex set of feasible alternatives form a quasi-concave frontier under the condition that different attributes are more important for the participants [30]. In this case, the auctions which have been discussed in literature, are likely allocative inefficient mechanisms, i.e., they do not maximize social welfare. This may result in an efficient solution that maximizes the bid-taker's surplus. However, it may be possible, as the discussion given in Section 3.2 indicates, to improve this solution for both the buyer and the seller.

The competitive force pulls the bid-makers towards the maximum value of the bid-taker utility. If the efficient frontier is concave, then we should consider the winning bid as a tentative but not the final solution. Rather than conclude the exchange, the participants may continue and seek win-win solutions as shown in Figure 1 (points B and D). In this later phase negotiation may be preferable because the bid-taker needs to get involved and propose potential alternatives as well as the required compensation.

Kersten, Wachowicz et al. [31] discuss a multi-bilateral negotiation procedure with verifiable and non-verifiable offers. The procedure is implemented in the Imbins system which is a multi-bilateral negotiations support system, however, it also allows running auctions. This is because in the verifiable offer option the best bid is automatically displayed to all bid makers. This allows the bid-taker to announce the auction rules to all participants at the beginning of the process and then withhold her participation until a winning bid is obtained. After the auction concludes successfully the bid taker reviews the alternatives, namely the bids preceding the winning bid, and selects one or more of them. For every selected alternative she determines the minimum compensation. The compensation is required in order to compensate the bid-taker for the loss she would incur if the winning bid was replaced with the selected alternative.

The determination of the type of the compensation may require that the bid-taker discusses the issue with the bid-makers because it is likely that it concerns attributes which were different from those which were used in the bidding process. When the compensation is established, the bid-taker determines the values associated with each alternative and submits these pairs for the bid-maker's consideration. This may initiate an auction or a negotiation process which, if successful, results in a solution that is better for both the bid-taker and one of the bid-makers.

The Imbins system, which provides verifiable offers, was experimentally compared with a multi-attribute auction system Imaras (Kersten, Wachowicz et al. [31]. The results show that some of the experiment participants (bid-takers) initially used Imbins as an auction system and subsequently became involved and negotiated with their counterparts (see Apendix A for a screen shot). Other bid-takers may have ignored the fact that the best offer (bid) they received was displayed to every bid-maker and they used Imbins as a negotiation support system. In effect, the bid-makers who used Imaras (see Apendix B for a screen shot) achieved significantly lower profit than those who used Imbins. On the other hand, the bid-takers' profit was significantly higher in Imaras than in Imbins. This is despite the fact that in both systems the bid-makers received the same the verified information.

This result shows that the bid-taker's active participation causes them to accept solutions that are worse when they do not participate in the exchange process. The likely explanation can be found in the reciprocity theory which posits that peoples' social upbringing leads them to reciprocate to both positive and negative acts made by other people [32]. Thus, when the bid-makers make concessions, then the bid-takers reciprocate and also make concessions. We conclude that reciprocity in multi-bilateral negotiations weakens the competitive forces and they are left intact in auctions.

Other results of the Imbins and Imaras comparative studies experimentally confirm the propositions made above. Social welfare obtained in verifiable negotiations significantly exceeds welfare obtained in auctions. More importantly, the potential improvement of the negotiated contracts is not only

significantly greater than contacts obtained through auctions but it is greater than the average welfare of the efficient solutions that dominate the contracts from auction. Social welfare in auctions can reach 42 monetary units (m.u.) on average while social welfare in the negotiations can reach 120 m.u. The difference of 78 m.u. can be distributed between the bid-taker and the winning bid-maker making then both better in negotiations than in auctions. Even if the auction winner receives revenue 0 m.u. and the bid-taker gets 42 m.u., they both lose compared to the bid-maker who gets 50 m.u. and the bid-taker who gets 70 m.u.

V. Winners and losers

In many procurement exchanges, both buyers and sellers make decisions based on many attributes rather than price only. A review of recent studies on single- and multi-attribute auctions indicates that multi-attribute auctions produce better results for both the bid-takers and the bid-makers than a single-attribute auction. When, however, multi-attribute bid evaluation functions are used (e.g., utility, profit, and total cost of ownership), then these functions are likely to violate the two key auction theory assumptions. These assumptions assure that auctions are efficient mechanisms, which allow maximization of the social welfare. They also allow maximization of the bid-takers' criterion.

We showed that if the "bid-taker and bid-maker" pairs of the evaluation functions form a quasi-concave efficient frontier, then the winning bid does not maximize social welfare. This means that, in these situations, auctions are not efficient exchange mechanisms. This is an important conclusion for public organizations because their mission is not limited to achieving the best deal for them but which is detrimental to the socio-economic growth. Public organizations may present these winning deals as the most economic (e.g., the cheapest), but this would be a narrow myopic perspective. Their stakeholders, that is society, are the losers. In extreme cases, these loses may be due to the contractors' bankruptcies and foreclosures. In less severe situations, the contractors loses lead to unemployment and underutilization of resources.

When the efficient frontier is concave, the winning bid may be improved not only for the winning bid-maker but also for the bid-taker. The improvement is possible even if the bid is efficient. Given that the bid-maker compensates the bid-taker for the loss, the bid-taker may accept an efficient alternative which is significantly better for the bid-maker than the winning bid. This means that the bid-taker who accepts the auction's winning bid loses because he/she could achieve a better bid. This result is important for both public and private organizations because they forgo the possible improvement. It is also important for suppliers (bid-makers) who could get better contracts than the contracts specified in the winning bids.

Acknowledgments

We thank Margaret Kersten, Norma Paradis and Bo Yu for their contribution to the system design and experiment organization.

***Abstract*—The article presents the performance analysis issues of buy-sell decisions agents' in a-Trader system. The system allows for supporting of investment decision on FOREX market. The first part of article contains a description of a a-Trader system. Next, the algorithms of the selected buy-sell decision agents is presented. In the last part of article the evaluation function of agents' performance is detailed, and the approach to performance analysis is proposed and illustrated.**

I. Introduction

SUPPORTING financial decision making process is performed with the use of methods based on mathematics, statistics, economy or artificial intelligence [2, 4, 5, 10, 12, 15, 17, 19]. The methods are often implemented as the algorithms of the functioning of software agents in multi-agent systems [22]. The paper [1] presents using a multi-agent system in the FOREX market (Foreign Exchange Market). This is one of the biggest financial foreign exchange markets in the world. Currencies are traded against one another in pairs, for instance EUR/USD, USD/PLN. Also a-Trader is the example of system, which enables to support taking investment decisions on the FOREX [13, 14]. This system used tick data, on the basis of which minute aggregates (M1, M5, M15, M30), hourly aggregates (H1, H4), daily aggregates (D1), weekly aggregates (W1) and monthly aggregates (MN1) are created.

Agents functioning in the system take buy-sell decisions with the use of diversified support methods. There arises the need of constant evaluation of the performance of the agents for the purpose of determining the agents giving advice, in the current market situation, regarding the best decisions. As a consequence, the agents' decisions which are given the highest evaluation may constitute the basis for the performance of the buy-sell transaction by the investor. Return on investment cannot be assumed as the only evaluation criterion because other aspects having influence on the effectiveness of the buy-sell decision taken, such as for instance investment risk [9] or transaction costs should also be taken into consideration.

The purpose of this article is to perform the analysis of the performance of selected agents functioning in the a-Trader system with the use of various measures and to elaborate the method of its measurement (evaluation).

In the first part of the article, the a-Trader system is shortly characterized. The algorithms of three selected agents are then presented. In the final part of the article the results of the performance evaluation of these agents is described.

II. a-Trader multi-agent system

The a-Trade platform is of the nature of a multi-agent solution supporting the analysis of high frequency time series, such as e.g. listing of currency pairs on the FOREX market. The basic features of this system include openness, enabling the integration and development of new functionalities of the system and ensuring appropriate communication between particular agents. The system operates in the real time, processing data from the currency market maker live, provided with the use of the MetaTrader or JForex software. After the processing of data provided, the a-Trader system returns the information on making the transaction of the change of the item parameters to the broker (stop loss, take profit). Detailed description of the architecture and its elements as well as information about the agents operating within the framework of the platform may be found in the previous works describing the a-Trader system [13, 14]. This study describes a sample information flow within the platform. The solution diagram regarding the problem of the transfer of information generated by over one thousand agents with the frequency of up to 100 signals per minute will be presented.

A sample route of the signal delivered by the broker (Data Provider 1) is shown in Fig 1. The information processed goes through all system components:

a. Notification Agent (NA),
b. Historical Data Agent (HDA),

978-83-60810-58-3/$25.00

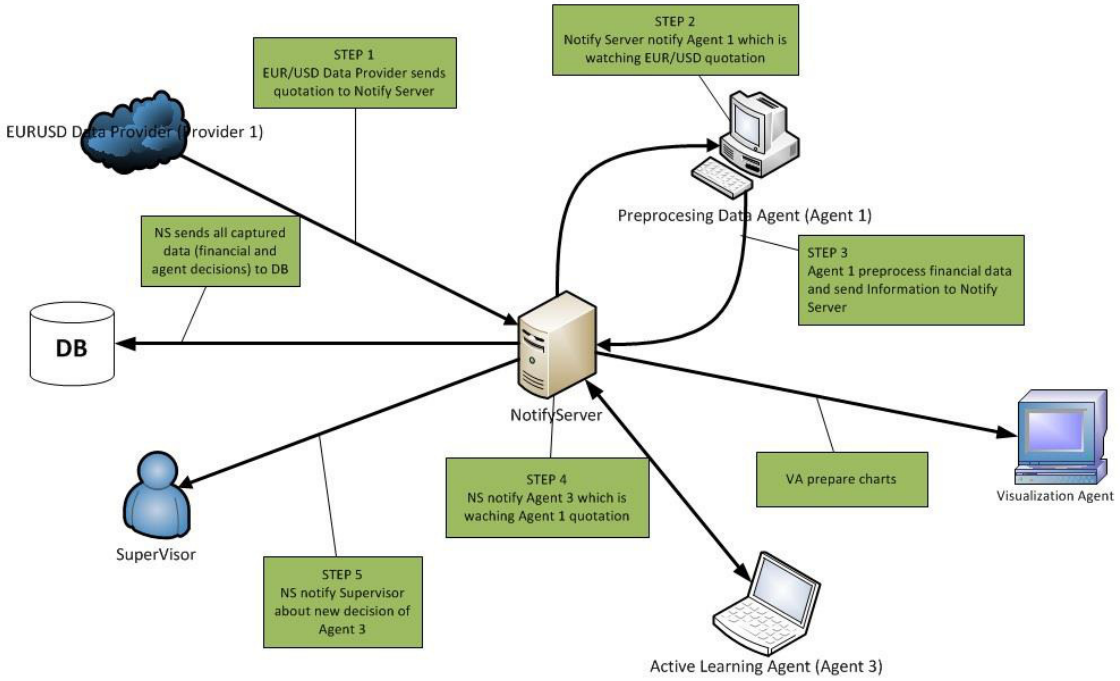

Fig. 1 Signal flow in the A-Trader system.
Source: Own work.

c. Cloud of Computing Agents (CCA),
d. Market Communication Agent (MCA),
e. User Communication Agent (UCA),
f. Supervisor (S),
g. System Database (SD),

Information about the change of quotation value goes directly to the Notification Agent (NA) – STEP 1. This agent decides of the further information flow sending it to all agents that listen to a given signal. Independently, the NA sends the signal to the historic data base. In the analysed case the signal is sent to the Data Processing Agent – STEP 2. The Data Processing Agent checks whether the signal is correct and may be subject to analysis by further agents. It sends the verified signal back to the Notification Agent (NA) – STEP 3. NA notifies Agent 3 (Active Learning Agent) about the signal received from Agent 1 – STEP 4. The Active Learning Agent processes information and sends it to the Supervisor through NA – STEP 5. The Supervisor Agent, on the basis of the decision of Active Learning Agent and the decisions of other agents, takes the final decision concerning the transaction. It sends it back to NA which saves it in the data base and sends to the market through the Data Provider Agent 1.

The Notification Agent (NA) ensures efficient communication inside the system. It is the intermediary agent in sending signals between agents as per declared indications (see Fig. 1). Each agent, the status of which changes, notifies its notification agent. The notification agents forwards the information about the change of the status of a given agent to all agents which are recorded in the notification register as clients/observers of its signals. The notification takes place by calling an appropriate web method (SOAP) at all agents from the list of the ones listening to the indicated signals. Then it records the information about the change of the status of the notification agent in the data base. The functionality of the notification agent elaborated this way makes the system flexible and scalable, gives the possibility of simple adding and removing agents and ensures making the system independent of the agent's location.

In order to be able to efficiently manage communication, the Notification Agent operates in a multi-threaded way. Information concerning the message flow, so which agent awaits signals from which agent, is read during the Notification Agent initialization to the Routing Table. Paralelly threads sending information to particular agents are created (Sending Threads Table). The sending threads are responsible for sending information to listening agents. After the creation they check whether the agent to which they are supposed to deliver the information is active and whether it is listening at a given addresses and is ready for processing data. Fig 2 shows the exemplary data flow inside the Notification Agent. The NA listens at the indicated port XXXX. After receiving information from Agent 4 it finds in the Routing Table which agents listen to the signals of Agent

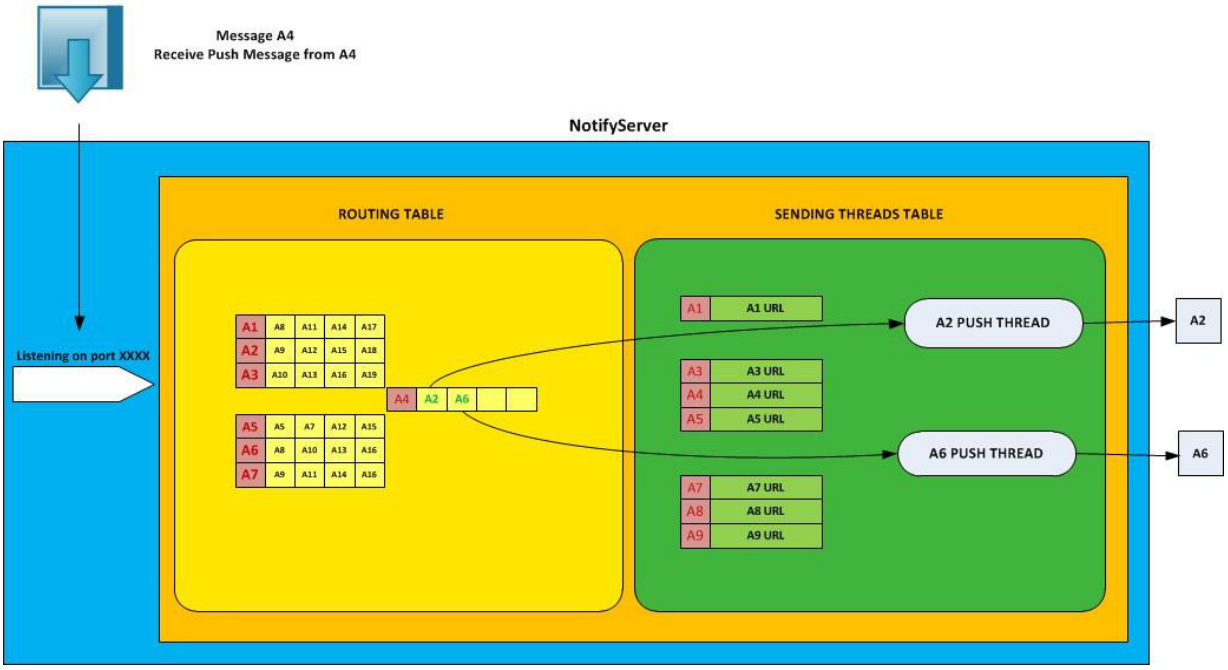

Fig. 2 Data flow inside the Notification Agent.
Source: Own work.

4. In the analysed case these are Agent 2 and 6. Then, the Notification Agent finds the threads sending to Agents 2 and 6 and it forwards the information received from Agent 4 to them, sending threads forward the received information from agents with which they communicate. In case when a problem with communication with agents occurs, the sending thread goes into inactive mode not to load the system. The information about the agent's inactivity is recorded in the event log. The inactive sending thread checks if the communication with the agent to which the information is sent can be established. In the case if the inactive agent starts working again, the communication is resumed.

The presented solution enables complete scalability of the platform. In case of excessive loading of the Notification Agent, another instance is activated. The Agents are notified about being assigned a new Notification Agent and they send their signals to it. One NA instance may receive signals from the group of agents, and the received signal must be sent to all agents awaiting given information.

The information received by the Notification Agent may be divided into three groups. The information division is presented in fig 3. The first one is standard information containing the signal generated by any agent working within the framework of the a-Trader system. The second group of information is the control commands. The third group is the warnings and errors sent by agents. Information flow from the first group was already described. Control information is used for managing the Notification Agent. With the use of this information the agents may demand sending information from other agents or demand that selected agents cease sending information. With the use of the control information an agent may resume its activity, the Notification Agent will then start sending signals to it. In case when an agent is being switched off, it should send information to the NA that it wants to stop listening. The sending thread will go into an inactive mode. The third group of information is used for forwarding the information about errors and warnings of particular agents to the central data base. It is sent to NA in the event of the occurrence of exceptional situations in the agent's operation. They include, e.g. too heavy load of an agent, receiving information which it should not receive and other exceptional situations.

The presented flow of the signal inside the a-Trader system allows for better understanding of processes occurring in the system. The agents described in the next part of the article operate in accordance with the presented convention. They accept other agents' signals generated in real time, process them and take financial decisions. The presented technological grounds of the system operation guarantee its scalability. The control messages, messages about errors and warnings increase the system reliability. This enables to process, almost in real time, thousands of signals generated by agents.

From the point of view of the user (investor) the most important components of the a-Trader system are the agents setting the buy-sell decisions (belonging to the cloud of computing agents) and the Supervisor agent. The functioning of these agents enables the investor to make transactions at

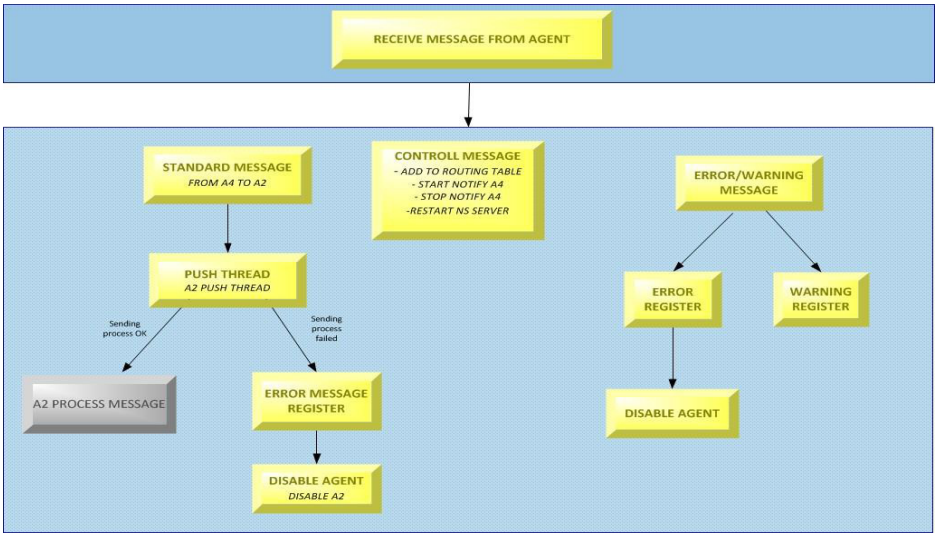

Fig. 3 Types of information received by the Notification Agent.
Source: Own work.

the FOREX market, in accordance with signals generated by them. The characteristics of selected agents setting purchase-sale transactions will be presented.

III. DESCRIPTION OF THE BUY-SELL DECISION AGENTS

Approximately 1000 agents function in the a-Trader system, including approx. 800 agents processing data concerning quotations at the FOREX market (for instance they calculate trend indicators, oscillators) and 200 agents (functioning in all time periods) setting the buy-sell decision. For the needs of this article, in order to perform the efficiency analysis, three agents were selected: TrendLinearReg, MultiTrendSignal and Consensus. These are agents taking decisions on the basis of more complex algorithms than the algorithms of typical technical analysis indicators. The specific nature of the functioning of selected agents will be presented in the further part of the article.

A. . The TrendLinearReg agent

The agent functions on the basis of the assumption that the trend of a certain number M of quotations is approximated with the straight line with the equation: y = ax + b. The straight line inclination depends on the value of the "a" parameter or the tangent value of the inclination angle with the use of linear regression [11, 21]. The agent generates the purchase signal when the coefficient value changes from positive to negative and the sales signal is generated when the coefficient changes value from negative to positive. The change of the agent's decision is made with the use of hysteresis, the level of which is defined by means of the coefficient Δ, the value of which should be higher than transaction costs.

The TrendLinearReg agent functioning algorithm is as follows:

Data: The vector of quotation value of the currency pair $w=<w_1, w_2, ... w_M>$ consisting of M quotations and the previous value the a coefficient marked as *preva.*

Result: The D decision (value 1 denotes „buy" decision, value -1 denotes „sell" decision, value 0 denote s „ leave unchanged") with respect to w and *preva* value.

BEGIN

1: Let i:=1;*sumy*:=0; *sumx*:=0.0; *sumxy:*=0; *sumx2*=0. *II* where: *sumy* means the sum of the value of M quotations, *sumx* means the sum of the quotation number in the vector, *sumxy* means the sum of the products of the quotation value and quotation number in the vector, and *sumx2* means the sum of the squares of quotation numbers in the vector.

2: $sumy:= sumy+w_i$; $sumxy:= sumxy+w_i*i$; $sumx=: sumx+i$; $sumx2:= sumx2+i*i$; $i:=i+1$;

3: If $i<M$ then go to 2. If $i \geq N$ then go to: 4.

4: $c:= sumx2*M-sumx*sumx$. If c=0 then c:=0,1.

5: $a:=(sumxy*M-sumx*sumy)/c$;

6: If $(a(+/-\Delta)=preva=0)$ or $((a+\Delta)<0$ and $preva<0)$ or $((a-\Delta)>0$ and $preva>0)$ then $D:=0$;
If $((a+\Delta)<0$ and $preva>0)$ then $D:=1$; If $((a-\Delta)>0$ and $preva<0)$ then $D:=-1$;

7: $preva:=a$;

END

The complexity of the algorithm, significant due to minimizing of the agent reaction time, amounts to O(M), where M means the number of quotations.

B. . The MultiTrendSignal agent

Agent MultiTrendSignal generates the purchase-sales decision on the basis of the decision of agents functioning with the use of most often used technical analysis ratios [3,

16]. The decisions of the following nine base agents are analysed:

- Average Directional Index (ADX),
- Relative Strength Index (RSI),
- Rate of Change (ROC),
- Commodity Channel Index (CCI),
- Moving Average of Oscillator (OsMA),
- Moving Average Convergence Divergence (MACD),

The agent considers four time periods (M1, M5, M15, M30) in such a way that the buy/sell decision in case of the period M30 is taken when the same decision is taken by most base agents also within the periods M1, M5, M15, M30.

The structure of the investment decision was defined in the study [7]. This decision is taken on the basis of financial instrument quotation such as, e.g. currency pairs EUR/USD, USD/GBP and it is defined as follows:

Definition 1.

Decision D about finite set of financial instruments $E=\{e_1,e_2,\ldots,e_N\}$ is defined as a set

$$D=\left\langle\{EW^+\},\{EW^\pm\},\{EW^-\},Z,SP,DT\right\rangle, \quad (1)$$

where:

1) $EW^+=\left\langle e_o,pe_o\right\rangle,\left\langle e_q,pe_q\right\rangle,\ldots,\left\langle e_p,pe_p\right\rangle$ - a positive set; in other words, it is a set of financial instruments about which the agent knows the decisions to buy, and the volume of this buying.

2) $EW^\pm=\left\langle e_r,pe_r\right\rangle,\left\langle e_s,pe_s\right\rangle,\ldots,\left\langle e_t,pe_t\right\rangle$ - a neutral set, in other words, it is a set of financial instruments, about which the agent does not know that buy or sell. If these instruments are held by an investor, that they should not be sold, or if they are not in possession of the investor, should not be bought by them.

3) $EW^-=\left\langle e_u,pe_u\right\rangle,\left\langle e_v,pe_v\right\rangle,\ldots,\left\langle e_w,pe_w\right\rangle$ - a negative set; in other words it is a set of financial instruments of which the agent knows that these elements should sell. Couple $\left\langle e_x,pe_x\right\rangle$, where: $e_x\in E$ and $pe_x\in[0,1]$, denote financial instrument and this instrument's participation in set EW^+, $EW^\pm$, EW^-.

Financial instrument $e_x\in EW^+$ is denoted as: e_x^+.

Financial instrument $e_x\in EW^\pm$ is denoted as: $e_x^\pm$.

Financial instrument $e_x\in EW^-$ is denoted as: e_x^-.

4) $Z\in[0,1]$ - predicted rate of return.

5) $SP\in[0,1]$ - degree of certainty of rate Z. It can be calculated on the basis of the level of risk related with the decision.

6) DT - date of decision.

The set of agents' decisions, on the basis of which the MultiTrendSignal agent sets decisions is called a profile. .

The agent functioning algorithm is as follows;

Data: Profiles $AM1=\{AM1^{(1)},AM1^{(2)},\ldots.AM1^{(9)}\}$
$AM5=\{AM5^{(1)},AM5^{(2)},\ldots.AM5^{(9)}\}$
$AM15=\{AM15^{(1)},AM15^{(2)},\ldots.AM15^{(9)}\}$
$AM30=\{AM30^{(1)},AM30^{(2)},\ldots.AM30^{(9)}\}$
consist of *9* agents' decisions.

Result: Decision $DEC=\left\langle DEC_+,DEC_\pm,DEC_-,DEC_Z,DEC_{SP},DEC_{DT}\right\rangle$ according the profiles.

BEGIN

1: Let $DEC_+=DEC_\pm=DEC_-=\varnothing,DEC_Z=DEC_{SP}=DEC_{DT}=0$.

2: *j*:=1.

3: *i*:=+.

4: If ($tM1_i(j)>4$) and ($tM5_i(j)>4$) *and* ($tM15_i(j)>4$) *and* ($tM30_i(j)>4$) then $DEC_i:=DEC_i\cup\{e_j\}$. Go to:6. // $tMxX_i(j)$ – the number of occurrences of the financial instrument in a positive, neutral or negative set in a given time period.

5: If *i*= + then *i*:=±. Ifi *i*=± then *i*:=- . if *i*=- then go to: 6.
Go to: 4

6: If *j*<*N* then *j*:=*j*+1 go to:3.
If *j*≥*N* then go to: 7.

7: *i*:=*Z*.

8: Determine *pr*(*i*). //ascending order

9: $k_i^1=(9+1)/2$, $k_i^2=(9+2)/2$.

10: $k_i^1\le DEC_i\le k_i^2$

11: If *i*=*Z* then *i*:=*SP*. If *i*:=*SP* then *i*:=*DT*. Ifi *i*:=*DT* then END.
Go to: 8.

END.

The algorithm complexity amounts to O(18N), where N means the number of currency pairs.

C. The Consensus agent

In the a-Trader system the agents take buy-sell decisions independently of one another. Thus a conflict situation may occur, in which (at a given moment) these decisions are mutually contradictory (for instance some agents suggest the purchase decision and other agents – the sale decision). In order to solve this conflict a few strategies were implemented into the system: the strategy of dominating decisions, the strategy based on moving average, the consensus strategy, the evolution strategy. The Consensus method [8, 18, 20] is described in the article.

The Consensus agent (characterized in detail in the work of [14] determines the decisions on the basis of the set of decisions generated by other agents functioning in the system.

The agent functioning algorithm is as follows:

Data: The profile $A=\{A^{(1)},A^{(2)},\ldots.A^{(M)}\}$ consist of *M* agents' decisions. //$A^{(1)},A^{(2)},\ldots.A^{(M)}$ – decisions of particular agents

Result: Consensus
$CON=\left\langle CON_+,CON_\pm,CON_-,CON_Z,CON_{SP},CON_{DT}\right\rangle$ according *A*.

BEGIN

1: Let $CON_{+}=CON_{\pm}=CON_{-}=\emptyset, CON_{Z}=CON_{SP}=CON_{DT}=0$.

2: j:=1.

3: i:=+.

4: If $t_i(j) > M$ then $CON_i := CON_i \cup \{e_j\}$. Go to:6.

// $t_i(j)$ – the number of occurrences of the financial instrument in the positive, neutral or negative set

5: If i=+ then i:=±
If i=± then i:=-
If i=-, then Go to:6
Go to:4.

6: If $j<N$ then j:=j+1 Go to:3
If $j \geq N$ then Go to:7.

7: i:=Z.

8: Determine $pr(i)$. // ascending order

9: $k_i^1 = (M+1)/2$, $k_i^2 = (M+2)/2$.

10: $k_i^1 \leq CON_i \leq k_i^2$.

11: If i=Z then i:=SP.
If i:=SP then i:=DT.
If i:=DT then END.
Go to: 8.

END.

The complexity of the algorithm amounts to O(3NM), where N means the number of currency pairs and M means the number of agents belonging to the profile (in the research experiment conducted in the next part of the article, M=25, N=1).

Computational complexities of the algorithms of the agents' functioning have impact on the performance of the whole a-Trader system. Taking into consideration the fact that the system is processing tick signals and a large number of agents function in it (approx. 1000), short time of computation made by particular agents is very significant.

In general, agents functioning in the system for the purpose of determining the decisions use the methods of technical analysis, fundamental analysis, neural networks, evolution algorithms, behavioural models.

The Supervisor agent also functions in the system and its major purpose is to maximize the rate of return and reduce the investment risk. The Supervisor's task is to coordinate the functioning of agents setting the buy-sell decisions and presenting the final decision to the investor. This agent uses various strategies, analyses them and evaluates the agents' performance.

A case study relating to the method of the measurement of the performance of selected agents taking buy-sell decisions is presented further in the article.

IV. The Agent Performance Evaluation Method – Case Study

The agents performance analysis is performed for data within the M5 range of quotations from the FOREX market. For the purpose of this analysis, a test was performed in which the following assumptions were made:

1. EUR/USD pairs, out of four randomly selected pairs of the following periods, were used:
   - 31-03-2014, 0:00 am to 31-03-2014, 23:59 pm,
   - 03-04-2014, 0:00 am to 03-03-2014, 23:59 pm,
   - 04-04-2014, 0:00 am to 04-04-2014, 23:59 pm,
   - 05-04-2014, 0:00 am to 05-04-2014, 17:00 pm,
2. At the verification the decisions (signals buy-value 1, sell-value -1, leave unchanged - value 0) generated by the agents TrendLinearReg, MultiTrendSignal are used (the example is presented in the Fig 4, where the green arrow means the decision "buy", the red one - "sell"), and Consensus.
3. It was assumed that the initial capital held by the investor amounts to USD 1000 and the difference between this amount and the amount which the investor will have after the last sales transaction in a given period is considered the rate of return. The rate of return is expressed in nominal units (USD).
4. The transaction costs are directly proportional to the number of transactions.
5. The capital management - it was assumed that in each

Fig. 4 The MultiTrendSignal agent decisions.
Source: Own work.

transaction the investor engages 100% of the capital held. The capital management strategy may be determined by the user. The investor every time invests 1000 at the leverage 10:1 and invests all the capital held.

6. The performance analysis was performed with the use of the following measures (ratios):
   - rate of return (ratio x_1),
   - the number of transaction,
   - gross profit (ratio x_2),
   - gross loss (ratio x_3),
   - total profit (ratio x_4),
   - the number of profitable transactions (ratio x_5),
   - the number of profitable transactions in a row (ratio x_6),
   - the number of unprofitable transactions in a row (ratio x_7),
   - Sharpe ratio (ratio x_8)

$$S = \frac{E(r) - E(f)}{|O(r)|} \cdot 100\% \qquad (2)$$

     where:
     E(r) – arithmetic average of the rate of return,
     E(f) – arithmetic average of the risk-free rate of return,
     O(r) – standard deviation of rates of return.
   - the average coefficient of variation (ratio x_9)is the ratio of the average deviation of the arithmetic average multiplied by 100% and is expressed:

$$V = \frac{s}{|E(r)|} \cdot 100\% . \qquad (3)$$

     where:
     V – average coefficient of variation,
     s – average deviation of the rates of return,
     E(r) – arithmetic average of the rates of return.
   - Value at Risk (ratio x_{10}) – the measure known as value exposed to the risk - that is the maximum loss of the market value of the financial instrument possible to bear in a specific timeframe and at a given confidence level [3].

$$VaR=P*O*k \qquad (4)$$

     where:
     P – the initial capital,
     O – volatility - standard deviation of rates of return during the period ,
     k –the inverse of the standard normal cumulative distribution (assumed confidence level 95%, the value of k is 1,65),
   - the average rate of return per transaction (ratio x_{11}), counted as the quotient of the rate of return and the number of transactions.

7. For the purpose of the comparison of the agents' performance, the following evaluation function was elaborated:

$$y = (a_1 x_1 + a_2 x_2 + a_3 (1 - x_3) + a_4 x_4 + a_5 x_5 + a_6 x_6 + \ldots$$
$$+ a_7 (1 - x_7) + a_8 x_8 + a_9 (1 - x_9) + a_{10} (1 - x_{10}) + a_{11} x_{11}) \qquad (5)$$

where x_i denote the normalized values of ratios mentioned in item 6 from x_1 to x_{11}. It was adopted in the test that coefficients a_1 to a_{11}=1/11.

It should be mentioned that these coefficients may be modified with the use of, for instance, an evolution method or determined by the user (investor) in accordance with his/her preference (for instance the user may determine whether he/she is interested in the higher rate of return with simultaneous higher risk level or lower risk level but simultaneously agrees to a lower rate of return).

The function is given the values from the range [0..1], and the agent's efficiency is directly proportional to the function value.

8. The results obtained by the tested agents were compared with the results of the Buy-and-Hold strategy and the strategies using EMA..

The agent efficiency tests were performed in the following manner:

1. On the basis of data from the first period each agent defined when to buy and when to sell EUR/USD currency.
2. In the next step, on the basis of the results of particular agents and Buy-and-Hold and EMA, for each purchase-sale operation the value of capital held and the rate of return in USD were determined.
3. At the final stage the value of performance ratios was calculated with respect to the rates of return resulting from all decisions generated by the analysed agents and the Buy-and-Hold as well as EMA strategies (not only from the final rates of return but from all rates of return calculated after each sales decision). The evaluation functions were also calculated.
4. Then the steps from 1 to 3 were repeated with the use of the data from the successive periods.

Table 1 presents the results obtained in the particular periods.

Generalizing the agent efficiency analysis results, it may be noticed that in the periods in question their decisions generated both profit and loss. Thus, in the efficiency analysis not only the rate of return should be taken into consideration but also other ratios, including the level of risk involved in the investment, which is enabled by the evaluation function elaborated in the article.

In fig 5 the diagram of the value of ratios and evaluation function of particular agents (and the B&H method as well as EMA) in the periods in question are presented. To illustrate relationships between ratios and agents the parallel

TABLE I.
PERFORMANCE ANALYSIS RESULTS

Ratio	TrendLinearReg				MultiTrendSignal				Consensus				B&H				EMA			
	Period 1	Period 2	Period 3	Period 4	Period 1	Period 2	Period 3	Period 4	Period 1	Period 2	Period 3	Period 4	Period 1	Period 2	Period 3	Period 4	Period 1	Period 2	Period 3	Period 4

Source: Own work.

coordinates are used, which is a common way of visualizing and analyzing multivariate data. An agent in n-dimensional space is represented as a polyline with vertices on the parallel axes; the position of the vertex on the ith ratio corresponds to the ith coordinate of the agent.

It may be noticed that the values of efficiency ratios of particular agents differ in each period and get the values (after normalization) in the range from 0 to 1. The values of such ratios as x_2,x_3 and x_{11} are approximate in case of all agents and the values of ratios x_5, x_6, x_8 are characterized by significant distribution in case of particular agents. It may also be noticed that in case of the agents TrendLinearReg, MultitrendSignal and Consensus the values of ratios x_1, x_2, x_3, x_9 and x_{11} are similar in each of the periods in question and the values of ratios x_4, x_5, x_6, x_7, x_8, x_{10} are characterized by much variability in particular periods. A large scope of changes of ratios significantly hinders the analysis by the user and, as a consequence, prevents taking decisions in time close to real time. And the application of the evaluation function allows for immediate appointment of the agent with the best efficiency. It may be noticed that the evaluation function values oscillate in the range from 0.03 – 0.59 thus despite large deviations in the values of particular ratios, the agents are evaluated in the range characterized by a smaller value deviation. The results of the experiment performed allow to state that the ranking of agents' evaluation differs in particular periods. In the first period the Consensus agent turned out to be the best agent and the MultiTrendSignal agent was ranked higher and the TrendLinearReg agent was ranked lower than the B&H benchmark evaluation. The EMA benchmark was ranked the lowest in this period. In the second period the MultiTrendSignal and TrendLinearReg agents and the Consensus agent were ranked higher than the EMA and B&H benchmarks. Considering the third period it may be noticed that the evaluation ranking is similar to the one in the second period. And in the fourth period the MultiTrendSignal was ranked the highest and the TrendLinearReg and Consensus Agents were ranked higher than the B&H benchmarks. The EMA benchmark was ranked the lowest in this period.

Taking into consideration all the periods in question it may be stated that the Consensus agent was ranked highest most often (3 out of 4 periods) although the rate of return of this agent was not always the highest. This evaluation results, however, from the low level of risk connected with investing on the basis of the Consensus agent decision. And, on the other hand, the TrendLinearReg agent was ranked low most often (3 out of 4 periods) because at a relatively high risk level it generated little rate of return. Rates of return obtained by the MultiTrendSignal lower than rates of return of the other two agents may result from the fact that this agent is characterized by a low number of transactions because it takes decisions with the use of a few quotation time slots. It may also be noticed that low evaluation of the EMA benchmark in all periods results not from the level of the rate of return but from a high risk level and a large number of loss transactions in a row.

Referring to the evaluation analysis performed in other systems (e.g. in the MetaTrader system) it should be emphasized that it is, in most cases, performed "manually" by the investor. Due to its time consumption, its utility in the systems operating in real time is very limited. Besides, these systems only offer the functions calculating the basic ratios (rate of return, number of transactions, highest profit, highest loss, total profit, number of profitable transactions, number of profitable transactions in a row, number of loss transactions in a row), and in the a-Trader system also additional ratios are calculated, such as the risk measures (Sharp ratio, average value coefficient, risk exposed value), or the average rate of return from transaction.

The evaluation function, elaborated in this article, enables the measurement and the performance evaluation of particular agents taking the buy-sell decision in the system. These operations are made automatically, in time close to real time, by the Supervisor agent which may then suggest the investor taking final decisions on the basis of decisions generated by the agent with the highest level of performance. In addition, enabling the user to change a_i and x_i parameters

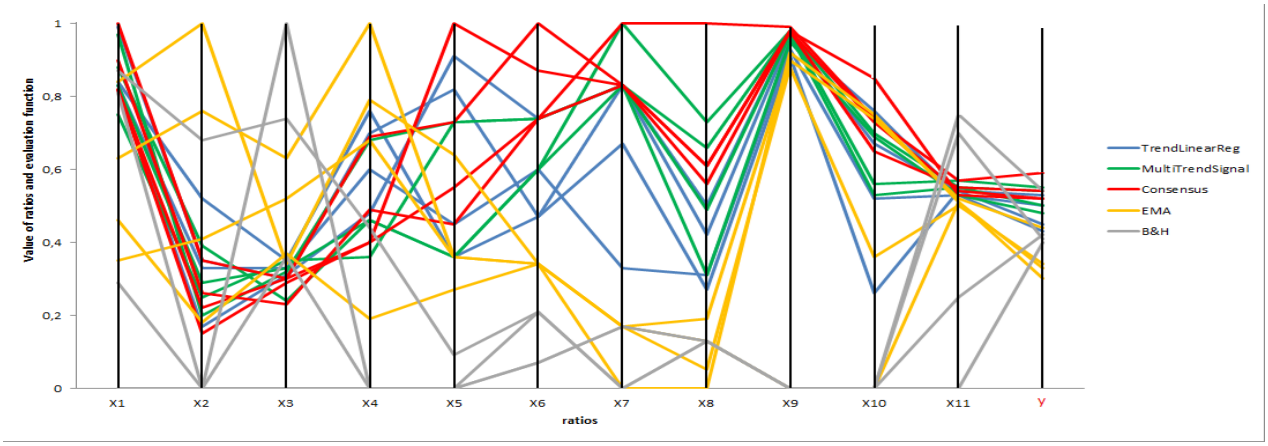

Fig. 5 Values of ratios and evaluation function of particular agents in the periods in question.
Source: Own work.

of the evaluation function allows for considering his/her preference concerning the criterion of importance of particular evaluation ratios. The evaluation value also considers the transaction costs with the assumption that the dependency between the number of transactions and the average rate of return from the transaction is reflected. However this simple principle cannot be adopted because a large number of transactions has impact on the reduction of the agent's efficiency level, especially for the transactions with a high rate of return.

The elaborated evaluation function may be extended with other ratios which do not have directly or (reversely) proportional impact on the function value. For example, this may be the correlation between the rate of return and the ratios defining the risk.

V. CONCLUSION

The agents in the a-Trader system take independent buy-sell decisions using various methods for this purpose. The functioning of these agents involves, however, the need to perform constant analysis of their performance, which should be performed by the Supervisor agent. As a consequence, this enables the investor to present decisions generated by the best agents. The analysis results presented in this article allow to draw conclusions that, depending on the current situation on the FOREX market, the level of performance of particular agent changes. There is no agent which definitely dominates over the other ones. And the use of this performance evaluation function allows for automatic setting of the best agent in time close to real time, which has, in turn, a positive influence on investment effectiveness.

Agents based on artificial intelligence methods also function in the a-Trader system. Neural networks recognize the models or sequences of changes of agent signals and on this basis they take a decision. Evolution algorithms are developed, which are able to calculate most effective combinations of agents over a few hundred seconds. Owing to this they adjust to the variable situations dynamically. intelligent methods will be described in the successive articles,

Currently works are being performed on the implementation of the "directional change algorithm" [6], the evolution method of determining a_i coefficients into the a-Trader system and the implementation of cognitive agents, performing the fundamental analysis and analysing experts' opinions in the scope of forecasts referring to quotations on the FOREX market.

***Abstract*—The aim of our study was to provide a contribution to the research field of the critical success factors (CSFs) of ERP projects, with a specific focus on smaller enterprises (SMEs). Therefore, we conducted a systematic literature review in order to update the existing reviews of CSFs. On the basis of that review, we led several interviews within German SMEs that have implemented ERP systems. As a result, we showed that all factors found in the literature also affected the success of ERP projects in SMEs. However, within those projects, technological factors gained much more importance compared to those factors that most influence the success of larger ERP projects. For SMEs, factors such as the Organizational fit of the ERP system as well as ERP system tests are even more important than Top management support or Project management, which were the most important factors for large-scale companies.**

I. Introduction

TODAY'S enterprises are faced with the globalization of markets and rapidly changing economies. In order to cope with these fluid conditions, the use of technology, as well as information and communication systems, is almost mandatory. Specifically, the adoption of enterprise resource planning (ERP) systems as standardized systems that encompass the activities of entire enterprises has become an important factor for today's businesses. The demand for ERP applications has increased for several reasons, including competitive pressure to become low-cost producers, expectations of revenue growth, and the desire to re-engineer businesses to respond to market challenges. A properly selected and implemented ERP system offers several benefits including considerable reductions in inventory costs, raw material costs, lead time for customers, production time, and production [1]-[4]. Therefore, the majority of enterprises around the world now use ERP systems. For example, according to a survey conducted in Germany from 2010 to 2011, ERP systems are used in more than 92 percent of all German industrial enterprises [5].

Due to the saturation of ERP markets targeting large-scale enterprises, ERP system manufacturers today are also concentrating on the growing market of small and medium-sized enterprises (SMEs) [3], [6]. This has resulted in a highly fragmented ERP market and a great diffusion of ERP systems throughout enterprises in nearly every industry and of every size [7]-[9]. Due to the strong demand and the high fragmentation of the market, there are many ERP systems with different technologies and philosophies currently available on the market. This multitude of software manufacturers, vendors, and systems implies that enterprises that use or want to use ERP systems must strive to find the "right" software as well as to be aware of the factors that influence the success of the implementation project.

The implementation of an information system (e.g., an ERP system) is a complex and time-consuming project, and in the process, companies face not only great opportunities but also enormous risks. To take advantage of potential opportunities without being affected by the risks of these implementation projects, it is essential to focus on those factors that support the successful implementation of an information system [10], [11]. Being aware of these factors, a company can positively influence the success of the implementation project and effectively minimize the project's risks [10]. Recalling these so-called critical success factors (CSFs) is of high importance whenever a new system is to be adopted and implemented or a current system needs to be upgraded or replaced. Errors during the selection, implementation, or maintenance of ERP systems, incorrect implementation approaches, and ERP systems that do not fit the requirements of the enterprise can all cause financial disadvantages or disasters, perhaps even leading to insolvencies. Several examples of such negative scenarios can be found in the literature (e.g., [12], [13]). SMEs must be especially aware of CSFs, since they lack the financial, material, and personnel resources of larger companies. Thus, they are under greater pressure to implement and run ERP systems without failure and as smoothly as possible.

These critical success factors have already been considered in numerous scientific publications. Several case studies, surveys, and literature reviews have previously been conducted by different researchers (e.g., [4], [14]-[16]). However, the existing ERP system success-factor research has focused mostly on the selection and implementation of ERP systems in large enterprises. Less attention has been paid to implementation projects in SMEs, despite the fact that research focusing on CSFs in smaller companies has been recommended by the research community for several years (e.g., [17], [18]).

Therefore, the aim of our study was to focus on the implementation of ERP systems in SMEs, focusing in

978-83-60810-58-3/$25.00

particular on the differences in CSFs between larger ERP projects and smaller projects. Prior to this study, we conducted a systematic literature review in order to update the existing reviews of CSFs. On the basis of the CSFs identified, we conducted multiple interviews within German SMEs that have already implemented ERP systems in order to obtain insights into the similarities and differences in CSFs for ERP system implementation in SMEs. Overall, our study was driven by the following research question:

Q1: What similarities and differences exist between critical success factors for ERP implementation projects in larger and smaller enterprises?

Therefore, the paper is structured as follows. The next section gives a short overview of the subsequently discussed and important CSFs before the section that follows deals with the results of our literature review. Here, we will point out which factors are the most important and which factors seem to have little influence on the success of an ERP implementation project. Next, our data collection methodology is described before the results of the interviews are presented and the research question is answered. Finally, the paper concludes with a summary of the results and discusses the limitations of our study.

II. Critical Success Factors Identified

A CSF for ERP projects has been defined by [15] as a reference to any condition or element that was deemed necessary in order for the ERP implementation to be successful. To provide a comprehensive understanding of the different CSFs and their concepts, these are described in this section before presenting the research methodology and discussing the results. However, only the most-important and subsequently discussed factors are described. The detailed definitions of the other CSFs can be found in [7] and [19].

ERP system configuration: Since the initial ERP system version is based on best practices, a configuration or adaptation of the system according to business processes is necessary in every ERP implementation project. Hence, as closely as possible, the company should attempt to adopt the processes and options built into the ERP rather than seeking to modify the ERP [20]. Following [21], the more the original ERP software is modified (e.g., even beyond the "normal" configuration), the smaller the chance is for a successful implementation project. Hence, a clear business vision is helpful because it reduces the effort of capturing the functionality of the ERP business model and therefore minimizes the effort needed for the configuration [20]. Again, extensive system modifications will not only cause implementation problems but also interfere with system maintenance. Therefore, the need for fewer adjustments reduces the effort of integrating new versions, releases, or updates [22].

ERP system tests: In ERP implementation, "go live" on the system without adequate and planned system testing may lead to an organizational disaster. Tests and validation of an ERP system are necessary to ensure that the system works correctly from a technical perspective, and that the business process configurations have been done the right way [23]. Therefore, testing and simulation exercises for both, the whole system and its separate parts and functions, have to be performed during and in the final stages of the implementation process [15], [24].

Organizational fit of the ERP system: The fact that the organizational fit of an ERP system should be examined and considered comprehensively before its implementation sounds logical. Nevertheless, ERP manufacturers often attempt to create blind confidence in their ERP packages, even if the organizational fit is obviously low. In [21], the extent to which the implementation success of an ERP system depends on the fit between the company and the ERP system was empirically examined, and it was found that the adaptation and configuration effort negatively correlate with implementation success. Therefore, the careful selection of an ERP system with consideration of its company-specific organizational fit, such as company size or industry sector, is essential, and appropriate ERP system selection is an important factor in the effort to ensure a good fit between the company and the ERP system.

Project management: Project management refers to the ongoing management of the implementation plan [15]. The implementation of an ERP system is a unique procedure that requires enterprise-wide project management. Therefore, it involves planning stages, the allocation of responsibilities, definitions of milestones and critical paths, training and human resource planning, and the determination of measures of success [25], [26]. This enables timely decisions and guarantees that such decisions are made by the "right" company members. Furthermore, continuous project management allows the focus to remain on the important aspects of ERP implementation and ensures that timelines and schedules are met [25]. Within project management, comprehensive documentation of the tasks, responsibilities, and goals is indispensable for the success of an ERP implementation [17].

Top management support and involvement: Top management support and involvement is one of the most-important success factors for ERP implementation [14]. Committed leadership at the top management level is the basis for the continuous accomplishment of every project [15]. Thus, innovations and, in particular, new technologies are more quickly accepted by employees if these innovations are promoted by top management. Before the project starts, top management has to identify the peculiarities and challenges of the planned ERP implementation. Since many decisions that must be made during the project can affect the whole enterprise, these decisions will require the acceptance and commitment of senior managers and often can only be made by them [27]. The commitment of top management is important for the allocation of necessary resources, for quick and effective decision making, for solutions to conflicts that need enterprise-wide acceptance, and for enlisting the cooperation of all departments [24].

User training: Missing or inadequate end user training is often a reason for failures in the implementation of new software. The main goal of end user training is to provide an effective understanding of the new business processes and applications as well as the new workflows that are created by the ERP implementation. Therefore, establishing a suitable plan for training employees is important [24]. Furthermore, during the implementation of such an extensive project, management must determine which employee is the best fit for which position or for which application of the new software. This depends strongly on the employee's previously acquired knowledge and/or additional training courses [28].

III. Literature Review of Critical Success Factors

In order to identify the factors that affect the success or failure of ERP projects, several case studies, surveys, and literature reviews have already been conducted by a number of researchers (e.g., [4], [15], [16], [20]-[22]).

However, most of the literature reviews cannot be reproduced because descriptions of the review methods and procedures are lacking. Some researchers have pointed out the limitations of literature review articles, noting specifically that they lack methodological rigor [29]. Therefore, in order to update the existing reviews by including current ERP literature, we conducted a literature review by systematically reviewing articles in five different databases as well as papers drawn from several international conference proceedings. More specifically, we conducted two separate literature reviews according to the same search procedure and steps. The first was performed in mid-2010 [7], [19]. Since we identified 20 or more papers published each year, it was essential for us to update this review every two or three years. Therefore, we conducted the second review in mid-2013. In the Appendix (see Tables 6 and 7) we provide an overview of the identified databases and conferences as well of the used search terms. The overall procedure for the literature review will not be part of this paper. It is described in detail in [7], [19], [30].

We identified 320 papers that referred to CSFs of ERP projects. These papers were reviewed again in depth in order to determine the various concepts associated with CSFs. For each paper, the CSFs were captured, along with the publication year, the type of data collection used, and the companies (i.e., the number and size) from which the CSFs were derived.

All 320 papers were published between 1998 and mid-2013. Table 1 shows the distribution of the papers by publication year. As is shown, most of the papers were published between 2006 and 2013.

Every year since 2004, approximately 20 papers about CSFs have been published, and since 2009, 30 or more papers a year have been published. Therefore, it can be argued that a review every two or three years is reasonable in order to update the results of previously performed literature reviews, especially when considering the rapidly evolving technology and changing system availability such as the concept of "Software-as-a-Service"-concept or ERP systems provided in the cloud.

TABLE 1. PAPER DISTRIBUTION BY YEAR

Year	Papers	Year	Papers
2013	30	2005	15
2012	31	2004	20
2011	39	2003	11
2010	37	2002	11
2009	42	2001	5
2008	22	2000	5
2007	24	1999	3
2006	24	1998	1

Overall, 31 factors influencing the success of ERP system implementation were identified. Figure 1 shows the results of our review, i.e., the CSFs identified, their ranks, and each factor's total number of occurrences in the reviewed papers. The factors *Top management support and involvement*, *Project management*, and *User training* are the three most-named factors, with each being mentioned in more than 160 articles. The factor *Top management support and involvement* stands out; it is ranked #1 and referred to in more than 200 papers. As mentioned above, we will not describe each factor and its concepts in detail in this paper. However, to provide a fuller understanding of the different CSFs and their concepts, we described all 31 factors in [19] and the top eight factors again in greater detail in [7].

Regarding the form of data collection, it must be stated that the papers consist of 144 single or multiple case studies, 118 surveys, and 58 literature reviews or articles where CSFs are derived from the chosen literature.

In most previous literature reviews, the CSFs were grouped without as much attention to detail; therefore, the number of CSFs used was lower (e.g., [4], [15]). However, we took a different approach in our review. For the 31 factors, we used a larger number of categories than other researchers because we expected the resulting distribution to offer more insight. If broader definitions for some CSFs might be needed at a later time, further aggregation of the categories is still possible. Comparing these results with other literature reviews (e.g., [15]), the top five factors are obviously similar, with only the ranked positions differing. Due to our large literature base, the total numbers of observed mentions are much higher. Therefore, the differences in the CSF frequencies are much higher as well, making the distinctions in the significance of the factors clearer.

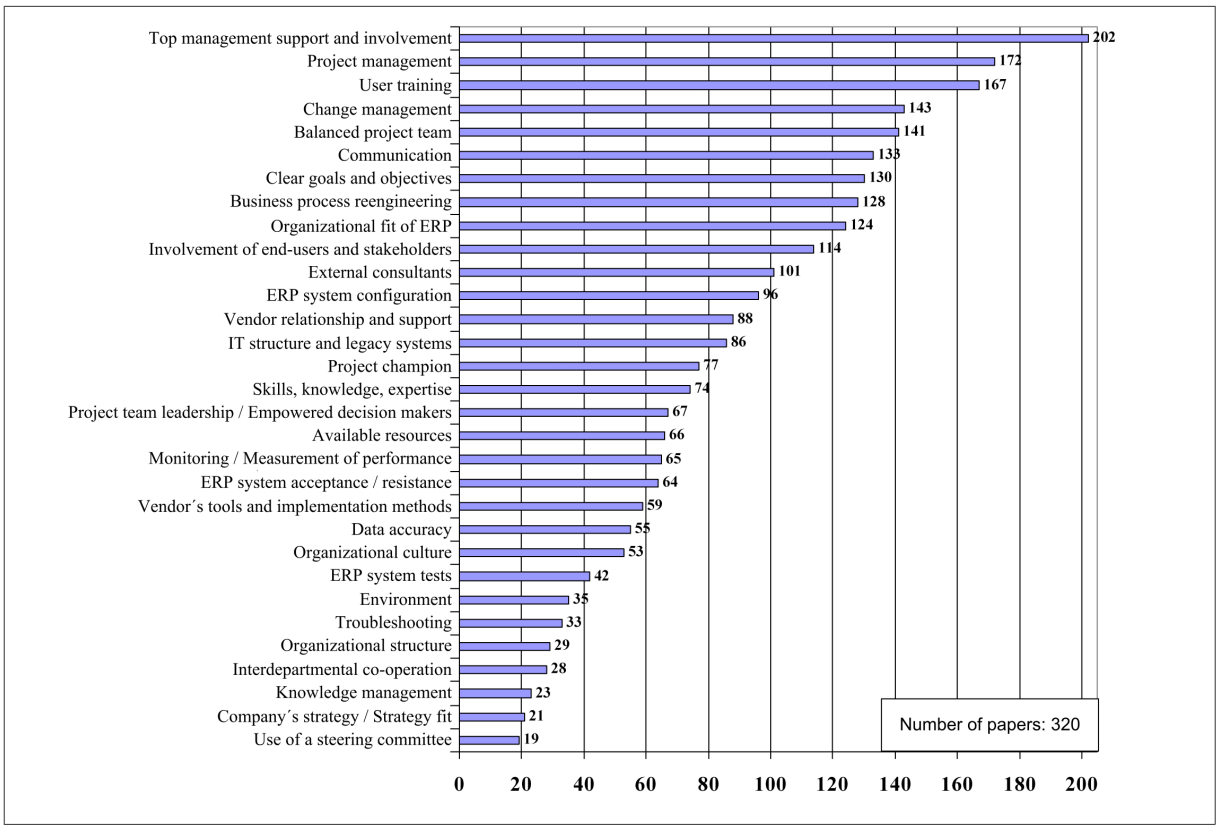

Figure 1. ERP Project CSFs in Rank Order Based on Frequency of Appearance in Analyzed Literature

Concerning company size during review 1 (conducted in mid-2010), only 12 papers explicitly focus on small and medium-sized enterprises (SMEs), mostly within single or multiple case studies. In the review update (conducted in mid-2013), 25 articles dealt with SMEs explicitly. In some surveys, SMEs are included and analyzed as well, but they are a minority in these surveys. Therefore, deriving CSFs that are important for SMEs is difficult and can be seen as still lacking in the CSF research.

Within these 37 papers focusing on SMEs, *Top management support and involvement* (mentioned in 25 articles), *Project management* (mentioned in 25 articles), and *User training* (mentioned in 22 articles) are again the most-frequently named factors for ERP projects in smaller enterprises. However, the differences in the CSF frequencies are only minimal and may be related to the small number of identified papers (see [30]). Therefore, deriving CSFs that are important for SMEs is difficult due to the small number of studies focusing solely on them. This is clearly a research gap in the research area of CSFs for ERP projects.

Therefore, our study focuses on this gap. We investigated these CSFs by interviewing SMEs that have implemented ERP systems. The results will be part of the following sections.

IV. Critical Success Factors for SMEs' ERP Projects

I. Study Design – Data Collection Methodology

To gain an understanding of the differences in the CSFs for ERP system projects in large-scale enterprises and SMEs, we used a qualitative exploratory approach within German small and medium-sized enterprises.

The units of analysis in our study are the implementation projects carried out within the SMEs. For the data collection, we conducted several interviews with members of the ERP implementation project teams, the department managers, or with the directors of the companies in order to identify the factors that they determined to be relevant for the success of their projects.

We interviewed employees of nine small and medium-sized enterprises located in Germany. The SMEs operate in different industry sectors and have implemented different ERP systems. Table 5 in the Appendix gives an overview of the companies and the interviewees.

Within these enterprises, there is a broad range of ERP systems (which cannot be named directly within this paper due to data protection). Only SME 1 and SME 3 have implemented the same ERP system; all other companies have implemented different systems. Some systems are quite small and industry specific and others are more widespread systems on the German ERP market. Most of the

implementation projects took place within the mid-2000s. All of the interviewees (except one of the department managers from SME 2) were directly involved in the ERP system implementation projects.

To gain an in-depth and detailed view of the enterprises and their structures, we chose direct structured interviews as our method of data collection. The interviews were conducted in retrospect to the ERP projects between April and July 2013. The interviews were designed as partially standardized interviews using open to semi-open questions as initial starting points for the conversation. Both personal (face-to-face) interviews, as well as telephone interviews, were conducted by the author. An interview guideline was developed based on the questions of [31], who conducted a similar study, as well as on the basis of one of our previous CSF-studies that had another focus [32]. We changed the questions to align with our identified CSFs (see Figure 1) to ensure that all of the factors were discussed in the interviews. The interview guideline consisted of 52 main questions with further sub-questions that referred to the 31 identified CSFs. These questions were formulated in an open way so that it would be possible to identify "new" CSFs that were not results of the literature review. This questionnaire was sent to interviewees before the interviews took place to allow them to prepare for their interviews. The complete listing of the formulated questions and their assignment to the success factors will not be part of this paper but will be provided by the author upon request.

For a better analysis of the results, we recorded all interviews (the interviews typically took between 70 and 180 minutes) and transcribed them afterwards (resulting in about 200 pages of written text). As a first step, non-verbal and para-linguistic elements and other elements that were not relevant to the study were excluded. To evaluate the CSFs, the interviews were analyzed with reference to each CSF question block, and the statements of the interviewees were classified according to a three-tiered scale (2–very important factor; 1–important factor; 0–less/non-important factor) as well as for a finer classification according to a five-tiered scale (4–very important factor; 3–important factor; 2–factor was seen as relevant; 1–factor was mentioned but not seen as being very relevant; 0–factor was not seen as relevant or important/factor was not mentioned at all). We used these two scales to get a preliminary understanding of whether differences would occur by using a finer/more-detailed scale. Here, the five-tiered scale could be seen as more appropriate to quantify the importance of the factors mentioned during the interviews. Also, we

TABLE 2. CSFS ACCORDING THE FIVE-TIER-SCALE RATING

Rank	Factor	Factor rating (five-tier-scale)	Rank	Factor	Factor rating (five-tier-scale)
1	User training	33	**18**	ERP system acceptance / resistance	16

discussed the factor rating with other researchers in this field to reduce the subjectivity of the rating.

II. Results of the Interviews

For each interview, a ranking of the critical success factors was set up by the author. A final ranking was created including all interviews and all individual rankings (see Table 2). As shown, the three most-important factors for ERP implementation projects in small and medium-sized companies according to our study are *User training*, *ERP system tests*, and *Organizational fit of the ERP system* with more than 30 out of a possible 36 points. Also, no further factors could be identified during the interviews. Each of the 31 factors stemming from the literature review was mentioned by at least one interviewee.

With the exception of *User training*, neither of the two other factors were part of the top five, within the ranking of the literature review (see Table 3). The factor ERP system tests was not even part of the top 20 in the literature review (see Figure 1). In addition, *Organizational fit of the ERP system* has gained more importance, according to our interviewees. The importance of both factors indicates that SMEs are forced to find the right ERP system that fits their needs and to test the system properly before the Go-Live. As mentioned in the first section, due to their lack of financial, material, and personnel resources compared to larger companies, failures during and/or after the Go-Live in SMEs can easily cause financial disadvantages or disasters, perhaps even leading to the insolvency of such small companies.

This is supported by the importance of the top two factors in our study. Reasons for this can be seen in the highly fragmented ERP system market as well as in the increasing multitude of software manufacturers and ERP systems. Enterprises are facing increasingly greater difficulties in identifying the best-fitting ERP system. Therefore, more emphasis is placed upon the selection of the "right" ERP system with a high *Organizational fit of the ERP system*. Together with selecting the right software, customizing the ERP system is also seen as an important factor for ERP projects in SMEs. The factor *ERP system configuration* is ranked at #5 in the interviews, whereas this factor was not part of the top 10 within the literature review. This also supports the statement that SMEs strongly depend on ERP systems that fit their needs, even more so than large companies do. SMEs cannot afford to be restricted by stiff ERP processes; moreover, it is important that the system is adapted according to the SME's own business processes.

To categorize critical success factors, in [20] a matrix scheme is suggested. Here, the authors consider the tactical or strategic direction of the CSFs and divide them into organizational and technological factors. Thus, tactical CSFs relate to short-term aspects and goals of the system implementation project itself, whereas strategic factors aim towards long-term impacts of activities with strong connections to the development of the organization in relation to mission, vision, and core competencies of the business activity. Considering the technological and organizational character of the CSFs, the specificity and significance of technological factors are strongly dependent on the ERP systems themselves, whereas organizational factors focus on corporate culture and its environment, with its specific processes and structures [20], [33], [34].

Table 4 gives an overview of the categorization of the identified CSFs in our study with a focus on their ranking. We oriented the classification and categorization of the factors according to [33] and [34]. The top 10 factors are highlighted.

It can be seen that only a few CSFs (six out of 31) are technological factors, whereas more than 50 percent of the factors (17 out of 31) are organizational factors with a strategic characteristic. However, the top 10 factors are spread out among all four categories, although most of them are part of the organizational category. Remarkably, two of the top three factors are part of the technological view. This supports the statement above that the technological aspects of ERP projects and their impacts on enterprises are considered more important for SMEs than for larger companies. However, smaller enterprises and ERP manufacturers should consider both the organizational and technological aspects when implementing an ERP system.

V. Conclusion and Limitations

The aim of our study was to gain insight in the research field of CSFs for ERP implementation projects, with a focus on ERP projects in small and medium-sized enterprises. Research in the field of ERP system projects and their CSFs provides valuable information that may enhance the degree to which an organization's implementation project succeeds [15]. As a first step, we carried out a systematic literature review to identify CSFs and to update existing reviews. Our review found a variety of papers, i.e., case studies, surveys, and literature reviews, focusing on CSFs. All in all, we identified 320 relevant papers dealing with CSFs of ERP system projects. From these existing studies, we derived 31 different CSFs (see Figure 1). Most of the identified papers and studies focus on large companies. Small and medium-sized enterprises are – if included at all – usually underrepresented in quantitative studies. Studies exclusively focusing on SMEs are rare. We identified 37 of the 320 articles with this explicit focus. These represent only 12 percent of all published papers with a focus on CSFs. Even though research focusing on CSFs in smaller companies has been recommended by the research community for several years (e.g., [17], [18]), our reviews reveal that SMEs are still not the primary focus of CSF research. Therefore, this still can be seen as a clear lack of research.

To address this concern, we developed a study with a specific SME focus. We conducted several interviews within SMEs that have implemented ERP systems. Using a guideline consisting of 52 initial questions about CSFs, we conducted nine interviews. We found that all 31 factors found in the literature review were mentioned by at least one interviewee, and therefore, all 31 factors also in some way affect the success of the ERP system projects in SMEs. However, contrary to the ranking resulting from the literature review, we identified factors with a more-

technological focus as being important for those ERP projects. Here, the factors *ERP system tests* and *Organizational fit of the ERP system* as well as *ERP system configuration* as part of the top five factors refer to more technological aspects. Hence, factors with an organizational characteristic could also be identified as part of the top five factors in our study (*User training*, *Clear goals and objectives*). For the interviewees, *User Training* is seen as the most important factor influencing the success of ERP implementation projects.

Regarding the research question, our study was able to show that all factors that influence the success of ERP system implementation projects in large-scale enterprises also influence ERP projects in SMEs. We could not identify any additional factors that were not already referred to in the literature. However, we could show that the importance of the factors differs a lot and that SMEs and also the ERP manufacturers have to be aware of these differences in the factors' characteristics, focusing also on technological aspects of the ERP implementations rather than focusing mainly on the organizational factors, as they are more important for large-scale companies.

A few limitations of our study must be mentioned as well. For our literature review, we are aware that we cannot be certain that we have identified all relevant papers published in journals and conferences, since we made a specific selection of five databases and five international conferences (see Tables 6 and 7 in the Appendix). Therefore, journals not included in our databases and the proceedings from other conferences might also provide relevant articles. Another limitation is the coding of the CSFs. We attempted to reduce any subjectivity by formulating coding rules and by discussing the coding of the CSFs with several independent researchers. However, other researchers may code the CSFs in other ways. For the interview study, the interviews conducted and data evaluated represent only an investigation of sample ERP projects in SMEs. These results are limited to the specifics of these enterprises. In light of this, we will conduct further case studies and several larger surveys to broaden the results of this investigation.

***Abstract*—Project management can be defined as a complex set of activities that are performed by project managers, individuals or larger entities, that requires proper application of skills, knowledge, tools and techniques in order to reach or exceed project requirements. Two of the most important skills or techniques that greatly influence the end result of a project are task delegation and resource allocation. Poor decisions while delegating tasks or planning resources' allocation can result in defective project results. Many project management applications and models aid project managers in proper task delegation and resource allocation. This paper presents models and task delegation algorithms that can automate task assignment, thus reducing manual delegation, reducing loss and improving projects' end results.**

I. Introduction

DURING a project's lifecycle many factors can change at any given point in time. In order to preserve the scope and objectives of the project and its sub-projects, developers have to take countermeasures swiftly. A single change during a task or an unforeseen event can trigger a chain reaction and derail greatly the project's development. Changing the terms and environment of the project can also add additional risks and the development team must be able to asses the situation quickly and make the proper adjustments in order to deliver the project successfully. The longer it takes for such countermeasures to be considered and performed the losses are likely to be higher and growing.

Therefore projects should be proactively managed by continuously improving and detailing the plan of action as more detailed and specific information and accurate estimations become available during the project's lifecycle. To achieve this, the project managers and project owners and stakeholders need to easily and fully grasp all aspects of the project. The bigger the project the harder it is to generate reports and project statuses. This is why it is recommended that developers use proper project management applications for their projects, allowing more focus to actual work than planning and calculating reports and project statuses. Furthermore, project management applications simplify a variety of tasks that project managers must perform with the help of dedicated tools and features [1][3].

Since task delegation and resource allocation are one of the most important aspects that greatly influence the outcome of a project, it is clear that simplifying, streamlining and possibly automating task delegations and resource allocations within projects would have positive impacts on overall results, costs and profits.

A concept application that automatically assigns, without any human intervention, newly created tasks within a project and its deployment model have been previously presented in [4]. The end goal of the concept application was to ease the project manager's job, to minimise costs and maximise resource usage to its fullest. The paper presented the database model, the base algorithm and a deployment scenario as software as a service of the presented concept application. The algorithm was used to reduce the role of a project manager as known today, allowing the usage of the project manager's knowledge for actual development.

This paper is structured as follows. Section 2 briefly describes the current proposed web application, its distribution model and task delegation mechanism presented in [4] which have shown promising results while being tested and studied in comparison to some other popular project management applications currently available on the market [5]. Section 3 presents enhancements and additions that can be applied to the noSQL model and to the task delegation algorithm that may improve the performance of the system and its yielded results. The 4^{th} section describes additional tests and studies that can be performed on the amended system to asses if the changes made have improved the performance of the system or not. The final two sections present future developments and conclusions, respectively.

II. Current State of the Task Delegation Model and Assignment Algorithm

Achieving automation in the task delegation process can be done by using a number of methods, most of them quite new and derived from the field of artificial intelligence. This includes, but is not limited to neural networks, evolutionary algorithms or swarm intelligence algorithms.

However, the application developed based on the proposed model [4] can potentially store vast amount of information, which would complicate the A.I. algorithms, especially with respect to computation times. Since time management is a critical part of project management and plays an important

role in a project's success, A.I algorithms may not be well suited for the task.

Different approaches such as the Gale-Shapely Courtship Algorithm described in [2] have been taken into consideration as well. However, the chosen model was the usage of classic iterative algorithms that create automation with respect to task delegation by applying a set of instructions to properly stored, sorted and indexed data available on the project's backend database.

Project data is being distributed across multiple nodes via NoSQL databases, specifically Apache Cassandra [6]. A case of why NoSQL is better suited than classic relational databases is also presented in [4].

The initial proposed model used NoSQL databases to store information regarding project tasks, their types, the people that have worked on them, the time required to complete each task, personnel availability for future tasks and more. An algorithm that used this data to programmatically determine the best match for a newly added task was created. Figures 1, 2, 3 and 4 present the original schema of the most important column families in the database while the initial task delegation method is presented by Alg. 1.

Fig. 1 stores information regarding the undergoing tasks of the project, such as metadata keywords, comprising project, deadline, if it were already assigned or finished or not. Fig. 2 stores the availability times of each user. Since the chosen database system has a default lexicographic indexing, each user's availability is stored by using a date and username key with its two parts separated by a hash tag. The value stored is the time during a day when a particular user is available. The performance score and number of tasks of each user based on task metadata keywords is also stored as shown in Fig. 3.

By automating the task assignment process the project manager was no longer required to manually perform delegations and was able to have a more direct impact in the actual development of the project, instead of only leading it. Moreover, programmatically assigning tasks resulted in fewer errors compared to those made by a human project manager. Therefore, the development costs and time required to complete projects were reduced [4].

Algorithm 1 Original task delegation algorithm as presented in [4]

```
def function addNewTask(task)

  foundUsers = null
  iter = 1
  taskAssigned = false

  while ( taskAssigned==false && iter<10 )
  do

    resetOverallScore(foundUsers)

    for keyword in task.keywords do

      foundUsers.push(
        getNUsersWithBestScore_taskAssign(
                keyword,
                Start = 10*iter -9,
                End = 10 * iter)
      )

      for user in foundUsers
        userScore =
           GetKeywordScore_userScores(
                keyword,
                user)
        user.overallScore += userScore
      end

    end

    foundUsers.sort_by { overallScore }

    count = 0
    while ( taskAssigned==false &&
                count<foundUser.size)
    do
      if foundUser[count].isAvailable?
        addTaskToUser(
                foundUser[count],
                task)
        taskAssigned=true
        return true
      end
    end

    iter = iter + 1
  end

  return false

end
```

    { "keyword_3#username_1": "score_1#tasksNo" }
}
```

Fig. 3. JSON representation of the userScores column family as presented in [4]

III. Enhancements to the Current Model and Algorithm

The initial algorithm described in [4] and presented in Alg. 1 worked in the following manner: when a new task was created the algorithm looped through the taskAssign column family (Fig. 4) for each keyword, starting from top to bottom, from the best score to the lowest possible, in order to assign it to the best suited user. The algorithm then computed each user's overall score counting zero if a user's score was null for a specific keyword. Following that, the user that got the best score and was available for work, according to its userAvailability (Fig. 2) column data, was assigned the task. If the user with the best score could not complete the task on time, the next user with the best score lower than the previous user's score was selected. Finally, if no suited users were found, the task remained unassigned and the project manager had to manually perform the delegation.

The study performed on the model and presented in [5] revealed the aforementioned un-assignment issue. On the first projects and for the first tasks within them, no users were selected since not enough data on their performance was stored in the database. The proposed modifications are designed to solve this issue such that all tasks, no matter their creation time, initial phases of the project, during the project or near its closing, are all automatically assigned by the proposed concept

```
{
    { "keyword_1#score_1#tasksNo1": "username_1" },
    { "keyword_1#score_2#tasksNo1": "username_2" },
    { "keyword_1#score_3#tasksNo1": "username_3" },
    { "keyword_2#score_1#tasksNo2": "username_4" },
    { "keyword_2#score_2#tasksNo2": "username_1" },
    { "keyword_2#score_3#tasksNo2": "username_2" },
    { "keyword_2#score_4#tasksNo2": "username_5" },
    { "keyword_3#score_1#tasksNo2": "username_1" }
}
```

Fig. 4. JSON representation of the taskAssign column family as presented in [4]

```
{
    { "skillset_1#keyword_1#username_1": "score_1" },
    { "skillset_1#keyword_1#username_2": "score_1" },
    { "skillset_1#keyword_1#username_3": "score_1" },
    { "skillset_1#keyword_2#username_2": "score_2" },
    { "skillset_2#keyword_1#username_1": "score_1" },
    { "skillset_2#keyword_1#username_3": "score_1" },
    { "skillset_2#keyword_2#username_1": "score_2" },
    { "skillset_2#keyword_2#username_3": "score_2" }
}
```

    { "keyword_1#username_2": "preference_score" },
    { "keyword_1#username_3": "preference_score" },
    { "keyword_2#username_1": "preference_score" },
    { "keyword_2#username_2": "preference_score" },
    { "keyword_2#username_3": "preference_score" },
    { "keyword_3#username_1": "preference_score" },
    { "keyword_3#username_3": "preference_score" }
}
```

Fig. 6. JSON representation of the userPreferenceScore column family

application and no manual input from the project manager is required.

In order to achieve the proposed scope, the cause of the problem had to be determined. The issue was in fact lack of data within the database, so the solution was to pre-populate the database with relevant information regarding each user. This could theoretically be possible for different projects within the same company or entity. However, this may not be the case for each developed project and it is therefore not a viable and feasible solution.

The proposed solution is a fallback within the task assignment algorithm that would be triggered when the original algorithm could not automatically assign a task based on data it can access from the userScores, taskAssign and userAvailability columns. This trigger would use two new column families that would store information about the users, mainly their skill-set, including all their certified and non-certified ones as well as their preference to what kind of work and tasks they prefer. Their skill-set information could be automatically computed by using predefined scores for different types of certifications. Their non-certified skills could only be scored and measured by an authority within the company or within the project, such as a HR or management representative. Fig. 5 shows the database schema for the user's skill-set score.

The mechanisms for generating a user's preferences score are trivial, each user having access to the project management application in order to set their preferences. The database schema of the preferences score is similar to that of the user's skill-set score and is presented in Fig. 6, while Alg. 2 presents the modified task assignment delegation process.

Another approach for modifying the algorithm would be to always take into account the skillset score and preference score of every user on the project. If this approach were chosen, a balance between users' past performance score, their skill score and preference score should be selected.

There are a couple of options for balancing the three different scores as follows. The first one is to allow manual

Algorithm 2 Modified task delegation algorithm with skill-set and preference fallback

```
def function addNewTask(task)
  foundUsers = null
  iter = 1
  taskAssigned = false
  while ( taskAssigned == false && iter < 10)
  do
    resetOverallScore(foundUsers)
    for keyword in task.keywords do
      foundUsers.push( getNUsersWithBestTaskAssignScore(keyword,
                        Start = 10*iter -9, End = 10 * iter) )
      for user in foundUsers
        userScore = GetScoreForKeywordFrom_userScores(keyword,user)
        user.overallScore += userScore
      end
    end
    foundUsers.sort_by { overallScore }
    count = 0
    while ( taskAssigned == false and count < foundUser.size ) do
      if foundUser[count].isAvailable?
        addTaskToUser(foundUser[count],task)
        taskAssigned=true
        return true
      end
    end
    iter = iter + 1
  end
  # trigger that takes skillset and preference into account
  while ( taskAssigned == false && iter < 10) do
    resetOverallScore(foundUsers)
    for keyword in task.keywords do
      foundUsers.push( getNUsersWithBestSkillSetScore(keyword,
                        Start = 10*iter -9, End = 10 * iter) )
      for user in foundUsers
        uSkillsetScore = GetScore_userSkillsetScore(task.skillset , keyword,user)
        uPreferenceScore = GetScore_userPreferenceScore(task.skillset , keyword,user)
        uSkillsetPreferenceScore = uSkillsetScore*0.75 + uPreferenceScore*0.25
        user.overallScore += uSkillsetPreferenceScore
      end
    end
    foundUsers.sort_by { overallScore }
    count = 0
    while ( taskAssigned == false and count < foundUser.size ) do
      if foundUser[count].isAvailable?
        addTaskToUser(foundUser[count],task)
        taskAssigned=true
        return true
      end
    end
    iter = iter + 1
  end
  return false
end
```

selections within each company and within each project. This way, management personnel could modify the ratio based on their preference and desired outcome within a project. The second option would be hardcoding the ratio for the three scores directly into the algorithm.

In order to obtain the perfect balance and ideal ratio, multiple tests with different ratios should be performed on the same set of tasks within identical projects in order to obtain relevant, comparable data. Alg. 3 shows the modifications required to use the balancing factor between users' performance, skill-set and preference scores, with their ratios being 50%, 25% and 25% respectively. The ratios were empirically determined as the algorithm allows modification for each project within different companies. Future work may include a more formal, mathematical approach to establishing the best ratios for the algorithm.

IV. Testing the Proposed Model and Algorithm Enhancements

The first step towards testing the modifications performed on the model and on the algorithm is to implement and deploy the changes into the web application developed based on the initial model [7]. The original model and its corresponding web application have already been tested and studied by using a small scale project developed by a small three-man development team [5].

The study revealed that the proposed concept is successful and overall performance improves with each new project that is managed via the application. The original study has been performed on a small scale construction project, a treehouse building process, and the results and outcomes may be completely different on larger projects and with larger teams or integrated ones. Therefore, future studies and tests of the enhanced model and task delegation algorithm should be performed by using larger, more complex projects.

The study presented in [5] also shown some drawbacks that interfered with the project workflow in the initial steps of the development, mainly because there was no information stored that could be used to automatically assign tasks to workers. The result of this test has generated the proposed enhancements presented in this paper. It is straightforward that if more tests are performed the likelihood to discover even more extensions and improvements that can be applied to the proposed concept will increase. It is therefore recommended that more diverse tests should be performed.

Additionally, tests should be performed on identical projects in order to obtain the golden ratio between the three scores: user performance, skill and preference, described in section 3 of the current paper, ratio that could be used for hardcoding the balancing factor within the task assignment algorithm.

V. Future Work

Proactive project management usually requires the following tasks be performed: identifying the requirements and objectives of the project, addressing the concerns and expectations of the project owners / stakeholders, balancing the project

Algorithm 3 Modified task delegation algorithm with performance, skill-set and preference balancing

```
def function addNewTask(task)
  foundUsers = null
  iter = 1
  taskAssigned = false
  while (taskAssigned==false && iter<10)
  do
    resetOverallScore(foundUsers)
    for keyword in task.keywords do
      foundUsers.push(
        getNUsersWithBestTaskAssignScore(
                keyword,
                Start = 10*iter -9,
                End = 10 * iter)
          )
      foundUsers.push(
        getNUsersWithBestSkillSetScore(
                keyword,
                Start = 10*iter -9,
                End = 10 * iter)
          )
      for user in foundUsers
        uPerformance =
           GetScore_userScores(keyword,user)
        uSkillset =
           GetScore_userSkillsetScore(
               task.skillset, keyword,user)
        uPreference =
           GetScore_userPreferenceScore(
               task.skillset, keyword,user)
        userScore = uPerformance * 0.5 +
           uSkillset*0.25 + uPreference*0.25
        user.overallScore += userScore
      end
    end
    foundUsers.sort_by { overallScore }
    count = 0
    while ( taskAssigned==false &&
                count<foundUser.size )
    do
      if foundUser[count].isAvailable?
        addTaskToUser(foundUser[count],task)
        taskAssigned=true
        return true
      end
    end
    iter = iter + 1
  end
  return false
end
```

constraints: scope, budget, schedule, resources, quality and risks [1]. The current proposed models and algorithms address only scheduling of personnel. An important aspect that can be improved upon is scheduling of hardware and other non-human resources.

Future developments may include enhancements of the current model such that tasks could be assigned to multiple individuals or such modifications that each task may or may not have preceding tasks to create proper dependencies. The current additions to the model allows tasks assignment based on user skill and preference. Similarly, a simple extension could be added such that more difficult tasks are assigned to individuals or teams with more experience and easier tasks assigned to the rest of the development team. This can be achieved if the model is modified in such a way that the database stores the difficulty of each task which could be assessed automatically or by the project manager. Similarly, one can also define some tasks as urgent, and these tasks should be assigned quicker based on their emergency level.

Future work may also include additional features such as estimating budget costs and automatically determining any risks before they affect the project. Another important aspect that would dramatically increase the potential of the application would be automatically identifying the requirements and objectives of the project from client communications, and translating them into tasks that developers understand and know how to perform.

VI. Conclusions

The proposed application concept reduces the role of the project manager by automatically delegating tasks and shows potential for large growth. Further more, the original application has performed up to 26.77% better than those of the competitors, as shown in [5]. The same test also shown that there is at least a 20% margin for improvement, leaving room for continuous and future developments.

The few cases when manual input by project managers was required [4] have also been reduced by the modifications performed on the original model and presented in this paper.

***Abstract*—The importance of organizational agility in a competitive environment is nowadays widely recognized and accepted. However, despite this awareness, the availability of tools and methods that support an organization in assessing and improving their organizational agility is scarce. Therefore, this study introduces the Organizational Agility Maturity Model in order to provide an easy-to-use yet powerful assessment tool for organizations in the software and IT service industry. Based on a design science research approach with a comprehensive literature review and an empirical investigation utilizing factor analysis, both scientific rigor as well as practical relevance is ensured. The applicability is further demonstrated by a cluster analysis identifying patterns of organizational agility that fit to the maturity model. The Organizational Agility Maturity Model further contributes to the field by providing a theoretically and empirically grounded structure of organizational agility supporting the efforts of developing a common understanding of the concept.**

I. Introduction

ORGANIZATIONAL agility is an important and relevant concept for more and more organizations in today's competitive and fast-changing environment. Especially in the software and IT service industry, organizations are faced with an environment of rapid technological changes, which are accompanied by just as much change in customers' expectations and requirements [1], [2]. In addition, the fact that software and IT have become essential components of many other products – consumer electronics, automotive products, etc. – has increased the competitive pressure further [3].

However, despite an increasing awareness that organizational agility is a key concept in coping with this competitive pressure, the term "agility" is nowadays often inflated by many organizations without reasonable seriousness. Agility is nothing that can simply be put into practice. The management of an organization has to understand that the organization itself cannot be agile, but its employees can be. However, people are not independent from their environment, and they have to share appropriate skills in order to work under agile conditions and with suitable technologies [4], [5]. Hence, the path to an agile organization is a development process affecting all parts of an organization from workforce through organizational structures and processes to technologies used and the overall organizational culture [6], [7]. This process shows that managing the transition to an agile organization is a complex and strategic task. To fulfill this task, the management of an organization has to go continuously through three steps: (1) assessing the current level of organizational agility, (2) identifying potential areas for improvement, and (3) planning, executing, and monitoring appropriate improvement actions. It becomes clear that supporting tools are necessary to accompany these steps.

Already at the first step – assessing the current level of agility – an organization is faced with a difficult challenge. The assessment of agility implies that the components of an agile organization are clearly described and that assessment tools or methods are available. However, there is a lack of a clearly defined framework for explaining agility from an organizational perspective [8], and, hence, there is no consensus about what constitutes an agile organization [9]. As a result, this missing consensus about the determinants and dimensions of organizational agility limits the applicability of research results in practice and restricts the possibility to develop useful assessment tools [10].

The aim of this study is to solve this problem by introducing a maturity model as an assessment tool for organizational agility. The core contributions are a theoretically and empirically grounded structure of the components of organizational agility supporting the efforts of developing a common understanding of organizational agility as well as a useful and practical tool that is able to actually reflect existent patterns of organizational agility in the software and IT service industry.

The remainder of the paper is structured as follows: Section II summarizes available assessment approaches of organizational agility. The research methods used for designing the maturity model are described in section III, while the maturity model itself is introduced in section IV. A first evaluation of the model based on a cluster analysis of empirical data is given in section V. The paper closes with a conclusion and a description of further research opportunities in section VI.

II. Literature Review

Due to the missing consensus about what determines organizational agility (see [9], [11] for a detailed discussion), a universal definition is also missing. The literature contains a huge variety of more or less comprehensive definitions, each heavily influenced by context and application domain. While a

978-83-60810-58-3/$25.00

detailed discussion of these definitions is beyond the scope of this paper, a number of authors have analyzed the differences in definitions (e.g. [7], [8], [12], [13]).

For this work, two definitions have been selected as a basis that fits well into the software and IT service context and complement each other in terms of content. First, the definition of Yusuf, Sarhadi, and Gunasekaran [14] generally describes the prevalent situation in the industry under consideration and emphasizes the role of customers as well as the importance of internal capabilities, structures, and people. They define agility as "the successful exploration of competitive bases (speed, flexibility, innovation proactivity, quality and profitability) through the integration of reconfigurable resources and best practices in a knowledge-rich environment to provide customer-driven products and services in a fast changing market environment" [14, p. 37]. This definition can be further extended to explain agility as "an effective integration of response ability and knowledge management in order to rapidly, efficiently and accurately adapt to any unexpected (or unpredictable) change in both proactive and reactive business / customer needs and opportunities without compromising with the cost or the quality of the product / process" [15, p. 411]. Here, the often unpredictable nature of change is further underscored. In addition, both definitions point out the essential role of knowledge in coping with these changes.

Taking these definitions as a foundation, the literature was analyzed according to existing assessment approaches of organizational agility prior to developing the maturity model. A useful summary is given in [16]. In general, these approaches can be roughly categorized into three groups: The first group consists of approaches assessing agility by various metrics. However, these approaches only focus on capabilities, omitting drivers or enablers of agility [16], and are often focused on specific subareas of an organization, for instance market-related activities [15] or the supply chain [17]. The second group utilizes methods like the analytic hierarchy process (AHP) to determine overall agility (e.g. [18]), while the third group is based on fuzzy logic (e.g., [16], [19]).

The available approaches suffer from some limitations regarding their applicability to determine the level of organizational agility in practice. This weakness stems either from a too specialized orientation and, hence, an insufficient reflection of the whole organization with its interaction of people, structures, process, and technologies, as outlined above, or from the utilization of relatively complex algorithms, limiting an intuitive and ad hoc usage by management. In addition, although the available approaches are able to determine the current state of agility, they normally do not support management in suggesting further actions for improvement or development.

The identified requirements of a comprehensive representation of the whole organization, an intuitive tool that is easy to use, a determination of the current state of organizational agility, and directions for further improvement can be fulfilled with a maturity model. A maturity model describes and determines the state of perfection or completeness (i.e., the maturity) of certain objects. The progress in maturity can be observed and managed by the definition of maturity stages or levels that measure the completeness of the analyzed objects via different sets of (multidimensional) criteria [20]. This explanation is well reflected in the definition by Becker, Knackstedt, and Pöppelbuß: "A maturity model consists of a sequence of maturity levels for a class of objects. It represents an anticipated, desired, or typical evolution path of these objects shaped as discrete stages. Typically, these objects are organizations or processes" [21, p. 213].

A systematic mapping study analyzing the field of maturity model research shows that there are no maturity models available tackling the field of organizational agility or agility in general [20]. This lack underscores the assumption that the introduced maturity model is able to contribute to the field of assessing organizational agility by proposing a new approach that has not been available yet.

III. Method

This study follows a design science research approach [22]–[24], with the purpose of developing a maturity model to assess organizational agility. Hereby, the main goal is to build a maturity model that is applicable in the software and IT service industry. To fulfill this aim, the development is based on theoretical work as well as empirical evidence.

Following [24] a typical design science project includes four basic phases: analysis, design, evaluation, and diffusion. The focus of this study is in the design and evaluation phases by describing the elements and the development of the maturity model, as well as a first proof of concept, by discussing the results of a cluster analysis in the targeted industry. The analysis phase has already been conducted prior to the work presented here and includes stating the problem relevance, formulating the research objective, and searching for existing solutions. The need for a comprehensive organizational view on agility is justified in detail in [9], [25], and an extensive literature review on maturity models is given in [20]. Both aspects have been briefly summarized in sections I and II.

Many maturity models are developed on a purely conceptual basis, and their utility is evaluated afterward, mostly by case studies. A portion of available maturity models is completely lacking any kind of empirical evaluation [20]. For the maturity model developed in this study, a different approach has been chosen to ensure its grounding in theory as well as in empirical evidence. In addition to a careful review of agility frameworks in the analysis phase [9], an exploratory quantitative survey with the overall aim of identifying the elements of an agile organization has been carried out worldwide among organizations of the software and IT service industry. This procedure prior to the design phase allows the author to include empirical evidence already in the initial design of the maturity model and, therefore, enhances its quality and applicability from the very start.

With the survey 437 valid and complete responses were collected. The sample is summarized in table I. The complete questionnaire and comprehensive descriptive results are found

TABLE I
SURVEY SAMPLE CHARACTERISTICS

Characteristic	Total	Ratio
Role within the organization:		
Chief Executive Officer	127	29.1 %
Chief Information / Technology Manager	36	8.2 %
IT / ICT Manager	59	13.5 %
Enterprise / IT Architect	155	35.5 %
Other (e.g. Managerial Board Members, other Senior Managers, ...)	60	13.7 %
	437	**100 %**
Location of the organization:		
Europe	259	59.3 %
North America	104	23.8 %
Asia	39	8.9 %
Other (e.g. Columbia, South Africa, Brazil, Australia, ...)	35	8.0 %
	437	**100 %**
Size (no. of employees) of the organization:		
less than 10	95	21.7 %
10 to 49	87	19.9 %
50 to 249	87	19.9 %
250 or more	167	38.2 %
n.a.	1	0.2 %
	437	**100 %**

in [26]. The survey results are used to identify possible dimensions of organizational agility by exploratory factor analysis [27]. In addition, a cluster analysis has been carried out to identify patterns of agile organizations. These clusters are used for a first proof-of-concept evaluation by comparing them to the structure of the developed model in section V.

IV. DESIGN OF THE ORGANIZATIONAL AGILITY MATURITY MODEL

This section introduces the Organizational Agility Maturity Model. Fig. 1 illustrates the structure consisting of three dimensions and four maturity stages. The development of the dimensions and stages is described subsequently. This structure is already the result of the second development iteration. The first version of the model had five maturity stages. However, the cluster analysis of the obtained survey data revealed that this structure of stages is not suitable to represent the empirical patterns of organizational agility appropriately (see section V).

Although the highest maturity stage is always the best one theoretically, many maturity models state that the highest stage should not automatically be the goal for every organization using the model. This is consistent with a perspective on maturity models where every stage yields a set of potential improvements. So, every organization has to individually assess its "optimal" stage. This has disadvantages for the practical applicability. Different interpretations and viewpoints may lead to difficulties for organizations in finding this optimal degree of maturity [20], [28], [29].

For the Organizational Agility Maturity Model, another approach has been chosen that is more related to the life cycle of an organization [29] that is going to become agile. The difference is that the single stages are not only seen as desirable improvement, but rather a representation of steps while evolving over time. Hence, the highest maturity stage is always the "final" goal. Although these differences are only nuances, they are important for interpretation and usage of the model [20], [29]. Therefore, the maturity model should be used by organizations that have the clear objective of achieving organizational agility and want to use the maturity model as a roadmap in accompanying this transition.

A. Dimensions

The proposed maturity model consists of three dimensions, each of them further detailed into two sub-dimensions. This structure was obtained by conducting an exploratory factor analysis on survey data from the software and IT service industry (see section III). Due to space restrictions, the whole factor analysis cannot be presented here in detail. Tables II and III contain a summary of the results and illustrate the obtained factor structure. In addition, table VI in the appendix lists the assessment items for every dimension. For more information about the survey, please refer to [26], [27].

The conducted survey includes agility-related elements extracted from 28 frameworks describing agility [9]. Hence, the dimensions of the maturity model incorporate a structure of organizational agility that is grounded in theory and based on the empirical investigation also existent in practice. The content of every dimension is described below:

Agility Prerequisites are the degree to which the people of an organization share agile values (mental prerequisites) and to what extent the organization establishes the required technological prerequisites to support agility.

- **Agile Values** include the establishment of an organizational culture following agile values like proactivity, responsiveness, trust, support of proposals and decisions of employees, and the handling of change as opportunity and chance. This culture is measured by the degree to which the agile values have disseminated throughout the organization.
- **Technology** represents the technological prerequisites supporting organizational agility by enabling efficient communication across all levels and departments; the sharing of information; and the utilization of standardized, comparable, and integrated technologies and information systems. Technology is measured by the dissemination of appropriate technological support across the whole organization.

Agility of People summarizes all necessary capabilities of the members of an organization to translate the agile values into actions. It is further distinguished into the capabilities of the workforce and the capabilities of managers to cope with change.

- **Workforce** is a very important sub-dimension and comprises mainly the capabilities of employees. They have to be multiskilled to reorganize themselves under changing

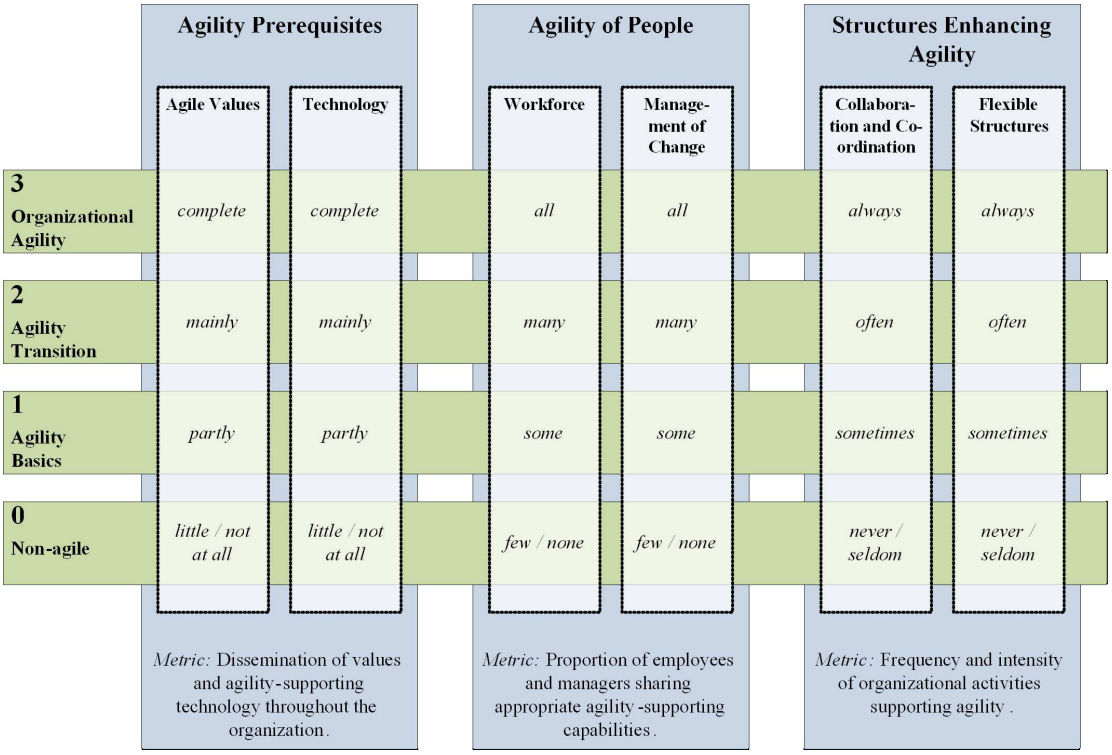

Fig. 1. Structure of the Organizational Agility Maturity Model

conditions. In addition, they should be able and willing to learn from each other to improve themselves continuously, communicate in a trustful way with each other, and take responsibility. Furthermore, they have to be able to think and act with quality and the market in mind. Workforce is measured by the proportion of employees of an organization sharing these capabilities.

- **Management of Change** involves capabilities, mainly of managers, to cope with changes appropriately and quickly (e. g., changing customer requirements, new markets, innovations, etc.). Managers have to inform the people of the organization accordingly and to inspire them to welcome these changes. In addition, they should be able to act with long-term vision and conduct IT investments strategically. Management of Change is measured by the proportion of managers of an organization sharing these capabilities.

Structures Enhancing Agility describes the ability of an organization to flexibly adopt and change itself combined with an organizational culture that supports collaboration and cooperation on every level.

- **Collaboration and Cooperation** summarizes activities of internal collaboration between departments and functions of the organization for decision making, new product/service development, etc. In addition, external cooperation with partners and customers focusing on quality, feedback, and intensive information sharing is covered by this sub-dimension. It is measured by the frequency of organizational activities enabling and supporting collaboration and cooperation.
- **Flexible Structures** describes the ability of the organization to quickly adapt organizational structures and processes to implement changes and stay competitive. Furthermore, it includes activities that enable quick decisions and a change of authorities when needed. Flexible Structures is measured by the frequency of organizational activities in establishing and incorporating flexibility.

B. Maturity Stages

The proposed maturity model consists of four distinct maturity stages that are assessed independently for every sub-dimension (see table VI). So, it may happen that an organization holds different maturity stages in the single sub-dimensions at a certain time. This difference is intended because the approach reflects the real state of the transition towards an agile organization, and it is unlikely that an organization is able to improve every aspect simultaneously and at the same pace. In addition, this approach enables an organization to determine further actions for a suitable path of improvement (see section V).

All six sub-dimensions are treated as equally important and the overall maturity score is simply the average of the single maturity stages. This unweighted and equal treatment is justified because the exploratory factor analysis revealed relatively equal proportions of explained variance between 0.09 and 0.17 for every factor (see Table III).

TABLE IV
DETERMINATION OF MATURITY STAGES REGARDING AVERAGE ASSESSMENT SCORE

Average score	Maturity stage
[1, 2.5)	0: Non-agile
[2.5, 3.5)	1: Agility Basics
[3.5, 4.5)	2: Agility Transition
[4.5, 5]	3: Organizational Agility

To determine the maturity stage of an organization, the assessment questions in table VI are used. Then, the average score is calculated for every sub-dimension. Finally, the organization is categorized to one of the maturity stages per sub-dimension according to the respective average score as outlined in Table IV.

The four maturity stages are:

0 – Non-agile: Organizations at maturity stage 0 show no or only rare properties of organizational agility. Agile values are principally unknown, and the technological basis is fragmented and unable to support communication processes effectively. Only a minority of employees and managers share capabilities necessary to implement agile values and actions. Hence, organizational activities for improving collaboration and cooperation and implementing flexible structures do not take place or only happen by chance. It may occur that single sub-dimensions show a higher score, but overall, these organizations are non-agile.

1 – Agility Basics: Organizations at maturity stage 1 share basic properties of organizational agility. Agile values and technological prerequisites underscoring agility are partly implemented in some but not the majority of departments, business areas, teams, or structural levels of the organization. Likewise, some but not the majority of employees share agile capabilities regarding communication, learning, responsibility, and customer-orientation, and some managers in the organization are able to manage change in an appropriate way. Often, these employees and managers are "concentrated" in single teams or departments. Activities to enhance collaboration, cooperation, and flexibility only take place sometimes, either by selective activities showing some "goodwill" or with a higher frequency but limited to a few agile departments or teams. These organizations have already realized and experienced the benefits of organizational agility, but in most cases only in some departments, teams, or situations, and therefore, the organizations only show some agility basics.

2 – Agility Transition: Organizations at maturity stage 2 manage to disseminate agile values and to establish an appropriate technological basis in most parts of the organization. Many employees and managers share the idea of agility and possess corresponding capabilities. Change is mostly welcomed and handled accordingly. In many instances, the organization carries out activities to support and promote teamwork and establishes organizational structures that are flexible enough to cope with upcoming changes. However, organizations at this maturity stage are characterized by weak-

nesses in one or two sub-dimensions of the model while others are already on a relatively high agility level (see section V for details). Hence, they are still in a transition phase towards a complete agile organization.

3 – Organizational Agility: Organizations at maturity stage 3 score high in every sub-dimension of the model and have overcome the partial weaknesses of the transition phase. They manage to establish a sufficient technological basis throughout the complete organization, and agile values are shared and accepted completely, too. All employees and managers have the capabilities to successfully work in an agile and changing environment. Collaboration and Cooperation are important aspects of everyday work and the structure is flexible enough to quickly and constantly react to upcoming changes. If any, there are only insignificant exceptions from the described agile attitude and behavior of the whole organization. Therefore, these organizations achieve complete organizational agility.

With this in mind, every maturity stage implies a specific goal while becoming organizationally agile. It is important for an organization to create an awareness of agility as an essential issue for staying competitive [1]. However, a particular solution affecting only one dimension of the maturity model is not sufficient, and the goal for maturity stage 1 is to get a basic understanding of agility with first transfers into practice in every dimension. This will create the foundation to generate agile solutions from the organization's own capacities [1]. Furthermore, the organizational changes that are needed have to be focused and appropriate to the characteristics of the organization, incorporating individual as well as organizational agility-related characteristics [1], [5]. Hence, the goal of maturity stage 2 is to get a clear vision of how organizational agility can be achieved, and based on this vision, a roadmap of the necessary actions has to be developed. Finally, the goal of maturity stage 3 is an equally matched interplay of all dimensions affecting agility: people, organization, and technology [5], [6].

V. Evaluation: Cluster Analysis

As a first step to evaluate the applicability of the Organizational Agility Maturity Model, a cluster analysis on the survey data has been performed to assess if the maturity stages are able to represent real-life configurations of organizations. As mentioned in section IV, the initial model had five maturity stages, due to the scales of the assessment questions used (see Table VI). However, after performing the cluster analysis, the lower two maturity stages were united to the form the maturity stage 0 (non-agile, see Fig. 1).

A. Clustering Method

To perform the cluster analysis, the dimensions of organizational agility have to be represented in the data. As described above, the sub-dimensions of the maturity model emerged from an exploratory factor analysis. Hence, average summed scales above a cut-off value of a factor loading of 0.3 were calculated for every factor [30] and used for cluster analysis. This procedure allows for the computation of a factor score for every sub-dimension, which is easily interpretable. The usage of the average allows that the original scale is retained [30], and the cut-off value of 0.3 ensures that only the variables that are included in the respective factor affect the resulting factor score (see Table II). The summed scales approach is especially suitable in this context because it is an exploratory research approach [30], [31].

Two important decisions in cluster analysis include the distance measure and the clustering method [31]. The cluster variables are the sub-dimensions of the maturity model. These sub-dimensions were extracted using an oblique rotation method (oblimin) in factor analysis and are, therefore, correlated to each other. To avoid distorted results because of correlated clustering variables, the Mahalanobis Distance has been used as the distance measure [31].

For clustering, the following procedure is recommended: First, a hierarchical approach should be used to determine the number of clusters, and second, a non-hierarchical approach should be selected to calculate the final cluster solution [31].

Here, a hierarchical approach using the Ward method was selected to estimate the number of clusters. This method is known to maximize in-cluster homogeneity by building clusters with a minimal increase of variance [31]. After that, the final cluster solution was calculated using a non-hierarchical approach, particularly fuzzy clustering [32]. Fuzzy clustering has been chosen because the clusters obtained by crisp non-hierarchical clustering methods turned out to be unstable when choosing randomized starting objects. However, the author recognized that a part of the data was stable. Such situations are well suited for fuzzy clustering because it bases the clustering on a membership function of every object to all determined clusters. In addition, it is possible to extract the "core objects" for further analysis. These objects have a high membership in one specific cluster (e. g., greater or equal to 0.7) and represent the most stable part of the data regarding the cluster solution [32]. The computation was carried out using the statistical software R [33].

B. Results and Discussion

Based on hierarchical clustering with the Ward method, a number of five clusters was the most appropriate solution. The results of the following fuzzy clustering approach are summarized in Table V. It shows the number of objects with different membership thresholds per cluster. Objects with a membership greater or equal to 0.7 have been considered as core objects and are used for further analysis.

To get an understanding of the clusters, Fig. 2 illustrates the mean values of the five clusters for every sub-dimension of the maturity model. Additional boxplots are given in Fig. 3. The first conspicuous aspect of the figure is that the lower part of the graphic is quite empty. This space does not mean that there were no respondents answering at the lower end of the scale used (see table VI) as the boxplots, particularly for cluster 3, show. But as cluster analysis reveals, they do not form a distinct cluster of their own. For this reason, the number of

TABLE V
RESULTS OF CLUSTER ANALYSIS (NUMBER OF OBJECTS) FOR DIFFERENT MEMBERSHIP THRESHOLDS ($n_{total} = 437$)

Cluster	Memb. $\geq$ 0.5	Memb. $\geq$ 0.7	Memb. $\geq$ 0.9
1	69	33	11
2	65	40	11
3	69	45	15
4	70	47	28
5	55	33	13
Total	**328**	**198**	**78**

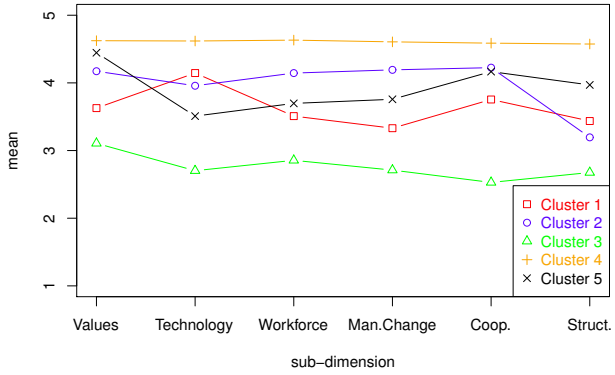

Fig. 2. Mean values of the clusters per sub-dimension

maturity stages has been reduced to four, combining the lower two scale values with no or nearly no agile attributes in the organizations (stage "0 – non-agile" in Fig. 1).

Furthermore, clusters 3 and 4 are easily distinguishable from the others. The organizations in cluster 3 score at a medium level on average regarding every sub-dimension. This cluster also includes organizations that have a lower agility assessment, but as a closer look into the data reveals, only in some of the sub-dimensions of the maturity model. Therefore, cluster 3 represents stage 1 (Agility Basics) of the maturity model where the covered organizations show initial initiatives and, hence, a basic development towards an agile organization.

Cluster 4, however, represents the opposite side of the scale. The organizations forming cluster 4 show a very high average score for every sub-dimension. As the boxplots in Fig. 3 illustrate, this cluster is the only one where 50 % of the objects score above an average of 4.0 in every sub-dimension, and, hence, describes the proportion of organizations that are most agile in the whole sample. This is represented by stage 3 (Organizational Agility) of the maturity model.

For clusters 1, 2, and 5 the interpretation is more complex. All have differing average values between 3.5 and 4.5 approximately. Therefore, the represented organizations are closer to each other but, nevertheless, show some distinguishing characteristics.

First, for cluster 2, we notice that most of the sub-dimensions show a relatively equal average score above 4.0 among the covered organizations and indicate a good advancement towards an agile organization. However, the score for the sub-dimension "Flexible Structures" clearly falls behind. This means that these organizations are characterized by a situation where a lot of agile potential (values, technology, capabilities, etc.) is lost due to structural obstacles. Their structures do not allow a fast adoption of processes, strategies, authorities, etc. to changing circumstances, and the agile potential has the risk of sticking to the team level [25]. This result is also consistent with literature where appropriate organizational structures are one central element to achieve organizational agility [6], [34].

Comparing the last two clusters (1 and 5) to each other, we recognize that they share an identical pattern for the dimensions "Agility of People" and "Structures Enhancing Agility" (the four sub-dimensions on the right in Fig. 2), with a slightly better average score for cluster 5. However, for the dimension "Agility Prerequisites," they show an opposite trend regarding "Agile Values" and "Technologies." While the organizations covered by cluster 1 score relatively high on "Technology," they score lower on "Agile Values." The opposite occurs in cluster 5.

From an interpretative perspective, this opposition means that the organizations in cluster 1 focus on the dissemination of agility-enhancing technologies. Technology is important because it is generally regarded as an essential enabler or driver of agility [9], [35], [36]. However, a pure concentration on technology also implies some risks. Increased IT spending, for instance, does not automatically lead to greater agility, and other elements represented in the maturity model have to be aligned with technology to achieve organizational agility [37].

The opposite situation is prevalent for the organizations in cluster 5. They score higher in every sub-dimension with the exception of "Technology." This lack may imply that these organizations are not yet aware of the mentioned role of technology as an enabler of organizational agility. However, in contrast to the organizations of cluster 1, they already manage to implement a culture based on agile values nearly completely. In addition, this is the only cluster, besides cluster 4, with an average score of 4.0 or above for the sub-dimension "Flexible Structures."

The organizations in clusters 1, 2, and 5 all would be assigned to stage 2 (Agility Transition) of the maturity model. They support the assumption of a transition phase that applies to the majority of organizations from the analyzed sample. This phase underscores that there are different approaches in becoming organizationally agile by concentrating on different dimensions or sub-dimensions of the maturity model. However, as cluster 4 clearly illustrates, it is important to achieve a balance between every dimension of the model. The considerations above show examples where an unbalanced or too focused improvement path may lead to risks instead of benefits.

The insights gained by conducting the cluster analysis above help to improve the structure of the developed maturity model. The main implications include the reduction of maturity stages

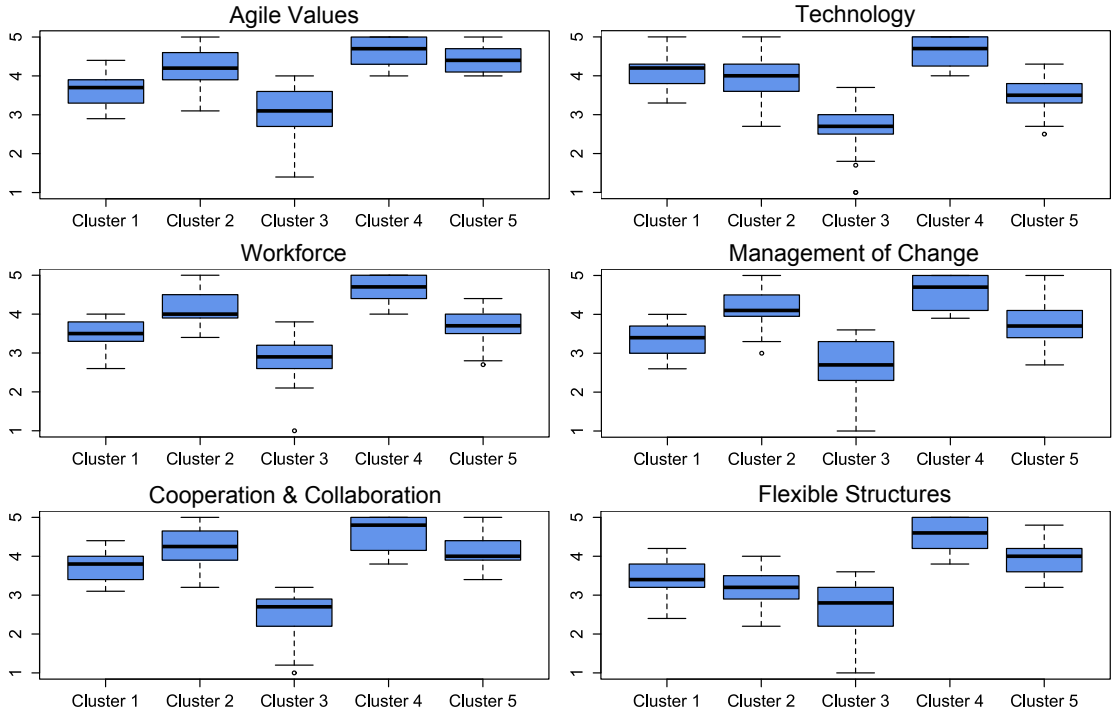

Fig. 3. Boxplots of the clusters per sub-dimension

from five to four to better reflect the empirically identified patterns of agility, a more precise naming of the maturity stages, and a better understanding of potential ways to improve agility by the three clusters assigned to the stage of Agility Transition. Furthermore, the fact that the identified clusters fit to the maturity model and are practically interpretable supports the principal structure and the applicability of the proposed Organizational Agility Maturity Model. Of course, further empirical investigation, for instance by case studies and expert interviews, is still necessary. Nevertheless, the proof-of-concept based on a cluster analysis of empirical data and the theoretically and empirically grounded development are already sufficient to confirm that the Organizational Agility Maturity Model is suitable to assess and describe the current state of organizational agility and to assist organizations from the software and IT service industry in taking further actions on their path to organizational agility.

VI. Summary and Conclusion

This study introduces the Organizational Agility Maturity Model as a new approach to assess organizational agility in the software and IT service industry. To fulfill the aim of achieving practical applicability and simultaneous theoretical grounding and rigorous development, a design-science research approach, including an extensive literature review [9], [11], [20] and an exploratory empirical investigation [26], [27], has been used. The maturity model is structured into three dimensions, each with two sub-dimensions, deduced from exploratory factor analysis, and four distinct maturity stages verified by cluster analysis.

The application of the maturity model creates useful benefits for organizations and underscores the strategic character of organizational agility. First of all, it generates an awareness of what constitutes organizational agility and creates an understanding about the complexity of organizational agility. Furthermore, it may serve as a reference frame to implement a systematic and well-directed approach for improvements and continuous assessment of actions taken.

The empirical investigation and the cluster analysis show that the industry under consideration is actually aware of the benefits of an increased organizational agility. Only a few organizations are classified as “Non-agile” in some dimensions, and they do not even form a separate cluster. Nearly all of the participating organizations have at least reached the stage “Agility Basics” and the majority is situated in stage “Agility Transition,” advancing towards “Organizational Agility.”

Interestingly, further analysis did not deliver any significant relationship of the clusters to the describing characteristics of the organizations like size, location, role, or customers. This lack indicates that organizational agility can be achieved by every organization that is really willing to take the actions necessary and that the maturity model is generally applicable to organizations in the analyzed industry.

Although an initial evaluation confirmed the applicability of the maturity model, further research should strive for additional validation. Of importance would be qualitative in-depth analyses, for instance by case studies or action research approaches, to validate the proposed stages as able to deliver helpful information for individual cases. In addition, the survey

used to identify the structure of organizational agility, and hence the structure of the maturity model, could be replicated with a different sample in other industries to check if the model is also applicable to other domains.

APPENDIX

Table VI lists the items that are used to assess the actual maturity stage. They are taken from the survey questionnaire (see section III) and represent the structure of organizational agility that was obtained by exploratory factor analysis [27].

TABLE VI
ITEMS TO ASSESS THE ORGANIZATIONAL AGILITY PER DIMENSION (TAKEN FROM SURVEY QUESTIONNAIRE; SEE SECTIONS III, IV)

Dimension	**Assessment items**	**Scale**
Agility Prerequisites: *Agile Values* [val1-5, pref1,5]	Our organization values a culture that... ...harnesses change for competitive advantages. ...considers team work as integral part. ...accepts and supports decisions and proposals of employees. ...is supportive of experimentation and the use of innovative ideas. ...considers changing customer-related requirements as opportunities. Our organization prefers... ...a proactive continuous improvement rather than reacting to crisis or "fire-fighting". ...market-related changes (e. g. new competitors, preferences) to generate news opportunities.	1: not at all 2: little 3: partly 4: mainly 5: completely
Agility Prerequisites: *Technology* [tech1-6]	Our organization has Information Systems and Technologies that... ...make organizational information easily accessible to all employees. ...provide information helping our employees to quickly respond to changes. ...are appropriate to our needs and allow us to be competitive in the marketplace. ...enable decentralization in decision making. ...are integrated amongst different departments and/or business units. ...are standardized or comparable amongst different departments and/or business units.	1: not at all 2: little 3: partly 4: mainly 5: completely
Agility of People: *Workforce* [capemp1-11]	Our employees... ...are able to act with a view to continuous improvement of our products, services, processes, and/or working methods. ...are able to sense, perceive, or anticipate the best opportunities which come up in our environment. ...are able to meet the levels of product and/or service quality demanded by our customers. ...use a broad range of skills and can be applied to other tasks when needed. ...communicate with each other with trust, goodwill, and esteem. ...are ready to learn and are prepared to constantly access, apply and update knowledge. ...are in general always willing to continuously learn from one another and to pass their knowledge to others. ...obtain and develop appropriate technological capabilities purposeful. ...can re-organize continuously in different team configurations to meet changing requirements and the newly arising challenges. ...are self-motivated. ...take responsibility and think in a business-like manner.	1: none 2: few 3: some 4: many 5: all
Agility of People: *Management of Change* [capman1-7]	Our managers... ...maintain an informal management style with focus on coaching and inspiring people. ...understand the value of IT investments from a company-wide perspective. ...have the knowledge and skills necessary to manage change. ...are able to quickly implement changes in products and/or services. ...are able to recognize future competitive advantages that may result from innovations in products, services, and/or processes. ...are able to flexibly deploy their resources (material, financial, human, ...) to make use of opportunities and minimize threats. ...manage the sharing of information, know-how, and knowledge among employees appropriately.	1: none 2: few 3: some 4: many 5: all
Structures Enhancing Agility: *Collaboration and Cooperation* [actorggen6,7, 9,10,12-16]	In our organization, we... ...jointly and intensively operate throughout different functions and/or departments for strategic decision making. ...encourage early involvement of several departments and/or functions in new product and/or service development. ...inform ourselves systematically about information technology innovations. ...strategically invest in appropriate technologies and have a clear vision how IT contributes to business value. ...monitor the performance of our partners and subcontractors very closely. ...select our partners and subcontractors by quality criteria (rather than pure cost-based decisions). ...align all our activities to customer requirements and needs. ...encourage compilation and internal dissemination of information on customers needs. ...closely collaborate with and encourage fast feedback from our customers.	1: never 2: seldom 3: sometimes 4: often 5: always
Structures Enhancing Agility: *Flexible Structures* [actorggen1-5]	In our organization, we... ...scan and examine our environment systematically to anticipate change. ...react to approaching changes by immediately updating our business strategy. ...react to approaching changes by immediately updating our processes. ...are quick to make appropriate decisions in the face of market- and/or customer-related changes. ...change authorities when tasks change.	1: never 2: seldom 3: sometimes 4: often 5: always

Comparison of architectures for service management in IoT and sensor networks by means of OSGi and REST services

Jarogniew Rykowski, Daniel Wilusz
Poznań University of Economics, Niepodległości 10, 61-875 Poznań, Poland
e-mail: {rykowski, wilusz}@kti.ue.poznan.pl

Abstract—In this paper two alternative architectures for service management in IoT and sensor networks are discussed. The first one is based on Open Service Gateway (OSGi) framework and Remote Services for OSGi (R-OSGi) bundle. The second architecture extends the notion of REST (Representational State Transfer) paradigm. There were few purposes of the extension. First, efficient, dynamic searching for devices capable of fulfilling certain requests within actual context was enabled. Second, both the devices and controlling services were distributed. Next, the devices were orchestrated in order to provide complex functionality. Finally, the access to the devices' functionality was standardized. OSGi-based solution was found simpler and better suited for homogeneous sensor networks, while more complex REST-based framework appeared as better suited for heterogeneous and widely distributed IoT devices and services.

I. Introduction

The Internet of Things (IoT) is the continuously evolving concept, which influences the business processes and even society on a global scale. Historically, the IoT was perceived as the intelligent network connecting objects, information and human beings to enable remote coordination of resources by people and machines [1]. First proposals of architectures of IoT networks were based on their natural predecessor – sensor networks. Nowadays IoT is perceived as cutting edge phenomenon, no longer limited to electronic identification of objects, but defined as technology integrating devices with information network, where these devices act as active participants in business processes [2].

Multiple applications of Internet of Things have been identified and implemented in such economy areas, as manufacturing, supply chains, energy, healthcare, automotive industry, insurance, financial services or research laboratories, to mention a few [2][3][4]. In the nearest future, the expansion of Internet of Things outside the internal infrastructures of companies is not only expected, but becomes the reality. The increasing popularity of Internet of Things causes the need for proper architecture, which will meet the requirements of IoT environment.

This work was supported by the National Centre for Research and Development under grant POLLUX-II-/1/2014

As IoT is very dynamic and heterogeneous, efficient management system for this environment should address these features. In this paper we discuss two alternative architectures for service management in IoT and sensor networks. The remainder of the text is structured as follows. Section II presents basic characteristics of IoT and sensor networks, which allows an enumeration of basic requirements of these environments. The Open Service Gateway (OSGi) framework is briefly described in Section III. Section IV focuses on the introduction of the Representational State Transfer (REST) methodology. OSGi-based architecture for IoT management is proposed in Section V. Next, similar architecture based on extended REST services is described in Section VI. Finally, Section VII concludes the paper.

II. IoT and sensor networks – basic features

At the first view sensor networks and Internet of Things are similar. Both networks are composed of small hardware nodes with limited resources, such as memory and CPU capabilities, both are physically distributed over certain area, both communicate by means of certain standards related with TCP/IP protocol. However, this similarity is seeming. Below, a comparison of basic features of these two network types , as well generic requirements for data acquisition and overall architecture are provided.

A typical sensor network is composed of many nodes having similar purpose, common goal and fixed functionality. Usually, one single point of interaction is assured, to contact the network as a whole, rather than particular nodes directly. As the nodes are usually small battery-operated hardware devices, several techniques are applied for energy saving and optimization of information routing.

Sensor network acts as single entity, thus it is usually controlled in the centralized manner by a single owner/administrator. The network is accessed as a "black box" of certain functionality, with strict access rights to particular global functions. As there is no need for individual addressing of devices and their functions, external access and control of individual nodes is usually blocked, and the

978-83-60810-58-3/$25.00

network is self-manageable. For example, for energy-saving reasons, some nodes are temporary deactivated, gathered information is pre-processed to minimize network transfer, etc. [5]

On the contrary, a typical IoT network is composed of heterogeneous nodes of different purpose and functionality. There is no common goal defined for the network as a whole except for very abstract goals such as "user comfort" or "energy savings". Instead, each networked IoT device, via continuous environment monitoring and information exchange with other devices, tries to act as a "good servant" [6] – invisible, however useful to maximum extent.

IoT networks are composed ad-hoc and as such they have no centralized management, single owner/administrator, global access rights, etc. The interaction with humans is incidental, sometimes even transparent to users – they are not necessary conscious about the functions provided, even if these functions rise the level of "user comfort" (such as automatic heating, air-conditioning, etc.), "energy savings" (automatic switching off of some devices once no human is detected in the neighborhood), "safety" (face scanning allows for transparent control of visitors of an office, rising "silent alarm" once an unknown person is detected inside), etc. This interaction depends on local and global context, based on such parameters as geo-location and environment features (temperature, lightness, etc.).

As the main stress is put on efficient ad-hoc interaction among humans and IoT devices, portability is the key. Interaction should abstract of such details as local addresses of IoT devices, communication means, data format, etc. Instead, an efficient searching/filtering mechanism should be provided, allowing to choose "the right" device to serve the request in given context. More precisely, portable interaction should be characterized by:

- a need for individual addressing of given network functions abstracting the implementation of these functions, including strict device addressing;
- a need for filtering "the best" device to be activated to realize certain request for function; similar – a need for searching for and choosing the "right" device(s);
- a need to distinguish several searching modes: "exactly one device capable of action X", "at least one", "everyone", etc.;
- a need for monitoring overall activity of devices (and accessibility of their functions) ;
- a need for portability due to ad-hoc nature of interactions at several places and for different situations: at least portability of requests – a need for common semantics/communication language to formulate the requests despite devices' specificity;
- a need for scalability, both for number of requests as well as the devices.

As may be drawn from the above enumeration of the needs, there must be a global (thus centralized) management mechanism for controlling the set of IoT devices, similar to a typical way of the management of the sensor networks. This is somehow contradictory to the requirement for the autonomy of the IoT devices and their ad-hoc composition and usage. However, without such centralized mechanism it is not possible to group the devices into bigger conglomerates (to orchestrate and thus multiply their functions), to search for the device which is optimal to serve given request, to balance the system load/energy efforts/network traffic, etc. Having in mind this trade-off, one may find that the optimum solution is to provide a local catalogue of devices' possibilities, extended by some statistical operations such as current load for each device, information about its accessibility and possibly temporal unavailability, number of served requests, last activation time, etc. The catalogue may also play a role of the request broker, mapping syntax and semantics of the incoming requests to the syntax and semantics used to contact the (heterogeneous by their nature) devices.

If starting the discussion on choosing the technology to implement the above-mentioned catalogue of the devices and their functions, we may point out two frameworks for centralized management of distributed resources: OSGi platform for Java programming language implementing a dynamic service registry, and extended REST services capable of centralized management of distributed REST resources and servers. In the next chapters we are going to present and compare these two frameworks, taking into account the following operations:

- registering the device/function;
- providing individual proxy for interaction/communication mapping – starting, stopping, and suspending/resuming the service;
- monitoring real-device state and providing information about device accessibility;
- searching for the device(s) to serve given request;
- if a request is to be possibly served by several devices, choosing one device based on context and statistical information collected during past activations;
- orchestrating device functions taking into account local context;
- administrating device parameters (individual GUI for each device).

III. OSGi FRAMEWORK

Open Service Gateway (OSGi) is a popular framework, which provides specification for dynamic module system for Java [10]. The core function of OSGi implementation is related with efficient management of modules (bundles) lifecycle, which may be dynamically installed, started, stopped, uninstalled, etc. Bundles are building block of OSGi-based modular systems, which are able to mutually interact. Following interactions among bundles may be distinguished:

- sharing Java packages with classes and interfaces;

- registering and calling services;
- managing the lifecycle of other bundles;
- sending and handling events to trigger specified actions.

OSGi implementations provides service registry to control functions provided by the bundles. There is no reference needed to invoke the service, as OSGi environment provides services based on their interface and additional metadata describing the service. The OSGi service registry may return zero, exactly one or multiple services compliant with the request. If there is no service of specified interface or meeting the additional constraints, null value is returned and must be properly handled. If the caller tends to invoke only one service, but in the registry there are few possible services meeting the requirements, OSGi environment returns the service of the highest rank (specified during service registration) and the lowest identifier (i.e., the oldest one) [11] [12].

Event based communication is a useful feature of the OSGi framework. Primarily it allowed handling data changes caused by dynamic behavior of the bundles or framework itself. Each bundle may be programmed to individually react to specified events, e.g., to stop if a dependent bundle is stopped or uninstalled. Since OSGi v.4, the mechanism of sending and handling the events defined by software developers has been introduced. The event-based communication allows the definition of events' topics and accompanied metadata, which are handled by dedicated `EventHandler` services [11][13][14].

Dynamic modularity, service registry and event-based communication seem to be out of the box solution for IoT systems. However, OSGi does not meet all the requirements listed in Section II that is the reason why some adaptations are needed. We propose such extensions further in Section V.

IV. REST

The Representational State Transfer (REST) style is an abstraction of the architectural elements within a distributed hypermedia system. REST ignores the details of component implementation and protocol syntax in order to focus on the roles of components, the constraints upon their interaction with other components, and their interpretation of significant data elements. It encompasses the fundamental constraints upon components, connectors, and data that define the basis of the Web architecture, and thus the essence of its behavior as a network-based application [7].

Key addressable entity of REST environment is a resource. Resources are any named pieces of information, being a target of hypertext links. Uniform Resource Locator (URL address) is used to get the value of a resource from the server: either static (if the resource is a file, piece of text, an image, etc.), or dynamic, being a result of an invocation of a piece of program code. In the latter case, the resource is treated as a "black box" from the point of view of its caller.

REST resources are frequently used to access the functionality of IoT devices, as this lightweight technology is well suited to limited hardware and software resources of the devices. Also, REST servers are used to proxy such access for very limited and non-standard devices [8]. Once the efficiency and simplicity of implementation rather than security is of primary concern, REST resources seem to be much better base than classical SOAP-based SOA services [8].

Although REST is a very useful proposition for the implementation of IoT-based framework, this technology must be substantially extended to meet the requirements presented in Section II. Thus, in Section VI we propose such extensions as a generic REST-based architecture for the Internet-of-Things environment.

V. OSGi-BASED MANAGEMENT

The IoT systems are characterized by their dynamic nature, as new devices appear, change their status including the availability, disappear or even suddenly break down. The OSGi framework with its support for dynamic modules seems to be the framework of the first choice to build on the IoT management system. Additionally, the OSGi service registry enables discovery of IoT specific features. Moreover, event-based communication allows ignoring the implementation details of services and substantially reducing the need for the standardization of interfaces. However, the IoT relies on network communication, which is not supported by pure OSGi specification. Another trait of IoT, which is difficult to be realized in OSGi framework, is a support for distributed vendors of IoT services. The next specific of IoT system is temporal unavailability of physical devices, which may be busy, broke down or temporary unplugged.

The requirement of choosing "the best" IoT service cannot be fully realized in pure OSGi framework because such choice is limited to fixed service ranking and age (e.g., a moment of first registration of the service). The last but not least important feature of OSGi-based IoT management system is the possibility to manage the devices manually by checking and modifying their status. The above described limitations were the main reasons to propose by us some extensions for OSGi. The architecture of extended OSGi framework for IoT management system is presented in Fig. 1

First, to deal with network communication among IoT services, the OSGi platform is extended by installing Remote Services for OSGi (R-OSGi) bundle developed in ETH Zürich [15]. R-OSGi provides dynamic proxy generation for remote invocation of services and register remote services, discovered in distributed registry, in local OSGi service registry.

Next, to handle modules provided by device vendors, the universal semantic (device descriptions) must be proposed, but this problem is out of the scope of the paper. Here, we

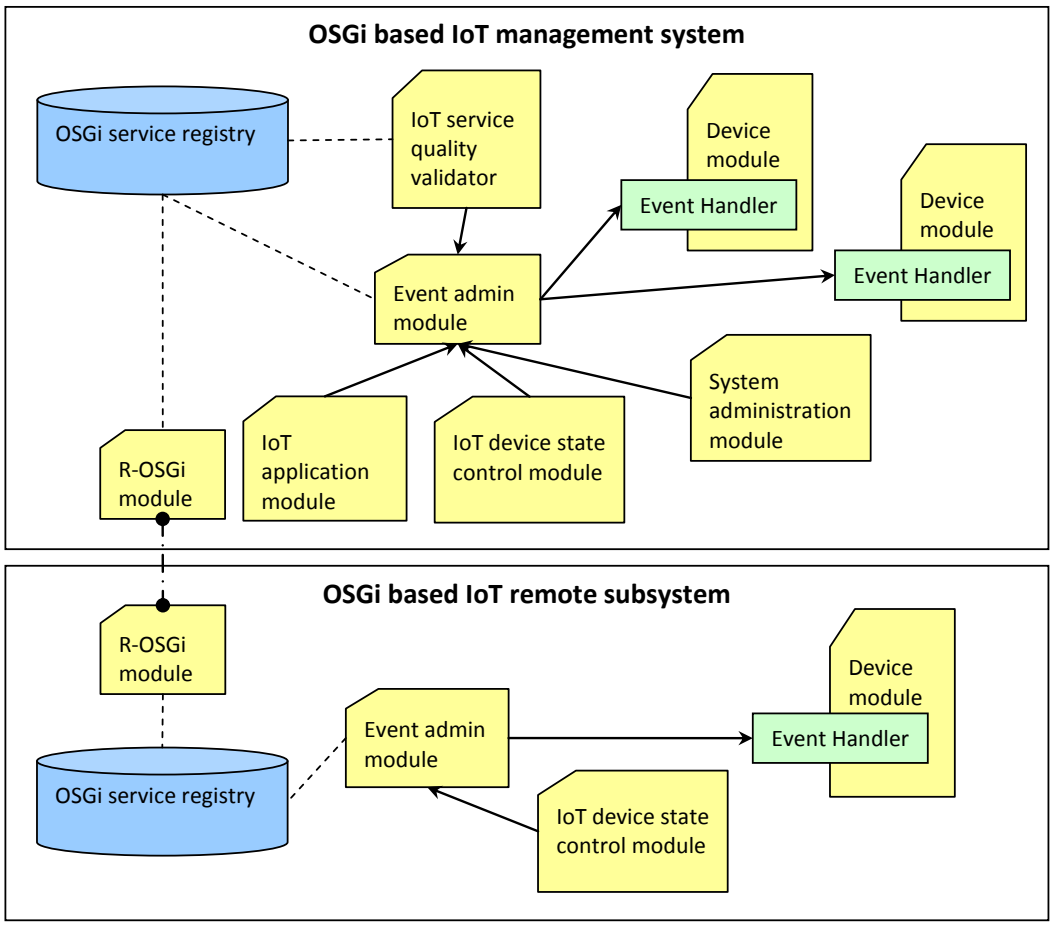

Fig. 1. OSGi based architecture for IoT environment

only point out the fact that OSGi enables specifying service metadata during service registration. The semantic information may be included in service metadata in the form of `java.util.Dictionary` object, containing OSGi event topics or additional properties.

In order to reflect the status of the IoT device related with given OSGi service, the metadata of the service may be dynamically changed, e.g., to restrict an access to unavailable devices. However, to continuously monitor the device status, such a function should be provided by the provider of the device module (corresponding OSGi bundle). IoT device-state control module, extending basic OSGi platform, should be able to send auditing events and get responses from related dependent services interested in the notifications of the device status.

The IoT management system should enable the user to invoke the most suitable service. As the capabilities of OSGi in this aspect are limited, the dedicated module needs to be provided. We propose to implement IoT statistics and validation module, which enable to validate the properties of the service and provide proper statistics on service performance. Such module should utilize the aspect oriented programming techniques to measure and store service properties such as performance time, moment of last invocation, number of invocations, number of generated exceptions (errors), etc.

For administration purposes, the OSGi console may be extended by the methods allowing manual management of available devices. The system administration module is responsible for the discovery of devices based on service metadata and allowing checking or changing the state of these devices.

We may list both the advantages as well as the disadvantages of the OSGi-based architecture, which are presented below.

The main disadvantages of OSGi based architecture are the following:

- Java dependent modules – the OSGi framework was developed for Java platform and in conclusion all module providers need to implement bundles in Java. As IoT is heterogeneous from its nature, the support for many programming languages should also be possible;
- limited built-in support for distributed services – OSGi was design to foster development of modular software running on one device (host), without taking into account distributed environments. The R-OSGi initiative mostly solves the problem, however the control over remote

services is limited and there is no built-in control over distributed bundles;
- lack of shared semantics – there is a need to propose standard semantic to enable unequivocal communication among system and the services – especially the ones provided by external entities;
- limited capabilities of service registry – the registry may provide additional information on services only in the form of `java.util.Dictionary` metadata. This solution is troublesome when extending the registry features to provide e.g., service quality information or device state control.

Despite of noticeable disadvantages, the OSGi framework is still prospective for building IoT management systems, as it has numerous advantages, which are listed below:
- support for dynamic modules – the bundle management allows to change the system capabilities in runtime. This feature is very useful, as in IoT system devices may be dynamically (dis)connected with the system at any time;
- event based communication – this trait of OSGi framework enables to separate the service invocation from its implementation. The OSGi events may carry orders in natural language, which are interpreted by event handlers, instead of directly invoking methods. What is more, requester does not need to know the location of a service, as event administrator sends events to all event handling services;
- code sharing and encapsulation – the OSGi bundles may share their code with one another, which prevents memory overhead. Additionally, each bundle directly specifies the code to share, thus enabling additional encapsulation by separating service interfaces from their implementations;
- compound services – the OSGi framework allows to compose compound services based on simple ones. The orchestration may be done just for calling specific feature, and the OSGi framework will provide the proper service and, after careful event handling implementation, even the most suitable for given request;
- providing interface for manual administration – OSGi framework provide possibilities to extend the console commands by a set of user-defined ones. This capability forms an easy way to implement IoT device administration interface.

VI. REST-BASED MANAGEMENT

The key requirement for the IoT system is an efficient method for the selection of device(s) for the incoming request in a given context. To this goal, the system must (1) know the devices' possibilities and characteristics, including their geo-locations (range of impact), (2) be able to search for the optimum device(s) to fulfill given request, and (3) activate the just-searched device in order to provide certain functionality. As already mentioned, these are basic tasks for a centralized catalogue. However, such catalogue is not a part of REST technology. Thus, we propose a uniform REST-based architecture with a dedicated catalogue (also REST-based) as the base for IoT system (Fig. 2). The architecture is based on using administrational extensions of REST servers to be observed as REST resources by the catalogue.

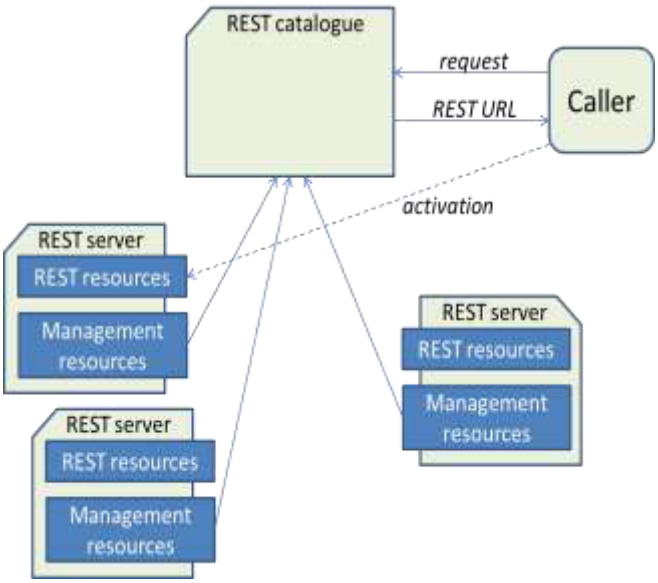

Fig. 2. REST-based architecture for IoT environment

The architecture is based on two principles: extending REST servers by some management resources, and providing mapping of semantically-expressed requests to URLs of REST resources.

To implement the first goal, we assume that each REST server is equipped with certain (predefined) resources to control and supervise the server, including:
- "management" resource to provide an access to some basic commands such as quit/suspend/resume/restart,
- "statistics" resource to provide some information about server usage (both divided to particular resources related with this server, as well as the server as the whole), for example: average service timings, number of requests served, number and description of invocation errors, etc.; this resource also provides an information about the real device (if any), connected to the resource and using this resource as its own proxy; in such way, the catalogue may be informed weather the device is accessible or temporary unavailable,
- "functionality" resource to provide some knowledge for the functions possibly served by this server (namely, by its resources); such function descriptions are defined according to common semantics for the whole system (c.f., interpretation of the request below).

Each REST server registers itself in the catalogue, providing its own URL locator. The locator (more precisely

– the resources mentioned above) may be periodically inspected by the catalogue to collect up-to-date information about server state. This information is used to search for ready-to-use devices (c.f., a description of request serving later on).

Once the internal state of the REST resource is changed, e.g., according to respective change of the state of real device connected to this resource, the server re-registers to the catalogue with the updated information.

Imagine one wants to activate certain function of the system. To this goal, he/she must address the catalogue with the semantic description of the desired action. This description is compared with the possibilities of the devices (however, only those declaring their state as currently accessible), and a device is chosen to meet the criteria. The caller obtains the locator of the resource linked with desired activity/device, to directly address respective REST service and, indirectly, the device. Note that the called URL was not known by the caller in advance, as it was (possibly dynamically) generated and sent by the catalogue. Once the situation is changed, some other resource/device may be activated according to the same request. Note also that the semantics of the URL locator of the resource to activate is not known to the caller, thus the details of the activation may be hidden towards the users of devices' functionality. This approach greatly improves portability of the system usage, on condition the semantics of the requests is common for all the callers and catalogues.

If given request is to be possibly served by several devices, the catalogue may choose one device based on context and statistical information collected from the management/statistical resources of the corresponding REST service. For example, one may address the less-overload resource, last-activated or most-unused device, the one with the shortest response time, etc.

We may also propose, instead of accessing a single resource for a single request, activating a set of resources – i.e., an orchestration of resources. To this goal, a mechanism is needed to map the request semantics to some program code, in turn responsible for the pipelining of the resources. The final result is provided as if all the activated resources are a single resource, thus the whole orchestration mechanism is transparent to the caller.

In most of the applications, connecting all the devices to a single host is not possible, due to (1) limited number of external connectors (such as USB), and (2) natural need for the distribution of the devices across a wider area. Thus, it is desirable to distribute not only the devices and hosts (proxies), but also the parts of the controlling framework. So far we assumed that there is only one central point for the control of the whole network. However, due to unrestricted distribution of REST resources it is possible to part this centralized point to a hierarchy of interconnected sub-parts, each one providing the control over certain network part (Fig. 3). To keep the control on the network as the whole, we propose to connect the sub-controllers as a graph and to span the controlling in the same manner as it is used to synchronize the resources of any peer-to-peer (P2P) network, with arbitrary restricted nesting level.

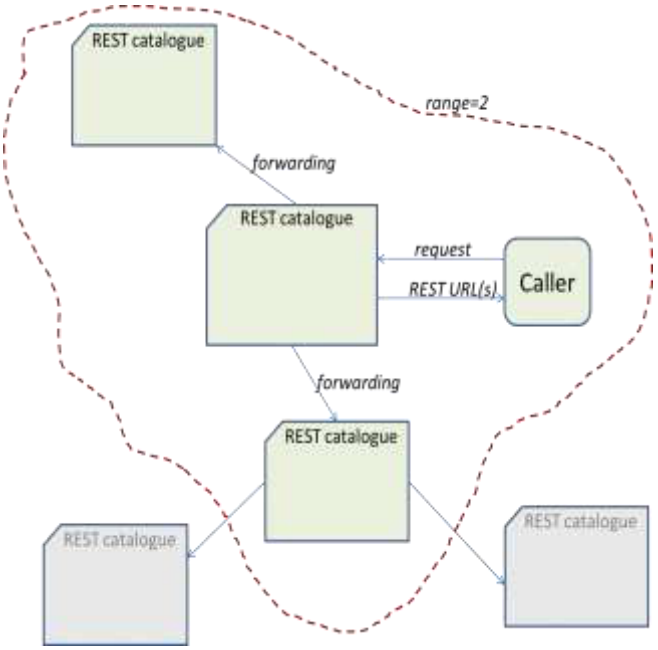

Fig. 3. Hierarchy of REST-based distributed management services

A device may choose any of the sub-controllers to register with. Then, this device is manageable locally by this sub-controlled in the direct way described above. Similar, all the local requests served by this sub-controller towards all its devices are processed locally. However, if there is a need to access remote (from the point of view of this controller) devices, then the sub-controller forwards the request to all its neighborhoods. In turn, if a neighbor is not able to process the request, forwards it to all its neighbors except the one which initiate the request, and so on. For each forwarding step, nesting level of the request (a range) is increased. While this level reaches certain value, the forwarding is stopped. Returning to Fig. 3, the request marked as "level=2" is forwarded only to three sub-controllers, while two "far" ones remain untouched. The stopping value is declared for each sub-controller by its administrator, and for the request by the initiator of this request – each time smaller of these two values is taken into consideration.

All the responses are collected by the forwarder of the request, and, if the request level is still greater than one, send as a common response to the caller. Finally, the originating node collects all the responses of all its neighbors, acting as a "global" response to the initial request.

To limit the possible cycles in the forwarding of the request, each request is identified, and the past-request identifiers are collected for some time in each of the sub-controllers. Once a request is coming already served in the past, this call is disregarded and no more forwarded. Thus,

even if the graph of interconnected sub-controllers contains cycles, these cycles are detected and never block the system.

In the same way we may obtain some global information about the network (statistics, information for certain-device of function availability, etc.), more precisely – about the local neighborhood ("no longer than N connections from the selected node"). More global is the request, more we must wait for the response, similar to typical P2P behavior.

As a typical IoT environment usually covers rather small geographical area (such as a room, a building or a public place – a market, a shop, a museum, etc.) – by restricting the level of spreading the requests to reasonable value one also limits the overall network traffic to the reasonable level, and the response delay is counting in parts of the second. We may also imagine restricting the bigger levels to those with special access rights, such as system administrators – for most of the requests, these will be addressed to local devices (level equal to 1). Then, both the possible delays and increased network traffic are not a sharp problem.

We may enumerate both the advantages and disadvantages of the proposed architecture, these are presented below.

The disadvantages are mainly related with two global observations – independence of the program code for the REST servers, and the need for shared semantics:

- there is no shared code even if identical parts of the program code (i.e., the libraries) are used by several REST servers. This feature results in large memory usage and may be relaxed by some shared-code techniques such as Dynamic Library Linking DLL;
- all the resources must know in advance the address of the catalogue, to register with. This restriction may be relaxed with non-standard usage of DHCP broadcasting;
- additional network traffic is observed to monitor device availability at real-time. However, with reasonable polling interval (for most of the system such timing as 5-10 seconds is completely enough) this restriction may be bypassed;
- one must provide strict definition of the semantics of requests and device activities (functions), shared for the whole system. This restriction is related with a need for the strict format of URL locators for additional REST resources (management/statistics). However, as this traffic is not observed by the end-users, this is a problem only for system designers;
- the activations of devices' functions are based on URL locators of the corresponding REST resources. Thus, only limited parameterization of such calls is possible – all the details must be coded and thus somehow hidden as URL locator parts. However, this is also mainly the problem of system designers, as end-users have no knowledge about the semantics of the device activations. Moreover, sometimes such information should be intentionally hidden for the end-users to limit the direct access to the devices (i.e., the access not controlled by the catalogue).

The advantages outweigh the above-presented restrictions and problems:

- it is a uniform approach – the whole traffic is realized as REST-compliant calls, which strongly facilitates the implementation of the system;
- small resources and servers dominate across the system, thus the consumption of computer resources such as CPU time is reasonably small. Our experiments showed that even hundreds of such servers on a single PC is not a problem, as a single resource typically consumes less than1% of computer resources;
- there is no problem with the synchronization of some resources "shared" among many REST servers, for example real devices, communication ports, etc. Such synchronization is needed only for a single REST server, however, as this server is programmed as a single entity and probably by a single programmer or small group of designers, such synchronization is easy to achieve;
- all the system parts (resources, devices) may be arbitrary distributed even in a local- or even wide-area network – on condition the distributed servers know and may access the catalogue host;
- REST servers may operate even with very limited hardware, also built-in to the networked devices,
- there is theoretically unlimited possibility of the orchestration of devices – providing "virtual devices" acting as real ones, however, possibly much more complex and powerful;
- the catalogue represents up-to-date information for device availability – continuous monitoring is undertaken not only for device state, but also some statistics for its usage;
- single- and group-based management for devices and their corresponding resources is possibly achieved, including server start, quit, restart, suspending/resuming, also GUI-based individual administration.

VII. CONCLUSIONS

As may be drawn from comparison of OSGi and REST based systems presented in Table I and discussed above, both approaches – OSGi-based and REST catalogue provide similar functionality and may be applied to implement an Internet-of-Things middleware. The amount of work for both approaches is similar – substantial extensions are needed to adapt the environment to the specific requirements of IoT applications. However, OSGi-based approach is better suited for sensor networks, i.e., the applications covering homogeneous devices and fixed, predefined system functionality, while the REST-based framework is more useful in ad-hoc, dynamic environment achieving heterogeneous devices and services. For the first, if we deal with shared device functionality and program code, we substantially limit memory usage. For the latter, we may

TABLE I.
COMPARING OSGI AND REST-BASED APPROACHES

IoT requirement	OSGi-based management	REST-based management
registering the device/function	X	X
providing individual proxy for interaction/communication mapping – starting, stopping, and suspending/resuming the service	X	X
monitoring real-device state and providing information about device accessibility	-	X
searching for the device(s) to serve given request	X	X
if a request is to be possibly served by several devices, choosing one device based on context and statistical information collected during past activations	X	X
orchestrating device functions taking into account local context (complex or virtual devices)	-	X
administrating device parameters (individual GUI for each device)	-	X
sharing basic libraries (functionality) for similar devices	X	-
adjusting scope of search for a device in the distributed access, managing a hierarchy of proxy servers	-	X

more easily provide distribution of proxies and devices as well as device/service orchestration, also in ad-hoc mode and based on some statistical information about past activations. If the amount of the shared code is low, due to the heterogeneity of devices/proxies, we do not observe the possible savings resulting from shared code, while still having the possibility of centralized management of the system as the whole as well as particular devices/resources.

9th Conference on Information Systems Management

THIS event constitutes a forum for the exchange of ideas for practitioners and theorists working in the broad area of information systems management in organizations. The conference invites papers coming from two complimentary directions: management of information systems in an organization, and uses of information systems to empower managers. The conference is interested in all aspects of planning, organizing, resourcing, coordinating, controlling and leading the management function to ensure a smooth operation of information systems in an organization. Moreover, the papers that discuss the uses of information systems and information technology to automate or otherwise facilitate the management function are specifically welcome.

Topics

The areas and topics of interest include, but are not limited to two groups:

- Management of Information Systems in an Organization:
  - Modern IT project management methods
  - User-oriented project management methods
  - Business Process Management in project management
  - Managing global systems
  - Influence of Enterprise Architecture on management
  - Effectiveness of information systems
  - Efficiency of information systems
  - Security of information systems
  - Privacy consideration of information systems
  - Mobile digital platforms for information systems management
  - Cloud computing for information systems management
- Uses of Information Systems to Empower Managers:
  - Achieving alignment of business and information technology
  - Assessing business value of information systems
  - Risk factors in information systems projects
  - IT governance
  - Sourcing, selecting and delivering information systems
  - Planning and organizing information systems
  - Staffing information systems
  - Coordinating information systems
  - Controlling and monitoring information systems
  - Formation of business policies for information systems
  - Portfolio management,
  - CIO and information systems management roles

***Abstract*—E-Government increases transparency and improves communication between the government and the users. However, users' adoption and usage is less than satisfactory in many countries, particularly in developing countries. This is a significant factor that can lead to e-Government failure and, therefore, to the waste of budget and effort. Unlike much research in the literature that has utilised common technology acceptance models and theories to analyse the adoption of e-Government, which may not be applicable for e-Government acceptance analysis, this study proposes a more comprehensive and appropriate framework for analysing the significant factors that could influence the adoption and utilisation of e-Government in Saudi Arabia, as this is becoming a necessity.**

I. Introduction

INFORMATION and Communication Technologies (ICTs) are considered to be the backbone of many activities used nowadays. They have tremendous potential to provide solutions and to solve problems in different aspects, which then leads to enhanced quality of life. Given the fact that the accelerated development of Information Technologies (IT) has led to a rapid increase in the number of websites and services provided by governments, nearly all governments of countries around the world have at least a web presence, or so-called e-Government [1]. Currently, the role of ICTs is crucial in governance processes, where they can help to create a structured network for service delivery [2], effectiveness and efficiency [3], interactivity, accountability and transparency [4].

The term e-Government has various definitions in the literature [5] [6], most of which refer only to providing online services (E-Services) to citizens, whereas the definition of e-Government is, in fact, broader and more comprehensive. Although defining e-Government from a single perspective is easy, defining it from general view is relatively difficult [7]. However, we can provide a more comprehensive definition, namely the utilisation of various Information and Communication Technologies (ICTs) for facilitating communication between the government and the stakeholders (citizens, businesses and governmental agencies), providing effective, efficient and integrated e-Services that enhance the relationship between the government and the stakeholders through multiple and flexible channels, leading to a more democratic system and increased engagement.

The field of Electronic Government is growing considerably; therefore, many research areas need to be studied in order to provide scientific insights [8]. One of the most important elements of implementing E-Government systems is the interaction between users and E-Government systems, specifically the adoption and utilisation by users, who are the main target when implementing such systems. This interaction element is considered the main method for measuring the utilisation and success of E-Government systems. If there is no interaction between users and E-Government systems, this means that there is no benefit of implementing such systems. Therefore, this research will investigate and analyse factors that could influence the adoption and utilisation of e-Government in Saudi Arabia from different perspectives, which will then lead to better understanding, ensuring that e-Government has a high level of success.

This paper is divided into five sections. The first introduced the proposed definition of e-Governance. The second section provides a literature review and background information regarding e-Government in Saudi Arabia. The third section explains the research model. The fourth section provides a brief discussion of the research model and the development thereof. The final section provides a conclusion and details our planned future work to utilise, test and validate the proposed model.

II. Background and Context

A. Literature Review

E-Government initiatives are still in the early stages in most developing countries, and face many issues related to adoption, implementation and utilisation. Users' adoption of e-Government systems is less than satisfactory in many countries, particularly in developing countries. Although large amounts of money have been invested in e-Government initiatives in some of these countries, such as the Arab countries, they still have many challenges and shortcomings that slow the adoption and minimise the utilisation of e-Government

978-83-60810-58-3/$25.00

systems, which influence the success of such systems [9]. Most of the studies in the literature have focused on implementing e-Government from technical and structural perspectives [10]. Several studies also focused mainly on analysing barriers to and challenges of implementing e-Government [11]. However, few recent studies have been conducted to discover and analyse factors that can affect the adoption and utilisation of e-Government from the users' perspective [12] [2] [13].

Several models and theories in the literature have been developed to study the acceptance and the diffusion of technologies, including the Theory of Reasoned Action (TRA), the Technology Acceptance Model (TAM), the Diffusion of Innovation Theory (DOI), Perceived Characteristics Innovation (PCI) and the Unified Theory of Acceptance and Use of Technology (UTAUT) [14][15][16][17][18]. Most of the research in e-Government literature has utilised some of these common models and theories to analyse the adoption of e-Government, either by using their original forms, by adding certain constructs to them or by combining them. However, some of the models that have been used for analysing the adoption of e-Government in the literature were critically analysed in this research in order to evaluate their applicability for studying levels of e-Government's adoption and utilisation. This will help us to fill the gaps and to overcome shortcomings, which exist in the conducted studies, while developing this research model.

Some significant constructs involved in the analysed models are important and are supported in the literature; thus, they will be integrated into the current model. However, certain other constructs are not supported in the literature, which means they are not significant and will therefore not be used for analysing the adoption and utilisation of e-Government. Furthermore, a number of significant factors that are likely to have influence on the adoption and the usage of e-Government were not addressed in some of the analysed models. Table (I) shows some of the reasons that certain commonly used models are not applicable to the analysis of the adoption and usage of e-Government.

As stated previously, some recent studies in the literature have analysed e-Government adoption, and most have utilised the common models that are given in Table (1) [2] [22]. Therefore, the outcomes were limited due to the limitations that exist in the frameworks utilised. Several studies have amended the original forms by adding extra constructs, such as risk and trust [23] [12] [24], or by combining some common models [19].

B. E-Government in Saudi Arabia

The Saudi e-Government programme 'Yesser' was officially launched in 2005 [25]. Yesser is an Arabic word that means 'make it easy'. Consequently, the Yesser programme aims to provide services and information to citizens easily [26]. It serves as an enabler and facilitator for transforming the public sector to the information society, whereas each governmental agency is responsible for the actual execution of its own website and is responsible for effective coordination

TABLE I: Inapplicability of common models for the e-Government context

The Model	Inapplicability for the e-Government context
TRA	• The *Subjective Norm* construct is one of least understood aspects of TRA [15]. The *Subjective norm (SN)* construct is likely to have an indirect impact on *Behavioural Intention (BI)* via the *Attitude towards a behaviour (A)* construct. This will make the differentiation between the direct effect of *SN* on *BI* and the indirect effect of *SN* on *BI* via *A* more difficult. • There is a lack of significant constructs that can analyse the adoption and utilisation of large and complex systems such as e-Government.
TAM	• *External Variables* that have been proposed as an influential factor that affect the *Perceived Ease of Use (PEU)* and *Perceived Usefulness (PU)* are not fully explored in TAM [19]. • *Attitude towards using* does not fully mediate *Perceived Ease of Use (PEU)* and *Perceived Usefulness (PU)* [15]. • TAM cannot capture and specify the complete essence of e-Government usage behaviour [20], due to the lack of many important factors and constructs that have direct impact on behaviour in term of intention to use, as well as on the actual usage of technologies, particularly e-Government systems. • TAM excluded some important resources of variance, and did not consider other important factors that could prevent users from using information systems, such as time and money constraints [2].
DOI	• The *Trialability* construct, which refers to how easily a new technology can be used experimentally, cannot be applied to certain technologies and systems, including e-Government, due to the nature of the data and the number of users; thus, such systems are not trialable. This does not, however, mean that testing and validating the system is not essential. • The *Observability* construct, which refers to the extent to which the innovation provides visible and tangible results, can be implicitly integrated into the *Relative Advantage* construct. • DOI Model also lack certain factors and constructs that are crucial when analysing the diffusion and adoption of new technology, particularly e-Government.
UTAUT	• UTAUT did not address some very important constructs and factors, such as perceived awareness and quality of service,although these are highly likely to have a strong impact on behaviours and intentions to use and adopt technologies. It also did not address constructs related to reliability aspects such as security, privacy, trust and perceived regulations. Moreover, UTAUT did not address the influence of culture on the adoption and utilisation of technologies. Although UTAUT considered the influence of certain personal demographic factors, including age and gender, it did not address other important demographic factors, such as the user's location, the user's education level and the user's income, which are likely influence the utilisation and adoption level. • UTAUT ignored the influence of some constructs on the others, although this is very important in such analyses. • Grouping and labelling of items in UTAUT is problematic, since a variety of disparate items is combined to represent a single construct [21].

with the Yesser programme [27][28]. According to the e-Government's first action plan document, the vision of the Saudi e-Government initiative is to provide better government services to users; thus, the vision statement can be summarised as [28]:

"By the end of 2010, everyone in the Kingdom will be able to enjoy from anywhere and at any time —world-class government services offered in a seamless, user-friendly and secure way by utilizing a variety of electronic means."

To achieve this vision, the Saudi e-Government aims to provide 150 top-priority services for citizens and residents by 2010, and to make them available 24/7 with a 75% usage level and an 80% user satisfaction rating [29]. Unfortunately, the Saudi e-Government's vision has not yet been completely realised, despite the fact that it is currently 2014. An evaluation study was conducted by Al-Nuaim in 2011 to evaluate the Saudi ministries' websites, which were considered to be e-Government service providers. This study indicated that nine Saudi ministries, which represent 41% of the evaluated ministries, did not implement a true e-Government website. Moreover, ten ministries, which represent 45.4% of the evaluated ministries, were completely or partially in the 'web presence' stage. Three ministries, which represent 13.6% of the evaluated ministries, were in the 'one-way interaction' stage [26]. Some improvements might have been achieved during the period between Al-Nuaim's study and the present, but we believe that this period is not sufficient to accomplish that which was expected by 2010, based on the vision statement.

The focus of Al-Nuaim's study was the evaluation of e-Government service providers' websites, which measure the achievement of the first important aspect of the vision of Saudi's e-Government, namely providing over 150 top-priority e-Services. However, the focus of our research work will be on the utilisation of e-Government from the user's perspective, which represents the second crucial part of the Saudi e-Government's vision (75% usage level and 80% user satisfaction rating). This is a significant contribution of this research and is one that could lead to a better understanding of the factors that can influence the adoption and usage level of e-Government.

Unlike developed countries, research and studies that investigate and analyse the adoption and utilisation of e- Government in developing countries are limited. Few studies have been conducted on e-Government utilisation, e-Usage and e-Engagement in any country, and this is particularly true of Arab countries, such as Saudi Arabia, [7][4][30] and most have limited findings as a result of the implementation of limited methodologies or the collection of data from limited samples. Therefore, the lack of sufficient and comprehensive studies that explore and analyse factors that influence the adoption and utilisation of e-Government in developing countries is considered an important challenge that needs to be addressed. The lack of utilisation of e-Services that are provided by e-Government is problematic, even though some of these e-Services have been implemented well. Implementing huge national systems, such as e-Government, involves a tremendous amount of effort and cost; however, unless it is utilised as expected, the result is a disaster. Thus, studies and research on investigating and analysing the significant factors that could influence the adoption and utilisation of e-Government in Saudi Arabia are becoming a necessity.

III. The Research Model

In order to analyse factors that influence e-Government adoption and utilisation, this research developed a comprehensive model called the e-Government Adoption and Utilisation Model (EGAUM). This model provides a comprehensive framework to analyse key factors that have crucial influence on the utilisation and spread of e-Government. EGAUM was developed based on a critical analysis of the literature on technology acceptance, in conjunction with insights from several models and theories that are commonly used to analyse the acceptance and usage of technologies. Defects and shortcomings that exist in the models used in e-Government adoption literature are addressed in EGAUM. The main goal of this research model (EGAUM) is to determine factors that could influence the users' beliefs and intentions, as well as the behaviour that influences their adoption and usage levels.

The EGAUM model consists of three dependent variables, namely *Intention to Use E-Government (ITU)*, *E-Readiness of e-Government (ER)* and *Actual Adoption and Use of e-Government (AAU)*. EGAUM also contains four groups of independent variables, which are *Personal Factors (PF)*, *Motivational Factors (MF)*, *Technical Factors (TF)* and *Reliability Factors (RF)*. These independent variables represent the fundamental factors that have a critical influence on the adoption and usage levels of e-Government. The research model, EGAUM, is shown in Fig. 1.

The relationships between the research constructs are represented in two ways, namely by arrows (direct relationship) and small circles (indirect relationship). Direct relationship means that a construct has a direct influence. For example, *Personal Factors (PF)* and *Motivational Factors (MF)* have a direct influence on the *Intention to use e-Government (ITU)*. *Technical Factors (TF)* and *Reliability Factors (RF)* also have a direct influence on the *E-Readiness of e-Government (ER)*. However, an indirect relationship means that one or more factors of a specific construct has/have indirect influence; in other words, one or more factors of a construct can indirectly affect the influence of other constructs. For example, one or more of the *Motivational Factors (MF)* indirectly affect the relationship between *Personal Factors (PF)* and *Intention to use e-Government (ITU)*. Moreover, one or more of the *Personal Factors (PF)* has/have an indirect influence on the relationship between *Technical Factors (TF)* and the *E-Readiness of e-Government (ER)*.

A. Personal Factors (PF)

It is proposed in this research that demographic factors such as the users' age, gender, education and computer literacy levels, as well as users' locations and income are factors

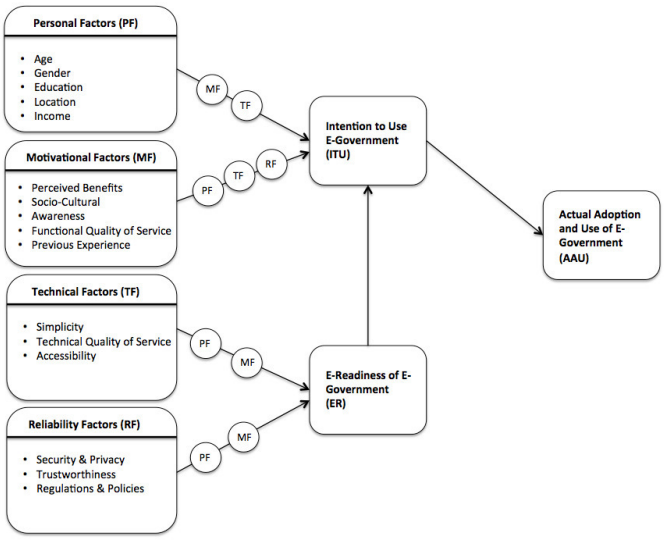

Fig. 1: The research model (EGAUM)

that potentially influence the adoption and utilisation of e-Government. It is further suggested that all these previous factors have a direct influence on the intention to use e-Government.

Age is an important factor that influences e-Government usage levels. Exploring the impact of the user's age on e-Government adoption will lead to better understanding of age-based aspects that need to be improved in order to increase the adoption and utilisation of e-Government. Several studies have found that age is one of the important factors that influence the adoption of Information Technologies (IT), particularly in the Arab countries [31][32]. Moreover, various studies have revealed different results regarding the influence of age on the adoption of e-Government. An early study found that older users tend to correlate positively with the use of e-Government [33]. On the other hand, some recent studies have found that older users are less likely to use e-Services, and that users under 25 years of age are more likely to adopt and use e-Services [34][35].

Gender is another crucial factor that needs to be addressed when analysing the adoption of e-Government systems, particularly in Saudi Arabia. Because of cultural and religious reasons, some Saudi governmental organisations and agencies allocate separate offices to serve women who need to perform governmental services physically. Although this division provides more privacy and comfort for the women and they are not as crowded as they would be in the main offices, these separate offices are not available in all cities, nor at all governmental organisations. This clearly influences the adoption and usage level on the part of women. Moreover, women are not allowed to drive cars in Saudi Arabia and there is insufficient public transport; thus, some women face difficulties when they need to go to government agencies. This also affects women's adoption and usage levels.

Education is also an important factor that needs to be investigated when analysing e-Government adoption and usage. This is because of the strong correlation between computer and information literacy and the education level of a user [36]. Computer and information literacy is defined as everything a person needs to know in order to be able to use computers [37]. Users with higher levels of education are more likely to adopt and use e-Government systems because they know how to use the Internet and computers, even if they are not Information Technology specialists. On the other hand, users with low levels of education are unlikely to adopt and use e-Government.

Location is another important factor that is not covered in any of the previous research into the adoption of e-Government. It is the right of all users to benefit from services that are provided by the government, regardless of whether they live in rural or urban areas; clearly, this poses a challenge for governments. In the context of Saudi Arabia, not all cities have governmental agencies and organisations that can provide governmental services for people who live in these cities. This challenge forces customers, who can be either citizens or business's representatives, to travel to the nearest city with the required governmental agency, a process that is both costly and time consuming. This will most likely have an effect on adoption and usage levels.

Income is another personal factor that will affect the intention to use e-Government systems. The EGAUM model included income as one of the Personal Factors (PF) that have a direct influence on the Intention to Use e-Government systems (ITU) because of two potential scenarios. The first suggested scenario is that income could prevent users from possessing computers and digital devices that could enable them to access e-Government services online, thus, preventing them from adopting and using e-Government systems. The second suggested scenario is that income could prevent users from travelling to the nearest city in the event that they live in rural areas without governmental offices in which to access governmental services physically. In both scenarios, the user's income is suggests a direct influence on the intention to use e-Government.

B. Motivational Factors (MF)

The Motivational Factors (MF) construct is one of the most important aspects to be investigated and analysed with regard to the adoption and utilisation of e-Government. This construct is comprised of four significant factors that are likely to influence the adoption and utilisation of e-Government.

Perceived Benefits in the E-Government Adoption and Utilisation Model (EGAUM) can be defined as 'the degree to which e-Government provides functional and non-functional benefits to its users'. This is related to the belief in gaining benefits and the expected outcomes of conducting e-Services using e-Government systems. The idea is to analyse the influence of perceiving the advantages of using e-Government systems on the adoption and utilisation thereof. The Perceived Benefit factor is classified into two categories:

- Functional benefits, which refer to 'any tangible benefits that a user can obtain from using the e-Government system'. These functional benefits include completing the intended services online from anywhere and at any time, synchronising and updating records among different governmental organisations, saving the history of conducted services, tracking the status of the conducted services, preventing bias from affecting the process of the conducted service and reforming the bureaucracy that exists in governmental procedures.
- Non-functional benefits refer to 'any intangible benefits that the user can obtain from using the e-Government system'. These non-functional benefits include time saving, cost saving, the comfort and convenience of conducting the service, avoiding crowds and long queues, reducing effort and independence, particularly for women in Saudi Arabia, as certain limitations exist.

Much of the research in the literature emphasised the importance of analysing the influence of the perceived benefits of a new technology on the adoption and diffusion of that technology [15] [16] [38] [39].

Socio-Cultural factor is also likely to have a strong impact on the implementation of a new technology, especially when that new technology is related to improving the lifestyle of society. It is a combination of two influential aspects, namely the social aspect and the cultural aspect. There is a strong correlation between them, since one aspect has the power to change the other. Social influence can be defined as "the normative pressure of associated members family or friends influences the intention to use e-government" [24]. Numerous research in the literature found that social influence, which is represented by friends, family members and colleagues, has a strong impact on the users' adoption level of a new technology, such as e-Government [40][41].

Cultural Influence can be defined as "the values, beliefs, norms and behavioural patterns of a group of people in a society for national culture, staff of an organisation for organisational culture, specific professions for professional" [42]. Cultural Influence has been widely investigated in the literature on the adoption of technologies, and it is proposed that cultural norms have a fundamental correlation with the intention to use e-Government systems [43] [44]. Many aspects of social and cultural influences need to be investigated and analysed in order to discover their impact on the adoption and usage of e-Government systems. The most important aspects that are suggested in this research can be explained in the following points:

- *Image* : This refers to the users' perceptions that using and adopting an e-Government system will afford them societal superiority. It is claimed in the literature that adoption of e-Government might reflect the adopter's familiarity with modern technologies, his or her proficiency in using computers and the Internet, a high degree of modernism and a higher level of education. These phenomena add a degree of prestige and social value to the adopter [20]. This research suggests that this phenomenon is even more influential in Saudi society.
- *Influence of others* : It is now widely accepted that "the most powerful influence on human behaviour is other people" [45]. The power of the social influence runs very deeply, since whom we know and how we feel about others affects our behaviour. In the Saudi context, the impact of others is even more influential, since the society in the Kingdom of Saudi Arabia is interrelated and coherent. Most of the relationships between family members, as well as the social relationships between different families and friends, are strong.
- *Resistance* : The adoption and utilisation of any new technology is greatly affected by the behavioural norms of the society, since individuals may tend to resist changes that technologies can make, which is likely to lead to negative consequences with regard to the implementation of such technology [46]. Resistance to change is considered one of the factors that can negatively affect the successful implementation of any system, including e-Government systems. Some users might resist using e-Government due to trust issues, whereas others might resist adopting e-Government because of the face-to-face culture that is still influential in terms of customer confidence [47].
- *The influence of interpersonal social networks (Connections or Wasta)* : Wasta represents one kind of corruption in many government organisations in developing countries [47]. In Arabic, wasta means personal connections with certain employees or top managers who can accelerate processes or break rules in order to complete paperwork and conclude transactions. Since e-Government will limit such corruption because services will be treated electronically and all actions will be controlled, some customers (including citizens and businesses) may resist the use of e-Government and continue to seek help from their personal connections instead. Moreover, some employees may also resist using the e-Government system in order to retain their ability to break the rules when processing their relatives' applications.

Awareness of the functions and services that any interactive system can provide for its users is a very important factor. Perceived awareness is a strong contributor to the adoption of e-Government [20]. Thus, all governments that intend to implement the e-Government system, especially in developing countries, need to be conscious of making users aware of and familiar with e-Government, particularly users in remote areas. Not doing so is likely to create a severe digital divide and fail to achieve the goals of e-Government. The research also assumed that awareness can be improved in a variety of ways, such as interactive advertising, social media and traditional advertising methods. Social media can play a fundamental role in enhancing the adoption and utilisation of e-Government by increasing awareness levels in this regard. Some recent research has begun to analyse the impact of social media on e-Government interaction [48] [49].

Functional Quality of Service refers to the quality level of functional aspects of a service that is provided by e-Government. Functional quality of service is a significant factor that must be studied from different aspects in order to achieve accurate and practical results. Delivery speed of and delivery options for required documents among government agencies and users are considered to be important aspects that can influence adoption and usage levels. Customer care is another important aspect of functional service quality and involves providing on-going technical support to customers, helping customers to perform e-Services, seeking customer feedback and ensuring their satisfaction. Other aspects of the functional quality of the services provided services are also likely to affect e-Government usage, such as providing different payment options for governmental transactions that involve fees, providing up-to-date information regarding e-Services and making e-Services available 24 hours a day, seven days a week.

Previous Experience is another important factor that has been addressed in this research model (EGAUM). It refers to experiences that users have encountered in the past with regard to e-Services. In this research, two aspects concerning the influence of previous experience have been proposed. The first is previous experience of using online applications and services such as e-Business services, e-Commerce services, online banking, online shopping and online payments. The second is related to previous experience of using e-Services provided by the e-Government itself. Positive and negative results of using online services, either e-Government services or any other nongovernmental services, are likely to have a strong impact on future interactions with the e-Government. Furthermore, this factor will also influence the adoption and utilisation of e-Government when first using it, as well as the continued use thereof. The Motivational Factors (MF), which include the Previous Experience factor, have indirect influence on all other factors. This will determine the influence of all the research factors on the first use and on the continued use of e-Government.

C. Technical Factors (TF):

In any interactive information system, there will be technical aspects that need to be addressed and taken into account in order to achieve the desired goals of implementing such systems. Unlike certain research in the literature that focused on the technical infrastructure aspects of the e-Government system itself, such as the network infrastructure and required applications [44] [50], this research will focus on the theoretical technical aspects that are related to the users' adoption and interaction. The technical factors that are addressed in this research model (EGAUM) can be listed as:

Simplicity refers to those factors that can simplify the e-Government system and make it easy to use. It has been established that the easier an information system is to use, a greater number of users will adopt it. This relationship is particularly applicable and important with regard to large systems such as e-Government, as large numbers of users are expected to utilise it, and their skills and abilities may differ significantly. Simplicity includes the following factors:

- *E-Government interface design:*
  E-Government's websites and interfaces are the interaction mediator between the e-Government system and its users. Therefore, they must be designed according to the users' requirements in order to achieve satisfactory levels of utilisation. E-Government interface design includes web page layout, design consistency, colour contrast, being free of spelling errors, having a clear font, clear labels, searchable contents and multiple language options.
- *Reaching e-Services:*
  This refers to how easy it is to reach to the intended e- Service on the e-Government website i.e. the ease of locating and navigating the intended e-Service after accessing the intended e-Government website. Difficulty in locating e-Services on e-Government websites is likely to have a negative effect on the adoption and utilisation of such e-Services, even if access to the e-Government websites is easy. Therefore, it is suggested in this research that if it is easier to reach e-Services, more e-Services will be performed; thus, the high adoption and utilisation thereof will be achieved.
- *Service description and hints:*
  This factor refers to the descriptions of services that are used to explain the e-Service to the users, as well as how to apply for it, the requirements thereof, the way in which the e-Service will be processed and how it will be delivered. Such information provides the users with a better understanding of the methods involved in successfully implementing e-Services. Furthermore, providing tips and examples for conducting e-Services and information regarding the required information type is also important in assisting users to utilise e-Government services.

Technical Quality of Service is another form of quality of service that needs to be addressed when analysing the adoption and usage of e-Government systems. It refers to the technical aspects that are visible to the users and which can affect their willingness and intention to adopt and use the system. These technical aspects reflect the quality of the system, and they include:

- *Suitability for people with special needs:*
  This refers to the e-Government system's ability to support features and technologies that can assist people with special needs to use and interact with the e-Government. Special needs include blindness, low vision, deafness, being hard of hearing and physical disabilities [51] [52].
- *Free of syntax, semantic and linkage errors:*
  This refers to ensuring that e-Government system is free from technical errors such as broken links, payment confirmation errors, and server and network errors. Such errors are likely to lead to user frustration and dissatisfaction, resulting in low levels of adoption and utilisation [26].

Accessibility Accessibility is another technical factor that refers to the users' ability to access the e-Government system, and includes the available methods for reaching and accessing services provided by the e-Government system. Several important aspects that are related to e-Government accessibility will be addressed in this research. These important aspects include:

- *The role of intermediaries in e-Government accessibility:* Intermediaries can be defined as any private or public organisation that facilitates communication and coordination between public services providers and users [53]. Many users will be excluded from benefiting from e-Government services due to certain access barriers, such as limited access to the Internet and computer illiteracy [54]. In this regard, Al-Madinah city, which is a large city in Saudi Arabia, has introduced so-called 'intermediary organisations' or 'e-offices', which operate under the legislation and authority of the Saudi government. They are physical intermediaries (organisations) that help people who have difficulty using e-Government. These difficulties include limited Internet access, computer illiteracy and the inability to pay online. Al-Sobhi et al. have studied the influence of the intermediaries, and the results show that intermediaries are an extremely useful channel for improving the adoption and utilisation of e-Government [24].
- *Mobile e-Government:* With the spread and popularity of mobile communication devices, e-Government has become more accessible and adoptable in many countries [55]. Mobile communication devices include mobile phones, tablets and PDAs (Personal Digital Assistants). E-Government services are often difficult for users in remote areas to access, as well as being problematic for users that are homebound, or who have poor computer skills or chronic illnesses [56]. Thus, m-Government can enhance access for users with these conditions easily and efficiently, which will have a positive effect on the adoption and usage level.
- *Digital divide:* The digital divide refers to the inequality between groups (individuals, households and businesses) in terms of access to and the use of Information and Communication Technologies (ICTs) [57]. Equality in terms of accessibility and the ability to use any information system is an important factor that can significantly affect the adoption and utilisation level. The importance of this factor is emphasised when the information system targets large populations and major users, such as e-Government systems.

D. Reliability Factors (RF)

The Reliability Factor (RF) construct is another important aspect of the EGAUM model that was developed in this research. This construct comprises fundamental factors that are related to the users' perceived risks and trust. These factors are:

Security and Privacy are two significant factors that need to be of a high standard in any interactive system. Their importance is emphasised when the system involves public users and sensitive data. In order to increase the adoption and usage level of information systems and applications, users need to feel safe when interacting with such systems. Implementing high standards of security and privacy is crucial, but it is not sufficient to increase the usage and utilisation level. Users need to be informed about the implementation of high security and privacy standards via the publication thereof, the sending of e-Services receipt confirmations, the requirement for further security criteria when performing financial transactions, and by informing the users when the e-Service requests the sharing of their personal information and requires permission to do so. Such factors are likely to influence perceptions of security and privacy, thereby increasing the users' adoption and utilisation of e-Government.

Trustworthiness plays a vital role in helping users to overcome the perceived risk and uncertainty involved in using online services. Trust issues can strongly affect the users' intention to share their personal information and to perform online transactions when using e-Government systems. Although trustworthiness has been studied and has proved to be an important factor in the literature on technology acceptance, there is still insufficient research that investigates and analyses the influence of trust on e-Government adoption and utilisation [30][58]. In this research, the trustworthiness factor will be investigated according to three aspects, namely trust in the Internet, trust in the e-Government system and trust in the e-Service provider. The importance of this factor is based on the fact that trust can be built from first impressions, and can also be affected by any later shortcomings. Moreover, trust is difficult to regain, particularly in an uncertain and virtual environment.

Regulations and Policies for using any interactive information system must be introduced and set up strictly and clearly in order to reach satisfactory levels of adoption and interaction. The importance of setting up clear, strict regulations is emphasised when the implementation of large public systems, such as the e-Government system, is involved. This factor includes several significant aspects, such as usage terms and conditions, e-Service delivery policies, payment policies, users' and providers' rights, data protection policies, and security and privacy policies. These examples of regulations must be introduced not only for the e-Service provider's records, but must also be published in order for the public users to be informed of their rights and to increase their confidence in the reliability of the system.

IV. Discussion

As stated previously, this research model was proposed based on a critical analysis of the common technology acceptance models that have been utilised in most of the recent e-Government studies. A number of significant factors in these common models were integrated into this research model, albeit with broader insight. For example, the Perceived Benefits

in EGAUM is similar to the concept of Perceived Usefulness in TAM and to Relative Advantages in DOI [15] [16], but has a wider interpretation. Moreover, the Simplicity factor is also more comprehensive than is the Ease of Use in TAM and the Effort Expectancy in UTAUT [15] [18].

On the other hand, several important factors in this research model were not addressed previously in most of the e-Government adoption and usage studies, especially those that were conducted in developing countries. This is because most of the e-Government adoption studies have utilised common technology acceptance models in the e-Government context that originally lacked many fundamental factors. These important factors have been added in this research model as independent factors, and include Cultural Influence, Personal Factors Influence, Awareness, Previous Experience Influence, Functional and Technical Quality of Service, Security and Privacy, Regulations and Policies, and Trustworthiness.

We believe that this research model has proposed and developed a simplified and comprehensive manner for providing a scientific framework for the analysis of e-Government interaction. Moreover, EGAUM is a universal model, which means that it can be utilised in countries other than Saudi Arabia. It can also be adapted and used to analyse the adoption and utilisation of different interactive systems and various service applications because it addresses influential factors that are crucial in such an analysis. EGAUM is currently being tested and validated to explore the influence of its constructs on e-Government adoption and utilisation in Saudi Arabia.

V. Conclusion

In order to investigate and analyse the key factors that can influence users' adoption and utilisation of e-Government services in Saudi Arabia, this research proposed a comprehensive and conceptual model (EGAUM) that would be the basis of our future work. A number of significant factors that have been integrated into this research model were taken from well-studied technology acceptance models in the existing literature. Other crucial factors have been developed and added in this research in order to conclude a model for e-Government adoption and utilisation analysis that is more comprehensive and appropriate.

The EGAUM model is now being validated and tested on various user groups, including public users of e-Government services, office workers that provide e-Government services and business managers who use e-Government services as part of their business activities, in order to determine the direct and indirect influences of the model's constructs on actual e-Government adoption and utilisation.

***Abstract*—The objective of this paper is to examine application possibilities of a conversion method in a new confrontational pattern-based design method used for IT systems evaluation. First, the authors present characteristic features and assumptions of the new methodology. Next, they conducted a study verifying the application of this methodology in the analyses preceding the execution of the project aiming at creating a new comparison engine, based on the model which received the highest scores in the evaluation. The results of the study were analysed, and the authors examined their usefulness with regard to the application of the presented method.**

I. Introduction

IN THIS article the authors present an application of the conversion method for the evaluation of websites. The conversion method may be considered as an extension of the novel methodology to design IT systems. The method is based on the averaging of distances from the average results of the surveys concerning the quality of IT systems [4]. This article shows that the application of the conversion method to the confrontational pattern-design method is possible. It refers both to the activities of project teams and on the other the modern methods of design solutions for design through the service (Service Desig) [10]. The main recommendations of this type are methods [3, 6, 12, 13]: focus on the needs of the user; full cooperation of the parties during the project, to present the full implementation of the service over time; formalization and a peculiar "materialization" of all elements of the service in a way comprehensible to the user and comprehensive account of the trial of the service by a single contractor.

They have one fundamental flaw: they do not provide models, procedures and practices which are the required contribution to the theoretical knowledge. Thus, they are not embedded in a broader economic or praxeological context. Therefore, they cannot be used for the purpose of the optimization of investment in IT (especially services), formulation of new service projects (based on the added value for the customer global and multicultural), and the implementation of projects that allows these project to be immersed in the realm of operation systems as much as possible. This is particularly important for electronic commerce tools.

The integration of these solutions with basic assumptions of modern management methods and some of the best proven traditional solutions can bring, as it seems, very good results with regard to creating design patterns. This conclusion is supported with a number of experiments conducted by the authors during the research into the assessment of e-business [2] and the possibility to use the findings in system designing. In the study the Authors used an iterative approach to identify ex ante needs of the user and confront them with the ex post experiences resulting from a deep analysis of the existing IT solutions of Confrontational Pattern-Based Design Method.

The basic assumptions and recommendations *Confrontational Pattern-Based Design Method* refer to the concept of *Service Design*, on the one hand, and *Agile Design* methods on the other [5]. They are as follows:

- in many cases user's requirements, even in the case of an informed client, are dominated by existing habits connected with the IT systems used in the organization: in the clients' opinion the questions concerning additional functionalities introduce elements of ambiguity, or even contradiction,
- project schedule becomes the result of negotiations between the user, expecting to reduce the time of the realisation of the project, or even be provided with the finished product immediately, and the possibilities of the contractor and his desire to offer a product which is of higher quality than the existing solutions,
- iteration between the initial recognition of the user's needs (even if they tend to be reduced to the experience of the previous installation), and best practices derived from the analysis of the existing solutions on the market; each successive iteration is a compromise bringing us closer to the final solution,
- there are methods of identifying best practices, consistent with the scientific basis of the evaluation of IT systems (and common sense); we should aim at constant

This work was not supported by any organization

978-83-60810-58-3/$25.00

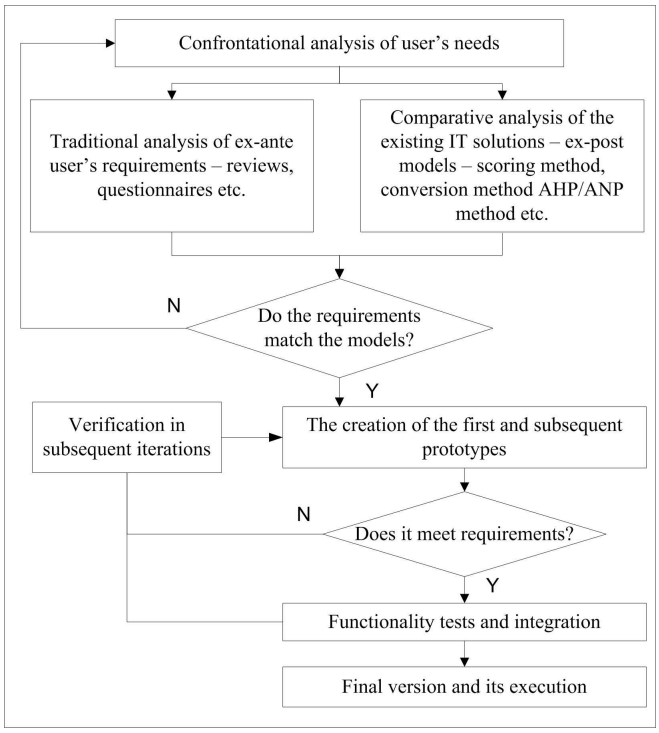

Fig. 1. Basic phases of the life cycle of the project in CPD model Source: on the base of [5]

improvement or creation of an IT system which allows for automatic selection of the method best suited to a particular decision-making situation,

- the user shows a specific tendency to overcomplicate systems, thus, we should aim at their greatest simplicity at the level of design, content, service and methods of solving basic design problems,
- parallel analysis of the user's requirements — on the one hand, the application of traditional analytical methodologies (questionnaires, interviews, conversations, ...), on the other, consideration of the user's evaluation of the existing systems in order to extract certain components which can meet his needs in the best possible way,
- coordination of the language describing design requirements with the assessment criteria of existing solutions,
- ongoing integration of selected components in accordance with previous arrangements in the present version of the project,
- solving, by way of negotiation, confrontational requirements resulting from the projection of the user's requirements, performance and usage analyses as well as expert requirements resulting from the best practices of completed projects in the same area.

The life cycle of the project according to CPD model (see: Figure 1), consists of four basic phases: confrontational analysis of the user's needs — parallel examination of the needs of the final user and of the existing IT solutions in the field. Based on the list of the best solutions, we create a project based on the optimal design patterns used in the existing portals. In the case of differences — negotiations with users which aim at bringing their position closer to the position resulting from the analysis of best practices; on this basis we create a prototype of an IT system — subsequently, it is presented to the client; in the case it does not meet the user's expectations — introduction of changes, creation of another prototype — presentation of the prototype to the user; in the case of fulfilling requirements — testing stage; functionality tests — subsequent versions presented to the client are tested before next modifications, which client may suggest at this stage. In case of doubts, we return to the creation of the next prototype and working on the final version of the project; the last iteration leads to the creation of the last, complete version of the project, which is then executed.

Methodology of the Confrontational Pattern-Based Design Method concerns mainly small and medium-sized e-commerce projects. It assumes full access to the existing software, from the user's perspective, and such a situation is taking place in the Internet. Apart from the classical analysis of the user's requirements, the practical approach consists in the examination of the existing solutions enabling: specification and accurate research into the area in which the software works, creating a ranking of IT solutions existing on the market, identification of the features which make particular solutions better than others.

However, there are concerns regarding: the creation of a coherent methodology which needs to be applied in the examination of the needs of a user of existing IT solutions, interpretations of findings of practical analyses, the necessity of taking into account the high dynamics of technological innovation in this field, the necessity of developing the mechanism of negotiations of the proposed solutions with the end user.

II. Assumptions of the Study

The issue of creating a project of a comparison site may be used as an example of the application of this method. The findings of a research company Tradedoubler [9] shows that Polish clients use comparison sites more and more frequently, anticipating constant growth of e-commerce (Poland and Czech Republic noted over 30% increase of internet sales in 2012, while the average in Europe is 22% [7]). The determinants of the success seem to be: the novelty effect, limited financial resources, which consumers may spend on shopping, promotional activity of comparison sites, the growing awareness of the opportunities posed by internet shopping, and the price, which is a key criterion in the case of buying branded goods. The destimulators are mainly phenomena such as:

- not all shops in Poland, especially new ones, present their offers on comparison sites,
- offers are not continuously updated,
- errors concerning the presented product price,
- there is no active verification of the prices provided by the shops [5].

The most popular software of this class on the market are: Ceneo.pl, Skapiec.pl, Nokaut.pl and Okazje.info.pl. The client verifies the price, brand of a product, reputation of a shop, client's opinions, and subsequently, based on the available data, he or she chooses the most attractive offer. At present, comparison sites are widely known and more commonly used — therefore, they prove to be very useful in conducting the mass research into the needs of the so-called average user of the Internet.

The assumptions of the study were as follows:

- the objective of the study is to design an online comparison service so that it meets the users' needs in a way which is optimal in terms of the qualitative characteristics: functional, technological, etc.,
- we should analyse users' requirements concerning the basic usability parameters of the portal. The study's objective is to indicate the parameters which are most important from the point of view of the websites' clients (considering the class of electronic agents),
- based on the above findings, we create a list of the most important evaluation criteria of the existing comparison websites,
- the list of criteria is used for individual evaluation of comparison websites known to users (one user can evaluate more than one website),
- the group of respondents is not chosen at random, it belongs to the class of convenient samples as the respondents are students of the selected universities in Warsaw (Faculty of Management of the University of Warsaw and Faculty of Information Technology of the Academy of Finance and Business Vistula); they represent all types of studies (B.A., B.Sc., M.A., PhD studies),
- the evaluation will be standardized according to the ten-point scale used to examine other types of IT systems,
- the results of the analysis of user requirements will be confronted with the evaluation of the characteristics of the existing comparison websites in order to identify the best possible implementation of those characteristics which are most important from the user's point of view,
- the analysis will be performed first by a scoring method, and, next by conversion method for minimization of subjectivity and thus their realignment,
- multiplying the preference scale by the table of results of the scoring analysis will allow for the realignment of the findings with the application of relations among particular criteria,
- the realignment will result in finding the design patterns of comparison websites which are considered best from the point of view of management, and which may be used in the creation of the design of the website of this class.

Initially, among the randomly selected five students of the Faculty of Management of the University of Warsaw and Academy of Finance and Business Vistula, declaring the use of comparison websites for making purchases, the authors carried out a pilot study concerning the factors which are most important when using software of this class. After the users' suggestions and as a result of standardization (unification of terminology and concepts of particular categories proposed by them), the following groups of characteristic features have been identified: design (visualization), information presented on the site and the ease of navigation, text search, data operations: selection (filtering) and sorting the results according to selected criteria and additional functionalities used for increasing user-friendliness.

Conclusions from the observation of students' behaviour supplied the initially established sets of features with the detailed criteria and subcriteria, which were thoroughly discussed with the respondents before placing them on the list used in the evaluation. The final list of criteria included:

- visualisation, information available on the website and the ease of navigation: brand awareness (the ease of memorizing data and reasons why we like the website), main page (readability and clarity of the main page, the ease of navigation and finding particular functions), the consistency of graphic elements, clearly marked colours, matching colours of elements, background colouring, icons symbolizing categories of products, colours and clarity of the text, carefully selected pictures of good quality, etc.), photo gallery (large, readable and clear images, which do not obscure navigation and present the actual features of the product etc.), completeness of information (characteristic features, minimum/maximum price, product image), clarity (appropriate font size, distinct colouring, the appropriate distribution of elements on the website), avoiding distracting elements (too much advertising, excessive number of photographs, etc.), opinions about shops (logo, delivery time, minimum price, clients' opinions), product reviews (if they are available, in what form, whether they meet clients' requirements), comparison engines (operating according to features specified by a client — e.g. price, number, delivery time), the ease of using categories (availability: lists, subcategories, characteristic features, etc.), the form of presentation of the product list (lists, different views, presentation according to the product features, icons, photos), rankings of products/shops (position in the ranking of shops/product categories), suggesting products (prompting — the latest model, at a similar price, other customers also bought ..., etc.);
- functionality of the text search (dynamic search of the selected product, without the necessity of looking through many categories): the accuracy of search results (the name of the product, the name of the product + producer, etc. combinations), prompting (lists displayed during the search, text field with autocomplete: prompting the name in the early selection stage, etc.), spellchecker (automatic correction of spelling);
- filtering and sorting results (simple and easy selection of products): filtering functionality (a large number of criteria, speed, limitations on operations which may be

performed by a client; the possibility of creating complex selection rules, etc.), sorting functionality in the product list (criteria of ordering and its combinations), sorting functionality in the list of shops (map, city, list according to prices);
- additional functionalities (functions improving usability) for the user (individually for websites): ordering at the level of a comparison site, memorizing a list of products, creating sets of products, loyalty program, the possibility of using mobile applications, price alert, tracking the changes concerning your favourite products (prices, characteristics).

In November 2013 the authors conducted surveys in the selected universities. Over 110 people filled the survey. Among the survey participants: women constituted 2/3, 1/3 of respondents were men. Most people, 80%, were in the age group of 18-25 — typical for students of full-time studies and 15% from the age group of 26-35 — characteristic of students of part-time studies. The participation of people over 35 years of age was small - 5%. 58% of the respondents were representatives of the cities with over 500,000 inhabitants, 22% of towns with 10-100,000 inhabitants, only 6% were from rural areas. Over 60% declared having secondary education, 28% were students of BA studies and 7% of MA studies. Three-quarters of the group declared the status of a student, 15% are employed in the private sector, 6% in the public sector and 4% are self-employed. Over a third of the sample belongs to the income group with over PLN 4,000 per month, 28% 2,000-2,500, 23% to PLN 1,500, and 12% to the remaining groups.

III. Analysis results by scoring method and their implmentation in the design

The first part of the survey available in the Internet and distributed in its traditional form was used to verify the importance and relevance of the list of criteria established in the interviews and direct discussions (information analysis) with clients of comparison websites (students) in a pilot survey. For all respondents, all the criteria connected with visualization, information contained on the website and the ease of navigation turned out to be the most important factors (34.2%). The second place was taken by the functionalities of the text search (33.8%); the last position (32.0%) was taken by the functionality of filtering and sorting results and additional functions improving usability. The differences in those groups were not very significant (up to 2 percentage points). For particular selected criteria, the differentiation did not appear to exceed (to a great extent) the observed results. The difference between the highest and the lowest scores amounted to 2.1%.

Relatively highest scores were assigned to the accuracy of search results — 5.68% and the completeness of information — 5.58%; the lowest were given to: suggesting products — 3.58% and additional functionalities — 3.83%. In total, this indicates the proper use of this tool (compatible with the objectives behind its creation) and its use in an elementary, rather than extended, range. In the case of website comparison websites, the evaluation of visualization criteria turned out to be very high — the graphic designs of home page obtained the score of 5.56%.

In the evaluation of the usability of criteria, 40% of responses were very high scores and about 31% of responses claimed that the criteria selected for the study were good: this means that almost 3/4 of criteria specified in the pilot survey are regarded as accurate. On average, only 3% of the respondents considered the criteria as poorly matched to the assessment of comparison websites. Small differences in the average scores do not induce the authors to reject any of the criteria. A similar situation occurs when we refer the average values of the obtained scores to the maximum possible score in the evaluation of comparison websites. In this way we obtained a list of functionalities of a comparison website which, from the users' point of view, best suits their expectations with regard to this type of service. Its importance has been verified by means of a survey conducted among the clients of selected comparison websites. All listed elements obtained more than 50% of the maximum possible value, so they may be applied in the ex post analysis of the existing comparison websites.

In the second part of the study, the authors conducted an examination of the comparison websites according to the previously adopted criteria. The examination analysed the four selected comparison websites which are the most popular among clients and the fifth one, which was selected individually by respondents. The first three websites: Ceneo, Skapiec and Nokaut have obtained a total score above the average; okazje.pl and individually chosen websites (different from the most popular ones (Cenuj.pl, Webkupiec.pl etc.)), are positioned below the average. Generally, there emerges one regularity which may be applied when establishing analytical characteristics for the project — it indicates which of the existing websites of this class can be used as a basic pattern to be imitated when creating a new website. Generally, we may conclude that Ceneo.pl will serve this purpose in the best way. However, the detailed analysis of the results is not so clear or univocal. In terms of the consistency of graphics, loyalty scheme and tracking the changes in the favourite products, the leading position is taken by skapiec.pl, in case of price alerts — Okazje.pl. Skapiec.pl, which takes a second position in the ranking, does not offer price alerts which are of considerable importance to clients. Okazje.pl, which takes the lowest place in the ranking, occupies the second position when we take into account the evaluation of the homepage and creating sets and a third place with regard to the photo gallery it presents on its website.

We can also consider individual sites taking into account the features which are evaluated as the best and the worst (see Table 1). In the most popular websites there occurs a puzzling consistency of the best and the worst scores. In other services some of the characteristics are beyond the scope of the list. Hence, we may assume that, basically, the most important elements of the comparison websites are: brand awareness, home page, consistency of graphic elements and the accuracy of search results. However, whenever a particular website feature receives the lowest scores, it points to the fact that

potential customers attach great importance to this particular element. Therefore, avoiding distractions, lack of spellchecker (or inappropriate corrections) and lack or limited number of additional functionalities should be added to the list. Also, we must appreciate the three remaining, important elements: completeness of information, the ease of using categories and filtering functionality. Thus, the design of the optimal comparison website should take into consideration at least the set of criteria presented in Table 1.

We may also analyse the results of the examination considering the number of scores in particular categories. Ceneo.pl was a leader in the ranking because it obtained the greatest number of very good scores. Also, the greatest number of good scores was assigned to Skapiec.pl, which came second in the ranking. The comparison website: Okazje.pl obtained the largest number of satisfactory or poor grades, other comparison websites — unsatisfactory. Nokaut.pl does not distinguish itself in any category. This table shows that it would be best to refer to the design patterns of ceneo.pl and Skapiec.pl when creating a new comparison website.

Apart from the possibility of limiting the number of basic features important for the creation of a prototype — which results from the studies of the existing websites in this category, the presented study shows a high discrepancy between the initial, average results of the clients' opinions concerning comparison websites and their characteristic features and average scores obtained from the ranking of the most popular websites existing in the Internet (see Table 3). Based on the initial evaluations, the first three positions are taken by: accuracy of search results, completeness of information, and the design of the homepage. When we take into account the evaluations of website analyses, the most important factors are: homepage, views of the product list, consistency of graphic elements.

The same situation occurs in the case of other features of comparison websites. However, if we consider not the values of the total of evaluations, but average values from initial analysis and the ranking of websites, then the importance of the features resulting from evaluations from initial analyses, more or less coincides with the importance of the features shown by the ranking of websites. What is the reason of such great variances between the opinions concerning the usefulness and importance of particular criterion for the evaluation of the comparison website, and low scores of these features in the analysis of particular comparison websites? It seems that the situation is caused by the users' awareness of high requirements which it should meet and, on the other hand, dissatisfaction with the implementation shown on the websites of existing comparison engines. It is also a clear indication for the system designer — we should not use the ready-made patterns in the cases where we observe high discrepancy between the user's expectations and the importance of the feature and its fulfilment. We should focus on these elements so that they are presented in the form which would meet the users' expectations.

IV. The Results of the Analyses of Comparison Engines by Means of a Conversion Method and the Application of the Findings in Project Works

The analysis by means of a scoring method (considered only from the point of view of a scoring analysis) faced the objections of far-reaching subjectivity [5]. The application of conversion method is an attempt to eliminate this subjectivity — the author's applied his own conversion method [14].

Here, we adopt the following assumptions: after constructing the experts' table of evaluations of particular criteria for each website, we need to perform the conversion with the established preference vector of the superior level criteria [2]. Next, the authors performs the transformation of the combined scoring table into the preference vector (first converter).

The next steps are:

- constructing a matrix of distances from the maximum value for each criterion in every website, establishing the maximum value; establishing the matrix of the distances from the maximum value, calculating the average distance from the maximum value for each criterion,
- as a result of the above operation, constructing a matrix of differences in the distance from the maximum value and the average distance according to criteria,
- for each bank website: constructing conversion matrices - modules of relative distances of particular criteria to remaining criteria (the distance from the same criterion is 0), the obtained distances below the diagonal are the converse of the values over the diagonal,
- averaging criteria conversion matrices — creating one matrix of average modules of values for all criteria,
- transforming the conversion matrix of criteria into a superior preference matrix (calculating squared matrix, adding up rows, standardization of the obtained preference vector; repeated squaring, adding up rows, standardization of preference vector — repeating this iteration until there are minimum differences in subsequent preference vectors).

As a result of the above operations we establish a criteria conversion matrix.

Subsequently, the author performed a transformation of the scores presented by experts on the level of a matrix specifying expert websites' evaluations for particular criteria (second converter) [14]. The results have been obtained in an analogical way:

- constructing a matrix of distances from the maximum value for each criterion and each website establishing the maximum value; establishing the matrix of distances from the maximum value,
- calculating the average distance from the maximum value for each website,
- constructing a matrix of the differences of deviations from the maximum value and the average distance of the features from the maximum,
- for each criterion: constructing a matrix of transformations (conversions) of the differences of the average distance from the maximum value between the websites,

TABLE I
THE MAP OF THE WEBSITE CRITERIA WITH THE HIGHEST AND THE LOWEST SCORES (WHERE: G - BEST-RATED FEATURES, B - WORST-RATED FEATURES)

Description/Website/Evaluation	Ceneo	Nokaut	Skapiec	Okazje	Other
Brand awareness	G	G	G		B
Homepage	G			G	G
Consistency of graphic elements		G	G	G	
Photo gallery				G	
Completeness of information					G
Avoiding distractions	B	B	B	B	
Product reviews				B	
Product comparison engines				B	
The ease of using categories					G
Accuracy of search results	G	G	G		B
Spellchecker	B	B	B		
Filtering functionality					B
Additional functionalities	B	B	B		

TABLE II
THE PERCENTAGE ASSESSMENT OF PARTICULAR COMPARISON WEBSITES

Evaluation/Comparison website	Ceneo.pl	Nokaut.pl	Skapiec.pl	Okazje.pl	Other
Unsatisfactory	3.50%	4.00%	3.45%	10.65%	**45,68%**
Poor	8.94%	18.55%	15.36%	**23.49%**	19.14%
Satisfactory	27.66%	32.55%	27.12%	**33.66%**	19.14%
Good	40.95%	33.45%	**41.38%**	24.70%	9.26%
Very good	**18.96%**	11.45%	12.70%	7.51%	6.79%

analogically as presented above (the distance for a particular feature in the same website from the same website is 0), values below the diagonal are the converse of the values over the diagonal,
- constructing a module matrix of transformations of the differences of average distance from the maximum value between the websites, for each criterion,
- for each module matrix of transformation of the differences of the average distance from the maximum value between the websites, squaring it, adding up rows, standardization of the obtained ranking vector and repeating this operation until the obtained differences between two ranking vectors for each criterion will be minimal.

As a result of the above presented operations we obtain a conversion matrix of websites' evaluations: using the obtained vectors to construct a combined ranking matrix

- heading names of bank websites by appropriate transfer of the obtained preference vectors for each criterion,
- multiplying the matrix obtained in such a way by the previously calculated preference vector,
- analysing final results and drawing conclusions (Note: the lowest distances in this case are the most favourable, comparability adjustments to other methods can be obtained by subtracting these values from 1 and their repeated standardization).

The basis for the creation of the presented method was the assumption that it should be easy to apply. The objective has been reached, which is visible in the number of the advantages presented below. The only disadvantage of the method is the fact that the transformation of the results of the survey is connected with carrying out many complex operations.

The advantages of this method are:

- the ease of application (similar to the realization of a scoring method) which results from the fact that in the survey form there are questions concerning the subjective evaluation of the element,
- in the case of considering a large number of evaluation criteria or alternatives there is no significant increase in the number of questions in the survey,
- the possibility of the application of the method with the participation of people who are not experts in a given field,
- there are no measures, as in the case of e.g. ELECTRE method — veto threshold, which may not be fully understandable for the respondent [14],
- the result of the calculations which takes the form of the importance of the evaluations of the examined objects.

Similarly to previous cases, the application of a conversion method resulted in flattening of the obtained results. It reduced not only the differences between particular comparison engines but also the differences among particular evaluation criteria. As a result, the obtained findings minimized the subjectivity of the evaluation, and additionally — as it turned out — brought the results closer to the findings of the preliminary analysis of

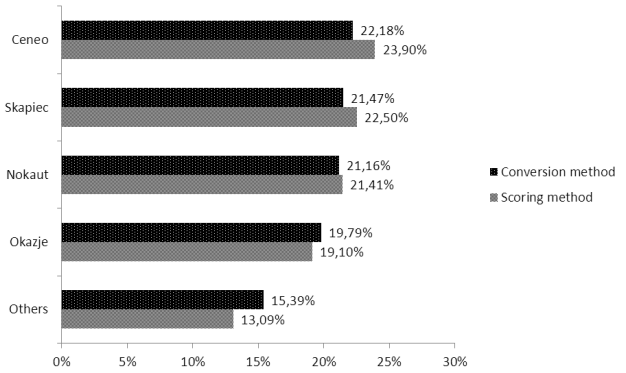

Fig. 2. Ranking of selected comparison engines websites according to a scoring method and a conversion method

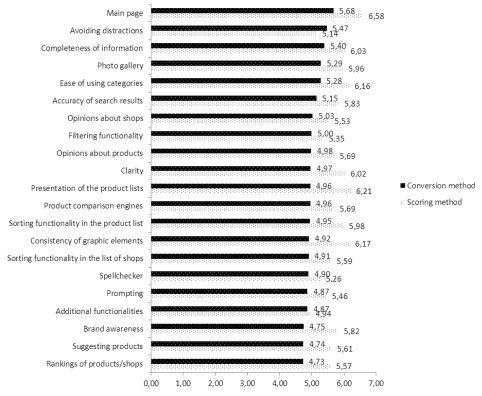

Fig. 3. Ranking of the degree of usefulness of particular criteria in the evaluation of the quality of comparison engines according to a conversion method and a scoring method

the requirements of comparison engines users. Figure 2 shows the results of calculations carried out by means of the scoring method and the conversion method brought to comparability.

In this case the conversion did not bring about any changes in the order of the evaluated comparison engines: it reduced the distance between them in such a way that for the engines which came first in the ranking there occurred differences in minus, and for the last ones in plus. Still, we can conclude that ceneo.pl may be seen as the best service among those selected for the evaluation.

However, there are no regularities with regard to the differentiation of criteria allowing for the detailed evaluation of each website. In this case we noted the reduction of the distances among the criteria. Also, the order of their evaluations changed in a significant way. The first positions were taken by: main page design, avoiding distractions and completeness of information about a product; the last ones were: brand awareness, suggesting products and rankings of products/shops. Only a third of the obtained criteria values exceed the average; thus, we may conclude that only those criteria may be seen as a model to be followed.

V. Conclusions

On the basis of the above results we can create — similarly as in the case of the application of the scoring method — the detailed basic pattern — a prototype which is a compilation of the best features of comparison engines, selected on the basis of the users' evaluations. This prototype should be confronted with the users' expectations established on the basis of their individual preferences.

The obtained findings (see: Table 3) allow for better matching of the results obtained in the rankings by means of conversion method (three times better than in the case of a scoring method). In this case good adaptation does not offer too much room for manoeuvre with regard to the selected evaluation criteria; however, it points to users' awareness of the most important features of the comparison engines.

Particular attention should be paid to those criteria where the discrepancies in the evaluations of the users' expectations and their realisations were the greatest. In subsequent iterations by way of "confrontations" (within the limits established by the obtained pattern), we refine the final prototype, and proceed to the next stage of the project. In the case of the application of a scoring method in the study, the discrepancies were significantly larger and concerned over 50% of the indicators. In the case of the application of a conversion method they do not exceed 10%. Further studies, however, may show whether there is a regularity resulting from the characteristics of a conversion method or it is just a coincidence.

The research is an extension of the previous one and will be continued. On the basis of the study findings the next method supporting website assessment will be applied. This time AHP/ANP method (T. Saaty) will be used, because it allows to remove (even better then conversion method) subjectivity of evaluations from the respondents questionnaires. Then, the selected methods of assessment websites will be compared with respect to their suitability for use inside a confrontational pattern-based design method. So, the theoretical and methodological achievements of this research will be enhanced and the verification will be conducted on the example of next Polish websites and portals.

Semantic Organization of Information Resources for Supporting the Work of Academic Staff

Ilona Pawełoszek
Technical University of
Czestochowa, Al. Armii Krajowej
36B 42-200 Częstochowa, Poland
Email: ipaweloszek@zim.pcz.pl

***Abstract*—The paper presents an on-going project in developing a semantic information portal for academic institution. The concept of a semantic platform called SemLib, grew out of many academic discussions and it reflects the information needs of researchers and educators from Technical University of Czestochowa. The proposed method of needs assessment is especially designed to create the starting point to build semantic structure of the digital library. The author proposes an approach for managing, organizing and populating knowledge by semanticizing existing information resources in the digital and traditional paper form. The prototyped solution is based on the Semantic MediaWiki software, that allows for cooperative resource building, maintaining and offers enhanced querying capabilities. Experimental results demonstrate the potentials of the proposed system as well as some obstacles that are the subject to improvement by further development of the SemLib platform.**

COLLABORATION and exchanging knowledge are vital to the effectiveness of the work of academic staff. In a world permeated with information technology and overwhelming amount of data there is a growing need to improve tools and methods of organizing information resources. The intelligent content management tools are crucial factor for every large organization.

In today's economy the universities play important roles of teaching and research. They are "central generators and repositories of knowledge in our society" [17 p.5].

At present it seems that the most successful research projects and most remarkable publications are characterized by their multidisciplinary environment and ability to tackle research challenges on a broader, wider scale. Effective collaboration and knowledge sharing requires the right information to be published and easily accessible to community members and external stakeholders (like enterprises and public administration seeking for academic partners to cooperate).

Discussions among academic community members reveal their unsatisfied information needs, and necessity for robust knowledge sharing and communication tools [16]. A remarkable improvement can be achieved by harnessing together Semantic Web and social networking tools. Such a combination is often referred to as Web 3.0 [18].

The aim of this paper is to present the concept of information portal based on Web 3.0 paradigm to organize information resources to support the university researchers and educators in their tasks. The main emphasis has been put on identifying and creating the semantic structure of the information resources in a way that would make them most useful and accessible.

I. The need for Semantic Organization of Information

University faculties often have hundreds of employees in teaching and scientific positions, whose tasks are "knowledge intensive" and require the access to the up to date resources including: books, journals, whitepapers, educative multimedia etc. A lot of these resources are created by the academics themselves and published in printed or electronic form. Even if the information is available, it may not be easily accessible, especially if we consider a large collection of information sources spanning diverse domains.

A number of discussions with academic staff of the Management Faculty of Technical University of Czestochowa revealed that the information in many cases is poorly accessible and the information flow between employees is impeded by the lack of appropriate IT solutions.

The activities like teaching, research, organizational tasks, writing publications and self-education, determine the information needs of the academics. Both the electronic and the printed form, appear to be poorly usable in terms of searching for particular information. Having hundreds of volumes such as manuals, conference proceedings, journals close at hand doesn't mean the information they contain is easily accessible. It is always easier to use search engine than to leaf through a book searching for a definition, reference or a person who is recognized as an authority on the given subject. The Author's own experience as well as the multiple discussions with coworkers acknowledge that even having the files in the electronic form (i.e.: pdf, doc or html files) is not very convenient for searching for particular information and it is one of the most time consuming task in the work of academics. Most of the local and global search engines serve a keyword-based method of finding information and are not able to respect the context of the query or to process the detailed query attributes. Finding information is a part of everyday work of every educator or scientist.

978-83-60810-58-3/$25.00

There are many reasons arising from the policies of educational institutions as well as global circumstances that compel the authors to promote their work to be cited by other experts in their domain. On the other hand the authors are supposed to contribute to the domain knowledge, and take into account "the state of the art" of the subject they are working on. Therefore the scientiometric evaluation is important for all of the academics.

In all types of scholarly research it is necessary to attribute the author and the source of information that underpin particular concepts, positions and arguments with citations. This good practice is important due to a number of reasons:

• the citations help readers to identify and retrieve the source work to verify the information, or to learn more about issues and topics addressed by the work,

• citations provide the evidence that the subject is important and grounded in prior research,

• by citing one gives credit to the author of an original concept or theory presented.

For these reasons, it is important to build the systems that facilitate the bibliographic description of information cited in an organized and thorough manner. At the same time there is a growing need for creating effective search engines oriented towards supporting the retrieval of scientific information.

II. The Concept of Semantic Organization of Information Resources

Currently the Semantic Web technology solutions are based on ontologies that describe the structure of domain instances, their classes, attributes, distinctions and relations. The term "ontology" in the context of information sciences and artificial intelligence is most often defined as an "explicit specification of conceptualization" [1]. Such specifications are necessary for knowledge representation and exchange [2]

A conceptualization can be defined as: an intentional semantic structure that encodes knowledge of a piece of some domain. Ontology is a (partial) specification of this structure, i.e., it is usually a logical theory that expresses the conceptualization explicitly in some language. Conceptualization is language independent, while ontology is language dependent. [3]. A shared or common ontology refers to an explicit specification of concepts [4, p.99] which can be used by a group of people or program agents in a multiagent system.

Ontologies can differ in terms of their expressiveness. Constructing ontology-based systems is time-consuming and must be realized by highly skilled staff – knowledge engineers cooperating with domain experts. For some applications it is worth the cost, i.e. investing a lot of time and effort in constructing a 'perfect' ontology, but in many cases this is not feasible [5 p.10]. There is always a need to balance the tradeoff between the complexity and the effort (and cost) of construction and maintaining of the ontology in question.

Thus there is a growing number of methodologies that specifically address the issue of ontology development and maintenance, for example:

• The methodology by Ushold and King [6] – worked out for the construction of Enterprise Ontology. The most interesting part of the methodology is the procedure of informal ontology development which is based on creativity techniques (brainstorming) to develop an informal ontology that can be easily understood and many people and works as a starting point to formalization.

• METHONTOLOGY by [7] is an example of evolutionary prototyping methodology that consists of a set of activities based on ontology life cycle and the prototype refinement;

• AFM:Activity-First Method in Hozo proposed by [8] is a method of building ontologies of tasks and domains by exploiting technical documentation. The task ontology provides the set of roles played by the users in the context of a given task. The domain concepts are organized according to the identified roles.

• 101 Method [9] is an iterative approach to ontology development. The method was worked out for the needs of development of wine and food ontology, using the Protégé-2000 environment. The 101 method proposes four activities for the development of an ontology: (1 definition of the ontology classes; 2) organizing the taxonomy of classes; 3) defining properties of the classes and their permitted values, and 4) filling the attributes values for the instances.

It seems there is no just one best methodology for developing ontologies that would be useful in all cases and could become a standard. The above-mentioned methodologies extensively rely on human creativity and skills. Despite many semi-automatic approaches that have been developed, the ontology construction is still an art rather than craft.

The semi-automatic ontology construction is still a relatively new concept. These approaches are often referred to as ontology learning (OL) techniques. The example of such a semi-automatic approach is presented by [5], and focuses on constructing enterprise ontologies to be used for structuring and retrieving information related to a certain enterprise. The ontologies are quite 'light weight' in terms of logical complexity and expressiveness.

The semi-automatic ontology construction requires creating rather complicated algorithms based on NLP (Natural Language Processing) techniques, therefore these are specific methods for solving partial problems.

III. The Methodology for Identification of Semantic Structure

To the needs of our project (called SemLib – the abbreviation of Semantic Library) we decided to adapt and particularize the aforementioned general frameworks of manual ontology building based on human experience. The semantic organization of information resources can be defined as a process consisting of the following steps:

1. Gathering electronic documents and metadata about printed documents and objects.

2. Identification of the semantic structure - a global structure of information in a document base.

3. Choosing a tool and a formal language for designing ontology and describing information resources.

4. Designing an ontology - network of semantic knowledge.

5. Applying the formal language to annotate the documents according to the structure identified in step 2 with the chosen tool.

Our methodology of organizing information resources is especially dedicated to the situations where there exists the set of documents that must be semanticized according to user's needs in a multidisciplinary users community.

Semantization of a document base means adding data and structure to the documents to make them understandable for intelligent search engines [see also: 19 p.70].

The first task is to decide about the scope of documents that are to be organized in the semantic structure. In our case the resources include:

- The users profiles containing the information about: the scientific degree, professional affiliation, interests, position. The users profiles already exist on the website of the university, but they are useless when it comes to search for the persons with particular attributes, professional background, interests etc.
- Publications: books, journals, whitepapers, reports, educative multimedia etc.
- Descriptions of research projects and grants – it is an important information while searching for partners with professional experience in particular field.
- Descriptions of external institutions cooperating in research project or education.

A lot of these resources are created by the academics themselves and published in printed or electronic form. Surprisingly both electronic and printed form, appear to be poorly usable in terms of searching for particular information. Having hundreds of volumes such as manuals, conference proceedings, journals close at hand doesn't mean the information they contain is easily accessible. Therefore the semantic organization of information resources is the prerequisite of semantic processing and searching.

Some of the aforementioned resources usually cannot be directly semanticized because their document format does not allow for adding annotations. Therefore in this case only the metadata can be the representation of the document on the semantic platform. The semantic platform plays the role of the catalog consisting of metadata of things that exist in a real world (employees, organization units, electronic and hardcopy documents). Some of the documents can be directly semanticized – the precondition is the possibility to transform the document to HTML format and having the copyright that allows to use, publish and edit the content.

The identification of the document base semantic structure can be performed in different ways. For example [10] propose systematic and automatic approach to ontology construction through the automatic identification of keywords from a corpus of randomly collected unstructured texts.

Different approach is presented in the study of [11]. The authors present an approach that starts with a list of relevant domain ontologies created by human experts, and techniques for identifying the most appropriate ontology to be extended with information from a given text.

Although the automatic approaches are very accurate they can be applied only to the texts in a specific domain. In our case study the documents are heterogeneous considering their domains and their structure. For example the descriptions of the academics, their scientific and professional attainment may differ significantly. On the other hand the descriptions of literature (journal articles, monographs and other publications) have quite similar bibliographic structure and can be easily cataloged using common metadata format like Dublin Core. The descriptions of projects realized by the academics can also be multidisciplinary and differ in terminology.

Therefore the automatic approach to ontology extraction would require to distinguish many categories and to run the procedure many times to extract separate ontologies. The next step would be mapping the ontologies because the documents from different categories are interrelated.

Taking into account the multidisciplinary character of the designed platform and the requirements of usability and maintainability we decided not to use automatic methods of ontology extraction and concentrate on recognizing the users' information needs as a base of ontology construction.

The semantic structure of the document base should be first of all meaningful and relevant for the users. The functions of the platform should be adjusted to the context of the work tasks of the users.

The next section describes the method for identifying the semantic structure in the context of the users work.

The aim of the designed solution is to fulfill the information needs of the users by exploiting the easily accessible document base with a semantic query interface. An information need is a gap in one's knowledge[12] that can be bridged by providing an answer to a question. Thus asking the users to specify the questions they ask while searching for information seems to be the most appropriate research method in this case. Table I summarizes the questions specified by 20 potential users of the system, the questions were assigned to the groups that represent categories of objects described in the document base. The categories reflect the areas of professional activities.

The areas of context are general categories (classes) of objects. Questions represent attributes and/or relations between objects.

For example finding "experts in particular domain" (let us call the domain: X) can possibly involve finding the persons who participated in conferences and projects in the domain X or teaching subject X.

The next important thing to specify was the form and the particularity of the answer to our questions – what additional information is to be displayed. This additional information presents the context of the query (Table II).

In our example of finding experts in the given domain the query result could include: The names of the persons inter-

TABLE I.
THE QUESTIONS SPECIFIED BY POTENTIAL USERS OF THE SYSTEM

Question about:	Categories of objects								
	publication	Person	Organization structure	External institutions	Projects	Conferences	Lectures	Domains and subjects	Places
Definitions	x							x	
Research results	x							x	
Research methods	x							x	
Citations	x	x							
Scientific degree		x							
Workplace		x	x						x
Experts in particular domains	x	x			x		x	x	
Universities and academic centers				x					x
Articles about a given subject	x						x	x	
Citations in articles	x								
Taking part in projects as a member of the team or leader		x			x			x	
Conducting individual research,		x	x		x			x	
Participating at conferences,	x	x				x			x
Authoring and co-authoring of research papers, books, chapters, etc.	x	x							
Editorialship of scientific publications	x	x							
Educational Multimedia resources							x	x	
Being in charge of organizational units		x	x						x
Cooperation with industry				x	x		x	x	x

ested in domain X, the scientific degrees, the affiliations, number of citations, number of research projects.

IV. THE SEMANTIC SOFTWARE PLATFORM

In order to benefit fully from the networked information it is vital for organizations to have a single point knowledge shop for quality information with certainty, authority and consistency. [4, p.103]

Today's software platforms are designed with the architecture of participation in mind, this means they are meant for active user contribution in creation of content, functions and services. Web 2.0 platforms continuously grow in popularity due to the phenomenon of "network effect" which is driving force behind a number of users joining online communities [13].

Information portals allow easy access to heterogeneous data resources, applications and services in a consistent way.

Portals may also improve corporate communication by exploiting various tools based on Web 2.0 paradigm. The semantically enhanced information portal SemLib for the community of academic staff was meant to be a user-centered web application exploiting selected Semantic Web technologies and adhering to the following requirements:

- Scalable and extensible architecture.
- The portal content should be created, reviewed, published, and managed by web Content Management System (CMS) using well-defined content authoring and publication process. web 2.o architecture seems to be the best choice considering the large number of internal stakeholders and the dynamics of information (new publications will be added frequently).
- CMS should provide multiple authorization levels.
- Users, involved in editing, reviewing and publishing content.
- Easy semantic query interface – many Semantic Web technologies like RDF and OWL only offer a SPARQL query interface, which is difficult for users not having SPARQL expertise and no background in knowledge engineering.
- The portal should serve as a tool for promotion of scientific research and collaboration.

After considering the above requirements, we chose Semantic MediaWiki (SMW) as the platform to present the structured knowledge and manage the knowledge reasonably.

The aim of wiki is to organize and share information resources in a collaborative environment. Collaborative authoring is the effective way of creating knowledge proved by many examples, of which the most spectacular is Wikipedia. Apart from many advantages and flexibility, the MediaWiki platform is not free from shortcomings. The main disadvantage is the lack of knowledge structuring functionality. The answer to this shortcoming is Semantic Mediawiki package which is a set of extensions that provide semantic annotations and reasoning features.

The SMW achieves most of the requirements we preset while few of the requirements cannot be fulfilled and some of them cannot be directly realized. SMW is a free and open source extension of MediaWiki, released under the GNU Public License. SMW collects semantic data by letting users add annotations to the wiki source text of pages via a special markup [14].

The additional features of MediaWiki, such as the possibility of setting the authorization for the groups of users, and searching for historical changes extensively facilitates management tasks.

One of the most important advantages offered by Semantic MediaWiki is its semantic query language that lacks the complexity of SPARQL (e.g. querying within a particular namespace) [15].

Semantic MediaWiki has become the most popular semantic wiki engine by far, achieving several hundred installations worldwide and engaging an active open source developer community.

V. The Semantic Structure of the SemLib Platform

The semantic structure defines the categories, subcategories and attributes of the entities described in the document base. The attributes can also be categories. The seman-

TABLE II.
EXAMPLE INFORMATION NEEDS AND CONTEXT PARAMETERS

Needed information	Query context parameters
definitions of concepts	author, year of publication, Author's affiliation
research reports and results	author, institution, year of publication, geographical region, branch
citations of one's own publications	years of the referencing work
figures, tables, charts	subject, year of publication, relevant definition
multimedia	creator, subject, year of publication, file type
bibliographic references	year and place of publication, isbn or issn, author/authors
potential partners in project realization or coauthoring.	people, interests, authorship, participation in projects
conferences	subject, place, publication type, price

tic structure was designed according to the users' information needs unveiled by the survey. The structure of the information needs were analyzed from the point of view of categories and attributes. Figure 1 presents the simplified class diagram with relations between categories defined and applied in the SemLib prototype platform. Some of the relations were omitted on a diagram to make it more legible. For example an article can be understood as a part of the journal or as the book chapter. We decided not to define the separate class for the entities like book chapter and article because they would have exactly the same attributes. Although it can be inferred that if an article is a part of the book it can be called a "chapter", so it would be possible to display the separate lists of articles and chapters if needed. The relation "is written by" can contain multiple values, each of the values points to one entity of the class "Author".

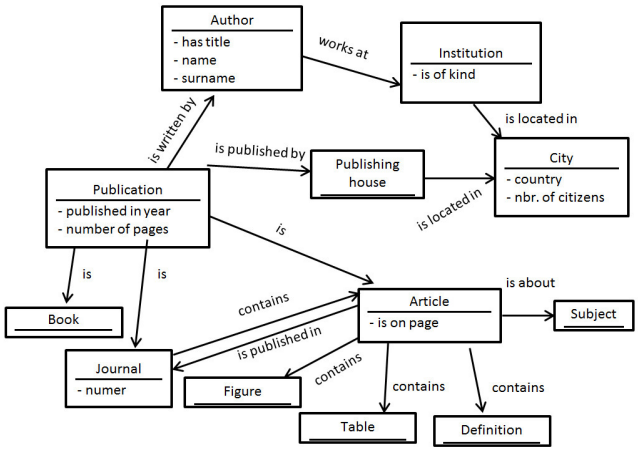

Fig. 1 Classes and relations in a prototype semantic platform

Source: Own study

The presented data model allows to ask compound queries respecting many context parameters.

The "subject" class that is used to categorize the content of publications, has many instances of the hierarchical structure. The example fragment of marketing subject class is:

- Marketing
  - o Customer relationship management
  - o Marketing mix
    - Promotion
    - Advertising
  - o Web marketing
  - o Customer service

The subjects hierarchy facilitates annotation tasks. For example if the described article is annotated with the tag "advertising", the search engine "knows" that the article is from the marketing domain although it may not be explicitly written in the page describing the given article.

Descriptions of example queries and their syntax are presented in table II.

The list displayed by the query 1 will also contain articles about promotion and advertising although they are not annotated with the word "marketing".

While designing the semantic portal based on SMW there is no need to define the whole categories structures in advance. For example the categories of subjects are created or developed when there is a need to describe the particular publication from a given domain. This ongoing iterative development approach will probably bring a better result of more accurate tagging if we assume that the authors will add their own publications in the domain of their expertise.

Analogously there is a possibility of searching for relations between projects, conferences and persons, so it is possible to list for example "all the publications from conference Y authored by person X" or "all the conferences in which the people from University C took part".

There are a lot of combinations of attributes and categories. Such lists can be settled according to date, place, institution, person and practically every attribute defined in the system. This functionality is very useful while preparing reports about activities of the University departments or individual employees.

Although the semantic wiki query syntax seems easy and intuitive thanks to its similarity to natural language the practice shows that after some time of disuse it is hard to remember the names of attributes used to pose the queries.

For now we are developing a help system in the form of example queries which users can modify according to their current needs. The example queries that were included in help system were chosen from the most often input queries. Additionally the users can use special wiki pages for listing the categories and attributes existing in the system. The namespace for special pages listing categories is: Special:Categories

VI. Conclusion and Future Work

The SemLib platform is very flexible and the directions of its evolution should be determined by analyzing the users' needs. The needs assessment method consisting in formulating example queries posed by users proved to be an appropriate and agile way to transform the users' needs to semantic categories and attributes.

The platform has been created and developed at Technical University of Czestochowa to complement the missing semantic functionalities of the existing information portals.

Probably the most time-consuming part of the discussed undertaking is the developing, maintaining and annotating the document base. Semanticizing the publications from conferences, journal articles and monographs is rather tedious task in spite of forms and templates that are accessible in Semantic MediaWiki interface. But the effort may turn out to be worthwhile if the portal brings results in facilitating collaboration and information access. It is hard to evaluate the success of the semantically enhanced portal in a quantitative way. Some measures can be applied, like: precision, recall, time spent to get answers to particular questions comparing to traditional keyword search or literature browsing, the number of emerging research teams or publications co-authored by groups using the SemLib platform.

At present the SemLib platform is continuously developed and it is perceived very promising and innovative.

Having all the metadata at hand makes the work faster when it comes to find particular information in the library. It is also possible to prepare multiple reports from the scientific activities much faster. The future research directions can encompass the proposition of a detailed methodology of assessing the performance of the system.

Apart from all the advantages there are also some obstacles that are subject to further considerations and development. One of potential problems is the possibility of inaccurate annotations. An idea to overcome that problem is to engage the community of end-users. If we assume the users are experts in their subject it is undeniable that after a short training, they can do the tagging far more accurately than the system administrators who will only perform the controlling functions.

As the practice shows the wiki passive users (the persons who are not editors) encounter some difficulties in using SemLib. The most often reported one was the lack of knowledge about wiki functions in general. Not all of the users seem to understand the nature of the wiki and the need for respecting some organizational guidelines, e.g. using the categories and attributes defined earlier by other users. Moreover it is in the interest of the users to describe their own publications in a way that ensures they will be frequently found, retrieved, and consequently more often cited.

The SemLib would be far more useful if all the described resources (books, journals, articles) were accessible in electronic form and linked directly to the semantic wiki site where they are described. Transformation of all the library resources to electronic form is inevitable in the future, but it requires a lot of work and changes in the copyright law. The old fashioned fossil library catalogs of publications do not have a potential to reveal the full value of information resources they describe because their data models are not flexible and cannot be easily adapted to dynamic users' needs. The semantic technology along with cooperative editing tools like MediaWiki support a community of participants, who interact with the content to varying degrees based on their permissions. All participants can be creators, editors, and curators [20].

The SemLib platform is quite new project that is still in the development phase, but we continuously add new publications to the semantic base and at the same time we are working to expand the ontology of research topics.

We are working on the concept of the more intelligent query interface that is based on the idea of contextual hints displayed to the user after analyzing the part of the query that has been already input into the search box.

***Abstract*—The article describes the obstacles that may arise during the planning phase of the project – Regional Business Spatial Community. The authors are working on a project to prepare RBSC . It involves creating a community around a selected GIS (Geographic Information System) software available in Cloud Technology. In the design of the project, the participants should be all the entities responsible for creating the infrastructure of the region. After conducting preliminary discussions with potential participants, the authors paid attention to the barriers and problems that threaten the planned project. Therefore, in the course of the study they drew attention to the mentioned aspect. The study identifies four groups of barriers: organizational, psychological, technological and financial.**

The authors also conducted empirical research to identify the most significant barriers to the creation of RBSC . The study involved five institutions providing utilities (gas, water, internet, TV) to the residents of the city . The results showed that the most significant barriers are organizational and psychological aspects. Slightly less importance is attributed to technological and financial barriers.

I. Introduction

REGIONAL infrastructure is one of the basic elements defining life standards and security of inhabitants in a given region. The aforementioned infrastructure consists of different elements, such as: roads, telecommunication, energy and gas networks, plumbing and different ones. Creating and maintenance of the mentioned elements of infrastructure are the obligations of many different entities, for instance enterprises functioning on commercial principles, community partnerships, government or local government departments or public services. All mentioned entities are interdependant.

Admittedly, decisions about the development of self-activity, at least a part of them, can be self taken, however, huge investments often demand intercommunication among the representatives of the selected entities. The necessity of the data exchange occurs, among other things, during planning and execution of municipal investments, crisis management [1] or different types of modernising infrastructure of media situated close to one another.

The authors of the study are working on the project called Regional Business Spatial Community (RBSC) - [2]. It seems that all the projecting entities, designing, owning or maintaining media should be interested in creating a proper system which enables data exchange and undertaking the cooperation within the confines of the suggested undertaking.

For the sake of the realization of RBSC, the GIS software functioning in Cloud technology available on the market was analysed, the group of potential entieties which should be interested in the creation of the suggested undertaking was selected and the condition of their IT infrastructure was examined.

The present study was dedicated to the analysis of the barriers which were singled out during the research and can make difficult or even impossible the realization of the mentioned undertaking.

II. The Idea of Regional Business Spatial Community Based on GIS in Cloud Technology

The idea of RBSC assumes the use of the Internet as the communication and spatious data exchange platform between the partners. After the analysis of GIS tools it was assumed that for the needs of the suggested project, the possible solution would be the use of Cloud Technology [3]. The mentioned technology enables a direct access to the worked out system (within the confines of the possessed entitlements) and the data content. It also enables electronic communication between the partners.

The worked out RBSC conception is based on the following assumptions:

- the GIS tool available in Cloud Technology is necessary,
- within the confines of the tool, a closed room, available for the entitled users only, is created,
- a communicator available for all the members of community functions within the confines of the room,

This work was not supported by any organization

- all the entities responsible for the infrastructure of a given region are invited to the community,
- the owner of the GIS tool is provides with the basic spatial data (geographic data),
- the other entities provide spatial data concerning their own infrastructure,
- data provided in the GIS tool should be accurate with the dictionary system and the codes used in the internal IT systems of the users (internal integration of different types of IT systems is desirable),
- participants of the community have access to the data on the basis of their entitlements,
- within the confines of RBSC, processes and code of conduction can exist.

The aim of creating RBSC is to build a platform enabling the access to the currently updating data concerning the infrastructure of the region [2]. By means of the communication tools, it will be possible to make arrangements between the entities concerned, involving different current or being planned investments, concerning the crisis management as well [4]. Within the confines of the tool, it will be possible to create a set of procedures facilitating the selected procedures of cooperation (on the level of investment planning or crisis management for example) (see also [11]). It can also be assumed that the provided maps will be intelligent. Due to it, it will be possible to capture all the problems arising on the project level (the representatives of the concerned entities will be informed currently about it) or they will facilitate the valuation of the arranged activity, for example. The conceptual model of RBSC is shown on figure 1.

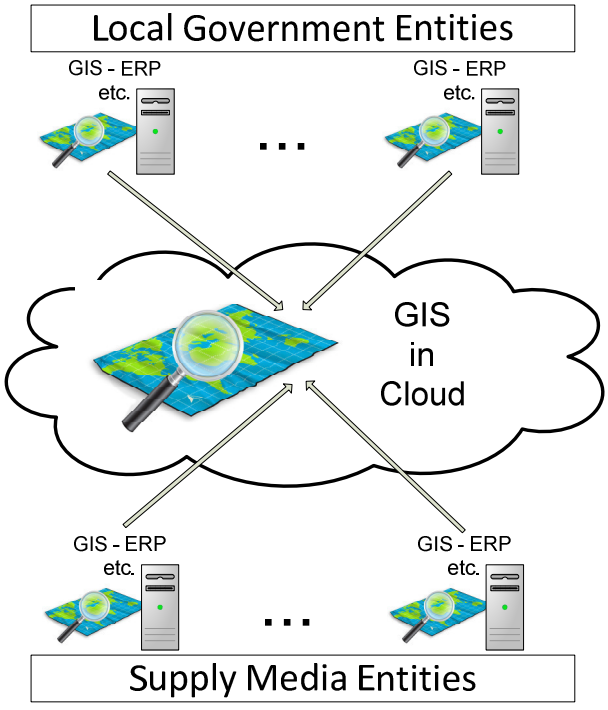

Figure 1. The conceptual model of RBSC
Source: [2]

Technological basis for the suggested project should be GIS tool available in Cloud Technology. Within the confines of the tool, the GIS software for visualisation, as well as actualisation of maps and project purposes should be enclosed. The supplier of the device should also provide the layers of maps which describe geographical object of the region. The demand of map intelligence means that the necessity of the description of link between individual layers of maps may be necessary. Intelligent maps would facilitate the process of infrastructure designing (pointing at all the potential conflicts in the infrastructure and enabling the preliminary valuation) – [5].

The use of Cloud technology system solves the problem of localization of the constructed system. The provider of GIS system in Cloud technology indicates the rules of access for the entitled users (the example is [6]).

RBSC are assumed to have limited territorial access of interaction. Usually they can apply to singular agglomeration, second level administrative units, however, only in the case of big systems they can include whole regions. As a result, one elaborated system can be duplicated in future for users from a different region. Generally, individual regions should be closed rooms. However, it may occur that some entities such as telecommunication enterprises can work in many regions. Then, the software supplier should decide the rules of using many rooms.

While creating electronic communities [7], the possibility of using GIS software only is not enough. GIS tools must be complemented with communicators which enable electronic consultation between the partners. It is vague especially in the case of these regions where the management or units responsible for designing and maintenance are outside the region. Due to this fact their share in the works of the agreement team (organized, among other things, during undertaking municipal infrastructural projects) is made more difficult. Another element which can be joined to the system is the tools used for designing processes (based on, for example; BPMN [8], BPML, UML, OWL and different ones). The mentioned tools enable to describe the procedures which would be conducted within the designed system. Introducing them can become the development of RBSC project.

The planned project originally should include all the entities responsible for the regional infrastructure. They can be, among the others, public administration offices, state or local government agencies, companies that provide utilities (municipal and commercial), and, to a limited extent, other social organizations and companies performing service functions with respect to infrastructure managing entities in the region.

Practically, in the initial stage of the project, a limited number of entities can join. Only with the development of the project other partners can join.

The supplier of the tool can be both a commercial company and the relevant departments of the State Geodetic. This second type of entities can provide the basic layers of maps. The suppliers of communicators and business process design tools can be commercial enterprises or groups of users working on the project. Using spatial data is done on the basis of reciprocity. Operators shall provide each other their spatial data and/or lexical systems and codes for the managing items of infrastructure. Most of the companies that form the infrastructure use in their business different IT systems, such as: MRP/ERP/BI, CAD/CAM, CRM, GIS. The used systems can be at different levels of internal integration. Taking part in RBSC should favor making work on the integration of internal integration and then support the integration of data available in GIS systems. The mentioned integration should not only allow the exchange of data between different systems, but also the creation of a coherent dictionaries systems and codes used in scale of enterprises, as well as in and RBSC. Each participant of RBSC receives appropriate permissions to use the data depending on several factors. These factors include, among the others: the existing law on the rights of access to data, the scope of services of its own data, the scope of the purchased rights (access to selected functions of the created system can be determined on a commercial basis). RBSC is meant a social enterprise rather. Admissibility of commercial solutions stems more from the need to maintain the system and the need to finance its development.

Preparing the project, it was taken into consideration that it is complex, both organizationally and technologically. Therefore, its conduction would be a multistep process. Its launch and eventual success will require overcoming many barriers.

III. TYPOLOGY OF BARRIERS

RBSC is a complicated undertaking mainly due to a large number of potential users coming from different organizations. Another problem that hampers the realization of the suggested project is of the environment system. It consists of several independent entities, none of which has decision-making powers to others. Environmental data binding components are only specific state legislation created by local law (enacted by local governments - concerning, inter alia spatial region), and the sense of community of interest (ie, projects that require collaboration infrastructure entities forming regions).

RBSC Organization should be treated as a project on two levels: organizational and technological. Its implementation should be carried out according to the methodology used in IT Projects.

Generally, IT Projects are carried out in several stages: the planned projects, analysis, modeling, verification and implementation. For each phase other measures are taken. Also at the various stages, various difficulties and obstacles, which should be overcome, are recorded.

In the case of RBSC the project is currently in the planning stage. Hence the occurring barriers must be overcome. Otherwise, the proposed project may never move to the implementation phase. The barriers existing in the planning stage can be divided into four basic groups:

- organizational,
- psychological,
- technological,
- financial.

A. Organizational barriers

Organizational barriers are the major obstacle to undertake the RBSC project. If they are not overcome, it will not be possible to undertake further work.

Analysing organizational issues, the following questions should be undertaken:

- defining the RBSC environment,
- identifying the processes and their targets in the RBSC environment,
- examining the sense of common interests of entities operating in the RBSC
- environment,
- identifying the relationship between the entities,
- suggesting the potential leaders of the project,
- identifying mechanisms to study the needs of users.

Defining the RBSC environment RBSC consists in determining the geographical impact of the system and determining the entities, which in the first instance must be acquired for the project. It is necessary to indicate whether there are entities that should definitely join RBSC.

The geographical scope may be a single or a set of contiguous administrative units. The problem is that the jurisdictions of individual organizations or their selected organizational units will not always perfectly overlap. It seems that the key factors for the success of RBSC will be adequate local government units. They have a real impact on the planning of spatial order, and may also initiate investment in infrastructure of an individual administrative unit. Moreover, they are responsible for crisis management. Their important asset are also the laws requiring them to collect specific type of data. These data can be collected on paper, but more and more frequently GIS are used. In addition, local government units may raise relatively greatest confidence.

The second group of entities represents companies supplying the media. Their importance lies in the fact that they design, build, and operate certain types of media in the region. They can affect the development of the region (still developing its infrastructure), as well as collect data on the course of networks providing a specific type of media. Very often their representatives are invited to the consultation, which are organized in order to arrange routes of particular media. On a smaller scale, access to these systems may also include sub-contractors involved in the construction,

maintenance or improvement of existing infrastructure networks.

When determining the environment of a project, as independent entities should also be considered IT companies providing IT tools, such as GIS systems, MRP / ERP and other Web and Cloud Services, and Business Procesess Modeling Tools. The closer the integration of information systems is assumed to be, the role of IT vendors will be greater.

The layout of the entities in the environment of a project enterprise should undertake the roles of particular entities. This will enable determining the objectives of the created community and to the basic processes carried out within its framework. In the course of the future formalization of processes, it will be possible to define RBSC functionality. Examining the sense of community of interest among potential participants RBSC is to determine the levels of cooperation that can be implemented using the proposed Community. In the future, it may be a basis for the negotiations on extending the scope of activity of the system.

Determining the relationship between the entities has to indicate that the mutual obligations of individual entities. What is results from the state law, local regulations, and what should be considered good business practice that should be encouraged, or in extreme cases, force the participants in their mutual relations.

The problem of every project is to create a suitable leader (integrator) of the project. In an environment where most companies are independent of one another it is a difficult task, taking into account the interests of the various participants. Generally for potential leaders, originators may be created, local government units or agencies designated by them, possibly IT companies providing IT Tools.

For the proper functioning of the created system it is necessary to create a mechanism to study the needs of users. It is a condition of the development of the system and may be a mechanism winding up the need for cooperation in this environment.

Taking into account the foregoing, the most serious potential organizational barriers include:

- lack of developed cooperation mechanisms or dislike between the identified entities in the researched environment,
- lack of widely respected leader,
- lack of knowledge of the proposed project,
- unclear legal provisions controlling the cooperation between these entities,
- marginality of the region for which RBSC is developed in the activity of suppliers of the individual infrastructure elements.

These elements can effectively prevent the adoption of this project.

B. Psychological barriers

Psychological barriers are a kind of supplement of organizational barriers. In the planning phase of the project, the key issues to be considered can include:

- a sense of common interests of potential participants in the project,
- self-independence,
- interests of individual entities operating in the environment.

The main problem is to develop a sense of common interests. At the stage of individual regions, it can be difficult especially when the provider of individual media are corporations, for which the region is of marginal importance. Investments for a given region are not of primary importance for their business. In contrast, the supervision over an infrastructure functioning in the region is held by units at a relatively low level in the hierarchy of the organization. Even more difficult situation may occur when supervisin over infrastructure can be taken over by an outsourcing company, whose only task is to maintain the infrastructure tools without permission for their development. Then, a tendency to participate in the proposed project may be relatively small.

Another element is the question of self-independence. Creating the infrastructure of individual media in the region could have signs of some kind of internal competition. The course of individual types of media is defined by the rules. Therefore, individual entities may be willing to act on the principle of the first in the game. Who is the first to take certain design and construction actions, can be given priority in the selection of the course of their own network. Other entities will be forced to adapt to a fait accompli. This type of phenomenon will occur, especially in those regions where there is no tradition of co-operation or where the local government has failed to practice cooperation with providers of media.

The phenomenon can still be affected by the internal systems of interest groups. Not all organizational units within individual companies may be interested in such a high level of IT system integration, fearing an increase in the level of internal control (external as well). Single IT service providers, for which in the event of realization of the proposed project may run out of space, can also be threatened.

To sum up the basic psychological barriers include, among others:

- too close corporate systems and closeness to cooperation among providers of media in the region,
- lack of tradition and willingness to cooperate,
- mutual dislike or distrust to cooperation between potential participants RBSC,
- negative attitudes of managers and selected organizational units of individual entities,
- disregard of project proposals,

- lack of knowledge about the range of costs and potential effects of the project,
- diversionary activities of external entities interested in maintaining the current status quo.

These barriers can have a particularly strong role in the initial stages of starting up the project, where there is still relatively large uncertainty about the potential effects of the project, whereas the current rules of functioning have been violated.

C. Technological barriers

Technological barriers are associated with the preparation of appropriate solutions for IT technology [9]. On the one hand, the proposed solutions should provide an appropriate level of quality of services provided. The indicators should include, among others: the appropriate scope of the data collected, clear and understandable rules of visualization, high level of intelligence of the implemented tools and system security.

Undertaking the project such as RBSC, it is necessary to assume that there are solutions available on the market which enable technical development of the system and achieving its full assumed functionality while maintaining economic rationality of the project.

In this case, among the others, the following issues should be analysed:

- analysis of commercially available IT tools (GIS application, instant messaging, BPM Tools),
- analysis of the IT systems used by potential participants in the project,
- possible integration of the systems used by potential RBSC users,
- analysis of potential and planned developments of previously used IT systems,
- providing an adequate level of security of IT systems,
- possibility of data flow between (system rooms) for entities operating in many regions.

On the IT market there are many different types of tools: GIS, instant messaging, BPM Tools. Requirements for GIS is a tool available in Cloud Technology for creating maps of the region, together with the use of technology of intelligent design. Intelligent solutions can be based on semantic technologies for defining the relationship between the various leyers (classes of objects in spatial databases). They can be an independent software which, however, must be compatible with the used GIS system.

Communication within the community may be also provided by the commercially available enterprise instant messaging (eg Microsoft Lync). Unlike traditional communicators they enable the smooth functioning of corporate they network, they have a high level of security and allow the integration of systems (eg ERP, GIS).

BPM Tools the expected part in the future. A prerequisite for its use is to create a community and define the basic processes that will be implemented in its framework. Its use will depend, inter alia, of information systems that will be used among community participants. Moreover, the question arises whether the participants would be interested in such a high level of integration. However, already at the planning stage, it is necessary to take into account this type of opportunity.

Another technological indicator of the discussed project are internal IT systems used by potential participants in the project. The point is the systems of MRP / ERP and BI, CRM, CAD / CAM types, various types of business systems and others. They are systems that will provide data on real events, and therefore create a description of the current state of the slice of reality. In addition, they will create the basis for the code, lexical and semantic of the planned project. Hence, the question of mutual integration of these systems will be crucial. IT Systems used by potential participants in the project are continuously being improved. Therefore, the suggested solution should not constitute any restrictions in this regard.

An important issue is the problem of security of data available in the system. On one hand, it is a technological challenge for manufacturers of IT solutions, on the other hand, an adequate level of safety should encourage increased willingness to cooperate in the planned community.

To sum up, the basic technological barriers include:

- The scope of the internal computerization of potential participants in the proposed project.
- The level of internal integration of IT systems.
- Ability of integrating GIS tools with the available instant messaging and BPM Tools.
- Ability to integrate all systems envisaged in the planned community,
- Providing an adequate level of safety.

From a technological point of view, planning, designing and implementation of the proposed system is feasible. The thing is, it is to be more economically rational, and therefore it is important to use as much as possible systems which can be duplicated.

D. Financial barriers

RBSC is a project in which it is difficult to determine the primary beneficiary. Moreover, the assumption is not to create a sense sricto economically effective project, but first of all, it has to be useful for the participants of it. Despite this, at its creation, and then the exploitation, economic rationality should be kept. In many cases of planned projects, financial considerations were the main reason for the failure of the project. RBSC is an extensive project and requires the cooperation of many entities. Therefore, it seems to be a cost demanding project.

In practice, the drawn up solutions should include, in the widest possible range, the ones which can be duplicated (thus, relatively cheap). On the other hand, the implementation of all the planned functionality of the system

can be decomposed into a number of stages and thus, extend it in time.

It can be assumed that analyzing the financial issues of the planned project the following issues should be considered:

- sources of project financing,
- the range of payments for the use of the created system,
- entities responsible for the functioning of the system.

Drawing up the proposed project requires work and commitment of many people from different organizational units. The primary objective of the project is to create a useful system. Therefore, at least the initial phase of the project can be financed from different types of funds. Only after activation of the project, it is possible to specify the rules for the financing of the system and to determine the extent of the payment for the selected system functions It is also important to define the principles of financing the development of the system in the future. Considering the fact that the system should be largely made up of duplicated tools, the need for payments to certain suppliers of IT services should be taken into account. Taking into consideration the issues presented above, the main financial barriers for the implementation of the project include:

- the need to pay the installments for the use of the system,
- reluctance to pay multiple suppliers for the use of similar IT services where some operators are already using systems with similar functionality,
- legal problems that might arise for certain entities (referring especially to the units of public administration), related with the possibility of the use of commercial systems,
- height and multiplicity of the charges for the use of the system,
- lack of decision-making powers to bear the costs for the use of IT tools selected at the regional level (referring mainly to corporations with head offices outside the region).

The presented barriers are just some of the problems to be dicussed before starting the project. The results of empirical research on the barriers to the implementation of RBSC in Częstochowa provide further points of the article.

IV. THE EMPIRICAL RESEARCH

In order to verify practically the issues brought up in the article, the authors conducted a study determining the most significant barriers connected with the formation of RBSC. The theoretical bases for the creation of RBSC and pilot studies in the area of information resources of such projects have been presented in previous publications written by the authors [2] [10].

Five entities with their own technological infrastructure, where resources are distributed and therefore can be managed through GIS systems, functioning in the region of Częstochowa were researched. Obtaining a larger study sample was relatively difficult because the entities are often a part of larger entities. People working in local offices are not authorized to provide information, and reaching the management requires complex formal procedures. Among the entities of Częstochowa region who have agreed to participate in the study are:

- Silesia Board of Amelioration and Water Division of Czestochowa,
- Polish Oil and Gas Company SA Upper Silesian Sales Department. Upper-Silesian Region. Customer Service Czestochowa,
- one of the nationwide providers of cable television, broadband internet and telephone services (did not give the permission for the use of the name),
- Częstochowa City Hall,
- Water and Sewage District Czestochowa SA in Częstochowa.

The research was carried out by notifying the appropriate application to the management of the enterprise. A representative of the board usually passed conducting the research on relevant departments. Additionally, a conversation with a representative of the company providing solutions in GIS Cloud was conducted. Representatives of the company have to prepare their own proposed solution within the confines of this concept. These studies are a pilot, expected to be extended in the future.

Research questionnaire, which was used in the study contained 16 questions divided into 6 main areas:

- Area 1 - (Questions 1-2) on the business nature of the entity,
- Area 2 - (Questions 3-5) on the level of computerization of the entity,
- Area 3 - (Questions 6-8) on willingness to cooperate with other entities,
- Area 4 - (questions 9-11) concerning the use of GIS,
- Area 5 - (Questions 12-15) for the local business communities - such as RBSC,
- Area 6 - (Question 16) concerning barriers to the creation of RBSC.

The study was conducted in April 2014. They will be a part of a larger project. For the purposes of this study only that part of the results that directly corresponds to the subject of the article (technology, level of computerization, barriers of accessment to RBSC) were taken into account.

Most subjects (4 out of 5 respondents) declared being a unit independent in decision making. This means that in spite of belonging to the structure of larger organizations or networks, they have autonomy and can take specific initiatives (e.g. accession to RBSC). Only the provider of cable television declared that they could not make decisions for themselves, and the management is done through the control panel.

The condition for the establishment a local business community (or joining such a project) is to have an appropriate level of computerization. The use of ICT solutions (information and communication technologies) is

the basis of RBSC. All the researched entities declared that they meet the basic requirements in this area, namely: they have broadband internet access, they use ERP and GIS. Unfortunately, no company has made a full integration of these systems. In the majority of cases (3 to 5) between ERP and GIS systems, only a simple (using files), or semi-automatic data exchange is possible. The other two entities (Water and Sewage and the City Hall) has integrated only some of trade systems.

The third group of questions contained in the form of research related to willingness of the entities to cooperate on the platform RBSC. Three entities (water, drainage, gas works) are interested in permanent cooperation, particularly in the area of investment planning and in crisis situations. A representative of the City Hall sees such a need only temporarily, in the implementation of the relevant investment. Internet, television and telephony supplier sees no need for such cooperation.

Entities interested in cooperation agree on the scope of the data that should be on the RBSC platform. The most important task in this area is to place the cadastral maps of infrastructure objects. This will help to streamline and accelerate processes of investment and planning the course of the subsequent parts of the network (gas, water, land reclamation). The most important part of the form of the research were questions that directly relate to the barriers to RBSC creation. These correspond directly with the theoretical considerations set out in the previous paragraph of the article.

The most important barrier to be considered is the organizational factor. This is indicated in the responses in all five forms. Respondents fear of who would organize a platform for cooperation and how they would define the powers and competences of the entities involved in the project.

Another important barrier is the psychological aspects (3 replies to 5). Respondents are concerned about the security of resources and the way of their share. Enterprises treat data and information as a resource of great strategic importance. The mechanisms to protect data are rooted in the mentality and psyche. RBSC in some way, destroys these behaviors, which may be unacceptable, even taking into account the common interests of the users of the platform of cooperation. Indication of technical barriers occurred in two cases.

Main barriers of creating Regional Business Spatial Community are shown on figure 2.

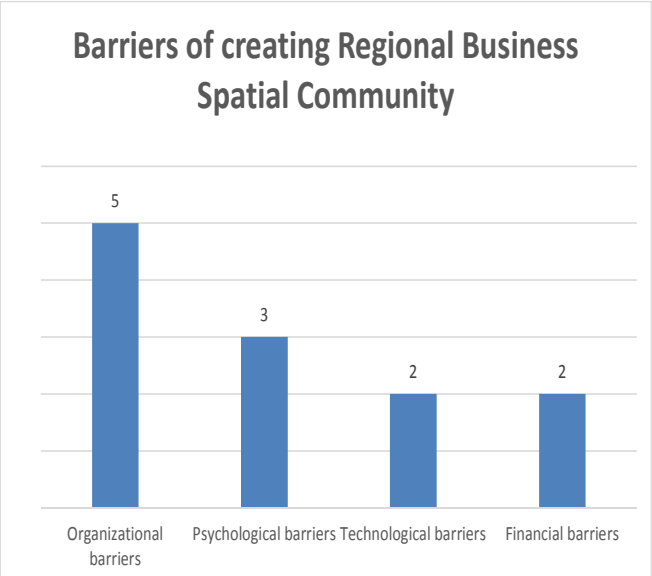

Figure 1. Main barriers of creation RBSC

Respondents believe that the integration of data on a common RBSC platform can be difficult due to the different formats of the data contained in the systems and incompatible software. Number of problems in this area will accumulate together with joining of other entities to the project. In two cases, respondents also related to the financial barriers. In the assumption, RBSC would exist as a separated entity.

Debatable would be platform budgeting, maintaining the necessary IT infrastructure, software or service.

V.SUMMARY

Inherent feature of the information age is the formation of the various communities that communicate using information and communication technologies. Factors affecting the formation of such communities are common interests, science, origin, occupation, etc.

The idea of RBSC is a new concept which indicates the possibility of the formation of business communities, based on ICT. Such communities can be formed only on the condition of cooperation and common benefit. A factor influencing the creation of RBSC may be having and infrastructure development of companies on a common geographical area. The article focuses on companies operating within the city, which provide utilities for the residents (water, gas, the Internet, etc.). The infrastructure possessed by these entities usually takes the form of a network. Networks of different companies often intersect, or are a barrier for itself. Creating a business community, which in cooperation would make specified information resources available, could help to improve the planning, development, and infrastructure repairs. As a survey among companies supplying the media revealed, there is a potential willingness to cooperate in this area.

The rise of RBSC, however, involves the occurrence of certain barriers. In the theoretical part of the article, four main areas of their occurrence were pointed out: organizational, psychological, technological, and financial. The study among potential participants and beneficiaries of RBSC confirmed these considerations. Surveyed companies have declared that the biggest problem may be psychological and organizational barriers. However, technical and financial aspects were considered less important.

***Abstract*—Cloud computing is an emerging new computing paradigm designed to deliver numerous computing services through networked media such as the Internet. This solution offers many possibilities that did not exist before for all enterprises but especially for small and medium sized companies, which very often cannot afford for huge investments in contemporary IT solutions. The aim of the paper is an attempt of barriers identification especially mental barriers of managers which hinder making decision concerning implementation of cloud computing in small and medium sized companies in Poland. In the paper the notion of cloud computing was presented as well as benefits in the aspects of: technical, financial, organizational ones and barriers of cloud computing adoption. Next the results of research conducted in Polish SMEs companies were presented. The research showed that the biggest mental barriers perceived by managers concern lack of trust, incomplete knowledge about cloud computing and not perceiving necessity of changes in currently used IT model.**

I. Introduction

CLOUD computing is currently the fastest growing IT service. This approach offers several advantages to potential users such as "metered" use (i.e., pay-as-you-go) which offers scalability, online delivery of software and virtual hardware services (e.g., collaboration programs, virtual servers, virtual storage devices) which would enable organizations to obviate the need to own, maintain and update their software and hardware infrastructures. The flexibility of this emerging computing service has opened many possibilities for organizations that did not exist before. Among those organizations are those engaged in healthcare provision.

Cloud Computing for many years has been mentioned among the most important trends of IT development. According to Forrester report the global market of Cloud Computing services in 2011 was 40,7 billion USD [1] and prognoses tell that in 2020 this market will grow to assessment value of 241 billion USD, it is six times.

The literature review reveals that many studies were and currently are being conducted on the use of cloud computing by large scale enterprises primarily on their perceptions about cost reduction, ease of use and convenience.

Cloud computing is adopted by enterprises [2],[3], public sector [4], eGovernment [5], regional business community [6], for education [7], for healthcare provision [8] and many other organizations.

The literature review reveals that many studies were and currently are being conducted on the use of cloud computing by large scale enterprises primarily on their perceptions about cost reduction, ease of use and convenience, reliability, sharing and collaboration and lastly but not the least, security and privacy [2], [9]. Large enterprises have quickly adopted this model of IT resources management [2] but among SMEs companies it is more and more often used solution [10], [3], [11]. The importance of cloud computing parameters on SMEs adoption in a large degree convergent with perspective of big companies e.g. King [3] indicated that the cost reduction, avoiding natural disaster mishaps, better security but lack of reliability in using cloud computing are the most important parameters. On the other hand Gupta et al [10] indicated that for SMEs companies which want to implement cloud computing model the most important are such factors as: ease of use and convenience which is the biggest favorable factor followed by security and privacy and then comes the cost reduction. The fourth factor reliability is ignored as SMEs do not consider cloud as reliable. Last but not least, SMEs do not want to use cloud for sharing and collaboration and prefer their old conventional methods for sharing and collaborating with their stakeholders [10].

The aim of this paper is to identify mental barriers in implementation of cloud computing in SMEs in Poland. There were proposed considerations of mental barriers from the perspective of: lack of trust, incomplete knowledge on cloud computing and not perceiving necessity of changes in the currently used model of IT resources management. The research was conducted in 134 SMEs companies, taking into consideration perception of mental barriers from the perspective of strategic level managers (CEO), tactical level managers and IT managers (CIO).

The rest of this paper is organized as follows: presentation of the notion and models of cloud computing, discussion concerning benefits of implementation of this solution and most often identified barriers of cloud computing implementation. Next the development of cloud computing in Poland was presented. As an introduction to presentation of research results and identification of mental barriers of cloud computing implementation the components of trust in cloud computing were presented.

II. Cloud Computing

There are many definitions of cloud computing, in which different aspects are underlined of this still new for some enterprises model of IT resources management. The technology is most often the key element of definition [12], some authors focus on the business model e.g. collaboration and pay-as-you-go [13] and the reduction in capital expenditure [14]]. Different authors have different opinions about the core conceptualizations of cloud computing. The reasons for these different opinions are as follows [15]:

- As an emerging IT service model, cloud computing has had only a relatively short lifetime in which to develop into a fully formed paradigm.
- Contributors to the development of cloud computing theory are extremely varied, both in terms of industry and academic background.

Grossman and Gu [16], described cloud computing as an infrastructure that provides resources or services over a network, often the Internet, usually at the scale and with the reliability of a data center.

Buyya et al. [17] defined cloud computing as a type of parallel and distributed system consisting of a collection of inter-connected and virtualized computers that are dynamically provisioned and presented as one or more unified computing resources based on service-level agreements established through negotiation between the service provider and consumers.

One of the most complex definition is provided by National Institute of Standards and Technology: cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction [18]. This cloud model is composed of five essential characteristics, three service models, and four deployment models.

The most important characteristics include: on-demand self-service, broad network access, resource pooling, rapid elasticity, measured service [18].

Cloud services delivery models can be broadly categorized into three types: Infrastructure-as-a-service (IaaS), Platform-as-a-service (PaaS) and Software-as-a-service (SaaS). Each of the service types serve different purposes and target different customers however they share a common business model. The fundamental of the model is an offer of making accessible of their computing resources including services, applications, infrastructures, and platform to customers.

Infrastructure as a Service (IaaS) means using computer hardware via the Internet. IaaS is divided into Compute Clouds and Resource Clouds [19]. Compute Clouds provide access to computational resources such as CPUs, hypervisors and utilities. Resource Clouds contain managed and scalable resources as services to users.

Infrastructure as a Service model refers to the tangible physical devices (raw computing) like virtual computers, servers, storage devices, network transfer, which are physically located in one central place (data center) but they can be accessed and used over the Internet using the login authentication systems and passwords from any dumb terminal or device [10].

Platform as a Service (PaaS) is a more advanced level of cloud computing service than IaaS. PaaS provides a full or partial application development environment that enables developers to access resources for application development and to collaborate with others online.

Clouds and Resource Clouds [19]. Compute Clouds provide access to computational resources such as CPUs, hypervisors and utilities. Resource Clouds contain managed and scalable resources as services to users.

Infrastructure as a Service model refers to the tangible physical devices (raw computing) like virtual computers, servers, storage devices, network transfer, which are physically located in one central place (data center) but they can be accessed and used over the internet using the login authentication systems and passwords from any dumb terminal or device [10].

Platform as a Service (PaaS) is a more advanced level of cloud computing service than IaaS. PaaS provides a full or partial application development environment that enables developers to access resources for application development and to collaborate with others online.

By choosing a specific model of cloud computing the service user defines the division of control over the IT resources employed between himself and the service provider [20]. Division of control in cloud computing models was shown in Fig. 1.

In the traditional model the user has almost total control over the infrastructure and software he owns. However, in many cases his self-sufficiency is somewhat limited by the necessity to use Internet Service Providers.

In the IaaS model almost the entire substantial part of the IT infrastructure is outsourced. The user retains control over his data and software.

In the PaaS model the service provider also provides the service customer with the operating environments, where the user may operate the applications he installs.

In the SaaS model the entire infrastructure along with the software is under the control of the service provider. The user retains control over his data.

There are four different cloud deployment models within organizations namely [21],[10]:

1. Public cloud: It is available from a third party service provider via Internet and is very cost effective for SMEs to deploy IT solutions.
2. Private cloud: It is managed within an organization and is suitable for large enterprises (managed within the walls of the enterprises). (…) Private clouds provide the advantages of public clouds but still incur capital expenditures.
3. Community cloud: It is used and controlled by a group of enterprises, which have shared interests. For example, the US federal government using community cloud (built on Terremark's Enterprise cloud platform) for forms.gov, flu.gov, cars.gov, USA.gov, Apps.gov.

Traditional model On-premise	Infrastruc-ture as a Service IaaS	Platform as a Service PaaS	Software as a Service SaaS
Data	Data	Data	Data
Application	Application	Application	Application
Runtime environment	Runtime environment	Runtime environment	Runtime environment
Virtual machine	Virtual machine	Virtual machine	Virtual machine
Server	Server	Server	Server
Data store	Data store	Data store	Data store
Network	Network	Network	Network

Under control of the user
Under shared control
Under service provider control

Fig. 1. Division of control in cloud computing models [20]

4. Hybrid cloud: It is a combination of public and private cloud.

For many users handing over almost total control over their own IT resources is hard to accept and that is why the users very often decide to apply private or hybrid cloud model.

III. CLOUD COMPUTING BENEFITS

Cloud Computing will have a profound impact on the cost structure of all the industries using hardware and software, and therefore it will have significant impact on [22]:

- Business creation
- Macroeconomic performance
- Job creation in all industries
- Job reallocation in the ICT sector
- Public finance accounts, through direct impact on public sector spending and the indirect one on the tax revenues.

Data processing in the cloud gives new possibilities thanks to which organization uses its resources in a more costly effective and flexible way. Benefits may be considered in a three aspects:

- technical benefits,
- financial benefits,
- organizational benefits.

Technical benefits are perceived by the prism of flexible usage of computational power. In case of typical computing architecture with dedicated servers for every application the computational power of big and expensive computers is not used by most of the time. In a cloud computing shared resources are made accessible to those applications which require it at a given period of time. Thanks to this solution [23]:

- an access to computational resources for every application is growing,
- investments into hardware are limited with simultaneous decrease of time needed for computing purpose,
- computing power is allocated for those applications which currently need it,
- the constant level for access to services is maintained regardless of the number of users (scalability),
- there exist the possibility of fast acquisition of external computing power.

In case of cloud computing usage enterprises pay only for resources which were used.

Providers of cloud computing ensure for their customers access to the latest version of software (automatic upgrade) and SaaS.

Financial benefits contain most of all cost reduction (installation and maintenance) [14]. Cloud computing allows for decrease of costs connected with purchasing software licenses. Shorter time–to-market, means the possibility of faster introduction of product onto a market and achievement of financial benefits.

Organizational benefits embrace increase of flexibility and enterprise's openness on introduction of new solutions and increasing efficiency of its functioning. Its sources may be find in:

- limitation of backstage resources in a form of resources (external companies, IT).
- faster implementation of new business applications and IT solutions,
- transfer of the risk connected with IT infrastructure on the service provider,
- easier access to applications for mobile employees.

Summing up considerations concerning benefits of cloud computing application it is worth mentioning IDC research results [24]: demonstrable, tangible economic benefits are available from the adoption of cloud in the EU amongst enterprises. Based on the survey conducted for this study, that included 479 enterprises already using cloud for their businesses, 81% reported lower IT costs with a 10 to 20% reduction being typical, but 12% reported savings of 30% or more. Business benefits included more effective mobile working (46%), higher productivity (41%), more use of standard processes (35%), better ability to enter new business areas (33%) and the ability to open up in new locations (32%) [24].

The main perceived benefits of the cloud computing model in SMEs were also the subject of The European Network and Information Security Agency research [25]. Fig. 2 shows the results of the study.

The costs savings are thought to be the most important benefits of cloud computing. 68% of SMEs specified that this solution would help to eliminate or minimize investments in IT infrastructure. Companies indicated that adjustment and flexibility of IT resources is also very

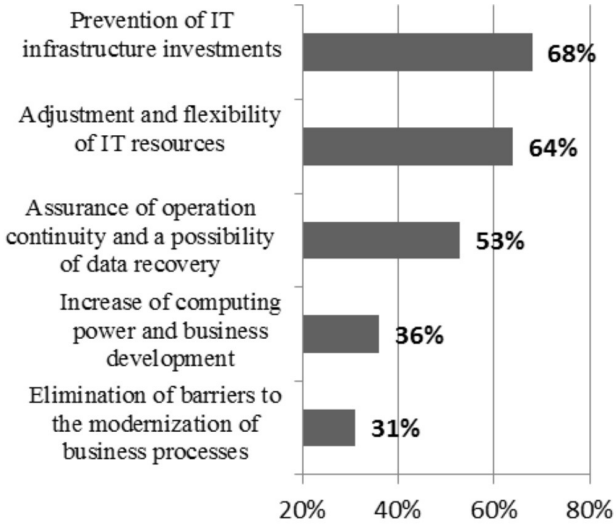

Fig. 2. Benefits of cloud computing model in SMEs [25]

important for them (64%), mostly due to the fact that the company do not need to handle software updates, new versions of products or any other necessary actions that should be undertaken to adapt systems to the changes in regulations (e.g. changes in tax rates). 53 % of respondents supported opinion that cloud computing offers business operation continuity and permits data recovery. The remaining part of the respondents (47%) is concerned with the efficiency of Internet connection, data transfer security and storage. The increase of computing power and business development (36%) and the elimination of barriers to modernization of business processes (31%) are not of a great importance to SMEs.

IV. Barriers in Cloud Computing Adoption

The managers who consider the change of IT resources model management from traditional one to cloud computing model have numerous less or more justified fears. Identification of these barriers is a subject of many research and scientific discussions [20], [26],[10].

In research conducted by IDC analysts [24.] the impact of 12 identified barriers was showed. In the assessment of managers the barriers which have the strongest impact are: legal jurisdiction, security and data protection, trust, data access and portability, data location, local support, change control, ownership and customization, evaluation of usefulness, slow internet connection, local language and tax incentives. As it was showed in the cited report none of the barriers cannot be accepted as the only most important one which was mentioned by most of respondents. There can be distinguished six strongly correlated barriers which are acknowledged as the most significant ones by 62% of respondents. They are: legal jurisdiction, security and data protection, trust, data access and portability, data location, local support [24.].

The relevance of the barriers to the cloud computing implementation was presented in Figure 3.

There are also interesting research results [26], where cloud computing providers were the respondents. Providers

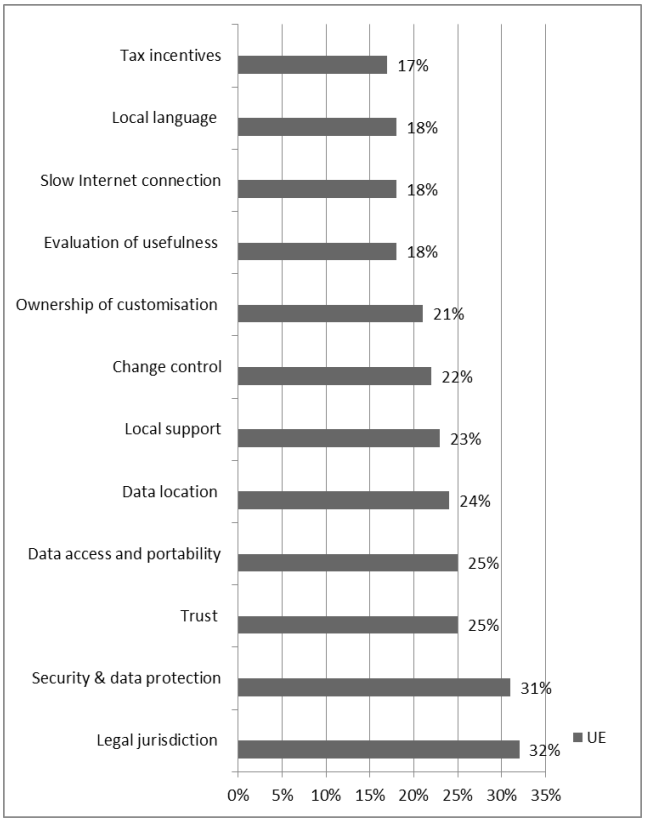

Fig. 3. The relevance of the barriers to the cloud computing implementation [24]

say that customers' main concern over switching to cloud is losing control – an issue voiced by almost half of all respondents (48%). As well, 39% say that data loss and privacy risks are a major worry. Worries of 41% customers concerned integration with existing architecture, a 28% were not sure the promise of cloud environment can be realized, 28% claimed that implementation of integration costs is too high, 27% worried of risk of intellectual property theft and lack of legal and regulatory compliance 22%.

Companies are afraid that their IT performance is controlled not by their own staff but by off-premises cloud providers; and that they may not be able to make necessary changes in application features easily and when needed [27].

Security concerning in particular privacy and data confidentiality, is one of the most cited objections to cloud computing [28].

In the light of above research in order to ensure cloud computing development technical, legal, organizational and mental barriers should be removed in the highest possible degree.

V. Development Of Cloud Computing In Poland

According to Business Software Alliance [29.] Poland takes 12th place among 24 countries in the ranking of government policies having influence on development of cloud computing. This ranking evaluates status in 24 countries, which are together responsible for 80 percent of world IT and communication resources and the policy of

these countries in 7 basic areas: data protection, security in cyberspace, cyber-crime, intellectual property, technological interoperatibility and law harmonization, free trade and IT infrastructure.

5 top places in the ranking were achieved by: Japan, Australia, Germany, USA and France.

Macroeconomics factors which positively influence on such high position of Poland are most of all [29]:

- good legal regulations in the scope of privacy protection, electronic signature, e-commerce, and cyber-crime which constitute a basis for building trust for cloud computing technology.
- Poland also possesses one of the most comprehensible systems of intellectual property protection. In 2008 legal regulations were amended in the scope of Internet provider responsibilities.
- Polish government promotes innovations and interoperatibility and apply non discriminating policy in the scope of governmental orders.

The factor influencing negatively on the position of Poland is still limited access to broadband Internet comparing to such countries as Germany or Japan.

Among microeconomics factors technological preferences of IT (CIO) managers have a big influence on implementation of cloud computing in Polish enterprises. In the table 1 were presented research results on the sample of 3000 (CIO) managers [30].

TABLE I.
TECHNOLOGICAL PREFERENCES OF IT CIO MANAGERS IN THE WORLD AND IN POLAND

Category	Global 2009	Global 2011	Poland 2011
Cloud Computing	33%	60%	49%
Mobile solutions	68%	74%	76%
Virtualization	75%	68%	81%

Presented in the table 1 research results indicate that technological preferences of CIO IT managers in Poland are strongly directed at virtualization (81%) and the application of mobile solutions (76%) and exceed percentage values in a global scale. Preferences in implementation of cloud computing model (49%) are lower than values in a global scale (60%), but comparatively to other countries are high.

Identification, analysis and trial of assessment of the rest factors having influence on development of cloud computing in Polish SMEs, with special consideration of factors having negative influence (barriers) will be presented in the next points.

VI. MENTAL BARRIERS AND COMPONENTS OF TRUST IN CLOUD COMPUTING

Many researchers claim that among barriers of cloud computing implementation the central place should belong to mentality, which can be in favor of open attitudes towards changes or it can constitute crucial barrier.

Swida-Zieba [31] defines mentality as a structure resistant to changes, deeply rooted, non verbalized and subliminal. It constitutes the result of the whole of socialization: system of situational incentives, own experiences, perception of reality and influence of education processes. It is formal and generalized structure, conditioning involuntary and spontaneous reactions on incentives and situations [31].

Mentality of managers is shaped in the process of interaction of many factors from social environment and their own experiences and in the future it has influence on their attitudes, leadership styles or undertaken decisions.

Mental barriers of managers manifest in natural perception reactions e.g. „cloud computing will not bring any benefits for the company", emotional e.g. „we do not trust cloud computing model" and behavioral e.g.. „cloud computing is not needed in the company and we are not going to implement it".

To best mitigate barriers to confidence, we need to understand the main components affecting cloud trust [32]:

- Security,
- Privacy,
- Accountability,
- Auditability

Security mechanisms (e.g. encryption) which make it extremely difficult or uneconomical for an unauthorized person to access some information [32].

Privacy - protection against the exposure or leakage of personal or confidential data (e.g. personally identifiable information (PII)) [33].

Accountability - the obligation and/ or willingness to demonstrate and take responsibility for performance in light of agreed-upon expectations, accountability goes beyond responsibility by obligating an organization to be answerable for its actions [32], [33].

Auditability – the relative ease of auditing a system or an environment. Poor auditability means that the system has poorly-maintained (or non-existent) records and systems that enable efficient auditing of processes within the cloud [32]. Auditability enables review of undertaken activities and stating responsibilities of persons (employees) or organization for undertaken activities, especially when they were not compliant with stated security policy.

Mental barriers are constituted also by insufficient knowledge of managers concerning notion of cloud computing, its advantages and disadvantages and risk connected with implementation of this solution. The current state of managers' knowledge on cloud computing is hardly to categorize as satisfactory one [20]. It causes ungrounded worries about: data location and connected with it data access and portability.

Managers very often do not perceive the needs of changes of current model of IT resources management for cloud computing model, because they assess its usability very low and the risk of introduction of changes is assessed very high.

VII. Mental Barriers To Adoption Cloud Computing. Research Results

In Poland exist 1.9 mln of enterprises, and over 1,8 mln is constituted by microenterprises (employing up to 9 employees), 55 thousand small enterprises (employing from 10 to 49 employees), 15 thousand medium sized enterprises (employing from 50 to 249 employees and 3,2 thousand of big enterprises (above 250 employees).

As far as research methodology is concerned it is worth mentioning that the study in the light of the above was carried out on the sample of 134 companies which are not representative to the entire Polish SME sector. Nevertheless in the authors' opinion, the results are an interesting attempt of building the image of Polish SMEs, which face the challenge of cloud computing implementation.

The aim of conducted research was to verify the following research hypotheses:

H1: Among mental barriers the biggest worries are connected with lack of trust for cloud computing model.

H2: Mental barriers connected with insufficient knowledge are not perceived by managers as „high barrier".

H3: Between "level of management" and perception of highlighted mental barriers occurs stochastically essential dependence.

The study involved: 80 micro-enterprises, 42 small-enterprises and 10 medium-enterprises from the following sectors: manufacturing - 39, trade - 65 and services – 30.

The study was conducted in January - February 2014 with the use of electronic questionnaire. Link to the survey was provided via email sent to the companies. Questionnaire return rate was 27%. In the research participated: 54 managers of strategic level, 48 managers of tactical level and 32 IT CIO's. The results of a few chosen survey questions are presented below.

In order to examine the relevance of each barrier to the cloud computing implementation decision, twelve questions from IDC report [24] research carried out on the sample of European enterprises were used.

- Security & data protection: "We are worried about the security and data protection guaranteed by cloud services"
- Trust: "It is difficult to judge which cloud services are"
- Data location: "We do not know and/or cannot control the location of our corporate data"
- Local support: "There is no local support for the services"
- Change control: "We cannot control software changes and upgrades made by the vendor"
- Ownership of customization: "We do not know who owns the customizations/changes we make to the cloud services"
- Evaluation of usefulness: "We do not know how to evaluate the usefulness of cloud service for our organization"
- Slow Internet connection: "Our Internet connection(s) is/are not reliable or fast enough"
- Local language: "There is no local language version of the services"
- Tax incentives: "Tax and other incentives make buying with capital more attractive than paying for what we use on subscription"
- Legal Jurisdiction: "If we have a dispute with the cloud service provider, I may have to go to court in another country inside the EU"
- Data Access and Portability ""Concern about our ability to move data from one vendor to another or onto our own IT"

Respondents rated each response on a scale: low barrier, average barrier, high barrier. Next all the barriers were grouped into three groups: mental, technical and legal barriers. In the opinion of respondents mental barriers are more frequent than technological or legal barriers perceived as a strong obstacle in the decision on whether or not to implement cloud computing solutions. Among all responses "high barrier" was indicated by as much as 38% of responses related to the mental barriers, 33% to the technical barriers and 29% to the legal barriers.

The next question involved more specific identification of mental barriers.

For the assessment of lack of trust barrier were used questions concerning: security and data protection, privacy, accountability and auditability. In the assessment of

Table II.
THE ASSESSMENT OF MENTAL BARRIERS INFLUENCE ON CLOUD COMPUTING ADAPTION

	low barrier	medium barrier	high barrier
	Trust		
Security and data protection	32	54	47
Privacy	33	50	51
Accountability	56	40	38
Auditability	51	40	43
	Lack of knowledge		
Data location	29	64	40
Data access and portability	19	70	46
	Lack of the need		
Evaluation of usefulness	50	57	27

insufficient knowledge barrier cloud computing model the respondents' answers concerning: data location and data access and portability were evaluated. In the assessment of lack of the need of change of IT resources model evaluation of usefulness was used.

In the table II was presented evaluation of mental barriers' influence on cloud computing adaptation.

In the table II the greatest number of „high barrier" indication obtained: privacy (51) and „security and data protection" (47). It means that respondents as the most important barrier perceive „lack of trust" for cloud computing.

Hypothesis H1 was positively verified.

The barriers connected with the lack of knowledge were most often assessed as „medium barrier", what confirmed rightness of H2 hypotheses.

In the further considerations „high barrier" indications of respondents were only taken into account. For „trust" barrier the number of „high barrier" indications was summed up for four analyzed of such components as: security and data protection, privacy, accountability and auditability. For „lack of knowledge" „high barrier" indications were summed up for data location and data access and portability.

In the correlation table presented in table III the responses of strategic, tactical and IT CIOs level managers were taken into account.

TABLE III.
CORRELATION TABLE

	Trust	Lack of know-ledge	Lack of the need	Sum-mary
Strategic managers	108 (93,79)	36 (45,06)	9 (14,15)	153
Tactical Managers	52 (66,82)	44 (32,10)	13 (10,08)	109
IT (CIO)	19 (18,39)	6 (8,84)	5 (2,77)	30
	179	86	27	292

In the correlation table quantities of indications were placed as well as numerical strengths in parentheses. Using the chi-square independence test (χ^2) we test the H0 hypothesis: concerning independence of investigated features in face of alternative H1 hypothesis: features are not independent.

This statistics has χ^2 out of (r-1)(k-1) layout of the degrees of freedom, where r - the number of columns, k - the linage. The calculated value of the statistics χ^2=17,11, the value from tables for χ^2=0,05 and 4 degrees of freedom χ^2_α = 9,45. Therefore the following condition is fulfilled:

χ^2=17,11 > χ^2_α = 9,45 and the hypothesis H0 can be rejected. This means that between the type of manager and perception of mental barriers connected with trust, lack of knowledge or evaluation of usefulness the stochastic dependence occurs.

For the measurement of the power of correlations of examined variable the coefficient of Czuprow convergence (T) was used. This coefficient accepts values from the [0,1] range. The nearer to the zero the coefficient of convergence is the dependence between variables is weaker. The calculated value of coefficient of convergence T=0,17 means that the dependence is weak, but statistically essential.

The obtained results allowed for positive verification of H3 hypothesis.

VIII. CONCLUSION

Presented research results among SMEs allowed to formulate the following conclusions:

1. Among mental barriers the biggest worries are connected with the lack of trust for cloud computing model.
2. Mental barriers connected with insufficient knowledge are not perceived by managers as „high barrier".
3. Between "level of management" and perception of distinguished mental barriers stochastically essential dependence occurs.
4. The trust as a high barrier was most often indicated by strategic level managers.
5. Lack of knowledge concerning cloud computing was most often assessed as „high barrier" by managers of tactical level.
6. IT CIOs recognize advantages of cloud computing model and very rarely assess "lack of implementation need" as „high barrier".

The key for liquidation of mental barriers rebounding negatively on attitudes of managers in the face of decision concerning implementation of cloud computing model can be consciously shaped program of general education, and the assurance of instruments by means of which it will be implemented. Operations should be directed at the wide formation of features and social competences, favoring open to changes attitudes. Not flexible enough attitudes of managers and management of specific levels, anxiety of undertaking risk and lack of interest in new solutions are consequences of low level of the needs understanding of modern information society.

***Abstract*—The transition from a government to e-government poses continuous challenges in employing increasingly sophisticated web portals as the gateway to government units, their information and services. The high quality of those portals is needed for the successful adoption of e-government. Therefore, the aim of this study is to assess quality of selected Polish e-government portals based on a proposed framework. This framework employs the International Organisation for Standardisation (ISO) standard. Firstly, the paper presents various definitions of quality and different theories/models for assessing the quality of e-government portals. Secondly, the framework for assessing the quality of e-gov portals is presented. Thirdly, the assessment of Polish e-government portals based on the proposed framework is shown. The paper concludes with a discussion of research findings and recommendations for studies on e-gov portals' evaluation. Finally, the future works are submitted. The obtained research findings will prove to be helpful for researchers in developing studies on e-government, especially in the research issue of e-gov portals. Moreover, they can be useful while undertaking empirical activities aimed at the e-government adoption.**

I. Introduction

THE research on e-government has a relatively short history. Analyzing the three most known bibliographic databases, that are EBSCO, ISI Web of Knowledge and Scopus, reveals that scientists have started exploring e-government research since the mid 1990s. By contrast, practical e-government initiatives have been launched since the late 1990s [1]. The European Union countries, including Poland, have written into their strategic planning the building of e-government since 1999 [2], [3], [4], [5], [6], [7], [8], [9]. Studies and empirical activities aimed at e-government have strongly been developing from 2000.

Generally, e-government means using information and communication technologies (ICTs) for [10], [11], [12], [13], [14]:

- supporting processes in government units;
- delivering e-government services at different levels of maturity to government stakeholders (i.e. citizens, enterprises and government units);
- improving government transparency, citizen's participation, and democratic decision making; and
- cooperation, networking, and maintaining partnership relations between government stakeholders.

Studies on e-government focus on the variety of issues relating to the above picture of e-government. They look at e-government from different angles. An important research issue relates to e-government maturity [15], [16], [17]. The maturity levels of e-government reveal the degree of technological sophistication and the degree of organizational transformation in a government. They reflect how enterprises and citizens can interact with government units and how government units can cooperate and communicate. The European model of e-government maturity is comprised of the following levels: information, one-way interaction (downloadable application forms), two-way interaction (electronic application forms, e-forms), transaction (full electronic) and personalization (targetisation/automation) [18], [19], [20]. E-government services (e-gov services) are another important issue of e-government research. Those services are investigated from different perspectives, e.g. their implementation [21], [22], [23] and acceptance by all government stakeholders [15], [24]. Furthermore, researchers are investigating factors that play key roles in successful adoption of e-government [25], [26], [27], [28], [29], [30], [31], [32], [33], [17]. Additionally, studies focused on implementation and acceptance of e-government portals (e-gov portals, e-government web sites) are carried out [34], [35], [36]. E-gov portals provide a single point of access to government services via the Web-enabled interface. Such portals deliver convenient online access to e-gov services for government stakeholders. Thanks to them, enterprises and citizens can interact with government units as well as government units can cooperate and communicate. Therefore, e-gov portals strongly influence successful adoption of e-government [36].

A review of the literature on e-gov portals reveals that research on evaluating them and assessing their quality is very limited. To address this gap, this paper aims to assess the quality of selected Polish e-gov portals based on a comprehensive framework. This framework employs the International Organisation for Standardisation (ISO) standard.

This paper is structured as follows. Firstly, the paper presents various definitions of quality and different theories/models for assessing the quality of e-gov portals. Secondly, the framework for assessing the quality of e-gov portals is presented. Thirdly, the evaluation of Polish e-gov portals based on the proposed framework is shown. The paper concludes with a discussion of research findings and recommendations for studies on e-gov portals' evaluation. Finally, the future works are submitted.

II. THEORETICAL BACKGROUND

A. Quality of e-government portals

The term "quality" means characteristic, feature, trait. It rarely relates to one thing or a phenomenon. Often, it refers to a sum of these characteristics against requirements. There is not a single definition of quality. The reason is that quality is basically only "the perception of quality" [37]. Many known experts have contributed to comprehensive quality definitions.

Garvin [38] defined and Kitchenham and Pfleeger [39] expanded five different perspectives on quality:

- The transcendental perspective tackles the metaphysical aspect of quality. From this standpoint, it is "something toward which we strive as an ideal, but may never implement completely;"
- The user perspective pertains to the suitability of the product for a stated context of use. In comparison, the transcendental view is volatile, the user view is more specific, based on the product attributes that satisfy user's needs;
- The manufacturing perspective indicates quality as conformable with requirements. This view of quality is stressed by ISO 9000, which defines quality as "the degree to which a set of inherent characteristics fulfills requirements" [40];
- The product perspective indicates that quality can be acknowledged by measuring the intrinsic attributes of the product; and
- The value-based perspective assumes that the different perspectives of quality may be approached differently by various stakeholders, especially with regard to its importance or value.

Quality is relevant for both products and services. This just refers to issues of the e-gov portals quality. The American Society for Quality perceives quality as "the totality of features and characteristics of a product or service that bear its ability to satisfy stated or implied needs" [41, p. 615]. Griffin referred to basic dimensions explored by Garvin, which determine the quality of a particular product or services. These dimensions are: performance, features, reliability, conformance, durability, serviceability, aesthetic, and perceived. For Juran quality is "fitness for use", and Deming believed that "quality should be aimed at the needs of the customer, present and future." Crosby said that quality is "conformance to requirement" [37]. Feigenbaum defined quality as "a customer determination based upon a customer's actual experience with a product or service, measured against his or her requirements – stated or unstated, conscious or merely sensed, technically operational or entirely subjective – and always representing a moving target in a competitive market" [42, p. 1].

In this research the quality of e-gov portals is considered as software product quality. However, a straightforward definition for software product quality is difficult to formulate. Depending on who is evaluating the quality of software product it can be either good or bad. For instance, to an end user, if a software product offers efficient and necessary functionalities to perform the task it was developed for, then software quality is good. A different perspective may have a software developer for whom maintainability or testability, how easy it is to maintain and eliminate bugs, are the main attributes of a good quality software product. And finally, a software architect can perceive good software quality from, for example, the angle of the reusability of the used software components or the scope and quality of the descriptive literature of the software product.

B. Models for assessing the quality of e-government portals

Approaches to assessing the quality of e-gov portals have been explored for a few years [43], [44], [45], [46], [47]. In the work on them, researchers indeed mainly examined, improved and adopted models, such as D&M [48], [49], [50], [51], TAM [52] and Wang's [53].

More generally, a framework for assessing the quality of e-gov portals covers three aspects of quality: system, information and service quality. System quality can be viewed as a measure of e-gov portals' functionalities. It is comprised of four constructs: usability, responsiveness, ease of access and privacy. Information quality is defined as the measure of the value which the information provides to a user. More specifically information quality can be described by four constructs: accuracy, dependability, coverage and ease of use. Service quality focuses on four others: empathy, interactivity, playfulness and aesthetic [36].

Wang and Liao [46] conducted an empirical test of D&M model adoption in the context of G2C e-government in Taiwan. Except for the link from System Quality to System Use, the hypothesized relationships between the six success variables were significantly or marginally supported by the data. The authors emphasized that "researchers can also use the validated model as the foundation for developing comprehensive e-government systems success measures and theories, exploring relationships between the proposed constructs, and comparing e-government success empirical studies" [46].

Almalki, Duan and Frommholz [43] suggested a conceptual framework for assessing e-gov portals' success which integrates the updated D&M model, TAM, self-efficacy theory and perceived risk. In this model 13 constructs are indentified for measuring success of e-gov. portals. Those are: system quality, information quality, service quality, computer self-efficacy, perceived risk, personal values, perceived usefulness, perceived ease of use, attitude towards using, behavior intention to use, user satisfaction, net benefits.

The next model is guided by both TAM, D&M model and the policies framed by the government of India. It includes dimensions for assessing e-service quality of government portals, such as quality dimensions: citizen centricity, usability, technical adequacy, privacy and security, usefulness of information, transaction transparency, comprehensive information, interaction [44].

Papadomichelaki and Mentzas conceptualized an e-government service quality model, eGovQual, where they indicate six constructs: ease of use, trust, functionality of the interaction environment, reliability, content and appearance of information, interactivity interaction [44].

Some researchers showed that navigation facility and accessibility are important in determining citizens' perceived system quality. Whereas information preciseness, timeliness, and sufficiency were found to be key measures in information quality in government e-services [54].

C. Basis of proposed framework for assessing the quality of e-government portals

The proposed framework for assessing the quality of e-gov portals is primarily built on the ISO/IEC 25010 [55]. This standard was chosen because of its breadth and completeness, and because of the prestige of the organization.

According to ISO/IEC 25010, the quality of a software product is "the degree to which the system satisfies the stated and implied needs of its various stakeholders, and thus provides value" [55]. The SQuaRE series of International Standards by quality models is based on those declared and indicated needs: the quality in use model and the product quality model in this International Standard, and the data quality model in ISO/IEC 25012. In this study the product quality model was employed. It defines eight main dimensions and related sub-dimensions for assessing software products (Table 1). Factors (items, constructs, metrics) in each sub-dimension should be defined individually according to the nature of assessed software product. The stated quality factors can build a checklist for ensuring a thorough handling of quality requirements, thus founding a basis for activities that will be necessary during software product development.

The ISO/IEC 25010 software product quality model relates to four layers of quality assessment explored by Halaris et al [45]:

- back-office process performance layer, addressing factors mainly found in quality of back-office operations (this layer relates mainly to the ISO/IEC *Compatibility* dimension);
- portal technical performance layer, addressing the factors of the technical performance of the portal (this layer relates mainly to the ISO/IEC dimensions: *Reliability*, *Security*, *Maintainability*, *Portability*, *Performance efficiency*);
- portal quality layer, addressing the factors of the portal usability (this layer relates mainly to the ISO/IEC dimensions: *Usability*, *Functional suitability*); and
- customer's overall satisfaction layer, addressing the overall level of quality perceived by the user against user's expectations (this layer relates mainly to the ISO/IEC dimensions: *Usability*, *Functional suitability*, *Security*, *Maintainability*, *Portability*, *Performance efficiency*).

TABLE I.
ISO/IEC 25010 SOFTWARE PRODUCT QUALITY MODEL

Quality dimensions	Quality sub-dimensions	Description
Functional suitability	Functional completeness	The software product's ability to provide functions and operations which are required to fulfill stated and implied users' needs
	Functional correctness	
	Functional appropriateness	
Performance efficiency	Time behavior	The software product's ability to offer sufficient efficiency and using reasonable amount of resources
	Resource utilization	
	Capacity	
Compatibility	Co-existence	The software product's ability to be interoperable with other software products
	Interoperability	
Usability	Appropriateness recognisability	The software product's ability to be easy to use, learnable and understandable
	Learnability	
	Operability	
	User error protection	
	User interface aesthetics	
	Accessibility	
Reliability	Maturity	The software product's ability to perform specified function under specified conditions for a specified period of time with the minimum crashes possible
	Availability	
	Fault tolerance	
	Recoverability	
Security	Confidentiality	The software product's ability to secure its internal information so that no unauthorized usage is possible
	Integrity	
	Non-repudiation	
	Accountability	
	Authenticity

The third model employed in the proposed framework for assessing the quality of e-gov portals was constituted and utilized by IT Project Centre in Poland [56]. This model focuses on usability of e-gov portals and includes 96 factors grouped into the following five dimensions: interface cohesion and user friendliness, pages design, navigation, content, e-gov services form, search engine, main page. Some factors of the IT Project Centre have been used in the *Usability* dimension.

III. RESEARCH METHODOLOGY

This study is a part of research on the holistic and systems approach to the e-government adoption in the context of sustainable information society [57]. Various methods and techniques have been applied in this research at three steps:

- The first step – a review of literature was conducted to explore various definitions of quality and different models for assessment of the e-gov portals;
- The second step – the framework for assessing quality of e-gov portals was established on the basis of literature findings, empirical observations, brainstorming and methods of creative thinking and logical deduction; and
- The third step – the pilot study (feasibility study, experimental trial) was carried out to verify and test the proposed conceptual framework. It was a small-scale, short-term experiment that helped pre-test the reliability and importance of indicated factors in assessing e-gov portals. The study was conducted in December, 2013. Three Polish e-gov portals that can be examples of "good practices" were evaluated. It was a self-assessment; each portal was evaluated by the qualified employees of the appropriate government unit. To classify each factor, the respondents had to carefully read and analyze their portal. E-gov portals' quality has been assessed on a two-point scale: 1 – the capability has been implemented correctly or the capability has been implemented partially; and 0 – the capability has not been implemented. All factors of the framework are equally important and none of them has been prioritized. The final evaluation of each portal is defined as the total sum of ratings of subsequent factors. Microsoft Excel was used to conduct the entire analysis. In the final step of our study, on the basis of creative thinking and logical deduction, recommendations on the evaluation of e-gov portals were formulated.

IV. Research findings

A. The proposed framework for assessing the quality e-government portals

In the proposed framework, a quality of e-gov portals is understood as their capability to satisfy stated and implied needs for the e-gov portal to be used under specified conditions. The dimensions and sub-dimensions of this framework were adopted from ISO standard. For each sub-dimension, the capability of e-gov portals is determined by a set of factors that can be measured. 89 factors were indicated that include 14 factors within *Functional suitability*, 6 factors – *Performance efficiency*, 6 factors – *Compatibility*, 27 factors – *Usability*, 11 factors – *Reliability*, 6 factors – *Security*, 13 factors – *Maintainability*, 6 factors – *Portability*. Detailed enumeration of these factors is presented in [58]. The dimensions, sub-dimensions and factors are structured in the framework as shown in Table 2.

The quality of e-gov portals can be evaluated by all government stakeholders, i.e. government units, citizens and enterprises. Maintainability concentrates on government units' self-assessment, while other dimensions put emphasis on citizens' and enterprises' as well as government employees' evaluation.

Table II.
THE CONCEPTUAL FRAMEWORK FOR ASSESSING THE QUALITY OF E-GOV PORTALS

Dimensions/ Sub-dimensions	Factors descriptions (capabilities)
1. Functional suitability (14 factors)	
1.1. Completeness	Delivering e-gov services at the different levels of maturity
1.2. Correctness	Correct operation of e-gov services
1.3. Appropriateness	Matching e-gov services to the current and future needs of stakeholders
2. Performance efficiency (6 factors)	
2.1. Time behaviour	Shortened time required to the settlement of the matter
2.2. Resource utilization	Reducing consumption of resources (e.g. paper, toner), decrease in employment in government units; reduction in various transaction costs
2.3. Capacity	Lack of restrictions for users while using portal (e.g. time, number of documents); swift loading and running
3. Compatibility (6 factors)	
3.1. Co-existence	Integration between portal, back-office systems and other e-gov portals; updated specification sheet comprising necessary information to integrate portal with other systems and portals
3.2. Interoperability	Unified and consistent layout and content of mandatory information about government units and e-gov services; standardized electronic forms for all e-gov services
4. Usability (27 factors)	
4.1. Appropriateness recognisability	Different assistance methods for users, e.g. help module, assistance available at every level of portal use, electronic courses, wizard for filling out electronic forms, advanced search engine accessible from every level of portal use, virtual adviser
4.2. Learnability	Intuitive operating of portal
4.3. Operability	Site map; at any time users know where they are and may return to any portal page at any time; not more than nine submenu level created for a menu
4.4. User error protection	Portal is protected against admitting wrong (incorrect) data; users are kept informed on the errors and the need to correct them; suggestions for users how to improve errors
4.5. User interface aesthetics	Defining the look of portal by users; portal pages are divided into clear blocks (sections); consistent layout and navigation on pages; highlighted important information (e.g. names of sections, names of e-gov services, names of government units); clearly formatted contents of pages; graphic signs (icons) facilitating portal use; clear and understandable descriptions of e-gov services; comprehensible electronic forms for e-gov services
4.6. Accessibility	Adjusting font sizes to users requirements; special version of portal for the visually impaired and the blind; foreign language versions of portal
5. Reliability (11 factors)	
5.1. Maturity	Portal is protected against non-standard behavior of users; certified information security

Dimensions/ Sub-dimensions	Factors descriptions (capabilities)
	management system according to PN-ISO/IEC 27001:2007 standard has been implemented
5.2. Availability	Portal accessible to the users 7 days a week and 24 hours a day; failure-free of portal working; delivering information on planned breaks in portal operations
5.3. Fault tolerance	In the event of non-critical errors on the portal, its other functions can still be used; in case of errors when sending the completed application form – the application is saved and it is available to the user after the next login
5.4. Recoverability	There is procedures in cases of portal failure to recover portal after failures and to create the archive data entered through the portal; there is a redundant portal (replacement) in the event of failure
6. Security (6 factors)	
6.1. Confidentiality	Users password is masked; required cyclical change of the password by users; encrypted the connection with the portal
6.2. Integrity	There is a procedure of data protection
6.3. Non-repudiation	For the study was combined with Accountability
6.4. Accountability	All of the actions on the portal are identifiable by the user (e.g. first name, surname) and the time when an action was completed (making history of actions undertaken)
6.5. Authenticity	Checking the complexity of the users' passwords from the viewpoint of safety standards
7. Maintainability (13 factors)	
7.1. Modularity	Modular construction of portal; updated specification sheet of relationships between portal modules
7.2. Reusability	Portal modules implemented in its different parts or other portals
7.3. Analysability	Easy analysis for change of modules and its impact on other modules or other integrated portals; informing about changes of module that affect other modules or integrated portals
7.4. Modifiability	Portal's functionalities can be modified and extended according to users' new needs and in accordance with the new letter of the law; users are informed about the availability of new portal functionalities
7.5. Testability	There are: a portal test environment, procedures for portal testing, procedures for changes of the production version of portal, procedures for returning to the previous version of portal; subsequent versions of portal are identifiable
8. Portability (6 factors)	
8.1. Adaptability	There is a mobile version of portal; portal can be used by any web browser and by any operating system
8.2. Installability	Use of portal does not require the purchase of specialist software and the installation of special software
8.3. Replaceability	Users are informed about the need to install the free software and its new version necessary for the proper functioning of the portal

B. Assessing the quality of e-government portals using the proposed framework

The cases of Polish e-government portals

Three Polish e-gov portals that can be examples of "good practices" were evaluated by using this framework. Those were: SEKAP (www.sekap.pl), Digital Malopolska (http://www.wrotamalopolski.pl) and the Gate of Podlasie (http://cu.wrotapodlasia.pl). Currently, all these portals are being improved and this research can help the local government authorities to manage improvement activities.

SEKAP is a result of strategic, innovative projects, that were carried out by the municipal and district authorities of the Silesian Voivodeship in 2005-2008 and 2009-2012 [13], [20]. It enables the provision of e-gov services, including five forms of the relations between government units and their stakeholders: C2G/G2C, B2G/G2B, G2G. The e-government services are provided at different levels of maturity, from the information level to the transaction level. Currently, 122 government units provide e-gov services through SEKAP to citizens, enterprises and other government units. SEKAP includes different kinds of 650 various e-gov services, while the number e-gov services delivered by an individual government unit is 27,264.

Digital Malopolska is a result of a strategic, innovative project that was carried out by the municipal and district authorities of the Lesser Poland (Malopolska) Voivodeship in 2004-2006. The e-gov services for government stakeholders are provided at different levels of maturity, from the information level to the transaction level. Currently, 187 government units provide e-gov services through Digital Malopolska to citizens, enterprises and other government units. Digital Malopolska includes different kinds of 128 various e-gov services, while the number e-gov services delivered by an individual government unit is 23,936.

The Gate of Podlasie is a result of a strategic, innovative project that was carried out by the municipal and district authorities of the Podlaskie Voivodeship and ended in 2006. The e-gov services are provided at different levels of maturity, from the information level to the transaction level. Currently, 97 government units provide e-gov services through the Gate of Podlasie to citizens, enterprises and other government units. The Gate of Podlasie includes different kinds of 1,060 various e-gov services, while the number e-gov services delivered by an individual government unit is 3,000. Currently, this e-gov portal is under reconstruction.

Assessing Functional suitability

All examined e-gov portals received very low scores in *Functional suitability* dimension (Figure 1). This mainly results from incomplete catalogue of e-gov services at the appropriate levels of maturity. In both cases of Digital Malopolska and the Gate of Podlasie the users of the portals pointed out at some malfunctions of the available e-gov services and the need to deliver new ones. Correct operation of the available e-gov services and the need to create new e-

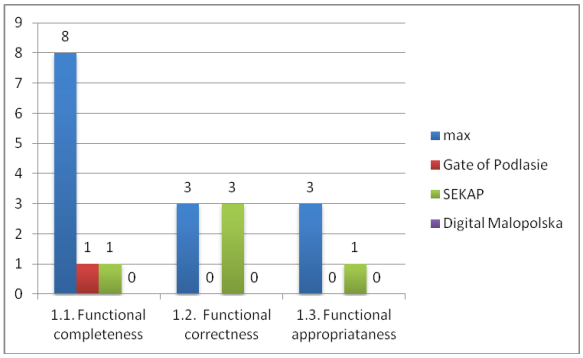

Fig. 1. Assessing *Functional suitability* of the Polish e-gov portals

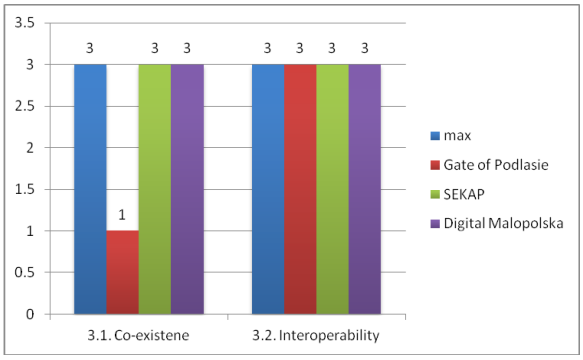

Fig. 3. Assessing *Compatibility* of the Polish e-gov portals

gov services were reported by e-gov employees to the SEKAP portal.

Assessing Performance efficiency

In *Performance efficiency* dimension, Digital Malopolska, received – 83% of all points, SEKAP – 67%, the Gate of Podlasie – 33% (Figure 2). All respondents indicated that the time of settling the matter initiated electronically is not shorter than of the matter initiated in a traditional way. Moreover, in both cases of Digital Malopolska and SEKAP there was smaller consumption of resources (paper, toner, etc.) and lower costs when dealing electronically than traditionally. In addition, in the case of these two portals there are no restrictions on their use, and government stakeholders did not report their observations on their operation being too slow.

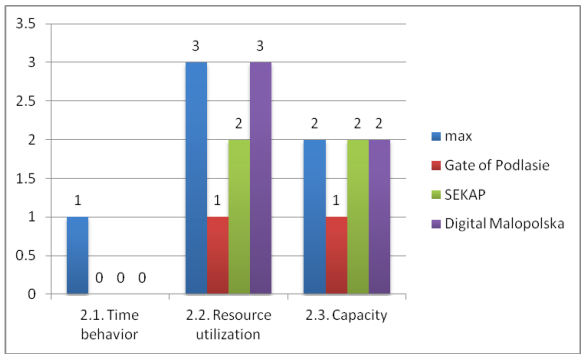

Fig. 2. Assessing *Performance efficiency* of the Polish e-gov portals

Assessing Compatibility

Digital Malopolska and SEKAP received 100% points in *Compatibility* dimensions, the Gate of Podlasie – 67% (Figure 3). All portals are integrated with different e-gov portals and back-office information systems (including different document management systems). Moreover, the documentation required to complete the integration is available. On all examined e-gov portals, information on e-gov services, information about e-government units and application forms is standardized.

Assessing Usability

Digital Malopolska received 85% of all points in *Usability* dimension, SEKAP – 74%, the Gate of Podlasie – 56% (Figure 4). All examined e-gov portals have help modules, providing assistance when filling out forms, and informing users about the errors made by them. They are protected against admitting wrong (incorrect) data. All examined e-gov portals have intuitive interface, easy navigation systems, not more than nine menu (submenu) levels. Only Digital Malopolska makes a portal map and e-learning on using the portal available. The portals do not have virtual advisers, and do not allow users to configure the layout of any portal (customization). Also, none of the portals is accessible for the blind, they do not offer voice messages, and there are also no foreign language versions of the portals.

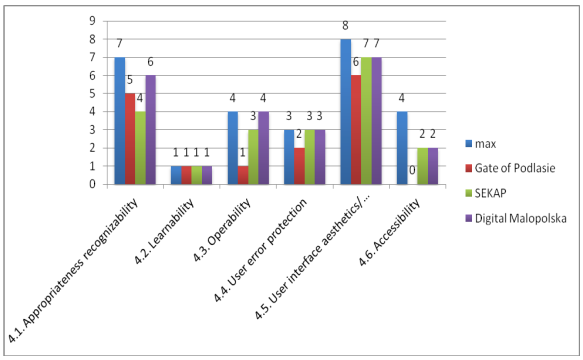

Fig. 4. Assessing *Usability* of the Polish e-gov portals

Assessing Reliability

SEKAP and Digital Malopolska received 91% of all points in *Reliability* dimension, the Gate of Podlasie – 73% (Figure 5). All portals are protected against non-standard behavior of users. It is worth emphasizing that the government units providing e-gov services on SEAKP and Digital Malopolska implemented certified information security management systems according to PN-ISO/IEC 27001:2007 [59]. All portals are accessible to users 7 days a week and 24 hours a day. Moreover, information on planned breaks in portals operations is delivered. In the event of non-critical errors on the portals, their other functions can still be used. There are procedures in cases of portals failures; to recover portals after failures and to create the archive data entered through the portals. SEKAP does not have a redundant portal (replacement) in the event of failure, while Digital Malopolska does not provide the re-send request after the failure of the portal.

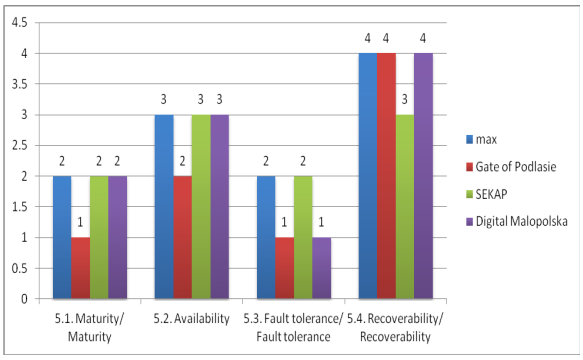

Fig. 5. Assessing *Reliability* of the Polish e-gov portals

Assessing Security

In *Security* dimension, Digital Malopolska received 100% of all points, whereas the Gate of Podlasie and SEKAP – 83% (Figure 6). Users' passwords are masked and the connection with the portals is encrypted. SEKAP and the Gate of Podlasie do not enforce the cyclical change of the password to the user's accounts. For all portals, procedures of data protection have been drawn. All of the actions on the portals are identifiable by the user (e.g. first name, surname) and the time when actions were completed. The complexity of the users' passwords from the viewpoint of safety standards is checked on the portals.

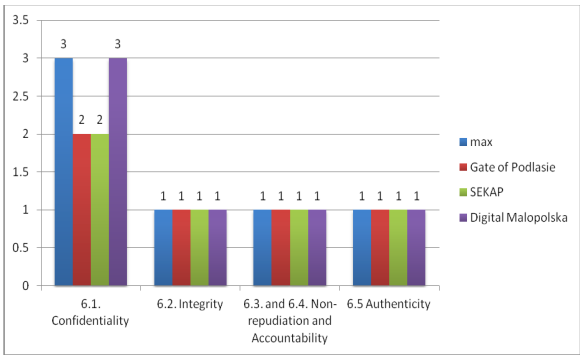

Fig. 6. Assessing *Security* of the Polish e-gov portals

Assessing Maintainability

In *Maintainability* dimension, Digital Malopolska received 100% of all points, SEKAP – 92% and the Gate of Podlasie – 31% points (Figure 6). All portals are made of modules and there are updated specification sheet of relationships between portal modules. Furthermore, the functionalities of the portals can be modified and extended according to users' new needs and in accordance with the new letter of the law.

Assessing Portability

In *Portability* dimension, Digital Malopolska received 83% of all points, whereas the Gate of Podlasie and SEKAP – 67% (Figure 7). All portals can be used by any web browser and by any operating system. There are not mobile versions of SEKAP and the Gate of Podlasie. The use of portals does not require the purchase of specialist software and the installation of special software.

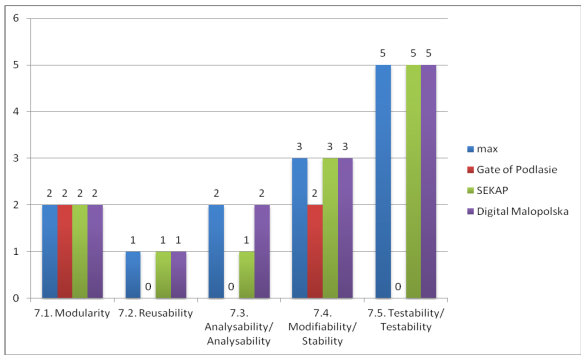

Fig. 7. Assessing *Maintainability* of the Polish e-gov portals

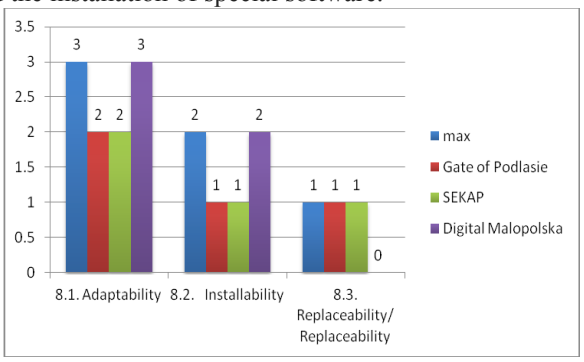

Fig. 8. Assessing *Portability* of the Polish e-gov portals

Overall assessing the quality of the Polish e-government portals

The study showed that Digital Malopolska portal meets the factors identified in the proposed framework (76%) to the greatest extent, the next one is SEKAP (74%), and the last – the Gate of Podlasie (48%). All in all, out of 89 points, the examined e-gov portals received sequentially – 68, 66 and 43 points (Figure 8). The lowest position of the Gate of Podlasie portal may be the result of its reconstruction. The portals have received the highest notes in *Compatibility*, *Reliability*, *Security* and *Portability* dimensions. They have been assessed worst in *Functional* suitability.

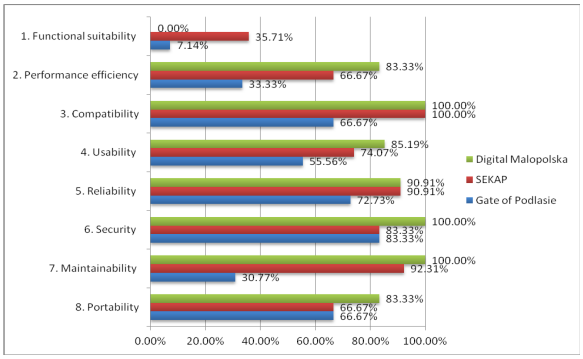

Fig. 9. The total assessment of Polish e-gov portals

V. Conclusion

So, in this paper a framework for the quality evaluation of e-gov portals based on International Organisation for Standardisation (ISO) standard is proposed. The aims of this research were to build a framework for a quality evaluation of e-gov portals and employ it in comparing three popular Polish e-gov portals. This framework can become a platform for developing a quality assessment of e-gov portals. Additionally, this work contributes to extant research by suggesting a framework based on ISO standard. The ISO was chosen because of its breadth and completeness, and because of its prestige.

Evaluation of three Polish e-gov portals confirmed each of the eight dimensions i.e. *Functional suitability*, *Performance efficiency*, *Compatibility*, *Usability*, *Reliability*, *Security*, *Maintainability* and *Portability* can be a good measure for e-gov portals quality. The identified factors measure the quality of e-gov portals from different points of views. At the same time, they show how e-gov portals should be improved.

This study provides several implications for research and empirical activities. It indicates an instrument which can identify the e-gov portals' features that are important for their quality. Researchers and scholars who develop studies on e-gov portals evaluation could find significant guidelines in this paper. They can use the instrument more confidently in their own research on e-gov portals and the successful e-gov adoption. Moreover, for practitioners, the results of this study can be used to undertake empirical activities aimed at evaluation and improvement of e-gov portals. Moreover, the framework can constitute important support for the procurement processes. The specified factors can be used to create the terms of reference for e-gov portal projects.

One limitation of this study was the small sample size, which is a concern because of reliability and validity issues. While this did not constrain the data analysis, a larger and more representative sample may yield more useful results. Another limitation was the verified and tested framework by e-gov employees only, while some factors of *Functional suitability*, *Performance efficiency* and *Usability* should be evaluated by citizens and enterprises. The third limitation was the two-point scale of evaluation, while generally the level of capabilities implementation should be measured. However, this study helps provide some insights that can lead to improvement of e-gov portals, not only in Poland but also in other countries.

The research will be continued. On the basis of the pilot study findings the factors will be modified and extended in each dimension, and Likert scale will be applied before launching a larger study. The theoretical and methodological paradigm of this research will be in-depth explored and the verification will be conducted on the example of Polish and other countries' e-gov portals.

***Abstract*—The information technology (IT) governance initiatives are complex, time consuming and resource intensive. COBIT, (Control Objectives for Information Related Technology), provides an IT governance framework and supporting toolset to help an organization ensure alignment between use of information technology and its business goals. This paper presents an investigation of COBIT processes' and inputs/outputs relationships with graph analysis. Examining the relationships provides a deep understanding of COBIT structure and may guide for IT governance implementation and audit plans and initiatives. Graph metrics are used to identify the most influential/sensitive processes and relative importance for a given context. Hence, the analysis presented provide guidance to decision makers while developing improvement programs, audits and possibly maturity assessments based on COBIT framework.**

I. Introduction

INFORMATION technology has become a vital and integral part of many business activities and also in the support, sustainability, and growth of enterprises. Business and IT departments, must understand each other and make the strategic / tactical plans together for achieving goals of the organization. IT should provide the necessary services to business, plan, manage existing services, be ready for agile developments, store and protect the data, consider operational jobs and so on. Managing that kind of complex organizations is very hard and to achieve well established management, a set of policies and processes are needed on corporate level [1]. IT governance is the structure of relationship and processes that ensure the effective and efficient use of IT to achieve organizational goals.

IT governance includes decision making structures, alignment processes and communication tools [2]. Demands of business departments, by force of competitive market, must be aligned with the plans of IT [3] [4]. IT needs to monitor all services, their life-cycles, and resources by considering the business expectations. To achieve this, enterprises seek for practical knowledge and well defined guidelines. The best known and generally accepted IT governance framework is COBIT. COBIT, now in its fifth edition, describes a set of good practices for the board and senior operational and IT management [5]. According to the ISACA COBIT 4.1 has been downloaded more than 100.000 times over 160 countries. Although COBIT version 5 is published, COBIT 4.1 is still in use in most organizations and widespread so that we use COBIT 4.1 as source in this research.

COBIT provides a governance framework, supporting toolset and maturity model to help an organization ensure alignment between use of information technology and its business goals in the areas of risk management, resource management, performance measurement, value delivery and regulatory compliance. It is based on best practice in IT management and control. COBIT framework defines 34 processes under four domains and also 318 detailed control objectives and associated audit guidelines. The framework identifies seven information criteria such as effectiveness, efficiency, confidentiality, integrity, availability, compliance and reliability as well IT resources as people, applications, information and infrastructure [6] [7] [8].

COBIT version 4.1 management guidelines provides a section, describe inputs and outputs for each process. These input and output tables represent a brief description for the processes' relationships. Examining the relationships provides a deep understanding of COBIT structure and may guide for IT governance implementation and audit plans and initiatives. In this paper, an investigation of COBIT processes' and inputs/outputs relationships with graph analysis is presented. We aim to analyze the relative importance of processes based on graph metrics hence provide information to decision makers for developing improvement programs, audits and maturity assessments based on COBIT framework.

This paper is organized as follows. Section 2 provides literature on analysis on COBIT processes. Section 3 presents the method used to obtain the COBIT graph. Section 4 and its sub-sections provide the results of graph metrics used. The last section summarizes the main findings.

II. Related Work

Although COBIT and its related sources have been investigated widely such as comparison with other frameworks, detailed investigation of a specific area like security or project management etc. there are not much published papers concerning the inputs and outputs of COBIT processes. In paper [9] Tuttle and Vandervelde

978-83-60810-58-3/$25.00

examine the conceptual model of COBIT in an audit setting. They used data from COBIT assessments made by a panel and confirmed the internal consistency of COBIT. But their perspective was IT audits and used the data from the experts not from the COBIT itself. In [10] Bernroider and Ivanov investigated COBIT for specifically project management control (PO 10). They also used an empirical survey as data source similarly as Tuttle and Vandervelde.

Morimoto argues that COBIT is too general-purpose and requires expert knowledge to implement [11]. Morimoto was interested in only security part of framework and tried to create a new framework from existing frameworks. For that aim he used combination of ISO/IEC 12207 and ISO/IEC 27002 with COBIT. Morimoto is not the only one argued COBIT is very abstract and hard to implement and control objectives are fundamental examples. There are numerous papers mentioned that abstraction in such papers as [10], [12] and [13].

In [14] Abu-Musa has made an empirical survey using self-administered questionnaire among 500 Saudi organizations and 127 valid respond was collected. His findings claims that banks and financial organizations show more concerns to IT governance than other industries. Paper also provides us important processes over domain level according to the respondents. PO7 (Manage IT Human Resource) is subtracted being the most important process in the plan and organize domain. PO1, PO2, PO5, PO10 and PO11 are important processes, as well. AI1, AI2 and AI4 are the most important processes in acquire and implement domain. For delivery and support domain most important process is DS5. ME1 is important in monitor and evaluate domain. According to the results of paper it can be concluded that the importance of COBIT processes may change so far as industry and organizations' aims. That variation of importance may be observed in Kerr and Murthy investigation, also. On the other hand COBIT's provides e.g. management guidelines, control objectives, RACI charts and inputs/outputs section. There are some fundamentals information may be used during in case of an implementation.

In [12] inputs and outputs of processes in COBIT 4.1 investigated directly. They used the number of inputs and outputs as inputs and investigated the importance of processes according to these numbers. Their findings includes the most influential processes that are sending more artifacts to all other processes as PO4, PO6, PO7 and PO8. It is claimed that any improvement plan sequence should include PO4, PO6, PO7 and PO8 in its initial phase. They also produced some key analyses such as sensitivity that is sum of total inputs. In that sensitivity graph ME1 is the top process due to many inputs from other processes to monitor their performance. Besides calculating the summation of all inputs and outputs of a process interconnection is measured. This research`s aim is similar with our paper. But they just used the total numbers of inputs and outputs of processes. In our research, we convert the relationships between processes among by inputs and outputs into a graph differentiating the inputs and outputs. Neto, Fonseca and Webster's approach aligns with degree calculations in this research and outcomes are exactly similar based on degree. On the other hand we go further than that, using other graph metrics. These findings may help developing improvement programs, audits and maturity assessments based on COBIT framework to optimize resources and time.

III. GRAPH BASED ANALYSIS OF COBIT

A. COBIT Graph

COBIT contains Management Guidelines, including Maturity Models, Critical Success Factors, Key Goal Indicators and Key Performance Indicators for each of the 34 processes that are under four domains (see Appendix A) COBIT also provides inputs and outputs on the management guidelines section of each processes. For 34 processes, input output information of each process' control objective by two different tables is also presented For example, Table I. represents the input output relation for the PO1 (Define IT strategic Plan) process. However, it is difficult to obtain any holistic information from these tables, 34 processes and their input/output table turned into a relationship matrix. Then that matrix is converted to a graph to be able to investigate the overall framework.

Using Gephi [1] the matrix is converted to a graph as Figure 1. To create the graph 34 processes represented as vertices or nodes and their relationships as edges or arcs. Three IT requirements, going outside of COBIT, also represented as vertices as OTHER1, OTHER2, and OTHER3. One output to the outside of COBIT represented as a node as OUTSIDECOBIT. So in Figure 1 there are process-like items as OTHER1, OTHER2, OTHER3 and OUTSIDECOBIT. The definitions of external requirement or outputs as shown below.

- OTHER1 is Business strategy and priorities, an input for PO1 (Define a Strategic IT Plan).
- OTHER2 is Programme portfolio, an input for PO1 (Define a Strategic IT Plan).
- OTHER3 is Legal and regulatory compliance requirements, an input for ME3 (Ensure Compliance with External Requirements)
- OUTSIDECOBIT is Classification procedures and tools, an output from PO2 (Define the Information Architecture)

[1] Gephi is an open-source software for network visualization and analysis and provides built-in functions to explore, manipulate and analyze the data. The software is for Exploratory Data Analysis goals to make hypothesis, to discover patterns by using visuality.

TABLE I

INPUT&OUTPUT SECTION OF PO1 PROCESS.

From	Inputs	Outputs	To
PO5	Cost-benefits reports	Strategic IT plan	PO2, PO3, PO4, PO5, PO6, PO8, PO9, AI1, DS1
PO9	Risk assessment	Tactical IT plans	PO2, PO3, PO4, PO5, PO6, PO9, AI1, DS1
PO10	Updated IT project portfolio	IT project portfolio	PO5, PO6, PO10, AI6
DS1	New/updated service requirements; updated IT service portfolio	IT service portfolio	PO5, PO6, PO9, DS1
*	Business strategy and priorities	IT sourcing strategy	DS2
*	Programme portfolio	IT acquisition strategy	AI5
ME1	Performance input to IT planning		
ME4	Report on IT governance status; enterprise strategic direction for IT		

To observe all interactions over COBIT the external IT requirements are included. Finally, The Graph has 38 nodes which are processes basically, 311 edges which are relationships between processes. The graph is a directed and weighted graph which means there can be a path from PO1 to PO2 but not counter wise. Edges have weights that the numerical value of edge shows actual number of edges from one process to another. If PO1 has two different outputs to PO2 that means the edge between PO1 and PO2 has a weight of 2.

Table III demonstrates betweensess centrality metrics as size of nodes. Visualization is prepared by force-atlas algorithm provided by Gephi in layout section. Visualized graph seems to be understood easier. Processes that not include in framework are out of the heart-like shape. And strong relationships between all processes may be concluded directly. Using graph metrics will provide a deeper understanding of COBIT structure and may guide for IT governance implementation initiatives. For this purpose in the following section, the graph metrics and obtained results are presented.

IV. GRAPH METRICS BASED ANANLYSIS

A. Degree

In a graph *degree* is total number of the edges belongs to a specific vertex. Degree is essential and effective measure to decide the importance of a node. In a directed graph two types of degree comes out, in-degree and out-degree. In-degree for a vertex v is the number of edges that v is the terminal vertex. Similarly out-degree of a node v is the number of edges that v is initial vertex. Degree basically, shows the strength of relationships between processes. In COBIT I/O graph the average degree is 8.184 that means approximately any process can have relationship with 8 other processes. But the graph is directed and weighted so average weighted degree is 10.842. As shown some of vertices have high degree, some of them have low degree. According to average weighted degree lowly linked and highly linked nodes can be noticed.

For a full degree list table II can be analyzed. PO4, PO6, PO7 and PO8 are the top four processes based on degree. But our graph is directed and weighted so both degree and weighted degree values have to be considered, respectively in table II. PO4 has the highest rank in total degree but in weighted degree list PO6 is in the number 1 rank. Moreover comparing table II it can be concluded that plan and organize processes dominates degree list.

From high level perspective can be concluded at domain level. PO (Plan and Organize) has the largest number of output information. So PO domain may be considered as a good starting point for governance initiatives. Then DS (Delivery and Support) domain is in the second rank.

Moreover COBIT governance initiatives can start based on their strategies not only domain level but also process level. For example implementation can start with DS 5 (Ensure System Security) and then continue with PO7. While these 2 processes are in progress monitoring should be active. So that parallel works can be done such as PO1 (Define a Strategic Plan), DS1 (Define and Manage Service Levels) can be in parallel. Also PO4 and PO7 enactment programs can be simultaneous. Hence, from the viewpoint of initiating governance programs the question of groupings of process may arise.

B. Centrality Metrics

Centrality is an important structural attribute of a graph meaning a centrality score is about how a node fits within a graph overall. Vertices that have highest centrality are likely to be key conduits of information. Low centrality modes can be named as peripheral. Lower centrality can be associated with less work overload in an organization [15]. Centrality of a vertex is the relative importance within a graph. There are two common and widely used centrality metrics which are betweeness and eigenvector centrality.

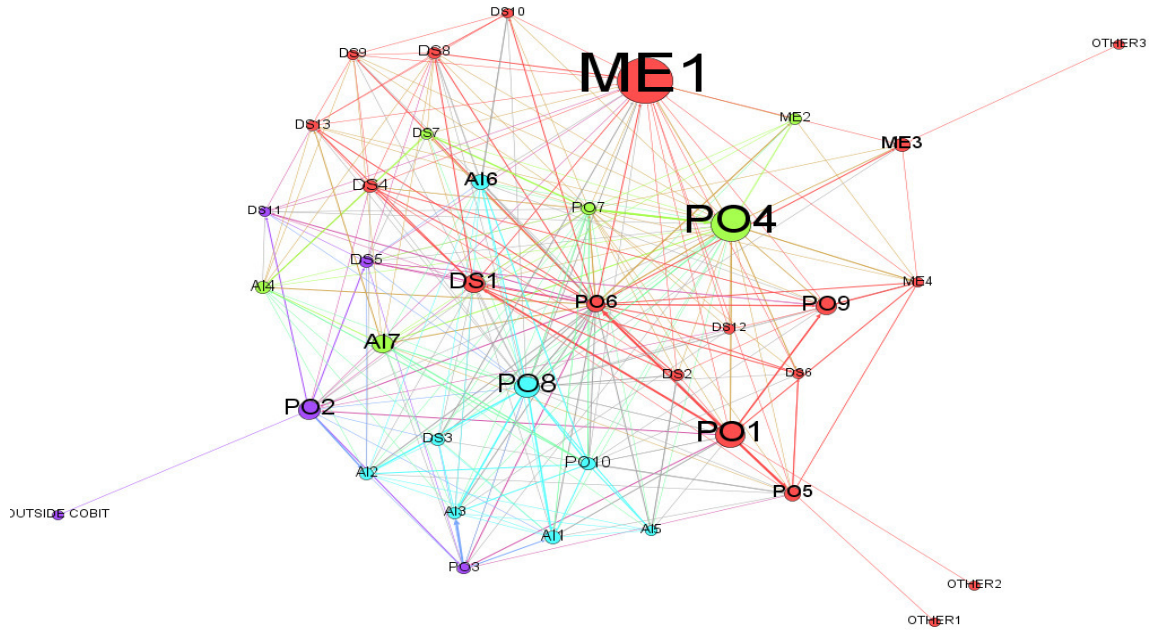

Figure 1 the Final Graph of I/O

C. Eigenvector Centrality

Eigenvector centrality or Gould index of accessibility [16] is calculated by assessing how well connected a node is to the parts of the network with the greatest connectivity. Eigenvector centrality is similar to the degree centrality but there is a difference that is eigenvector measures the importance of a node by the importance of its neighbors. A node receiving many edges does not mean receiver node has a high eigenvector centrality. Moreover, high eigenvector centrality node is not necessarily highly linked. That node may have a few edges to the other but they may be all important nodes.

Table III shows the eigenvector measurement. ME1 (Monitor and Evaluate IT Performance) has the highest score for eigenvector centrality. ME1 has a strong relationship with other processes as expected. But in the second rank is DS8 (Manage Service Desk and Incidents). DS8 gives outputs to AI6, DS10, ME1 and DS7. ME1 and AI7 have neighbors that have many connections and also takes inputs from 9 processes. As a conclusion DS8 is important because of its neighbor's importance. When top 5 processes are considered, they are similar in a manner. DS8 is for service desk, DS1 is for service levels, AI6 is to manage changes and finally PO9 is for risk management. These 4 processes are responsible to improve IT information criteria effectiveness and efficiency.

D. Betweenness Centrality

Betweenness centrality is a measure that is derived from shortest paths between nodes in a graph. The number of times a node acts as a cutpoint in the shortest point between two other nodes. In COBIT I/O graph that metric will show critical nodes to collaborate through all processes for spread of information. Algorithm in [17] is used to measure the centrality metric.

High betweenness nodes often don't have the shortest path to other nodes, but they have the greatest number of shortest path that have to go through them. Vertices that have high betweennes centrality metric, are critical to collaborate between other nodes. They are traders of information through the graph. Table III shows all nodes' betweeness centrality..

ME1 process has the highest betweenness centrality, PO4 follows it. DS6 (Delivery and Support domain – Identify and Allocate Cost) has the lowest betweenness centrality so that it can be inferred DS6 is an isolated process. DS6 is not a good point to maintain the spread of new information

TABLE III

FULL LIST OF DEGREE RESULTS

Process	Weighted Degree	Weighted In-Degree	Weighted Out-Degree	Degree	In-Degree	Out-Degree
PO6	75	9	66	39	6	33
PO4	53	15	38	42	9	33
PO8	52	7	45	39	6	33
PO7	46	7	39	37	4	33

AI4	4	23.51	0.42
AI5	4	6.39	0.43
OTHER3	4	0.00	0.00

E. Eccentricity

The eccentricity [18] is the distance of a starting node to the farthest node in a graph. COBIT graph here is weighted so that distance is a fundamental indice. In a graph minimum eccentricity value is its radius and maximum value is its diameter. In COBIT graph radius is 2 and diameter is 4. In Table III eccentricity values can be seen. PO4, PO6, PO7 and PO8 are in the list with value 2. But AI1 (Identify Automated Solutions), PO1 and ME1 are also in the list. Using eccentricity values it can be concluded that PO1, PO4, PO6, PO7, PO8, ME1 and AI1 are central vertices of the graph.

The overall results based on graph metrics are presented in Table IV.

V. CONCLUSION

Business dependency for IT services has been more crucial than ever. When the organization grows that dependency is increasing, too. To achieve organization's plans and business requirements IT governing the IT becomes tougher. Implementing an effective IT governance framework model becomes a necessity. Although providing a framework and toolset, it is hard to implement COBIT improvement initiatives. This study provides useful information about COBIT 4.1 framework from a holistic perspective. The findings presented in this paper can be used to develop a roadmap to plan the IT governance or audit initiatives.

Especially, plan and organize domain is found to be the most influential domain and processes PO4, PO6, PO7 and PO8 are particularly important. These processes produce many information items for the others, therefore these processes should be considered in first phase of the COBIT improvement initiatives. However it is important for an enterprise to decide based on specific objectives. The importance of the process implementation may change for the specific organization's approach. If the organization's aim may be to improve the current situation, then starting with PO2 process can be a good point, or the organization's aim may be to improve security then DS5 followed by AI6 and PO9 can be a starting point.

Also it is important to consider already enacted processes. Higher maturity level processes may produce mature outputs and in reverse processes that have lower maturity levels may be needed first as they may be central in the information flow. Using eccentricity values it can be concluded that PO1, PO4, PO6, PO7, PO8, ME1 and AI1 are central vertices of the graph.

As mentioned in the introduction, COBIT version 5 has been published. As a further research, we are planning to investigate COBIT5 in near future. In addition, usefulness of findings should be verified in practice.

TABLE IV

OVERALL RESULTS

Metric	Description	Outcome
Eccentricity	The distance of a starting node to the farthest node	AI1,ME1,PO1,PO4,PO6,PO7,PO8
Closeness Centrality	Close center node can communicate with the other without need of many inder-mediaries	PO4,PO6,PO8,PO7
Betweenness Centrality	The number of times a node is in the shortest path between other two nodes	ME1
Eigenvector Centrality	The summation of the centrality values of a nodes that is connected to	ME1
Degree	Total number of edges of a node	PO4
Weighted Degree	Total number of edges of a node with weights in each edge	PO6
In-Degree	The number of edges that node is terminal itself	ME1
Out-Degree	The number of edges that node is initial itself	PO4,PO6,PO8,PO7
Weighted In-Degree	Total number of edges that node is terminal itself with weights in each edge	ME1
Weighted Out-Degree	Total number of edges that node is initial itself with weights in each edge	PO6

Abstract— **The aims of this paper are to: 1) outline and discuss the framework for linking theater e-marketing with customer equity; 2) assess the impact of digital theater services on the metrics connected with Customer Lifetime Value. The results of empirical research suggest that art-oriented young Internet-users, who do not attend traditional theaters, can be attracted to digital theater services. Digital services can influence the potential patron's engagement in the theater's website, favorable word-of-mouth, and also their intention to visit traditional performances.**

INTRODUCTION

Marketing for performing arts organizations is mostly investigated through the lenses of the traditional marketing-mix, experience marketing or/and relationship marketing. As a new approach to marketing, based on customer equity, has been developing in the business sector (Blattberg & Deighton 1996; Rust et al. 2004; Hogan et al. 2002), it is tempting to start a discussion about the contribution of this approach to marketing of the non-profit cultural sector.

In this paper the problem of acquiring a digital audience is placed within the boarder context of customer equity. It aims to: 1) outline and discuss the framework for linking theater e-marketing with customer equity; 2) assess the impact of digital theater services on the metrics connected with Customer Lifetime Value (and therefore customer equity), such as a patron's intention to purchase theater services and to spread positive word-of-mouth referrals.

The paper is organized as follows. In the next section we discuss the research problem and outline the research framework. The third section refers to the results of the questionnaire study. The article concludes with the summarized results.

RESEARCH FRAMEWORK

A. The problem

Relationship marketing aims to build the loyalty of patrons, increase patron retention rate and to shift customers from the status of 'potential customer' to the level of 'partner' and is perceived as the base of theater strategy (Rentschler et. al 2002; Quero 2007). Relationship marketing differs from the customer equity approach. Customer equity emphasizes the role of profitability of the customer (not all relationships should be maintained from the company's perspective), and customer equity approach is also useful for the situations while building strong relationship between the company and the customer is difficult (e.g. FMCG market).

In the case of the theater audience, customer equity marketing[1] relies on:

- Relationships build with patrons. Classic theaters rely on building a relationship with their patrons, and the consumers often repeat their purchases for years. Therefore there is a possibility to evaluate Customer Lifetime Value (CLV) at an individual level or segment level (as opposed to the situation where single purchases cannot be traced e.g. buying washing powder, and only segment level data is available for evaluating customer equity)
- The valuation of the segment of regular theatergoers. The segment of frequent theatergoers is often the core audience (see e.g. - Instytut Teatralny "Raport – Badanie publiczności teatrów w stolicy" 2012; [http://www.instytut-teatralny.pl/projekty/raporty; 05.04.2014],

[1] Customer Equity Marketing is defined "[…] as a management approach for acquisition and retention, geared to individual lifetime values of current and future customers with the aim of continuously increasing Customer Equity" [Bayón et al. 2002, p. 214].

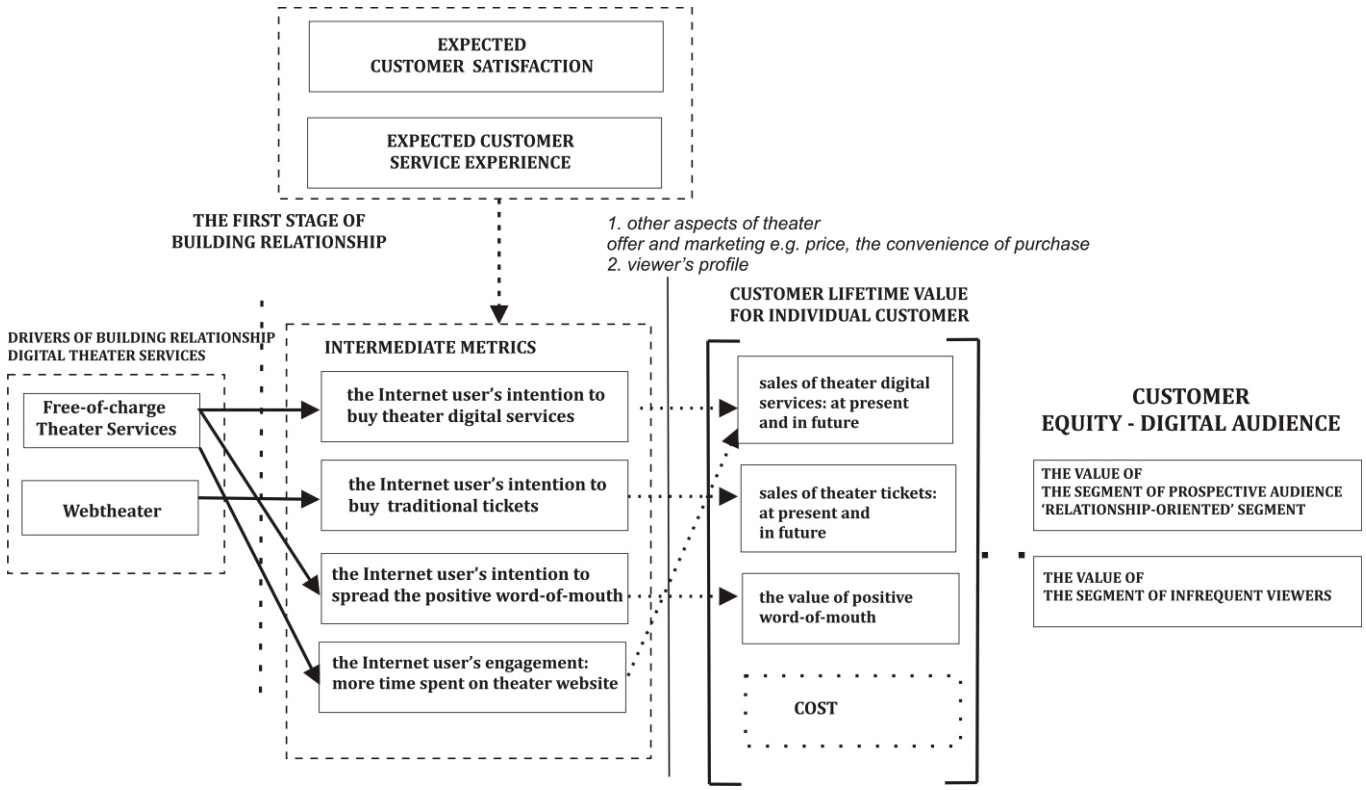

Fig. 1 The framework connecting theater e-marketing to customer equity

- Access to the data. The theater can often evaluate CLV at individual level (due to the data of subscribing patrons). The data referring to the market, such as number of viewers, number of performances, and cost of productions, is also often publicly available.

For overall theater strategy, customer equity management should be framed into boarder objectives such as objectives relating to artistic or curatorial quality, educational objectives, objectives relating to access for the public, objectives relating to knowledge, and social goals (Bakhshi & Throsby 2012 pointed out five dimensions for non-profit cultural institution). The idea of looking through the lens of maximizing customer equity may shape the theater's strategic decisions especially in other-than-product areas e.g. the selection of promotional channels, in the process of customer service before and after performance, or additional theater services. The advantage of applying customer equity lens lies in the shift from the product-oriented perspective to the customer-oriented perspective. The customer equity management (if implemented) would also 'force' theaters to investigate and manage the drivers of customer equity.

There are different approaches to the spectrum of drivers influencing customer equity. In the model developed by Rust, Lemon and Zeithml, brand equity is one of the drivers of customer equity along with value equity and relationship equity (Rust et. al 2004). Other researches point out that the concept of brand equity and customer equity are not the same constructs, but they can be seen as two sides of the same coin - marketing activities leading to the influence of brand equity also influence customer equity and vice versa (Bick 2009; Leone et al. 2006).

In this paper we raise the question whether the implementation of e-marketing tools can impact the variables influencing the first phase of building a relationship with prospective digital viewers, and therefore their Customer Lifetime Value and customer equity (as indicated in the research framework – Fig.1). We focus on the Internet as a tool of attraction strategy for a few reasons. Firstly, the Internet plays a significant role in theater e-strategy as:

1. The Internet facilitates innovation strategy for cultural organization in areas such as innovations in audience reach and in artform development, innovations in value creation and/or innovations in business management and governance (Bakhshi & Throsby 2012);
2. Websites or use of social media can ease the effect of constrained availability and uncertain outcomes of a 'difficult' theatrical brand. The Internet allows the establishment of 'persistent presence of the theater brand in patrons' mind' and the creation of 'small worlds - communities of performing art patrons' (see Preece & Johnson 2011);
3. The Internet can be effectively used in improving the responsiveness of theaters to different stakeholders, in enhancing the image, in attracting volunteers or sponsors and in selling tickets (Turrini et. al. 2012);
4. Social media can support marketing in the area of promotion and communication, word-of-mouth referrals, market research and innovation

management, and in reputation management (Hausmann & Poellmann 2013).

Moreover, as there is a steady decline in participation in art events and also with the problem of aging audiences (Turrini et al. 2012), the Internet allows theaters to reach young people, who are uninterested in traditional theater, but may become the theater audience within cyberspace. We assume that winning over a young audience in the competitive market of leisure activities needs 'the most untraditional approach'. Therefore in the empirical study we included the concept of theater services which are not only interactive, but break with the traditional perception of the role of the viewers. The tested concepts of new digital theater services are:

- free-of-charge digital products such as newsletters, ebooks about theater, webseminars about theater, webseminars about acting, gadgets connected with the theater, job posts, marketing research reports about theater;
- webtheater – the new artform which was described to each respondent as a possible option embedded on the website. So far, the live broadcasts of art performances (such as concerts, opera or even theater performance) lack the basic value of virtual communication, as they do not allow the spectator to co-create the product. The idea of the webtheater performance is based on co-creation of the play – the Internet-user can influence the flow of the performance by voting online on selected decisions e.g. the Internet-user can decide the fate of the main hero. Therefore the second part of the performance depends on the audience's decisions.

We assume that the Internet lowers the threshold of building the relationship between the prospective young viewers and the theater. For traditional performances "[t]he organization invests time, money and commitment to its mission to give the patron a rewarding experience. The audience also invests time, money and an emotional and social commitment in the arts organization." (Rentschler et. al 2002, p. 124). The Internet allows audiences to 'try' digital theater services, and makes theater attendance more convenient for young, digital audience. Is it 'the same theater' as traditional theaters from the aspect of the customer's experience? Probably not, but if traditional theatres do not attract young audiences, maybe 'digital theater' would meet their needs and enable the beginning of a young audience's relationship with traditional theater.

The customer equity approach raises questions about the drivers of customer equity for digital theater. We assume that the value of customers visiting the theater website (with developed interactive services) would be connected with at least:

1. financial value connected with direct purchases on the Internet e.g. tickets or other theater products (e.g. gadgets, ebooks);
2. indirect value connected with:
   a. enhancing the attractiveness of the website for advertisers (more engaged visitors stay longer on the website, probably paying more attention to its content including advertisements);
   b. Internet-user's referrals (performance, the theater website itself) to others;
   c. Internet-user's contribution, such as expressing and sharing opinions, which allows for improvement to the theater services (we did not capture this construct in the study).

B. The framework of empirical survey

The conducted survey was an exploratory study, and at this point of the research we focused on a selected problem - the link between online theater marketing and the rate of acquiring digital patrons. Therefore not all of the interrelations indicated in framework Fig. 1 were investigated.

We based the survey on a "what-if" scenario, while respondents were asked to what extent the new forms of free-of-charge services and interactive theater (webtheater) attracts their attention and influences their intention to purchase paid products.

In the study we measured the Internet-user's intention to purchase or consume the theater website services, assuming that strong intention leads to real purchase - if other aspects of the theater offer will be acceptable for the Internet user. The measured metrics, such as intention to buy theater services or tickets, the intention to recommend theater services or to be engaged on theater website, are linked with Internet-user's perception of service experience and expected satisfaction.

We want to emphasize that:

- we test the concept of digital theater services, not of developed and produced digital products;
- we do not include the costs, as the cost is 'unpredictable' at this point of research;
- the constructs of expected Internet-user' satisfaction, and perception of the expected experience are boarder than 'intentions' measured; although we presume that the user's intentions are linked with these constructs.

TABLE I.
THE QUESTION: NOWADAYS MOST THEATERS HAVE THEIR OWN WEBSITES, FACEBOOK, GOOGLE PLUS, TWITTER PAGE OR RUNNING BLOG. IF THE THEATER EMBEDDED THE FOLLOWING INTERNET SERVICES AND OFFERED THEM FREE-OF-CHARGE, HOW THIS WOULD AFFECT YOUR VISIT TO THE THEATER WEBSITE E.G. YOU SPEND MORE TIME ON THEATER WEBSITES ON A MONTHLY BASIS DUE TO VISITING MORE OFTEN OR TO CONSUMING MORE CONTENT OF THE WEBSITE? IF THESE SERVICES WHERE TO BE PAID FOR, HOW IT WOULD AFFECT YOUR ATTITUDE?

C. The data and the sample

Although the construct of customer equity as a value of the customer base is agreed, there is no consensus on how to calculate it and what drivers influence customer equity and what intermediate constructs and metrics should be used to assess customer equity. Kumar & George (2007) point out that the approaches to calculate customer equity which appear in literature can be divided into two main streams:

- aggregate-level approaches evaluate customer equity using customer life time value (CLV) for a segment or "average CLV" in the company. Therefore these methods focus on segment- or firm- level, and on such metrics as the acquisition rate, the average average contribution margin or the average CLV from a sample;
- disaggregate-level approach is based on the sum of the calculated individual CLVs, therefore this approach needs to be based on detailed and individual level data.

In our study we collected the data from the sample of individual respondents who filled in the questionnaire. As we do not have the data connected with costs, we concentrated on assessing the customers' willingness to purchase the product and in spreading positive word-of-mouth recommendations.

Our approach to Customer Lifetime Value refers to the model proposed by Kossecki (2007, 2011) in which CLV for individual customer c is evaluated as:

$$CLV_C = \sum_{t=0}^{CL} \frac{P_t}{(1+r)^t}$$

P_t –profit per individual user in t-period. This profit should be understood as financial profit coming

from two sources: direct purchases and positive word-of-mouth
CL – customer lifetime
r – discount rate;

From an aggregated level perception the digital audience can be divided into segments according to their willingness to build a relationship with the theater. The customers who focus on 'one-time' contact with theater (e.g. interested in receiving free-of-charge theater digital gadgets) are less valuable than the relationship-oriented customers. Valuation of the customers of the 'one-deal' segment may be based on such metric as the profit per transaction, but the CLV approach is more suitable for the segment of 'relationship-oriented' customers (Kossecki 2007; Kossecki 2011).

In the survey we implemented a questionnaire which was distributed in January 2014 among 146 respondents, within two different groups of young adults (under the age of 30 years-old): the students of a filmschool in Poland (whom we regarded as experts in the field of theater production, n=44) and students of business studies (whom we regarded as non-experts, n=102). There is a significant difference between the filmschool students and the business students in attendance to classic theaters (test U Mann-Whitney, $p<0.05$): both in the variable 'when last theater visit occurred' and the variable 'frequency of visiting theater during last year'. Most of the filmschool students attended classic theaters more than once during the last year (20% of filmschool students attended more than 3 times). In contrast, 76% of business students did not take part in theater performances for the last year, and 17% attended only once during the last year. In the study this group of business students is considered as the group of 'potential audience', who rarely or not at all attend classic theater. In the study we did not capture the socio- and demographical profile of respondents, but the sample is homogenous with the age of respondents.

D. Hypothesis

The framework for research (Fig. 1) leads to following hypotheses:

• Hypothesis 1: • The free-of-charge Internet services embedded on a theater website enhance customer's engagement
• Hypothesis 2: Free-of-charge Internet services embedded on a theater website enhance the sale of paid products.
• Hypothesis 3: The free-of-charge Internet services embedded on a theater website enhance customer referrals
• Hypothesis 4: The new digital interactive artform 'webtheater' enhances the customer's willingness to buy traditional tickets

We arbitrarily agreed that the percentage of the 'prospective audience' which we would consider as 'significant enough' to justify theater efforts to develop digital services should be at least 51% of the sample for services offered free-of-charged and at least 30% of the sample for paid theater services.

THE RESULTS

A. *User's interest in* subscribing to free-of-charge newsletters about theater is an important factor in market segmentation.

In the questionnaire the respondents were asked if they would be interested in subscribing to a newsletter about the theater. Among the group of 'potential audience' (n=102) 36% declared that they would not be willing to subscribe the e-newsletter (1 o 2 on the scale 1-5), 20% expressed a neutral statement (3 on the scale), and 44% stated that they are willing to accept the newsletter (4-5 on the scale). Further analysis showed that this factor - acceptance of newsletter subscription - can be used as a segmentation criterion of the potential audience. The group with lowest and the group of the highest acceptance of subscription perceived theater services differently (Table I). Therefore among the group of 'potential young audience' we identified the segment called 'art-oriented segment' (AO), and the segment of young people who are uninterested in classic theater and seems to be outside the possible reach as the theater audience ('out of target market' - OT).

TABLE II.
THE CORRELATION BETWEEN THE INTENSIONS TO USE FREE-OF-CHARGE THEATER SERVICE AND INTENTION TO PURCHASE THE SAME PAID SERVICE – SPEARMAN, $p<0.05$

	Young adults (general) (n=102)	**Art-oriented segment (n=45)**	**Filmschool students (n=44)**
e-book about theater	0.28	0.30	0.61
webseminar about theater	0.44	0.45	0.64
e-report about theater market (e.g. audience market research)	0.28	-	0.33
job posts connected with theater	0.30	-	-
gadgets	0.39	0.36	0.46
webseminar of acting	0.54	0.66	0.57
e-newsletter about theater	0.39	-	0.45

TABLE III.
WOULD YOU RECOMMEND THE THEATER WEBSITE IF…

		Negative (1-2)	Neutral (3)	Positive (4-5)	Average
the theater offers free services (these as indicated previously)	Art-oriented segment (n=45)	17.8%	8.9%	73.3%	4.0
	Out-of-target (n=37)	29.7%	8.1%	62.2%	3.7
	Filmschool (n=44)	18.2%	18.2%	63.6%	3.8
the theater offers paid services (these as indicated previously)	Art-oriented segment (n=45)	64.4%	20.0%	15.6%	2.2
	Out-of-target (n=37)	73.0%	18.9%	8.1%	1.9
	Filmschool (n=44)	59.1%	22.7%	18.2%	2.3

As the respondents were asked about their intention to visit theater websites on a regular basis (more visits, more consumed content in the month), this 'art-oriented' customers can be also regarded as 'the relationship-oriented' segment of internet users.

B. Hypothesis 1: The free-of-charge Internet services embedded on the theater website enhance customer engagement

The results indicate that a young audience can be attracted to the theater website as the result of offering free-of-charge theater services (Table I). Not surprisingly young people value the services as being useful in their potential jobs, such as webseminars about acting (public presentation is part of the modern job) or posts about jobs. Free gadgets attract the majority of users to the theater website. There are differences between the perception of website content by fimschool students and business students. It can be explained by access to other information sources with similar content (e.g. easier access to other materials connected with general art by filmschool students).

The percentage of art-oriented users attracted by theater services differs depending on the particular product, e.g. webseminars about theater attract about 30% of the potential audience; webseminars about acting, about 60%, with similar percentages for free-of-charge gadgets and e-books about theater. Among the art-oriented segment the average percentage of Internet-users willing to use free-of-charge services is 52% (compared to 35% of the "out of the target" segment).

C. Hypothesis 2: Free-of-charge Internet services embedded on theater websites enhance the sale of paid products.

Although the young audience is not very likely to buy services offered by the theater (Table I), the percentage of art-oriented internet-users willing to buy theater services ranges from 13% (webseminars about theater) to 44% (webseminars about acting). For this segment the average percentage of users willing to purchase theater services is 23%.

The correlation between the user's interest in free-of-charge services and willingness to purchase one is quite

TABLE IV.
THE PERCEPTION OF INTERACTIVE THEATER –WEBTHEATER. QUESTION: DO YOU THINK THAT TAKING PART IN WEBTHEATER YOU FEEL…

	Art-oriented segment (n=45)	Out of target (n=37)	Young audience (general) (n=102)	Filmschool Students (n=44)
The sense of belonging to theater community	3.2	2.5	2.9	3.0
Being immersed in storytelling	3.3	3.0	3.1	3.0
Reflection connected with art performance	3.5	2.8	3.2	3.8
Being with creative people	3.0	2.8	2.9	2.9
Taking part in special event	3.5	2.6	3.1	3.3
Intensive esthetic experience	3.0	2.5	2.8	2.7
Spending free time in meaningful way	3.6	3.5	3.6	3.5
Intensive emotion	3.5	2.8	3.3	2.9
The feeling of discovering the world	3.3	2.8	3.0	2.7
Intellectual challenge	3.4	3.1	3.2	3.1
Personal growth	3.8	3.3	3.6	3.0
Feeling being together with others during event	3.6	2.8	3.3	3.0

TABLE V.
QUESTIONS: DO YOU AGREE WITH THE FOLLOWING STATEMENTS

	Young audience (n=102)	**Art-oriented users (n=45)**		**Filmschool Students (n=44)**
	average (1-5)	average (1-5)	positive opinion (4-5)	average
The idea of webtheater sounds interesting to me	3.3	3.6	64.4%	3.4
I would like participate in such event	3.3	3.6	55.6%	3.3
Webtheater allows me to take part in theatrical performance more often	3.6	3.8	62.2%	3.2
Webtheater is a good idea for art promotion	3.6	3.6	62.2%	3.9
Webtheater encourages me to watch the performance in traditional theater	3.4	3.6	66.7%	3.1

strong among filmschool students; weaker among other respondents (Table II). It is especially worth noticing that offering free gadgets does not necessary lead to the purchase of one (there is a weak positive correlation). As an exception we can point to webseminars – in this case using free-of-charge webseminars about actors performing can probably lead to buying a paid one.

D. Hypothesis 3: The free-of-charge Internet services embedded on theater websites enhance Internet-user referrals

About 73% of Internet users from the 'art-oriented' segment declared that they recommend the theater website to others if the website includes free-of-charge services. The percentage drops to about 16% in the case of offering paid products (Table III).

E. Hypothesis 4: The new digital interactive artform *'webtheater' enhances the customer's* willingness to buy traditional tickets

The digital theater (webtheater) was assessed by respondents in two areas: their perception of the expected experience connected with attending a digital theater (Table IV) and their general assessment of this idea (Table V).

The respondents assessed their expected experience in 12 dimensions (see - Walmsley 2011). The art-oriented viewers valued their experience highly in the following dimensions: personal growth, the feeling being together with others during the event, spending free time in a meaningful way, taking part in special event, intensive emotions and reflection connected with art performance. This aspect of digital webtheater needed to be explored more, and further, with much deeper research. For our purpose, the main conclusion is that the idea of a new digital interactive theater was not rejected by the young possible audience.

In the second area, respondents were asked if the

TABLE VI.
SUMMARIZED RESULTS

	Out-of-target segment	**Art-oriented users**	**Filmschool students**
H1: The free-of-charge Internet services embedded on theater website enhance customer's engagement [at least 51% of the sample expressed a positive opinion towards using particular free-of-charge service]	Confirmed for gadgets	Confirmed for e-book, gadgets, jobs posts, webseminar about acting	Confirmed for job posts, e-newsletters
H2: Free-of-charge Internet services embedded on theater website enhance the sale of the paid products [at least 30% of the sample expressed a positive opinion towards buying paid content and there is at least a medium positive correlation between using the free-of-charge content and the intention to purchase]	Rejected	Confirmed for webseminars about acting	Rejected
H3: The free-of-charge Internet services embedded on theater website enhance internet user's referrals [at least 51% of the sample expressed a positive opinion]	Confirmed	Confirmed	Confirmed
H4: The new digital interactive artfom 'webtheater' enhances the customer willingness to buy traditional tickets [at least 51% of the sample expressed a positive attitude about watching traditional performance]	Rejected	Confirmed	Rejected

webtheater influences their willingness to attend traditional theater performances. About 67% of the art-oriented users declared that the digital performance sparks their interest in visiting a traditional theater.

CONCLUSIONS

The summarized results of empirical study (Table VI) suggest that the theater strategy of audience broadening (attracting a new group of audience) can be based on offering free-of-charge services and offering the new artform of webtheater. The main conclusions are:

- The digital theater services mainly attracted the 'art-oriented' young people, and this segment of potential digital audience can also be perceived as the 'relationship-oriented' segment.
- The results underline the importance of the e-newsletter as a digital tool aiming to create a relationship with a patron.
- The sale of paid content is not driven by offering free-of-charge content. At this point of the research we may presume that customer equity for theater website may be based mostly on indirect values such as a patron's referrals and engagement.
- Free-of-charge digital content on the theater website can influence positive word-of-mouth referrals.

However, the presented results should be further investigated as our research has at least the following limitations:

- The data is based on the convenient sample, and therefore it is difficult to generalize the results for a larger population. On the other hand, the Internet rarely allows researchers to base a survey on a more controlled sample (with the possibility of verifying the identity of the user).
- As we tested the concept of digital services we did not include the cost connected with the digital offer.
- We based this study on the assumption that a declared intention to buy leads to a real purchase.
- We did not differentiate between the theater brand and the theater website brand, assuming that these constructs are very close related;
- We did not include socio- and demographical profiles of respondents into the analysis e.g. current consumption of art, the income or the place of living.

Customer equity management for the cultural sector is the under-researched area, in which deeper theoretical and empirical research is needed. We consider of particular importance, further investigation into the following problems:

- Developing the framework outlined in this paper, aiming at building a CLV model - which would be applicable for theaters.
- Identification of the spectrum of drivers of customer equity in theaters;
- Further research about the concept of webtheater. This new product – allowing the patrons to shape the digital theater performance - raises the question not only about the possible income connected with the sale of tickets, but also about the patron's new experience.
- The connection between Internet-audience equity and traditional theater-audience equity.

3rd Workshop on Information Technologies for Logistics

THE main purpose of the workshop is to provide a forum for researchers and practitioners to present and discuss current issues concerning use of ICT in logistic applications (hardware and software). There will be also an opportunity for hardware integrators, software developers and logistics companies to demonstrate their solutions, as well as achievements, in different logistic systems.

Topics

The topics of interest include but are not limited to:

- Innovations in information systems supporting logistics and its management (WMS, SCM, TMS, LIS, VMI, CRP, PLM, and others)
- Innovative technologies in warehouse management: RFID, Voice Picking, Image Recognition, Pick Radar, etc.
- Logistics process modeling, including influence of warehouse automatic
- Optimization of logistics processes:
  - optimal vehicle routing and management, boundary conditions
  - optimal picking routing (global optimization, fast search, collision prediction and prevention)
  - shared mobility systems
  - day-to-day dynamic traffic assignment models
  - effective methods of picking (multi picking, batch picking ect.)
  - relationships between picking efficiency and products decomposition in warehouse area
- Environmental protection (for example carbon-aware transportation)
- Artificial intelligence systems and decision support systems in logistics
- BI, data mining and process mining in logistics
- Quality management algorithms and methods
- Material Flow Theory and applications

Abstract— An evolutionary algorithm with elitist selection and an immunological procedure has been developed for Pareto task assignment optimization in logistics. A multi-criterion optimization problem has been formulated for finding a set of efficient alternatives. Some criteria have been applied for evaluation of solutions: bottleneck machine workload, a machine cost, and a system performance. Moreover, some numerical experiments have been performed and the machine constraints have been respected.

I. Introduction

Genetic algorithms, evolutionary algorithms and evolution strategies are the alternative evolutionary approaches to the other meta-heuristic multicriteria optimization methods such as simulated annealing, immunological systems [1, 6], tabu search [12], scatter search or Hopfield neural networks [4]. Evolutionary calculations process simultaneously a solution population, which permits finding a subset of P-optimal alternatives by one run as a replacement for several isolated runs of the other multiobjective optimization techniques [7]. From this reason evolution approaches are convenient, if we look for the subset of Pareto-optimal solutions [16, 17].

Experimental outcomes demonstrate that elitism can increase performance of multi-objective evolutionary algorithms radically [18]. Moreover, elitism avoids the damage of non-dominated alternatives, if they have been established. A concept of elitism for multi-criterion evolutionary algorithms is taken from evolution strategies regarding evolution strategy developed for combinatorial and multi-objective optimization problems [5]. The other evolution strategy with an archive for finding P-optimal solutions has been suggested in [13].

In this paper, a problem of task allocation in logistics has been verbalized as a combinatorial and multi-objective optimization question characterized by some partial criteria: a machine cost, a bottleneck machine workload, and the system performance. Moreover, three kinds of constraints have been considered. The first constraint sort is related with the assumption that each task should be allocated to the machine, and the second one – with assumption one and only one machine should be allocated to a place of the task performing. Furthermore, the resource constraints are respected.

II. Evaluation Criteria

We assume that some important logistic tasks are performed by some machines, automatically. A bottleneck machine is characterized by the heaviest logistic task load. A bottleneck workload is should be minimized as a critical factor that can balance a whole load among elements. The weight of the bottleneck machine is calculated, as below:

$$Z_{max}(x) = \max_{i\in\overline{1,I}}\left\{\sum_{j=1}^{J}\sum_{v=1}^{V} t_{vj}\, x_{vi}^{task} x_{ij}^{p} + \sum_{\substack{v=1\\ u\neq v}}^{V}\sum_{\substack{u=1\\ k\neq i}}^{V}\sum_{i=1}^{I}\sum_{k=1}^{I} \tau_{ikvu}\, x_{vi}^{task} x_{uk}^{task}\right\}, \quad (1)$$

where

t_{vj} – a time of the overhead performing for the task number v by the machine sort number j,

τ_{ikvu} – a time of a resource transport between the task number v at the place w_i and the task number u at the place w_k.

$$x = [x_{11}^{task},\ldots, x_{vi}^{task},\ldots, x_{VI}^{task}, x_{11}^{p},\ldots, x_{ij}^{p},\ldots, x_{IJ}^{p}]^{T},$$

$$x_{ij}^{p} = \begin{cases} 1 \text{ if } p_j \text{ is assigned to the } w_i, \\ 0 \text{ in the other case.} \end{cases} \quad i=\overline{1,I},\ j=\overline{1,J},$$

$$x_{vi}^{task} = \begin{cases} 1 \text{ if task } T_V \text{ is assigned to } w_i, \\ 0 \text{ in the other case,} \end{cases} \quad v=\overline{1,V},\ i=\overline{1,I}.$$

The machine cost is determined regarding the formula, as below:

$$K(x) = \sum_{i=1}^{I}\sum_{j=1}^{J} \alpha_j x_{ij}^{\pi}, \quad (2)$$

where α_j is the machine cost for the sort number j.

The total machine performance is calculated, as follows:

$$\Theta(x)=\sum_{i=1}^{I}\sum_{j=1}^{J}\beta_j x_{ij}^{p}, \quad (3)$$

where β_j is the logistic machine performance for its sort number j.

III. Mutiobjective Optimization Problem

An optimal configuration of task in a logistic system that can be modeled as a task assignment may reduce the total cost of a set of tasks execution or the workload of bottleneck machine. It can decrease the cost of machines because of the machine sort selection, too. A total amount of system performance is another measure that can be maximized by task scattering and by the machine sort selection. An advantage of the system with an optimal task assignment may exceed 50% value of any criterion for a system with a task scattering designed without an optimization technique [2]. The bottleneck machine load is assessment criterion of the system configuration that causes the load balance and also minimizes a response time [3].

In that problem, the admissible solution satisfies three classes of constraints. Because each unit is allocated to one node, the logistic task allocation constraints are devised, as below:

$$\sum_{i=1}^{I} x_{vi}^{task}=1,\ v=\overline{1,V}. \quad (4)$$

We assume one and only one machine should be allocated at each node. It implies the machine allocation constraints, as follows:

$$\sum_{j=1}^{J} x_{ij}^{p}=1,\ i=\overline{1,I}. \quad (5)$$

Each machine provides some resource capacities to perform some assigned tasks. Let some resources $z_1,...,z_l,...,z_L$ be required in a logistic system. We introduce μ_{jl} to represent the lth resource capacity in the machine p_j. We assume the task number v holds η_{vl} units of z_l. The values μ_{jl} and η_{vl} are nonnegative and limited.

The resource capacity limit in any machine in the ith place cannot be exceeded, what can be written, as bellows:

$$\sum_{v=1}^{V}\eta_{vl}x_{vi}^{task}\le\sum_{j=1}^{J}\mu_{jl}x_{ij}^{p},\ \ l=\overline{1,L},\ i=\overline{1,I}. \quad (6)$$

The multiobjective optimization problem may be established a triple $(\mathcal{X}, F, P)$ to find the Pareto representation of some optimal solutions, as follows [15]:

1) $\mathcal{X}$ - an admissible solution set

$$\mathcal{X}=\{x\in\mathcal{B}^{I(V+J)}\mid \sum_{j=1}^{J}x_{ij}^{p}=1,\ i=\overline{1,I};$$
$$\sum_{i=1}^{I}x_{vi}^{task}=1,\ v=\overline{1,V};$$
$$\sum_{v=1}^{V}\eta_{vl}x_{vi}^{task}\le\sum_{j=1}^{J}\mu_{jl}x_{ij}^{p},\ \ l=\overline{1,L},\ i=\overline{1,I}\}$$

$\mathcal{B}=\{0, 1\}$

2) f – a multi-objective optimization criterion

$$f:\mathcal{X}\to\mathcal{R}^3, \quad (7)$$

where $f(x) = [K(x), \Theta(x), Z_{max}(x)]^T$, $x\in\mathcal{X}$

3) P - the relationship of optimization preferences [14]

IV. Mutiobjective Optimization Algorithms

Some advanced evolutionary algorithms have been developed for several multi-objective optimization problems [8, 9, 11]. What is more, some of them have been tested for finding the set of Pareto-optimal task assignments [2, 3].

A ranking idea for non-dominated individuals was introduced to avoid the prejudice of the interior Pareto solutions [10]. Then, the first algorithm called NSGA with the ranking procedure has built on the ideas mentioned by Goldberg [15].

In a current population, some non-dominated individuals get a rank equal to 1. Then, the second level of non-dominated alternatives is assigned the rank 2. This assigning procedure is recurred until the population is preceded. It is worth to mention that all non-dominated individuals have the same reproduction fitness because of the equivalent rank.

Deb et al. have improved NSGA by introduction an elitist procedure [8]. In an evolutionary algorithm called NSGA-II, a selection of potential parents is based on a binary tournament. Both an offspring population and a parent population are combined to select a new parent population. If two chromosomes are characterized by the other ranks, it with smaller rank is preferred. If individuals have the same rank, there is preferred the logistic configuration of tasks in a less overcrowded region.

V. Adaptive Multi-Criterion Evolutionary Algorithm with Elitist Selection

Adaptive evolutionary algorithm with elitist selection called AMEA+ is noticed as an advanced optimization technique for multi-criterion logistic task assignment [3]. Figure 1 shows a diagram of AMEA+. The preliminary set of chromosomes is erected to satisfy constraints (4) and (5)

(Fig. 1, line 3). Generated individuals are constructed by integer coding, as below:

$$X = (X_1^{task},..., X_v^{task},..., X_V^{task}, X_1^p,..., X_i^p,..., X_I^p), \quad (8)$$

where $X_v^{task} = i$ if $x_{vi}^{task} = 1$ and $X_i^p = j$ if $x_{ij}^p = 1$. Besides, $1 \le X_v^{task} \le I$ and $1 \le X_i^p \le J$.

Fitness function is calculated for some admissible solutions (Fig. 1, line 4), as below:

$$F(x) = P_{max} - \lambda(x) + \lambda_{max} + 1, \quad (9)$$

where $\lambda(x)$ is the admissible solution rank, $1 \le \lambda(x) \le \lambda_{max}$.

1. BEGIN
2. φ:=0, enter ψ – the size of chromosome population, γ – the chromosome length, p_m:=$(\psi\ \gamma)^{-1}$;
3. Create a preliminary set **Pop**(φ), **M**(φ):= **Pop**(φ);
4. Compute ranks $\lambda(x)$ and values of fitness $F(x)$, $x \in$ **Pop**(φ)
5. work:=TRUE
6. WHILE work DO
7. BEGIN /* create a new population */
8. φ:= φ +1, $\mathbf{Pop}(\varphi) := \varnothing$
9. Estimate probabilities $p_s(x)$, $x \in \mathbf{P}(\varphi - 1)$
10. FOR ψ/2 DO
11. BEGIN /* reproduction cycle */
12. 2WT potential parent selection (**a,b**) from **P**(φ -1)
13. S-crossover of a pair (**a,b**) with the adaptive crossover rate $p_c := e^{-\varphi/T_{max}}$
14. S-mutation of an offspring pair (**a',b'**) with p_m
15. **P**(t):=**P**(t) $\cup$ (**a',b'**}
16. END
17. **P**(φ):= **M**(φ) $\cup$ **P**(φ)
18. Compute ranks $\lambda(x)$ and values of fitness $F(x)$, $x \in \mathbf{P}(\varphi)$
19. An elitist selection of ψ solutions with the largest F(x) in **P(t)**; if more than ψ items have the same rank, use the crowd measure to select ψ solutions;
20. IF ($\varphi \ge T_{max}$ OR **P**(φ) converges) THEN work:=FALSE
21. END
22. END

Fig. 1. A diagram of an adaptive multi-criteria genetic algorithm with elitist selection

The 2WT potential parent selection is the two-weight tournament because two times the roulette rule is made.

The chromosome crossover point is randomly selected and two offspring are formed regarding $p_c := e^{-\varphi/T_{max}}$. The first part of the parent **a** is concatenated with the second part of the parent **b**. Similarly, the first part of the parent **b** is concatenated with the second part of the parent **a**. Each pair of potential individuals is randomly chosen for crossover with the probability pc. If chromosomes are not taken for crossover, parents are transferred to a set of offspring. A crossover rate decreases during the progressing of evolution. So, the changes of a search area retire slowly.

The S-mutation is based on the integer random modification by another feasible value. For X_v^{task}, the set $\{1,..., I\}$ is considered, and for X_i^p, the set $\{1,..., J\}$ is adequate. A constant mutation rate is assigned.

A search space for the considered evolutionary algorithm consists of $I^V J^I$ elements. It can be proved that S-crossover and S-mutation give ability for obtaining each solution in the search space. So, we can expect to find non-dominated assignments after an exhausted search.

Some numerical experiments demonstrate that elitism may improve the quality of alternatives [13, 14, 18]. An improved elitist selection is carried out as follows. Let M(t) be an old population P(t-1) and P(t) be a new population created from M(t) by mating, crossover and mutation. Firstly, a sum of two populations M(t) $\cup$ P(t) is created. Secondly, ranks are calculated for an entire population M(t) $\cup$ P(t). Each non-dominated solution in the extended set is characterized by the fitness value regarding its rank. Finally, L solutions are qualified with the higher fitness f (x) to P(t).

Let T_{max} be a maximal number of new populations that is O(n), where n = max{I, V, J}, I is O(J), and V is O(J). Moreover, let a size L of population be O(n), too. Now, we can assess a complexity of the AMEA-II. Fitness (Fig. 1, line 18) is calculated $O(n^2)$ times what gives the complexity $O(n^6)$ for the AMEA-II applied to the multi-objective logistic problem.

VI. Convergence Measure

The convergence of the studied algorithm can be considered by measuring the quality of obtained logistic task assignments to the Pareto front. So, we introduce a closeness measure for the obtained efficient points to the given Pareto points $\{P_1, P_2,..., P_U\}$. They may be found by enumerative search for small instances. An evolutionary algorithm can find the set of sub-efficient points $\{A_1, A_2,..., A_{U'}\}$, where $U' \le U$. If there is an outcome $A_u=(A_{u1}, P_{u2}, A_{u3})$ with the same cost of computers as the uth Pareto result $P_u=(P_{u1}, P_{u2}, P_{u3})$, then the distance between these points is equal to $\sqrt{(P_{u1} - A_{u1})^2 + (P_{u4} - A_{u4})^2}$. If A_u is missed by the AMEA+, then the distance $\sqrt{\sum_{\substack{i=1 \\ i \ne 2}}^{3} (P_{ui} - A_{ui}^-)^2}$ is considered, where A_{u1}^- is the maximal load of the bottleneck machine, and A_{u3}^- is the minimal performance of machines, for the instance of the problem (7).

Some ξ initial populations are generated, and ξ values of the distances S_u^1 are calculated. A convergence criterion to the P-set is calculated, as below:

$$S = \frac{1}{\xi}\sum_{l=1}^{\xi}\sum_{u=1}^{U} S_u^1. \qquad (10)$$

The AMEA+ gives better results than AMEA without an elitist procedure. In the 200 iteration, S is 1.3% for the AMEA+ and 1.6% for the AMEA. Above algorithms have been run 30 times.

For the instance with 2 places, 10 tasks, and 5 machines types, 30 binary variables generate 1 073 741 824 solutions in the search space. Θ is a value from [200, 600], K is from [2, 10] [money unit], and Z_{max} is from [26; 75] [time unit].

A formula $I\,^{V}J\,^{I}$ permits to calculate an upper bound of the number of an admissible set. Figure 2 displays the two criteria space of evaluations. The ideal point y^o and the anti-ideal point y^- can be used for finding a compromise solutions.

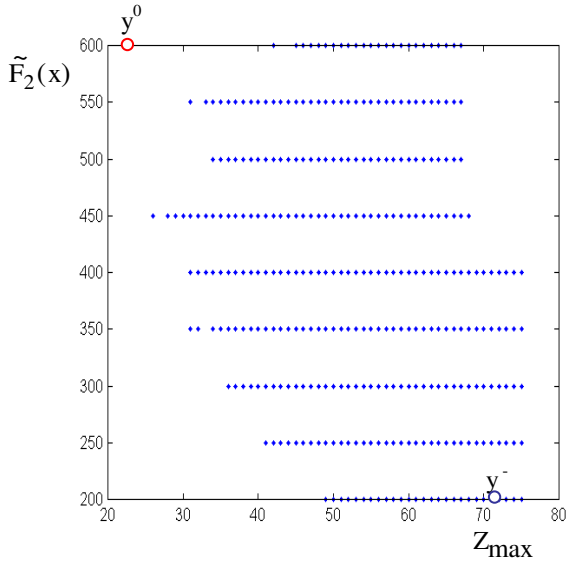

Fig. 2. Bi-criteria evaluation space

VII. Concluding Remarks

The AMEA+ is capable techniques for solving a multiobjective optimization problems focused on finding logistic task allocations that minimize the cost of machines, a workload of the bottleneck machine, and maximize performance of logistic system.

Every one of non-dominated solutions in the combined population is assigned a fitness based on the rank of solutions. Dominated solutions are assigned fitness worse than the worst fitness of any non-dominated solutions in a population. This assignment of fitness makes sure that the search is directed towards the non-dominated solutions, too.

Our future works will focus on finding the combination the multicriteria evolutionary algorithm with the immunological algorithm to include some ranking procedures to handle constraints and for improving the obtained Pareto-optimal task assignments.

***Abstract*—Arctic Development is one of the strategic goals of Russia and other circumpolar countries. Solution of this problem is faced with the problem: most of the coastal seas and the Arctic Ocean is covered with ice. For large vessels and icebreakers problem is solved by applying remote sensing of ice with spacecraft and aircraft. This solution has a very high cost and low efficiency. The authors propose to use for this purpose unmanned aerial vehicles (UAVs). This paper describes the solution of choice of UAV. This paper describes the solution of choice UAV. The features of the use of equipment for photo and video and microwave sensing of ice.**

I. Introduction

THE Arctic is extremely important military-strategic significance for Russia. Mission of Northern (Arctic) Federal University named after M.V. Lomonosov - formation and development of competitive human capital in the North-West Federal District through the creation and implementation of innovative services, development from the perspectives of the development of the Russian North and the Arctic. To achieve this mission NArFU has highly skilled specialists, high-tech equipment, the ability to introduce new developments in the production and achieve the desired result. Russian Government commissioned a comprehensive research in the Arctic is the NArFU

Arctic exploration is largely hampered by the presence of ice in the Arctic Ocean and adjacent seas. The problem of predicting the state of the ice: its thickness, density, size of the ice fields - is one of the most important issues of today. Methods of direct examination by the state of the ice landing on the surface is not always applicable for reasons of safety. For forecasting ice conditions are more commonly used methods of distance study.

Remote sensing - sensing the Earth's surface is on board aircraft or equipment from space using the properties of electromagnetic waves emitted, reflected or scattered by the sensed objects, for the purpose of providing information for disaster management, improve management of natural resources land use management and environmental protection.

Remote Sensing - a set of methods for study of the atmosphere, the earth's surface, the oceans, the top layer of the earth's crust by air aerospace methods based on the decoding of images obtained at a distance from the aircraft.

The result is:

1. Aerial photographs obtained from a height of preferably 500 m up to 10 km, but not more than 30 km;
2. Space images - from a height of 150 km.

Operating regions for the filming freeze commonly use the following satellites:

1. The radar KA RADARSAT-1 and ENVISAT-1 to provide a guaranteed all-weather shooting at any time of day.
2. Highly optical satellites EROS A/B for a detailed analysis of regions ice and flooding, SPOT multispectral optical unit 4 for the analysis of ice on rivers, ice crossings and in areas of potential ice blocks.

All remote sensing techniques for observing the Earth's surface use electromagnetic (EM) radiation in the visible/near-infrared (VNIR), thermal infrared (TIR) or microwave bands of the electromagnetic spectrum. There are three principal measurement techniques applicable to ocean and sea ice observations:

1. Measurement of the part of the incoming solar radiation that is reflected at the surface of the Earth (visual and near-infrared remote sensing).
2. Measurement of the thermal radiation from the surface (thermal infrared and passive microwave remote sensing).
3. Measurement of the return signal from an active source, such as a microwave radar, using several types of instruments that measure backscattered radiation from the surface.

The sea ice surface can be considered to have three macroscopic components:

1. Open water in leads, polynyas and melt ponds on top of the ice in summer.
2. Ice with varying amounts of salt water intrusions (salt pockets).
3. Snow on top of the ice.

978-83-60810-58-3/$25.00

The following properties of the macroscopic components have impact on the remote sensing measurements:

1. Percentage and distribution of the three components.

2. Temperature of the components.

3. Salinity of the components and the distribution of salt intrusions in the ice.

4. Crystal structure of the ice and the snow.

5. Occurrence of snow and ice layers, and rough surfaces (e.g., floes, ridges, frost flowers).

In addition, there are variables defined by the remote sensing instrument that also have significant impact on the measurements:

1. Frequency (wavelength) of the radiation.

2. Angle of incidence of the radiation.

3. Polarization of the radiation if the view is not from directly above.

The main disadvantages of the methods at work in the Arctic:

1. The use of space or air assets has a high cost, so it can be used only for large vessels (nuclear icebreakers, military ships, tankers). For smaller vessels, which often carry out scientific research and commercial activities (fishing, harvesting of marine animals, environmental activities) use of these funds because of high prices is impossible.

2. Low levels of efficiency: for taking pictures requires considerable time. Receive data in real time is difficult.

3Files aerial and satellite images are quite large, making it difficult to transmit this information via communication channels. In the Arctic, there are problems with communication, mainly by satellite, which is unsustainable. This leads to the fact that the communication channels are quite narrow and has a high data transfer rates [1].

We propose to explore the question of the use of unmanned aerial vehicles (UAV).

II. UNMANNED AERIAL VEHICLES

Stimulus to the development of unmanned aircraft in the world was the successful and widespread use of UAVs by the armies of the United States and Israel during the military operations (Persian Gulf, Yugoslavia, the Middle East, the Arab-Israeli wars). While drones have proven to be an effective means of intelligence, combat support, as false targets for the detection of enemy air defense systems, delivery of goods, to perform other missions.

UAV - in general, this aircraft without crew on board. The notion of an aircraft includes a large number of types, each of which has its analogue drone. In this article the definition of UAV misses the following concept: aircraft without crew on board, using the principle of creating aerodynamic lift by fixed or rotary wing (UAV aircraft and helicopter type), equipped with an engine and having a payload and flight duration, sufficient to perform specific tasks.

One of the major problems with UAVs - management of the unit.

There are the following control methods:

1. Manual control of the operator (or remote piloting) with remote control within optical observability or specific information from the forward-looking video camera. This control operator primarily solves the problem of piloting: maintaining a desired course, altitude, etc.

2. Automatic control provides the ability to fully autonomous UAV flight along a predetermined path at a predetermined height at a given rate and the stabilization of the orientation angles. Automatic operation via onboard software devices.

3. Semi-automatic control (or remote control) — flight is performed automatically without human intervention using the autopilot initially set parameters, but the operator can make changes to the route online. Thus, the operator has the ability to influence the outcome of the operation that is focused on the task of piloting.

Manual control can be one of the modes for the UAV, and may be the only way to manage. UAVs, deprived of any means of automatic flight control.

Last two methods are currently the most popular among users of unmanned systems, as impose the least training requirements and ensure safe and efficient operation of UAV systems Fully automatic control can be an optimal solution for a given section of aerial tasks when you need to shoot at a great distance from home base is in contact with the ground station. At the same time, as the responsible person for the flight, the launching, the opportunity to influence the flight from the ground station can help avoid emergency situations.

To perform specific tasks, particularly for aerial photography and remote sensing, UAV should be considered in conjunction with its instrumentation and payload, which introduced the term unmanned aircraft system (UAS).

UAS, in addition to the UAV consists of onboard control complex, payload and ground control station.

1. Onboard complex:

- Integrated Navigation System;
- Satellite Navigation System Receiver;
- Autopilot. Autopilot problem:

a) Piloting: automatic flight on a given route, automatic takeoff and landing approach, maintaining the desired altitude and airspeed, the stabilization of the orientation angles, forced landing in the event of engine failure or other serious problems.

b) Software control onboard systems and payloads, such as camcorder stabilization and synchronization time and coordinates of the camera shutter, release the parachute.

- Drive flight information.

2. To payload for remote studies of ice refers digital camera, can be used as addition video camera, thermal imager, infrared camera, microwave complex.

3. Ground control functions: Flight tracking, Data receiving, Transfer commands.

Formulate a series of signs to determine the UAV used for the remote research of ice:

1. Type: UAV aircraft or helicopter type.

2. Control mode: automatic or semi-automatic.

3. UAV remote research of ice must have on board a complete autopilot, capable of withstanding the shooting parameters (route angles equipment, the percentage of longitudinal and transverse floors, height, etc.) even at low weight machine in a wide range of weather conditions.

4. Payload: calibrated automatic digital camera or microwave module (possibly as an adjunct video camera, a thermal imager and infrared camera), no excessive payload needed for military drones.

5. For today it should be models flying at low altitudes (in the class G airspace with a height of up to 4.5 km in unpopulated areas, within which it is planned to introduce a notification procedure for small and fly unmanned aircraft). Obtaining permission to fly in Class A and C while it is possible only by the military.

4. Commercially available - stood the test flights and entered production.

5. The model performed photogrammetric projects that have links on the site, or based on projects released article. The company's website is an indication that the main or one of the purposes is aerial photography.

III. MICROCOPTER

In 2006, the German enthusiasts Holger Buss and Ingo Busker created a microcopter (MC) around which gathered a large community of enthusiastic people - modelers, designers and programmers. Already in mid-2007, through the efforts of the founders and the entire community of this project MC has hovered steadily and quickly moved through the air. Microcopter is a radio-controlled flying platform with 4, 6, 8, 12 brushless motors with propellers. In flight platform takes horizontal position relative to the earth's surface, can hover over a certain place, move left, right, forward, backward, up and down. Nowadays, thanks to the additional equipment developed microcopter has the opportunity to actually perform semi-autonomous flight.

Along with other quite successfully implemented similar projects MC project has a very extensive support that will be needed and the novice and the experienced modeler that uses all the features of this unit.

MC flight can be considered an example hexacopter (option unit with 6 motors), sets with different number of motors are controlled in the same way. Hexacopter has propeller pairs which rotate in the opposite direction. Machine Diagram is shown in Fig.1.

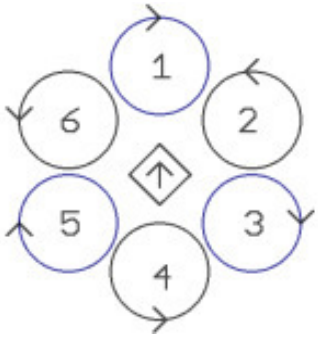

Fig. 1. Schematic rotation of hexacopter propellers.

As shown in the diagram, 1, 3, 5 hexacopter propellers rotate clockwise and 2. 4, 6 counterclockwise. To soar, all propellers must rotate at the same speed. Since the same number of propellers rotate in opposite directions at the same time, the force between them is equalized and allows to the hexacopter stably float in the air, not rotating around its axis. Photo of the machine shown in Fig.2.

Fig. 2. Hexacopter photos during the flight.

To fly in any direction, hexacopter should come out of balance, which increases the rotational speed of the propeller, opposite the direction of movement required. It makes hexacopter bend and move in this direction. For example: to fly forward, rear propeller must spin faster ("nick"). The word "nick" is used as the name for the movement of the machine forward or backward. Left or right movement called "rolls". Turn on the spot called "yaw". To implement "yaw", need to upset the balance of speed between the front / rear and left / right propellers: to turn the unit around its axis in a clockwise direction, front / rear propeller must rotate faster, and left / right propellers bit slow. Thus, carried hexacopter turn clockwise keeping the height at which the unit is located.

To ensure sustained flight controller is required which main task is to manage the flying platform stabilization in the air in a horizontal position by supplying control signals engines. It uses data from multiple sensors and calculates a speed for each propeller. The controller also compensates for external influences, such as wind. The controller works in a special program.

Key design MC elements: Baseboard (FlightCtrl), Brushless motor controllers (BL-Ctrl), Brushless motors (BLmotors), Chassis, LiPo battery, Propellers, Radioreceiver, Transmitter, Connecting wires, connectors.

Additionally microcopter can be equipped with the following elements:

1. Height sensor (barometer) - with the help of the device acquires the ability of flight at a constant altitude;

2. Magnetic compass (magnetometer) - with the help of the machine is able to hold the longitudinal axis in a constant direction;

3. GPS-receiver, which determines the coordinates of the vehicle in space and, therefore, it can provide a securing position for the given coordinates, i.e. fly on the specified points on the routes, and return to the starting point (this arrangement can also provide additional data for such telemetry as altitude, speed, direction,);

4. Sound locator (sonar), with which it is possible more precise hold altitude (it is used at an altitude of up to 6 m as an alternative barometer; moreover, it is used in the automatic takeoff and landing);

5. Optical sensor that allows precise positioning of the aircraft vertically to a height of 2.5 m

To use MC also needed: Chargers for LiPo batteries, Set of tools and accessories.

Issues requiring resolution:

1. Increased flight time - in research requires more flight time, at least 45 minutes;

2. Increase in all weather and range use microcopter;

3. Automation of some operations use multicopter;

4. Improved safety - a safe landing when connection is lost, the protection of propellers, etc.

A configuration microcopter was decided to use the UAV with six rotors (Hexacopter). Choice is due to the aerodynamic scheme balanced multi rotor aircraft. Unlike quadrocopter, failure of one or two rotors can be controlled landing. Despite lower gas-dynamic efficiency due to a smaller propeller group wheelbase engines selected design is more secure.

Depending on the task many rotary UAV can:

- lifted to a height of the payload of up to 2,000 m (the load is fixed at the central portion of the machine, around which are located coaxially or from 3 to 12 engines);
- «hang" on a user specified height with the ability to smoothly zoom in and outперемещаться во всех направлениях с полезной нагрузкой со скоростью до 50 км/ч;
- be in flight up to 30 minutes (flight time the machine depends on its configuration and payload);
- operated in a wide range of ambient temperatures and wind speed of 20-25 m / s (operation in rainy weather and snowfall during the difficult, but still possible);
- perform autonomous flight route specified coordinates on the navigation map, with stops at the desired points on the operator specified time;
- perform at stops aerial photography area, holding a given operator height and position using GPS coordinates;
- back to a place of take-off from any point on the route and from any position held by a signal operator;
- upon loss radio implement decrease with pre-programmed speed or to return to the starting point of a GPS;
- have a mobile structure (about the size of 30 × 30 × 50 cm when folded), allowing to bring the machine to a working state from traveling for 1-5 minutes;
- provide guidance onboard aerial camera television system to the subject.

Unmanned complex has on board three independent radio telemetry and positioning. One of the channels displayed on the computer, the other is connected to a standalone module indicating that lie directly in the pilot. The third channel is built into the radio equipment control. Telemetry provides continuous monitoring of all critical flight parameters and operating modes of complex systems. Management also dubbed by second post connected to a personal computer via radio. It records all flight data on the memory card, which allows for the completion of the flight to make his "analysis." Onboard video transmitter broadcasting provides high quality images to a ground monitor in real time to provide accurate guidance photos and video. The complex is equipped with a gyroscopic stabilization system with camera tracking mode. It provides image stability and vibration-free even under difficult conditions, aerial photography. Video transmitted to the monitor board operator who controls the position of the camera during the aerial survey.

IV. Features with UAV aerial data

Aerial UAV is not fundamentally different from shooting with "large aircraft", but has certain features that we continue to consider. UAV flight, usually made with a cruising speed of 70-110 km / h (20-30 m / c) at altitudes of 300-1500 m. Usually used for shooting non-metric camera household with matrix size 10-20 megapixels. Focal length of the chamber is typically about 50 mm (35 mm equivalent), which corresponds to pixel size in the terrain (GSD) of from 7 to 35 cm. Often images are processed with UAV simple lax methods (affine transformation pictures to the plane). As a result, the user receives a block layout, which, in addition to low precision circuits may contain gaps at the joints adjacent shots.

In this article, we start from a rigorous photogrammetric data processing, as a result of which we can expect the accuracy of the results (usually orthophoto mosaics) about one GSD. When the parameter values taken, the above

results correspond to the scale accuracy orthophoto from 1:500 to 1:2000 depending on the height of the shooting.

For rigorous photogrammetric aerial data and obtain the most accurate results to images in the same route had a triple overlap, and the overlap between adjacent strips in areal recording is at least 20%. In practice, when taking UAV these parameters are not always maintained. Affect the flight of the UAV gusts, turbulence, and other confounders. If shooting with conventional aircraft plan overlapped along the route 60%, and between 20-30% of the routes, the design should be shot with UAV along with overlapping routes 80%, and between routes - 40% [2].

To improve the quality of the images is recommended to install on the flight chamber lenses with fixed focal length. When shooting should exhibit focuses on infinity and disable the "AF".

Pictures of digital cameras, both amateur and professional, have a rectangular shape. "Advantageous" position the camera so that the long side of the image extends across the flight - it can take a large area with the same length of the route. Survey should be carried out with the highest quality - with the smallest jpeg compression or in RAW, if the latter is possible.

The present level of navigational aids allows for measurement of exterior orientation directly in the process of shooting. Typical accuracy of such measurements reach a few centimeters over the spatial coordinates X, Y and Z and 0.005 degrees angles roll, pitch and yaw for the most accurate systems. Often this is enough to make processing without the use of reference points. In any case, the presence of such data greatly simplifies the handling and enables some of the processing steps in fully automatic mode. Recent advances in microelectronics allow to collect the mechanical (or rather MEMS - electro-mechanical) gyroscope package size of a few mm, costing from $ 250. Such precision gyroscopes do not give a professional, have considerable care (about one degree per hour) during operation, but greatly simplify subsequent data processing. Passport accuracy GPS devices is 10 mm + 1.5 mm × B (B - removal from the base station in km) horizontal and 20 mm + 1.5 mm × B adjustment. Unfortunately, usually on board the UAV mounted cheaper GPS receivers and shall not establish IMU sensors. Data centers in the projection images are shot through telemetry data NMEA protocol and have in this case, the accuracy of 20-30 m, and the angles of pitch, roll and yaw are calculated from the velocity vector of GPS measurements. Yaw angle accuracy in such telemetry data is low and can exceed 10 degrees and the values themselves contain systematic errors, which complicates the subsequent data processing.

When shooting with a dual-band GPS receiver used in differential mode (or PPP data processing GPS), then the minimum number of control points for the most accurate results processing. Usually enough points 100 1-2 shots, in some cases the treatment can be carried out without GCP. In the case where there is no accurate projection centers, the requirements for horizontal and vertical justification of the standard, one horizontal and vertical point on 6-10 shooting bases.

V. Microwave Sensing

Work systems radiophysics diagnostics and control interference environments based on an analysis of the reaction medium under investigation by the probe signal.

Task adequate description of the interaction of electromagnetic waves with the probed environment characterized by complex permittivity (ε*), is one of the most pressing. This is due to the fact that the material of the medium of sensed are complicated dielectric structure. In reality, these media are in constant contact with a variable temperature field and the water in its various states of aggregation. These variables determine the components, mainly the dielectric properties of such media.

In solving problems of radiowave diagnostic status and properties of layered media is necessary to consider the spatial distribution of ε*. Data on their core distribution ε * can be obtained either from a priori data or using approximate theoretical models or experimentally. Analyze the value of the reflection coefficient of plane waves vertical and horizontal polarization at oblique incidence on a controlled environment. Sharing the results of sensing vertically and horizontally polarized waves can extract information on the dielectric properties of sensed layers.

Of free space (ε * = 1, μ * = 1) on the layered dielectric medium falls flat electromagnetic wave at different angles Θ (Fig.3) [3].

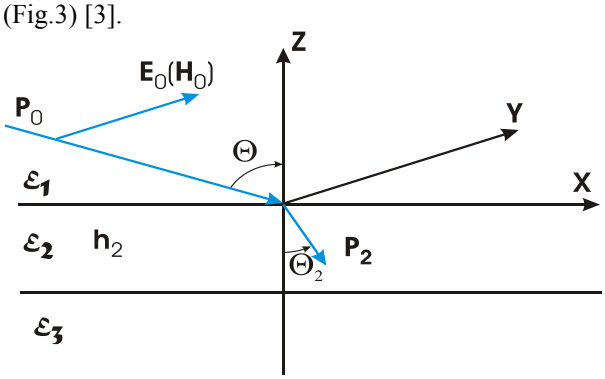

Fig.3.Geometry of the problem, the vertical and horizontal-E0-H0 polarization

Required to determine the value of the reflection coefficient K of the investigated medium, depending on the angle of incidence of the waves of horizontal and vertical polarization in the case of a finding on the medium surface of the dielectric layers. The upper and lower layers have a semi-infinite thickness, and the thickness of the relatively thin second layer - and the variable commensurate with the

wavelength. In this case, the first layer - the air, the second layer - the ice, and the third - the water. ε* values of the second and third layer are changed during the experiment..

To carry out numerical simulation environment with specialized distribution ε * can be represented as a multilayer system. In this case, ε * is a function of the coordinates of Z, and at the boundaries between the layers, this function may be discontinuous. Dependence of ε * (Z) within each layer is given by the numerical values at certain points Zi. To simplify the calculations, we set ε * between points Zi and Zi +1 is a constant and uniform in X and Y directions in layers.

Reflectance of a multilayer medium can be determined by the recurrence formula [1]:

$$K_{1,n} = \frac{K_{1,2} + K_{2,n} e^{-j\frac{4\pi h_2}{\lambda\sqrt{\varepsilon_2}}}}{1 + K_{1,2} K_{2,n} e^{-j\frac{4\pi h_2}{\lambda\sqrt{\varepsilon_2}}}} \quad (1)$$

$$K_{i,i} = 0, \quad K_{i,i+1} = \frac{\sqrt{\varepsilon_{i+1}} - \sqrt{\varepsilon_i}}{\sqrt{\varepsilon_{i+1}} + \sqrt{\varepsilon_i}} \quad (2)$$

$$K_{i,k} = \frac{K_{i,i+1} + K_{i+1,k} e^{-j\frac{4\pi h_{i+1}}{\lambda\sqrt{\varepsilon_{i+1}}}}}{1 + K_{i,i+1} K_{i+1,k} e^{-j\frac{4\pi h_{i+1}}{\lambda\sqrt{\varepsilon_{i+1}}}}} \quad k \neq i, k \neq i+1 \quad (3)$$

Using the formulas (1-3), we find the formula for the reflection coefficient K1-3 in the case research we have adopted the model:

$$K_{1,3} = \frac{K_{1,2} + K_{2,3} e^{\gamma_1}}{1 + K_{1,2} K_{2,3} e^{\gamma_1}}, \quad \text{де} \quad \gamma_1 = -j\frac{4\pi h_2}{\lambda\sqrt{\varepsilon_2}} \quad (4)$$

then for horizontal polarization:

$$K_{1,2} = \frac{\sqrt{\varepsilon_1}\cos\Theta - \sqrt{\varepsilon_2 - \varepsilon_1(\sin\Theta)^2}}{\sqrt{\varepsilon_1}\cos\Theta + \sqrt{\varepsilon_2 - \varepsilon_1(\sin\Theta)^2}} \quad (5)$$

$$K_{2,3} = \frac{\sqrt{\varepsilon_2}\cos\Theta_2 - \sqrt{\varepsilon_3 - \varepsilon_2(\sin\Theta_2)^2}}{\sqrt{\varepsilon_2}\cos\Theta_2 + \sqrt{\varepsilon_3 - \varepsilon_2(\sin\Theta_2)^2}}, \quad (6)$$

$$\text{де}\ \Theta_2 = \arcsin\left(\frac{\sin\Theta}{\sqrt{\varepsilon_2}}\right)$$

for vertical polarization:

$$K_{1,2} = \frac{\varepsilon_2\cos\Theta - \sqrt{\varepsilon_1(\varepsilon_2 - \varepsilon_1(\sin\Theta)^2)}}{\varepsilon_2\cos\Theta + \sqrt{\varepsilon_1(\varepsilon_2 - \varepsilon_1(\sin\Theta)^2)}} \quad (7)$$

$$K_{2,3} = \frac{\varepsilon_3\cos\Theta_2 - \sqrt{\varepsilon_2(\varepsilon_3 - \varepsilon_2(\sin\Theta_2)^2)}}{\varepsilon_3\cos\Theta_2 + \sqrt{\varepsilon_2(\varepsilon_3 - \varepsilon_2(\sin\Theta_2)^2)}} \quad (8)$$

By (4-8) for different states of the environment were calculated modules reflection coefficients for horizontal waves | KH | and vertical | KV | polarizations at various angles of incidence Θ on sensed environment. In this varied thickness of the thin layer h2, set different values ε * thin layer and the third layer. For clarity, the thickness of the thin layer was set in relative units and normalized with the wavelength in the medium

$$\gamma_1 = -j\frac{4\pi h_2}{\lambda\sqrt{\varepsilon_2}} = -j\frac{4\pi H}{\varepsilon_2}, \quad \text{де}\ H = \frac{h_2}{\lambda_{cp.}}, \lambda_{cp.} = \frac{\lambda}{\sqrt{\varepsilon_2}} \quad (9)$$

We simulated the situation. One of the results for the horizontal and vertical polarization is shown in Fig.4 and Fig.5.

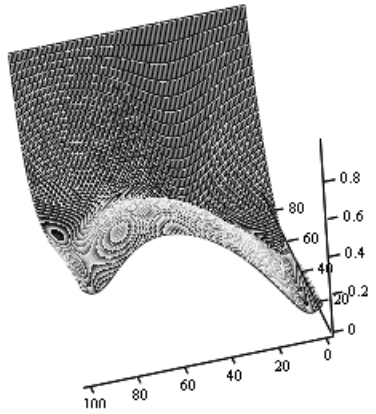

Fig. 4. Model for vertical polarization

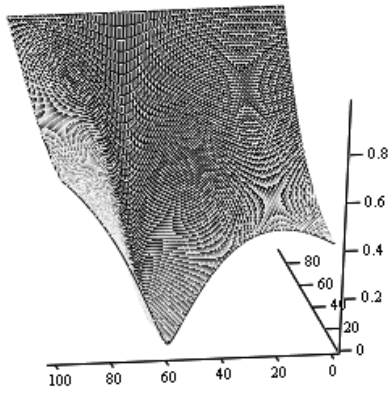

Fig. 5. Model for horizontal polarization

The X axis shows the angle Θ, on the Y-axis the thickness of the ice along the axis Z - the reflection coefficient. Chart analysis shows that horizontal polarization wave we have higher reflectance. Therefore, we will use the antenna, allowing to receive horizontal polarization. For microwave module to reduce the weight of the flight apparatus we used stroboscopic method.

VI. Experimental research

Experimental study was conducted in the delta of the Northern Dvina and dry sea near the island Mudyug.

UAV showed good performance on the stability of the en-route. Photo and video possible to determine accurately enough to crack the ice and to estimate the size of ice fields.

Microwave sensing results are shown in Table I. Analysis of the results showed that the error in determining the ice thickness is about 15%.

TABLE I.
EXPERIMENTAL RESULTS

Measurement point	Ice thickness (m)	
	Microwave sensing	Drilling
Point number 1 r. Northern Dvina 64°26'59.27"N 40° 49'2.7"E	0,21	0,38
Point number 2 r. Northern Dvina 64°28′10.23″N 40°48′42.93″E	0,58	0,42
Point number 3 r. Northern Dvina 64°27′1.93″N 40°51′5.07″E	0,43	0,4
Point number 1 Dry sea 64°52′25.32″N 40°18′10.27″E	0,61	0,48
Point number 2 Dry sea 64°55′3.55″N 40°18′39.94″E	0,57	0,47
Point number 3 Dry sea 64°54′22.63″N 40°23′8.14″E	0,6	0,49

In our data detected by sensing was carried out expeditionary ground survey of ice cover. Ground survey data confirmed the presence of breaks plots autumn ice ships that were detected on the river was probed image even in the presence of ice on the surface of the snow layer thickness of 35-40 cm.

Fig. 6. Route Map for the Northern Dvina River

This happened due to the nature of hummocky surface and metamorphosed ice structure, consisting of the frozen broken ice, slush and slush interspersed with lots of ice and fine sand particles. Due to scattering of light has broken-ice has a characteristic white color, and so it is sometimes referred to as white ice (as opposed to dark crystal clear - "black" - ice).This type of ice texture in contrast to dark ("black") reflecting intense electromagnetic waves in the centimeter range. The presence of intense white spots and stripes on the was probed image is an important deciphering sign of milled icebreakers of ice cover. Such assessment of ice covered with a layer of snow, it is impossible according aerorazvedki or visual ground survey, as well as methods of remote sensing in the optical wavelength range. The study traced the route on the Northern Dvina River (Fig.6).

VII. CONCLUSION

In the study of the possibilities of remote ice research, we concluded that the application of classical methods: spacecraft and aircraft uneconomical and has low efficiency. In addition, using these tools, we are faced with the problem of transmitting data through a narrow channel.

To solve this problem, we selected unmanned aerial vehicles (UAVs), which lack the above drawbacks, but have weight limits of the equipment used. We conducted an analysis of existing UAV and concluded that the best fit for our problem microcopter.

UAV have the following advantages:

1. Low cost.
2. Small size and weight that allows you to place equipment even on small vessels.
3. Data may be transmitted from UAV quickly in real time.
4. With a small UAV flight range can be used for broadband data transmission channel. This allows you to use equipment with high resolution.
5. Can be used in disaster areas without risk to life and limb of the operator (debacle, flooding).

Disadvantages of using UAVs:

1. Low level of accuracy of the measurements.
2. The limited size of the payload.
3. Dependence on weather conditions.

To capture an image, we propose to use a digital camera with a fixed focal length.

For remote sensing of ice, we propose to use the frequency range 1-2 GHz and microwave sensing stroboscopic method.

Experiments have shown the possibility of using UAVs for remote sensing of ice. Error in determining the thickness of the ice was not more than 15%.

***Abstract*—Logistics and its involved parties are nowadays faced with demanding challenges, in order to fulfill their customers' needs. Hence logistics service providers are constrained to cooperate with each other, which leads to the challenge of 'understanding' each other's service descriptions and integrating the strongly differing IT-systems. An emerging approach to solve this problem is the operation of cloud platforms. Main tasks are service retrieval and composition. However, a suitable visualization is needed to generate a high user acceptance. With the service map concept a first step is taken, that certainly needs further improvement. This paper briefly gives an introduction to general information visualization and analyzes the suitability of several approaches for improving the service map concept with regards to different scales of measurement. After their comparison a general guideline for fostering the visualization concept is derived. Objective is the increase of information content while keeping an intuitive usability.**

I. Introduction

TRADITIONALLY, the field of logistics is mainly dominated by logistics service providers, which are characterized as small and medium-sized enterprises (SME) [1]. Fig. 1 shows the distribution of logistics companies in the European Union (EU) categorized by the number of employees, for the year 2011.

In the last few years, but especially since the establishment of the European Union (EU), these SME are constantly facing new challenges. The abolition of traditional trade barriers and the simplification or even elimination of customs regulations led to a specialization of certain geographical regions in the field of production. Another problem for these companies is the strong wage gap between Asian countries and the EU and North American countries, which results in the manufacturing industry migrating resources to these countries. This wage gap is also existent within the EU itself, caused by constant expansion and integration of new EU member states. For instance, in 2004 ten new member States (Cyprus, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia and Slovenia) joined the EU. At that time these new

The work presented in this paper was co-funded by the German Federal Ministry of Education and Research under the project LSEM (BMBF 03IPT504X) and the CENTRAL EUROPE programme co-financed by the ERDF under the projects LOGICAL and ESSENCE.

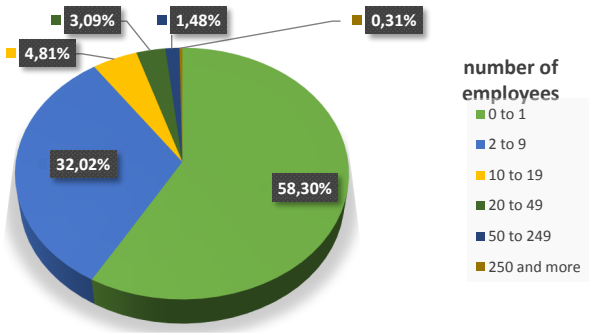

Fig. 1. Distribution of logistics companies in Europe categorized by number of employees[1]

member states had significantly lower average wages than the other incumbent member states. As a result, a non-minor number of manufacturing companies moved their locations to the south-eastern borders of the EU. This - in combination with other factors - leads to the fact that the supply chain of individual companies and company networks is stretched and thus less predictable. One of the major resulting challenges for LSP is to meet the needs of their customers furthermore [2], [3].

To cope with this challenge the division of labor and outsourcing are suitable concepts, as they provide flexibility as well as the possibility for SME to participate in larger networks. Hence, LSP have to cooperate with each other to fulfill their customers needs [4]. The most basic level of reliable networking is to publish the offered services, in order to combine them to more complex logistics services. However, by publishing the services further challenges arise. As LSP usually got a varying quality and style of service description (i.e. based on different description languages, emphasizing different aspects) as well as a wide range of implemented IT-systems (e.g. from SAP down to handmade MS Excel-sheets), an integration of information flow is hard to realize in an IT-supported way [5], [6]. In order to overcome this challenge

cooperating partners should make use of a common platform or cloud platform, respectively.

Project ESSENCE, an project within the Central Europe program - co-financed through the European Regional Development Fund (ERDF), aims to create an information and communication technology (ICT) platform. The general objectives of this platform are an increased effectiveness of transports, reducing its environmental burden, and the neutralizing of current deficiencies in SME to increase their productivity and competitiveness. ESSENCE strives to establish an ICT network that SME are encouraged to use - free of charge - to manage their logistics and optimize their supply chain by designing their own business networks. [7] Finding the right partners for fulfillment of atomic process steps is a difficult task. In the past, several scientific approaches to this problem have been developed.

To be a connecting tool between the participating LSP, the main functions of such a platform comprise retrieval and composition functions for services. Those functions are to be customized in an easy-to-understand and intuitive way in order to gain a high user acceptance. Visualization is outlined in literature as important aspect to aid users in exploring, understanding, and analyzing data through progressive, iterative visual exploration, especially in data analysis applications of business informatics related fields (e.g. visual analysis of business data, scientific data, images and videos, auction data, search results) [8]. Hence, the importance is given of visualizing service retrieval, composition and management in heterogeneous logistics clouds in a sophisticated way. One strategy is a combined approach of catalog and modular service construction system - the logistics service map (SM) [9]. Since the state of the art of the SM concept is still in draft mode, experiences with SMs still contain potential for improvement. The current structure is quite simple and the offered range of functions and displaying possibilities is way too small.

After the introductory part the basic principles of information visualization are being presented. Section three gives an overview on the current state of cloud platforms and provides basic definitions of terms such as service, process activity and process model within the context of project ESSENCE. The reader gets an impression on how the ICT platform and underlying principles are working together. In addition to that, the concept of SMs will be introduced to the reader together with an adaption to the logistics sector (logistics SM). In section four several approaches on increasing the information content of the SM by applying different combinations of scales of measurement and visual strategies are proposed and analyzed. Finally a comparison of the approaches leads to a guideline for an enhanced visualization for SMs. The paper is concluded by a short summary and future research prospects.

II. Information Visualization

As already outlined information visualization is an important aspect in business information systems. A comprehensive design study *methodology* is proposed in [10] with different phases from preliminary general preconditions (e.g. general design science knowledge acquirement, casting of all stakeholders) over core activities (e.g. problem analysis, developing alternatives, implementation and deployment) to outward-faced validations. As they assume the design process for information visualization done by specialized domain-foreign designers and the authors only focus on core activities and claim to have sufficient knowledge in the logistics and cloud domains from previous research and development projects with partners from industry and service sector, the most important and influencing parts for our purpose are the following. When developing information visualization the essential points are at first a sufficient range of possible solutions to be considered (i.e. different visual encoding and data abstraction). Afterwards those solutions are to be filtered down to a narrow proposed selection. Further [10] advise to refer on generally accepted design principles and guidelines. The major points are briefly introduced in the following paragraphs.

Commonly accepted and generally applied aspects on *design principles* for information visualization are outlined by [11]. First, he summarizes 'perception and purpose' as important aspects with appropriate visual affordance (e.g. differentiating contrast of brightness easier for human eye than contrast of colors or getting a common basis for optical comparison), identifying the right objectives, goals and tasks (e.g. setting right basis for comparison) and aesthetics (e.g. complementary colors or sectio aurea (golden ratio)). As these aspects often collide Dix further highlights 'interaction' as a solution. For this aspect drill down and hyperlinks, overview and context are highlighted as well as dynamization (i.e. changing parameters and representations, temporal fusion of different information views). Moreover, the 'visualization mantra' of [12] is mentioned with: "Overview first, zoom and filter, then details on demand". 'Information scent' [13] is a term describing the intuitiveness of handling information. In order not to click through every possibility in a matter of trial and error even if total information is not available, the user always needs a kind of clue to 'scent' on where to seek next for suitable, more detailed information. With focusing on the wider context, the perspective on different stakeholders and the resulting effects of information visualization shall be taken into account (e.g. analysts, customers, senior management). Other literature analyzes the capacity limits of attention and the subsequent influence on information visualization [14]. They conclude grouping similar objects in some cases as a powerful guideline. Moreover a proper legend or key, as well as a reduction of categories actually displayed help working with visualized information. With regard to capacity limits of attention the number of nominal categories should be dedicated to data with high dynamic range or different categories. Generally they tend to a smaller number of categories and colors to keep the user focused.

In [8] an extensive literature review on *challenges of information visualization* is conducted. As a conclusion of their paper they summarize the following five major technical challenges:

1) Usability: As the user of a system is inevitably involved in the visualization and toolkit system to accomplish its analysis, retrieval and composition tasks, the visualization shall support the user in an intuitive and efficient way.

2) Visual Scalability: Following the former mentioned visualization mantra [12], the capability of effectively displaying large data sets is an important challenge. The core part is constituted in data reduction techniques [15], as the amount of data easily exceeds the display capacities.

3) Integrated Analysis of Heterogeneous Data: The aspect of handling data from multiple sources is marked as one of the biggest challenges.

4) In-Situ Visualization: This point mainly focuses on the effective visualization of streamed data (e.g. in social networks like twitter) and how to share same processor and memory space in order to synchronize data processing and visualization task. As the concepts presented in this paper do not deal in any aspect with streamed data, this point does not hold any relevance for our purpose.

5) Errors and Uncertainty: Errors in data sets (e.g. noisy and inconsistent social media data, imprecise data from sensors) and/or resulting errors by data transformation are to be displayed to the end-user as well, in order to strengthen the truthfulness of visualization. As homogeneous data from a proven source is assumed, this point does not apply big relevance to our purpose.

The visualization pipeline is a technical infrastructure fostering information visualization is introduced by [16] with reference to [17]. However, they outline the concept, which is applied for visualizing service-oriented architectures (SOA), the concept could be abstracted and thus, also be transferred to other similar context. The four sections of the pipeline contain a typical ETL-process (i.e. the first three sections) extended by a reporting in terms of a final graphical representation. At first, heterogeneous data from different sources (e.g. UML, BPMN, XML) is extracted. Secondly, a transformation to a consistent and semantically correct form is conducted to gain the relevant meta data. Thirdly these data are loaded in a central repository as well as the pre-processed data from the repository is loaded to the next section, tailored by stakeholders' configuration (e.g. pre-defined views for different stakeholders are possible). Fourthly and finally, the graphical representation is processed from the pre-processed data from the repository taking the stakeholders' configuration into account.

Summarizing, the phases of developing alternatives and their evaluation are important and to be solved using general design guidelines. The challenges of usability and scalability are the emphasized designated requirements for the visualization approaches of the SM. As the paper focuses on visualization more in cognitive than in a technical way, only the last two sections of the visualization pipeline are considered.

III. Logistics Clouds and Service Maps - State of the Art

After giving a briefly discussing information visualization and its importance in business information systems the paper now proceeds by introducing a current approach of a cloud platform that could be used in the logistics sector. After introducing the SM concept as well, general visual disadvantages of both concepts are outlined, that are to be solved during the latter progress of the paper.

A. Logistics Cloud

At this point, the focus is on describing an existing approach - as a representative for cloud platforms in general - as detailed as possible within the restricted frame of this paper.

1) Working Definitions of ESSENCE: The ESSENCE platform [7] encourages SME in exploring the use of customized eServices that give logistics support their business. Supply chains are modeled by application of three different entities. Those entities are named: process activity, process model and service. In order to fully understand the operation principle of ESSENCE the aforementioned terms have to be defined in a short way.

Process activities are the smallest units in the ESSENCE supply chain. They are single atomic actions, described by the values 'Name', 'Description' and 'Type'. While the meaning of 'Name' and 'Description' are self-descriptive, 'Type' subdivides the activities into four distinct categories. 'Standard activities' are to be fulfilled at the side of the activity creator. It's counterpart - the 'At customer'-activities are done at the customers side. 'Latency activities' are fulfilled either at creators or customers side. Each of those latency activities has a predecessor whose completion is obligatory. The fourth category is being shaped by the so called 'custom process activities'.

Further, a *process model* results from the combination of one or more of those process activities. Similar to the aforementioned process activities these models are specified by a 'Name' and a 'Description' which are free-text fields. The values 'Duration', 'Quantity' and 'Cost (EUR)' are assigned additionally to each process activity enclosed in a process model. Furthermore, process activities within a model can be sequenced by using the field 'Sorting'.

The superior entity *service* consists of one or more process models and is specified by free-text fields containing 'Name' and a 'Description' (each twice, both in local and in common platform language 'lingua franca'). In addition to that a service could also contain 'Functional parameters', a 'Classification', 'Attachments' and 'Dependencies'.

2) ESSENCE Operation Principle: After having introduced the terms service, process model and activity in the context of the ESSENCE platform this section shows its current operation principle [7]. The workflow for designing process models is shown in a roughly simplified mainstream manner without considering any exceptions or irregularities, which is illustrated in Fig. 3.

After the initial registration process, which is approved by the platform provider, the user is able to log in. In order to publish its company's service offer on the platform the service list view is used. Each service needs a name and a short description in local language and lingua franca as well.

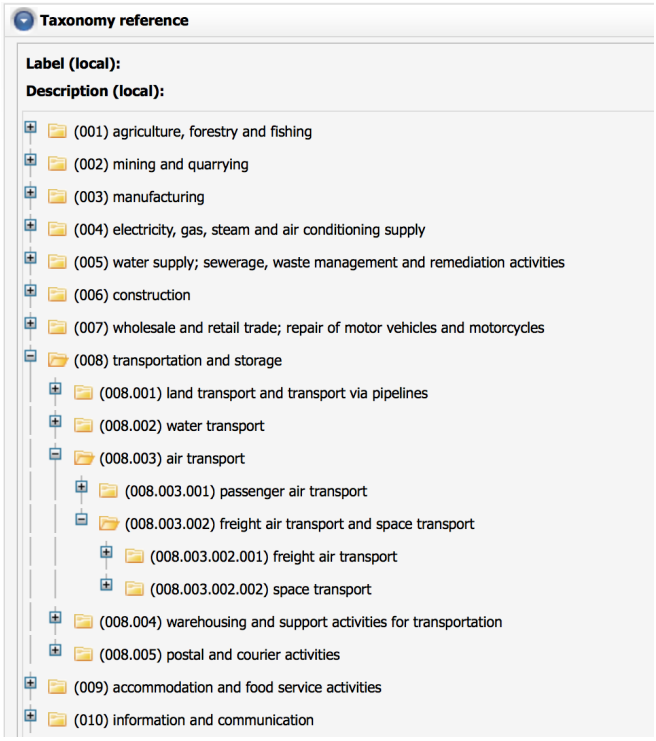

Fig. 2. Example of the taxonomy used by the ESSENCE platform.

In addition a service can have one or more parameters, e.g. number of packages of the shipment. Those parameters are used during process modeling to transfer information from one activity to another. Services can also be categorized by the ESSENCE taxonomy. This taxonomy is a tree with industrial sectors as nodes and leaves. Fig. 2 shows an example of the taxonomy tree. In addition services can have attachments and depend on other services.

To create process models the user first needs to create atomic activities in the activities list view. Therefore the user has to set a name and a description for the particular activity. After creation of this activity the user has to assign one or more supplier services to this activity. Such supplier services are alternatives, i.e. during process model execution one of the alternatives is selected.

After defining the process activities a process model is created as a orchestration of the process activities. An example of a process model consisting of three activities is shown in Fig. 4 with local language Hungarian.

During the whole process model creation the most time consuming and important step is the selection of the service suppliers and their services for the activities. To add a service of a service supplier to an activity the user first has to select the supplier and then the service of the supplier. There is no possibility to find similar services of different suppliers or filtering of services for some criteria yet. Nonetheless such a functionality would be very helpful and result in a higher usability and subsequently user acceptance. A first attempt towards such a functionality was done by implementing the taxonomy of services mentioned before. This taxonomy enables the selection of services according to their purpose. The main disadvantage of this approach is that although the taxonomy is very fine-grained it is not flexible as it offers just one dimension to categorize the offered services.

As the number of services within a network is growing the challenge of finding and selecting appropriate services is growing more than linear. Hence, an advanced approach for visualizing, filtering, revealing and combining the services of a cloud platform is needed.

B. Service Map Concept

As already outlined in the context of collaborating logistics service providers, participants are faced with the major challenge of a lack in standards for service descriptions (activity descriptions, respectively) and IT-systems in logistics [5]. Hence, in a network of logistics service providers a wide range of description types with differing wording and formats arises. Representative survey conducted within a network of small and medium logistics enterprises motivating this topic can be found in [6]. To solve this problem cloud platforms - like the introduced ESSENCE platform of the former subsection - have been developed, to support the main functions of presenting the available services (or activities, resp.) of a network (catalog function) and combining them to complex composite services (modular service construction system function), in a way that is commonly accepted by all network participants. As current approaches lack in providing a suitable visualization (e.g. the ESSENCE platform, see also Fig. 2) sophisticated approaches are needed. This issue is solved by the concept of the service map (SM). As the concept is based on another set of wording definitions the according terms of the ESSENCE platform are always given in parentheses.

In literature exists a wide variety concerning the SM concept. Either (1) the term 'service map' is used and also the functionality meets (partly) the requirements mentioned above or (2) the term is used, but a different substantial functionality is addressed or (3) the term is not used, but the described concept (partly) includes functionality for the mentioned purpose.

The approaches of (1) [18], [19], [20], [21] are situated in a wide range of scientific fields. The highest relation to the described context could be found in [18]. The SM provides an overview of existing service portfolio of a company (in the field of financial industry). Main objective is the merging and outsourcing of different companies' portfolios or business models and the related IT-systems, respectively. The catalog-related objective of service retrieval and the construction system-related objective of creating atomic and composite services are not addressed. In [19] the authors categorize mobile services and apps with the help of a scale involving dimensions of 'customer needs'. The revelation of 'empty spaces' within the maps helps identifying yet not satisfied combinations of different customer needs that could be covered by innovative new services or apps. The authors of [20] propose an XML-

Fig. 3. BPMN diagram of the ESSENCE workflow for designing process models.

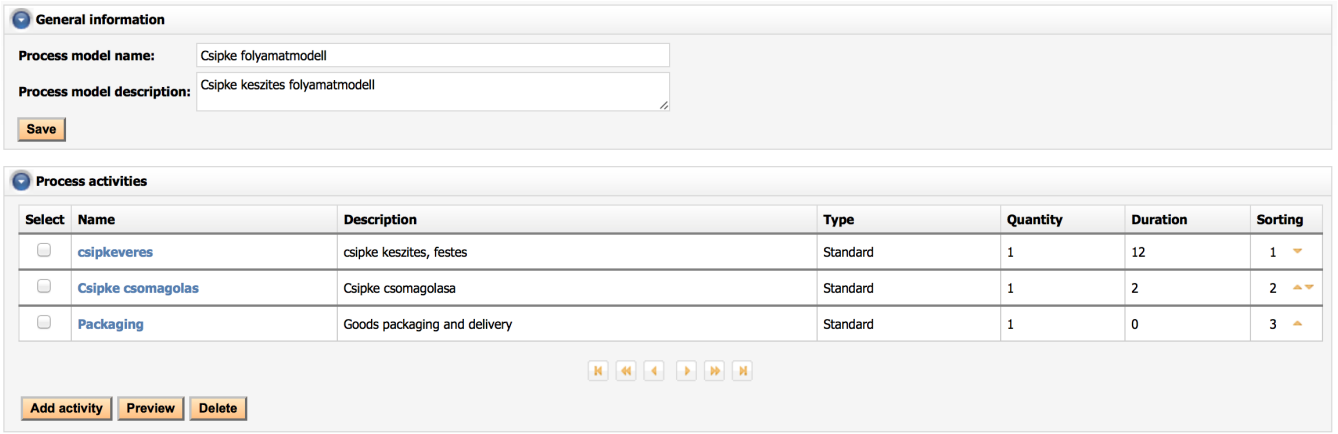

Fig. 4. Example of an ESSENCE process model with 3 activities.

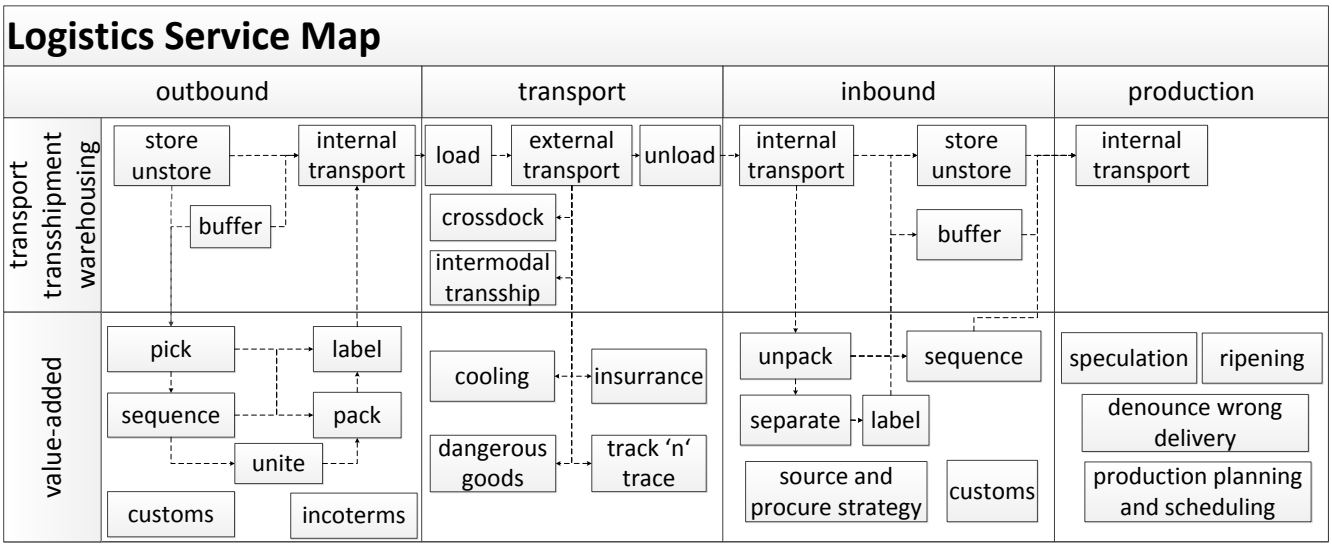

Fig. 5. Exemplary service map catalog with two dimensions: 'classic logistics function vs. value-added' and 'stage-specific'. Dashed arrows mark suggested services for composition.

based approach for structuring and categorizing services with new association and combination operators based on XML-tags. However, the approach lacks in maturity because a clear usage concept and a proper visualization is missing. [21] present a mobile data management approach. With obtaining a detailed view of available networks and their inherent capabilities, attributes and offered services in the surrounding of a mobile device. However, their categorization pattern is spatial-based and the combination functionality is missing.

The case (2) [22] addresses a SM for mapping or matching, respectively, of Quality of Service (QoS)-classes. The approach deals with data quality in heterogeneous networks consisting of several network technologies. The goal is a mapping of performance parameters of the different technologies. Neither overview of services nor building composite services is focus of the approach.

The first concept of (3), the 'service portfolio management framework' [23] combines service science with portfolio management. Hence its focus lies on strategic service management and the construction system functionality is missing. In [24] the 'business capability map' is introduced. Like [18] it focuses on comparing different companies concerning their

capabilities of serving special tasks in order of outsourcing but does not provide retrieval or construction function.

Summarizing, an approach combining both, the catalog and the construction function, is not a part of the above mentioned concepts. Subsequently, the concept of the SM introduced by [9] addresses the challenge by combining the two functions. First a catalog of all available services and process activities is provided, that could be categorized by the user's needs in different abstraction layers. As shown in Fig. 5 a graphical representation with two spatial dimensions for the user-chosen categories simplifies the interaction for the users when searching for services or process activities. Hence, service retrieval is enhanced and done in an intuitive way. Further, the concept includes a modular service construction system in order to combine atomic activities to composite services. With this approach, the network participants are supported in retrieving services in different use cases. Firstly, adding a new service provider (supplier) to the network and matching its offered services to the existing set of services by just adding the new service provider to the provider list of the particular services. Secondly, developing a new composite service (process model) to meet a specific customer's need by selecting and composing services from the SM. Service-specific information and attributes can be displayed when changing the selected granularity to a more detailed level to foster planning and monitoring. Moreover, the unique standard of the used set of services within a network and the visualization foster a precise mediation and communication between all stakeholders during the whole service life-cycle. Thirdly, finding compensational service (activity) or provider (supplier), when realizing the urgency for replanning or elimination of errors because of unpredictable disturbance in the network. Consequently, a SM is considered to be a core element of a service-oriented engineering and management platform or cloud-based service platform, respectively.

As the SM concept is an still evolving draft, certainly further development is needed to exploit its full potential. Especially, service retrieval is in the focus as this function is limited by two spatial dimensions and realized by 'highlighting categories' (1. displaying them at all, 2. reduction of displayed services by adding another category). The following section gives a more detailed introduction of the shortcomings and potential approaches for improvement.

IV. Visual Enhancement of Service Maps

The idea of a SM shown in the previous section has two points with potential for improvement. This section introduces these two ideas in detail and concludes with a brief guideline for the visual enhancement of SM concepts.

A. Preliminary Consideration

The first enhancement could be provided with the possibility of having more than only two dimensions displayed in the SM at a time. This point gains more importance with an increasing number of services available in a network that are to be displayed. Since existing approaches of SMs are only two-dimensional, the benefit of using a SM is limited in terms of category quantity. Especially with a high amount of services available in a network, the service representation lacks in clarity due to this limitation. The possibilities of integrating further categories by adding more dimensions are needed to improve the work with the SM.

Another shortcoming is that the SM categorization is fixed and cannot be changed on demand in runtime. An enhancement could be reached with the possibility of adapting the categories of the SM on the fly according to the current user needs. This would provide the user with an even more intuitive experience on the service retrieval and composition.

As summarized in the section concerning information visualization, the paper follows the methodology of [10] and focuses on developing alternatives, which are evaluated with reference to the main requirements 'usability' and 'scalability' [8]. As categories are taken into account for service retrieval and each category follows a particular type of scale, the following four scales of measurement [25] are considered. A *nominal* scale is able to display distinct named values with no natural order at all. An *ordinal* scale capable of displaying nominal values that can be brought to a natural order but have no measurable distance metrics between two values. A *interval* scale is capable of displaying quantitative numbers, which can be naturally ordered and own a distance metric between the values and a *ratio* scale as a special characteristic of a interval scale that includes a origin of ordinates.

B. Adding Further Dimension

Via brainstorming the authors and partly the ESSENCE consortium figured out the following attempts, that are compared and discussed in detail: (1) spatial dimension, (2) colored dimension and (3) shape dimension.

1) Spatial Dimension: As the current version of the SM only displays two dimensions, adding another spatial dimension is an obvious option. [16] figured out a lack in understanding and representing SOA (service-oriented architectures) (i.e. 3 layer: business-process, service interface, application) as well as the inherent intra-layer and cross-layer connections and dependencies. Reason to this is an unappropriate visualization. Outlined disadvantages of two-dimensional visualization are either overlapping connection lines or a lack in displaying different diagram types simultaneously. Hence, they summarize a loss of context with a growing number of information units and thus, propose a three-dimensional approach to visualize processes and their related services modules and classes. Drawing an analogy between the visualization of a SOA and a SM, a common evidence can be found for the requirement of an appropriate visualization with a growing number of services and inter-relations to be displayed and hence, adapt this idea to the SM.

Adding a spatial dimension to the SM leads to two possible approaches: either bringing the three-dimensional SM on a two-dimensional output device like in computer games (i.e. ordinary screen) or an three-dimensional output device (i.e. virtual reality environment, 3D display). As the latter one puts

high requirements on technical infrastructure it proves rather unsuitable for the usage in SME. As a consequence, the usage of a two-dimensional output device is proposed. Advantages are the intuitive usage and the possibility of appealing views. Whereas the main disadvantages are a difficult navigation within the SM, a high development effort and the limitation of only one further dimension.

2) Colored Dimension: Another approach of adding further dimension is visualizing categories by colors which means that the services that are shown in the SM will be colorized with an corresponding color.

Tufte states, "The fundamental uses of color in information design [are]: to label, to measure, to represent or imitate reality, to enliven or decorate." [26]. Further, he provides some basic guidelines on how to use colors for visualization of information. Small color spots on light gray background highlight the information. Such spots should be of no more than 20 to 30 colors found in nature, else negative returns would be produced by the colors. It is also important to use colors of the same hue and with maximum differentiation (e.g. yellow, red, blue, black).

"Color itself is subtle and exacting. And, furthermore, the process of translating perceived color marks on paper into quantitative data residing in the viewer's mind is beset by uncertainties and complexities. These translations are non-linear (thus gamma curves), often noisy and idiosyncratic, with plenty of differences in perception found among viewers (including several percent who are color-deficient)." [26] As already stated before [14], the usage of color as a further dimension shall be taken very carefully.

The first step for using color coding is to identify the scale of measurement of a dimension. Because of the different characteristics of the different scale of measurement it is necessary to use different colorization models for different scales of measurement. A commonly used approach for color coded scales is the *color gradient* as shown in Fig. 6. A color gradient either consists of two colors for a minimum and a maximum value or includes intermediary colors for intermediary values. To determine the exact color of a specific characteristic service within a category it is necessary to compute the characteristic's distance to the end points of the scale. The color of the service is proportional to the distance to the ends of the color gradient. Since it is necessary to compute a distance such a color gradient can only be applied to interval and ratio scales. A widely used color gradient coding is the red to green gradient where red stands for poor values and green stands for appreciated values, e.g. referring to a logistics delivery schedule whereas red stands for *all deliveries out of schedule* and green stands for *all deliveries in time*, for intermediary ratio of *50% of deliveries in time* a yellow colorization would be used as it is situated in the center of the gradient. Red-green-gradients are only suitable for assessment category dimensions referring to the maxima poor and optimal, because people always perceive red as bad and green as good due to the extensive common usage of this coding. Hence, for other categories it is obligatory to select other colors as endpoints of the scale. Categories presenting the intensity of one distinct characteristic in interval or ratio scales are likely to use a gradient from 'non-colorful' color like white to a colorful one. Again, the usage of green and red is to be considered carefully.

Another important step is the selection of the color space for the gradient. RGB and HUV are well used and well known color spaces. The main problem with these color spaces is that the perceived distance between two colors is not the same as the computed distance, hence RGB and HUV are not a good choice for the gradient. A color space addressing this problem is the CIE-LUV color space where the distance of all colors is proportional to the perceived distance [27] For dimensions of ordinal scale it is possible to use a color gradient with uniform partitioning. This results in a clear visualization of the order of the categories to the user. For nominal scales there is no method to assign special colors to categories of the dimension. If the CIE-LUV color space is applied the colors of all the categories should have a maximum distance to each other to ensure an optimal discriminability. To provide the user of the SM with a basis for interpretation of the categorization color-coding it is necessary to show a legend giving information on the meaning of the colors and the scale.

However, the main problem with color coding of categories and their particular characteristics is a lack of a common way of perception. Every person perceives colors in a different way. There are people with color vision deficiency, e.g. monochromacy, red-green or blue-yellow. Those people will possibly not be able to perceive the information that is color coded. Hence, an ideal solution provides an option to disable color coding or to use another coding instead.

3) Shape Dimensions: Another approach is to add a dimension by dedicating distinct shapes to different categories. In the beginning, the proposed forms related to geometrical shapes (e.g. circle, ellipse, rectangle, polygon, star-shaped, heart-shaped, cloud-shaped and arrow-shaped). For instance, one approach included a matching of shape and semantic of a service (e.g. transport services were presented with an arrow, while warehouse services were illustrated by pentagons in house shape). Unfortunately, preliminary tests revealed an enormous lack in usability. In other cases it was much more difficult to illustrate dimensions with appropriate shapes e.g. presenting a characteristic with a n-cardinality with the assistance of an n-sided polygon or visualizing dimensions with an ordinal scale. Further disadvantages are an unfavorable behavior in line break of labels as well as a tricky cognitive differentiation when a category with a multitude of characteristics had to be represented by a multitude of different shapes (high range of different n-shaped polygons). However, as the matching of shape and service semantics appears to be an appealing and useful approach, the decision was made to transform this idea to a more practical level. The classical rectangle-shape for services was retained and the shape dimension is integrated by reducing forms to pictograms that are to be displayed within or next to the rectangles as shown in Fig. 7. Another finding integrated in the concept is that this dimension is only useful

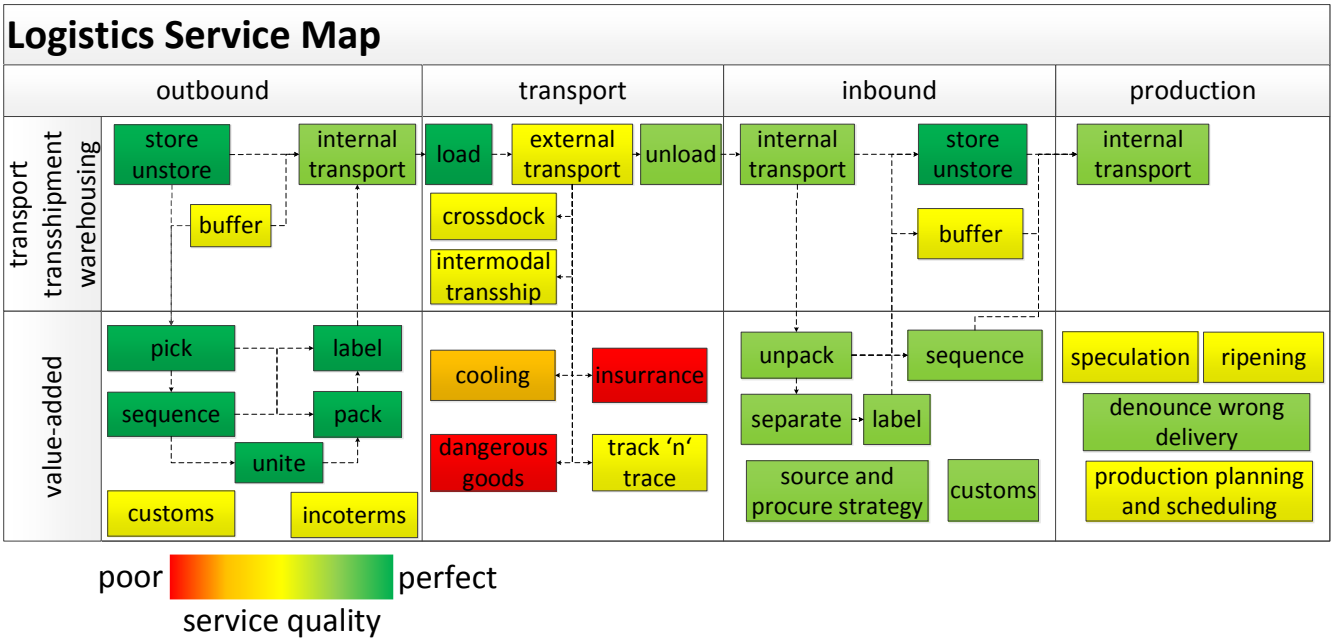

Fig. 6. Example of color gradient dimension for service map catalog.

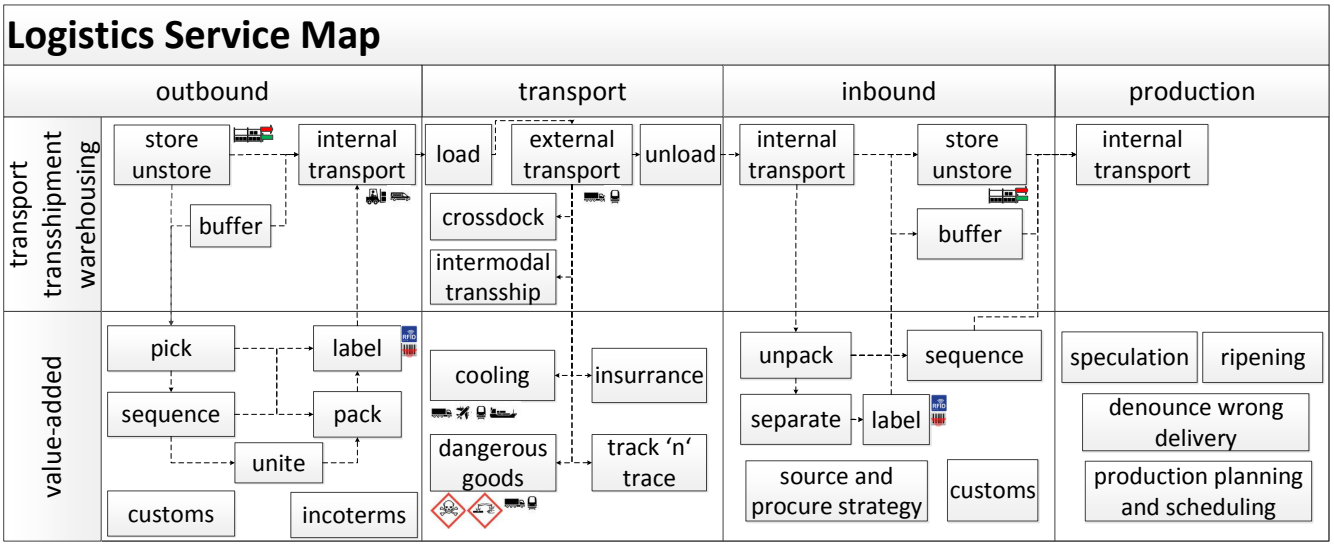

Fig. 7. Example of pictogram dimension for service map catalog.

for categories, which rely on a nominal scale.

Results of short interviews—conducted in our research group and partly the ESSENCE consortium—for *comparison* are shown in Table I. *Spatial dimensions*, i.e. 3D-SMs, were rated very poor. The only possible usage is for nominal and ordinal scales. The navigation within the 3D-space of the SM was the main problem for most of the participants in the interview. Spatial dimension do not scale well with higher number of services since they just add space in the third dimension but this space is limited for every characteristic because of clarity. Most of the participants of the interviews stated that *color dimensions* are suitable for ordinal, interval and ratio scales because they are easy to understand and can be processed pre-attentively which leads to intuitive usage. Color dimensions are also suitable for displaying nominal scaled categories but only with limited number of characteristics, as a too colorful impression only leads to user confusion. All participants agreed that *pictograms* are very suitable for nominal scales. As pictograms are not very capable in displaying order or metric, other scales than nomial are not suitable. Pictograms are appropriate for small as well as for high numbers of services. A possible problem of pictogram

TABLE I
COMPARISON OF USABILITY AND SCALABILITY OF PROPOSED APPROACHES WITH VALUES FROM 0 (POOR) TO 10 (OPTIMAL) (N—NOMINAL SCALE, O—ORDINAL SCALE, I—INTERVAL SCALE, R—RATIO SCALE)

Approach	Usability				Scalability				Advantages	Disadvantages
	N	O	I	R	N	O	I	R		
Spatial	6	7	2	2	-	-	-	-	intuitive usage, adds space for categories instead of using the exitsing space	high development effort, only one further dimension, difficult navigation
Color	5	8	9	8	6	7	8	8	easy to understand, pre-attentive processing	problems with color blind people, unclear if used with nominal scale with many categories
Pictogram	10	2	0	0	9	2	0	0	ideal for nominal scales, easy to understand, pre-attentive processing	not suitable for other scales than nominal scale, high development effort

dimensions is that there is a need for particular pictograms for every characteristic of the scale.

The paper concludes the following *guideline*: the usage of pictograms for nominal scales and color dimensions for ordinal, interval and ratio scales is proposed. If there is the need of having multiple ordinal or nominal scales then a spatial dimension could be taken into consideration. However, with two spatial dimensions and further added color dimension and pictograms there are four dimensions in total displayed in the SM. Regarding the capacity limit of attention, four dimensions are sufficient as too much categories (and the related dimensions, respectively) are counter-productive and reduce clarity and usability.

Referring to the visualization pipeline concept [16], the integration of this guideline is proposed for the third section where a stakeholder could choose options for the resulting visualization due to its requirements.

C. Dynamization

Despite the possibilities of codings for further dimensions of services, the other problem remains: if there are too many services in one category to be displayed all at once. To address this problem the visual information seeking mantra "Overview first, zoom and filter, then details-on-demand" [12] can be applied. Hence, an aggregation of the individual services (and their characteristics and visualization, resp.) is needed. The result is an overview of this category, which is a compromise between information content and possible perception. Best practice depends on the type of the chosen dimension coding. If color coding applies, one approach for n distinct characteristics in a category is to have n equally sized parts of the category with a distinct color. Another approach is to size the colored parts proportional to the ratio of the characteristics of the same color. In case of the shape coding with pictograms it is feasible to show all the pictograms of all the service once. In addition it is possible to size the pictograms or to adjust their opacity according to the ratio of characteristics for each pictogram. If the user filters services or zooms in so that the size of the displayed part is sufficient, the view changes to the small service boxes without names but with colors or small pictograms. If the user zooms further, the services will be shown normally. If the user wants to know the details of a service he can hover or click the service and the details will be shown in an overlay or a pop-up. This way it is possible to have a multitude of services shown in one category in a perceptible manner.

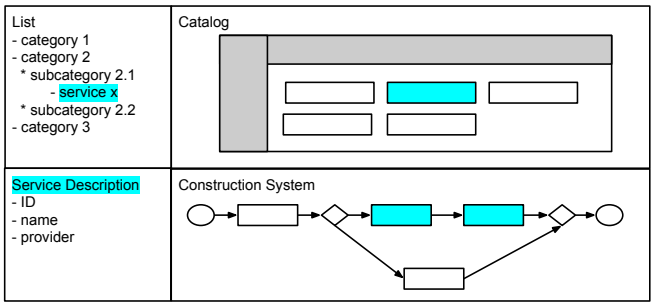

Fig. 8. Rough sketch of temporal fusion for service map concept.

Another approach for enhancing the usability of the SM concept is temporal fusion, shown in Fig. 8. By a simultaneous and identical marking of the same aspect in different views, context-specific relations can be visualized.

V. CONCLUSION AND FUTURE PROSPECTS

This paper presented an improvement of the information visualization for the service map (SM) concept by adding further dimensions. Starting with an introduction to information visualization a profound basis for the enhancement is given with an appropriate methodology, commonly accepted design guidelines, general challenges and a technical approach for implementing a visualization pipeline. Afterwards, the state of the art of the ESSENCE platform, as an representative example of a logistics cloud, was introduced as well as its current shortcomings, i.e. poor clarity in overview and difficulties in orchestration because of a poor user interface. Hence, the paper further introduced the SM concept as a combination of a catalog and a modular service construction system, in order to improve the current cloud platforms' disadvantages. Nevertheless, there were also some visual shortcomings for the SM concept.

The particular contribution of the paper is a profound analysis of information visualization aspects and a derivation of an enhanced visualization approaches for the SM concept. Further 'dimensions' for the SM are realized by the possibility of adding categories represented by colors or pictograms. Finally, the paper determines suitable approaches by giving a guideline on choosing a particular visualization approach dependent on a given scale of measurement.

Future research prospects will address challenges of technically integrating the SM concept in logistics clouds like the ESSENCE platform. Furthermore, the realization of the introduced approach of temporal fusion will be implemented and analyzed towards its usability. Further research prospects comprise sophisticated visualization approaches. Potential ideas are situated in advanced field of free spatial service positioning in a graph theory oriented manner, whereas edge lengths could be related to similarity measures between services.

***Abstract*—Collaboration planning is vital for achieving sustainable logistics. In this paper, we present an ISM based approach for modeling enablers for sustainable logistics collaboration integrating Canadian and Polish perspectives. Enablers can be defined as the key elements (or drivers) for achieving successful collaboration. A comprehensive literature review is conducted to identify 17 enablers for sustainable logistics collaboration. Based on these enablers, a questionnaire study is conducted with 20 logistics experts in Canada and Poland to identify their importance. Based on the aggregated expert ratings, an Interpretive Structural Model (ISM) is developed to identify the relationships among the various enablers. The results of our study show that not all enablers to sustainability collaboration between logistics partners require the same amount of attention. This classification will help Supply Chain managers to help them to focus on those variables that are most important for the transformation of collaboration between logistics partners.**

I. Introduction

COLLABORATION is vital to achieving success in sustainable logistics operations. Modern logistics operators are under increased pressure and administrative regulations in order to fulfill environmental objectives, reduce congestion and make parking space available for public space. For example, vehicle timing, access and sizing regulations are limiting the areas, timing and size of delivery vehicles. Likewise, tax rebate policies may encourage the use of clean energy vehicles or energy efficient goods distribution practices. Under these conditions, collaboration seems a logical and viable strategy for many logistics operators to achieve operational performance as well as successfully meet environmental targets. Several researchers emphasize the importance of collaboration in value creation in supply chains [1]; [2]; [3]. Langley [4] advocates that with the complexity and dynamic nature of today's rapidly evolving business world, any firm stands to lose if trying to "go it alone." [5]. Barratt [6] addresses supply chain collaboration through customer buying behavior and service needs, identifying elements that make up supply chain as well as investigate the interrelationships among the cultural, strategic and implementation elements of supply chain. Cassivi, Garner Group, Ovalle and Márquez (2003) present e-collaboration tools for supply chains [7], [8], [9]. Holweg et al. [10] classify collaboration initiatives using conceptual water-tank approach; and discuss their dynamic behaviors and key characteristics. Kale et al. [11] investigate internet-based collaborative transportation networks. Muckstadt et al. propose guidelines for collaborative supply chain system design and operation [12]. Zhou et al. investigate strategic alliance in freight consolidation [13].

Supply chain management is defined as "the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long term performance of the individual companies and the supply chain as a whole" [14]. Supply chain structure defines the way various organizations within the supply chain are arranged and related to each other. The supply chain structure falls into four main types: Convergent: each node in the chain has at least one successor and several predecessors. Divergent: each node has at least one predecessor and several successors. Conjoined: which is a combination of each convergent chain and one divergent chain. Network: which cannot be classified as convergent, divergent or conjoined, and is more complex than the three previous types [15, 16, 17].

In this paper, our research objectives are:

- to identify and rank the enablers for collaboration between logistics partners in the context of Poland and Canada
- to find out the relation and interaction among identified enablers using ISM
- to suggest for future research.

The paper is organized as follows. In section 2, we will present a list of enablers aimed at the identification of cooperation between business partners. A brief characteristic of questionnaire, the ISM methodology along with its application will be covered in sections 3-5. The MICMAC analysis will be presented in section 6. Finally, the article will

This work is supported by Poznan University of Technology and Concordia University

end with a recapitulation which includes the most important conclusions and directions for future works in sections 7-8.

II. Identification of enablers for collaboration between logistics partners

An enabler is defined as "as one that enables another to achieve an end" where enable implies to make able; give power, means, competence, or ability to (Merriam-Webster). An enabler is considered as a variable that enables (ability to) the attainment of the Sustainable Supply Chain. This definition is consistent with the use of the term enabler in ISM models [18], growth enablers in construction companies [18], information technology (IT) enablement in the Supply Chain [20], enablers of reverse logistics [21], supply chain performance measurement system implementation [22], modelling the barriers of global supply chain [23], supply chain sustainability – analysing the enablers [24].

On the basis of the literature as well as the experience and knowledge of experts, enablers were proposed for collaboration between logistics partners. 17 important variables (enablers), have been differentiated, which, in the opinion of experts, are of significance in business cooperation. Enablers, discussed and selected for analysis, are presented below.

A. Information sharing

Information sharing among logistics partners can take place about anything that leads to amelioration of operational efficiency and attainment of environmental objectives. For example, customer demands, vehicle resources, warehousing capacity, goods inventory or technological know-how. Information sharing leads to visibility in supply chains which in turn leads to cooperation among supply chain partners.

B. Coordination

Coordination can be defined as alignment of project objectives and resources in order to achieve the successful collaboration. Effective coordination among all enterprises cooperating with one another in supply chain is essential to its success [25]. Lee and Whang suggested that information is a basic enabler for tight coordination [26]. Coordination allows for the efforts and the aims of the individual enterprises to be unified. The coordinating actions are fundamental, those that (1) stimulate the supply chain through the creation of a supply chain growth concept, (2) regulate the supply chain by redistributing the possessed resources (3) integrate the supply chain by linking resources, monitoring and an assessment of the actions [27].

C. Trust

In a supply chain, trust is one of the key cooperation factors (e.g. trust that a supplier or a subcontractor perform their duties according to specifications; trust that a supplier with which the enterprise did cooperate previously, will supply a product of a proper quality; trust that the customer will pay within agreed period of time and will not cause a payment gridlock, etc) [28]. It is during cooperation when complex trust-based reactions occur, since one entity's gains depend on the other. The risk and uncertainty connected with trust and cooperation develop as the number of participants increases.

D. Willingness to collaborate

Willingness to collaborate is vital in achieving successful collaboration. Disinterested partners lack commitment and may leave the collaboration anytime leading to waste of resources, time, money and personnel.

E. Communication

According to Hahn et al. effective communication among all elements of supply chain. Clearly communicated goals across members of all hierarchy in the organization leads to efficient realization of planned objectives under given time, pressure and resources [25].

F. Common business goals

Common business goals are one of the main reasons behind any organization's interest to collaborate with other partner organizations. Similar business goals lead to common practices, techniques, and efficient sharing of knowledge leading to win-win situation for all the organizations participating in collaboration.

G. Responsibility sharing

Responsibility allocation and sharing among the participating organizations leads to increased trust, information sharing, and commitment from the involved partners and fosters strong collaboration.

H. Planning of supply chain activities

Efficient and timely planning of supply chain activities reduces waste of time, resources and money arising from last minute changes in customer demands or unstable market conditions. For successful collaboration, right planning also leads to efficient realization of goals, sharing of resources, and profit allocation.

I. Flexibility

Organizations participating in any collaboration do not always have the same experience, culture, technological readiness, or brand image. Under these situations, it is vital for participating organizations to be flexible to adapt to others needs for joint success. Richey et al. identify technology and flexibility as key enablers for logistics collaboration [29].

J. Benefit sharing

Benefit sharing among participants is vital for retaining loyalty towards collaboration. Benefit sharing can be done

equally among partners or depending upon the stakes of major contributing organizations after mutual consensus.

K. JOINT DECISION MAKING

All the organizations involved in collaboration should work together and perform joint decision making to achieve operational and environmental goals. This will lead to increased trust and commitment which is essential for long term success of any collaboration.

L. ORGANIZATIONAL CULTURE

Organizational culture is very important in sharing of common vision and goals for any collaboration. Participating organizations should have a good understanding of other participant organizations culture to avoid any misconceptions and gaps that can serve as barriers in realization of project objectives.

M. ORGANIZATIONAL COMPATIBILITY

Organizational compatibility in terms of product-service types, size, location, strategy, employee culture, technology, management commitment, budget, resources etc. aids in developing successful collaborations among the participating organizations.

N. RESOURCE SHARING (INTEGRATION)

Once organizations enter into collaboration, it is important to address the goals of all participants efficiently, uniformly and in time either through partial and/or complete sharing of resources. This will also help in achieving successful project co-ordination and completion.

O. TOP MANAGEMENT SUPPORT

Commitment from management includes an effort and financial backing from the upper management to implement sustainability in logistics operations. Top management commitment retains employee interests in implementing sustainability practices and continuous improvement goals [30]. In order to achieve long term success, management support and commitment is very important and should be accompanied with employee rewards and training programs.

P. TECHNOLOGICAL READINESS

Use of IT tools to monitor the supply chains and sharing information among the partners leads to visibility in supply chain, thereby providing better cooperation among different levels of the supply chain [30]. Electronic data interchange and internet have enabled partners in supply chains to act upon same data rather than rely on distorted and noisy data that emerges in an extended supply chain [26, 31]. Swafford et al emphasize the role of IT integration and flexibility in achieving supply chain agility [32].

Q. TRAINING

Training helps employees with expertise to perform their tasks efficiently. Company's power comes from the physical and mental strength of their workers. Organizing employee trainings and maintaining occupational safety and health are among the main functions of human resources management departments. These two functions interact and they both serve the aim of protecting employee's physical, psychological and social health [30].

III. QUESTIONNAIRE-BASED SURVEY

In order to determine the relative importance of enablers, we conducted a questionnaire study. The main objective of the questionnaire-based survey was to facilitate experts in developing a relationship matrix as a first step towards developing an ISM-based model. In this survey the respondents were asked to indicate the importance of 17 listed enablers on a five-point Likert scale [18]. On this scale, 1 and 5 correspond to 'very low importance' to 'very high importance', respectively. In total, questionnaires were sent to 20 experts in Poland and Canada. All of them were analyzed.

TABLE I.
ENABLERS ACCORDING TO RESEARCHERS FROM POLAND

lp.	Enablers	Mean score
1	Communication	4,6
2	Information sharing	4,6
3	Coordination	4,4
4	Willingness to collaborate	4,3
5	Planning of supply chain activities	4,1
6	Trust	4,0
7	Responsibility sharing	3,9
8	Common business goals	3,8
9	Benefit sharing	3,6
10	Flexibility	3,4
11	Joint Decision Making	3,4
12	Resource sharing (integration)	3,4
13	Organisational compatibility	3,3
14	Organizational culture	3,3
15	Top management support	3,1
16	Technological readiness	2,5
17	Training	2,5

Tables 1-2 show the difference between perceiving the relevance of the enablers in relation to the collaboration between business partners in Poland and Canada. According to researchers from Poland (Tab. 1), the most significant enabler is communication (4,6). The lack of information often leads to misunderstandings, and these, in turn, cause uncertainty, ambiguity, difficulty and failure in communication, and in effect failure in collaboration between business organizations.

TABLE III.
ENABLERS ACCORDING TO RESEARCHERS FROM CANADA

lp.	Enablers	Mean score
1	Trust	4,4
2	Coordination	4,3
3	Information sharing	4,3
4	Common business goals	4,3
5	Flexibility	4,1
6	Willingness to collaborate	4,1
7	Organizational culture	4,0
8	Organisational compatibility	3,9
9	Joint Decision Making	3,9
10	Responsibility sharing	3,9
11	Technological readiness	3,9
12	Communication	3,7
13	Benefit sharing	3,7
14	Resource sharing (integration)	3,7
15	Training	3,7
16	Planning of supply chain activities	3,6
17	Top management support	3,4

TABLE IIIII.
ENABLERS APPLIED IN THE RESEARCH

lp.	Enablers	Mean score
1	Information sharing	4,45
2	Coordination	4,35
3	Trust	4,20
4	Willingness to collaborate	4,20
5	Communication	4,15
6	Common business goals	4,05
7	Responsibility sharing	3,90
8	Planning of supply chain activities	3,85
9	Flexibility	3,75
10	Benefit sharing	3,65
11	Joint Decision Making	3,65
12	Organizational culture	3,65
13	Organisational compatibility	3,60
14	Resource sharing (integration)	3,55
15	Top management support	3,25
16	Technological readiness	3,20
17	Training	3,10

While researchers from Canada (Tab. 2) deemed trust (4,4) as key in proper collaboration. Practically each commercial transaction contains an element of trust. Trust has its practical, real, economic value, since it results in the increase in the effectiveness of the system and allows for more goods to be produced.

The explanation of the occurring differences is cultural differences - different behaviors, social norms or a different system of values. Despite the fact that social, political, economic changes as well as technological achievements have made inter-cultural contacts become an everyday matter, cultural differences still take place and play a significant role in the 21st century.

Table 3 includes the joint list of enablers, which was accepted in the research and analysis.

IV. METHODOLOGY

Interpretive Structural Modeling (ISM) is defined as a process aimed at assisting the human being to better understand and clearly recognize what one does not know [33]. The ISM process transforms unclear, poorly articulated mental models of systems into visible and well defined models. ISM is an interactive learning process. In this technique, a set of different directly and indirectly related elements are structured into a comprehensive systematic model. The model so formed portrays the structure of a complex issue or problem in a carefully designed pattern implying graphics as well as words [18, 34].

Interpretive Structural Modeling was first proposed by Warfield [35]. It enables individuals or groups to develop a map of the complex relationships between many elements involved in a complex decision situation [22].

A. THE IMPORTANT CHARACTERISTICS OF ISM

The important characteristics of ISM are:

• This methodology is interpretive, as the judgment of the group decides whether and how the different elements are related.

• It is structural on the basis of mutual relationships as the overall structure is extracted from the complex set of elements.

• It is a modelling technique, as the specific relationships and overall structure are portrayed in a digraph model [34].

B. THE VARIOUS STEPS INVOLVED IN THE ISM TECHNIQUE

The steps involved in the ISM are represented in the form of a flow diagram (see Fig. 1).

The various steps involved in the ISM technique are as follows [18]:

Step 1: Different enablers (or variables), which are related to defined problems, are identified.

Step 2: A Structural Self-Interaction Matrix (SSIM) is developed for enablers. This matrix indicates the pair-wise relationship among enablers of the system. This matrix is checked for transitivity.

Step 3: A Reachability Matrix (RM) is developed from the SSIM.

Step 4: The RM is partitioned into different levels.

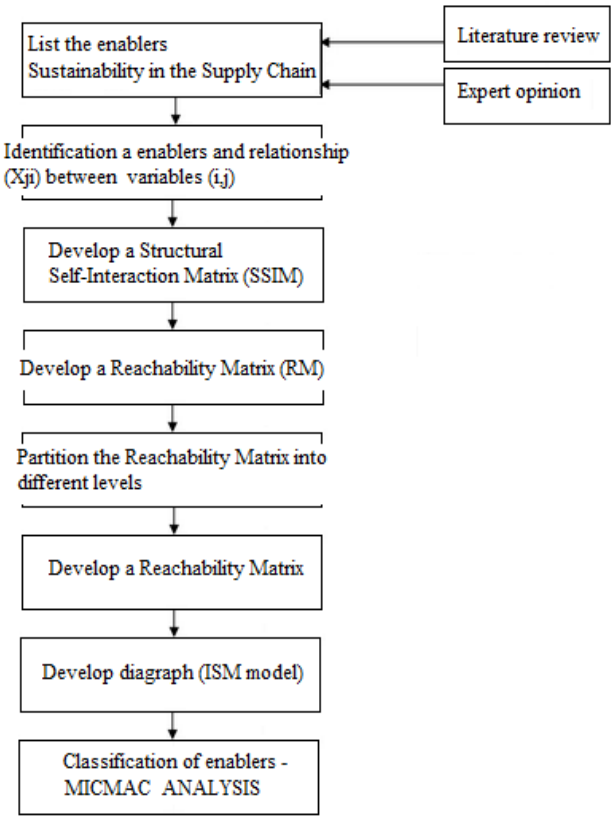

Fig. 1 Flow diagram for constructing an Interpretive Structural Modeling; based on [35]

Step 5: The Reachability Matrix is converted into its conical form, i.e. with most zero (0) elements in the upper diagonal half of the matrix and most unitary (1) elements in the lower half.

Step 6: Based upon the above, a directed graph (digraph) is drawn and transitivity links are removed.

Step 7: Digraph is converted into an ISM model by replacing nodes of the elements with statements.

Step 8: The ISM model is checked for conceptual inconsistency and necessary modifications are incorporated.

C. The Formation of Structural Self-Interaction Matrix (SSIM)

After identifying the 17 enablers through the review of literature and expert opinions, the next step is to analyze these enablers. For this purpose, a contextual relationship of "leads to" type is chosen. Bearing the contextual relationship for each enabler in mind, the existence of a relation between any two enablers (i and j) and the associated direction of this relation has been decided [18].

From the enablers identified in step 1, a contextual relationship is identified among enablers with respect to which pairs of variables would be examined. This step transforms the list into a matrix and marks dependencies using expert opinions. After resolving the enablers set under consideration and the contextual relation, a Structural Self-Interaction Matrix (SSIM) is prepared.

Four symbols are used to denote the direction of relationships between the enablers (i and j):

- V: for the relationship from enabler i to enabler j and not in both directions;
- A: for the relationship from enabler j to enabler i and not in both directions;
- X: for both the directional relationships from enabler i to enabler j and j to i;
- O: if the relationships between the enablers did not appear valid (enablers i and j are unrelated) [18].

TABLE IVV.
STRUCTURAL SELF-INTERACTIVE MATRIX (SSIM)

Ip.	Enablers	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2

14	Resource sharing (integration)	A	X	V													
15	Top management support	A	V														
16	Technological readiness	O															
17	Training																

Based on the review of literature and expert's responses, the SSIM is constructed as shown in Tab. 4. The following statements explain the use of symbols in Structural Self-Interaction Matrix, e.g. [18]:

- Symbol V is assigned to cell (1, 15) as enabler 1 influences or reaches enabler 15.
- Symbol A is assigned to cell (2, 17) as enabler 17 influences the enabler 2.
- Symbol X is assigned to cell (5, 16) as enablers 5 and 16 influence each other.
- Symbol O is assigned to cell (6, 16) as enablers 6 and 16 are unrelated.

The next step is to develop the Reachability Matrix (RM) from the Structural Self-Interactive Matrix. This is obtained in two sub-steps.

In the first sub-step, the Structural Self-Interaction Matrix is trans-formed into a binary matrix (see Tab. 5), called the initial reachability matrix by substituting V, A, X, O by 1 and 0 as per the case. The rules for the substitution of 1s and 0s are as follows:

- If the (i, j) entry in the SSIM is V, then the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry becomes 0.

• If the (i, j) entry in the SSIM is A, then the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry becomes 1.

• If the (i, j) entry in the SSIM is X, then the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry also becomes 1.

• If the (i, j) entry in the SSIM is O, then the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry also becomes 0 [18].

TABLE V.
INITIAL REACHABILITY MATRIX

13	Organisational compatibility	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0
14	Resource sharing (integration)	1	1	1	0	1	0	1	0	0	0	1	1	1	1	1	1	0
15	Top management support	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	1	0
16	Technological readiness	1	1	0	0	1	0	0	1	1	0	0	0	1	1	0	1	0
17	Training	1	1	1	1	1	1	1	1	1	0	1	1	0	1	1	0	1

In the second sub-step, the final reachability matrix is prepared (see Tab. 6). The concept of transitivity is introduced so that some of the cells of the initial reachability matrix are filled by inference. The transitivity concept is used to fill the gap, if any, in the opinions collected during the development of the SSIM [18].

V. BUILDING THE ISM MODEL

The diagraph for interpretive structural modelling is drawn. Having identified the levels of the elements, the relations between the elements is drawn with the help of an arrow. The level I enablers are in the top level in the hierarchy. The enablers of the same level are kept on the same level of hierarchy [36]. The diagraphs give information about the hierarchy between the elements of enablers for the collaboration between logistics partners (see Fig. 2). It can be seen in Fig. 2 that the most important enablers (level I) are 'Common business goals' and 'Training'.

The purpose of Cross-Impact Matrix Multiplication Applied to the Classification analysis (MICMAC) is to analyse the drive power and dependence power of enablers. This is done to identify the key enablers that drive the system in various categories [18]. The variables are classified into four clusters (see Fig. 3).

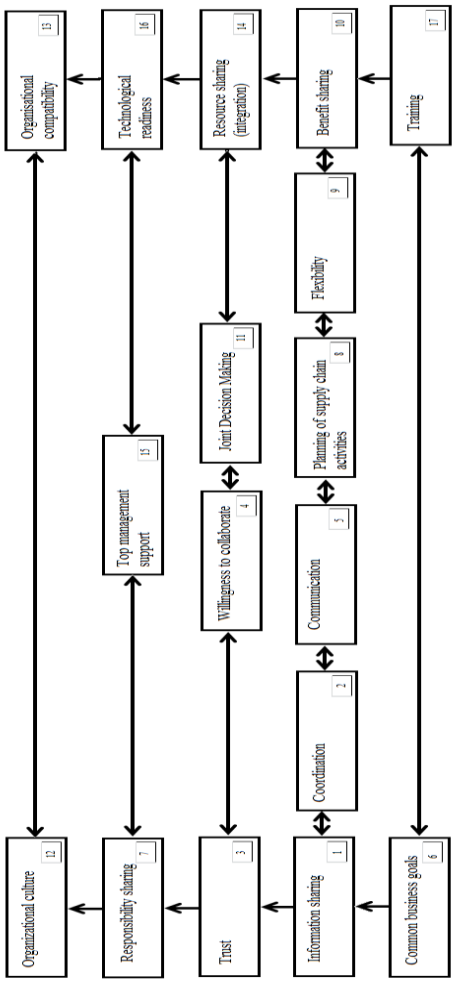

Fig. 2 The ISM based model for enablers for collaboration between logistics partners

VI. MICMAC Analysis

They have been classified into four categories:

• The first cluster consists of autonomous variables (Autonomous enablers). These enablers have a weak drive power and weak dependence. They are relatively disconnected from the system, with which they have few links, which may be very strong.

• The second cluster consists of the dependent variable (Linkage enablers). These have strong drive power as well as strong dependence. They are also unstable. Any action on them will have an effect on others and also a feedback effect on themselves.

• The third cluster has the linkage variables (Dependent enablers). This category includes those enablers which have a weak drive power but strong dependence power.

• The fourth cluster includes the independent variables (Independent enablers). These have a strong drive power but a weak dependence power. It is generally observed that an enabler with a very strong drive power, called the 'key enabler' falls into the category of independent or linkage enablers [18, 20, 24].

Enablers is constructed as shown in Fig. 3 (The driver power-dependence Matrix).

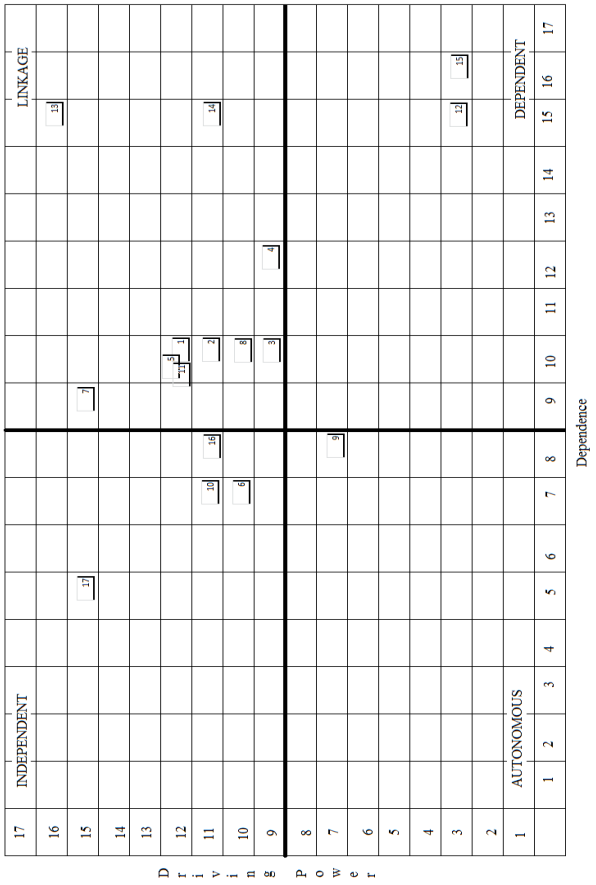

Fig. 3 Clusters of enablers in the implementation of collaboration between logistics partners

VII. Description of the Most Important Implementation Elements

In this research, an ISM-based model has been developed to analyse the interactions among different enablers [18]. The main objective of this research is to analyse the effectiveness of various enablers which help in the implementation of collaboration between logistics partners. The methodology proposed here identifies the hierarchy of actions to be taken for handling different enablers' ability to implement sustainability collaboration between logistics partners.

The managers can gain insight into these enablers and understand their relative importance and interdependencies. The driver dependence diagram gives some valuable insight about the relative importance and interdependencies among the collaboration sustainability enablers between logistics partners.

Some of the important implications emerging from this study are as follows: Figure 10 shows that in Autonomous enabler is one enabler: 'Flexibility' (enabler 9). Autonomous

enabler is weak driver and weak dependent and do not have much influence on the system.

Two enablers are Linkage enablers. Linkage enablers are 'Information sharing' (enabler 1), 'Coordination' (enabler 2), 'Trust' (enabler 3), 'Willingness to collaborate' (enabler 4), 'Communication' (enabler 5), 'Responsibility sharing' (enabler 7), 'Planning of supply chain activities' (enabler 8), 'Joint Decision Making' (enabler 11), 'Organisational compatibility' (enabler 13), 'Resource sharing (integration)' (enabler 14). They have a strong driving power as well as high dependencies [18]. If they are implemented in a proper way they can create a positive environment for the successful implementation of collaboration between logistics partners.

Enablers' 'Common business goals' (enabler 6), 'Benefit sharing' (enabler 10), 'Technological readiness' (enabler 16), and 'Training' (enabler 17) are Independent enablers. They have a strong driving power and weak dependency on other enablers.

'Organizational culture' (enabler 12) and 'Top management support' (enabler 15) are Dependent enablers. These enablers are weak drivers but strongly depend on one another. The managers should take special care to handle these enablers.

VIII. Conclusions and Future Works

This model proposed for the identification of enablers of sustainability collaboration between logistics partners can help in deciding the priority to take steps proactively. The results of this research can help in strategic and tactical decisions for a company wanting to create sustainability collaboration between logistics partners.

The main strategic decision relies on 'Common business goals' and 'Training'. These enablers, which are at the bottom of the ISM-based model and are the most important enablers that initiate strategic activities.

The analysis reveals that enablers 'Common business goals', 'Benefit sharing', 'Technological readiness' and 'Training' are ranked as Independent enablers as they possess the maximum driver power. This implies that these variables are key barriers in the successful implementation of sustainability collaboration between logistics partners. The most important among them are 'Common business goals' and 'Training'.

The ISM-based model provides a very useful understanding of the relationships among the enablers. The present model can be statistically tested with use of structural equation modelling (SEM) which has the ability to test the validity of such models [18].

Abstract— The most important topic for researchers is supply chain, that takes into account environmental factors and social aspects. That is why top managers prefer taking into account key performance indicators currently. Harmonization of social, environmental and economic components makes development of supply chains sustainable. This document is based on environmental protection; it details the main features of sustainable supply chain. It presents supporting tools of collaboration in sustainable supply chains. The main examined areas: system identification, order picking, inventory control systems, city logistics, intermodal logistics processes, routing, and logistics processes of earthwork. The tools: neural network, simulation, genetic algorithm, ant colony algorithm.

The paper is structured as follows: First chapter defines sustainability and Sustainable Supply Chain (SSC). The second chapter presents supporting tools of collaboration in sustainable supply chains.

I. Introduction, Environmental Protection, Sustainable Supply Chain

Environmental sustainability depends on the interaction between organizations in supply chain, products and ecosystems [1]. Sustainability is playing an increasingly significant role in planning and management within organizations and across supply chains [2], [3], [4].

Supply chain management is defined as "the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long term performance of the individual companies and the supply chain as a whole" [5].

Supply chain structure defines the way various organizations within the supply chain are arranged and related to each other. The supply chain structure falls into four main types [6]: Convergent: each node in the chain has at least one successor and several predecessors. Divergent: each node has at least one predecessor and several successors. Conjoined: which is a combination of each convergent chain and one divergent chain. Network: which cannot be classified as convergent, divergent or conjoined, and is more complex than the three previous types [7], [8], [9].

Sustainable supply chains are essential to sustain modern business growth and ensure healthy market environment [10]. In contrast to traditional SCM, which typically focuses on economic and financial business performance, sustainable SCM (SSCM) is characterized by explicit integration of environmental and/or social objectives which extend the economic dimension to the TBL [11]. In this context, SSCM focuses on the forward SC only [12] and is complemented by closed-loop SCM (CLSCM) [11], [12] including reverse logistics, remanufacturing, and product recovery [13].

Sustainable SCM is the management of material, information and capital flows as well as cooperation among companies along the supply chain while integrating goals from all three dimensions of sustainable development, i.e., economic, environmental and social, which are derived from customer and stakeholder requirements. In sustainable supply chains, environmental and social criteria need to be fulfilled by the members to remain within the supply chain, while it is expected that competitiveness would be maintained through meeting customer needs and related economic criteria. [4]

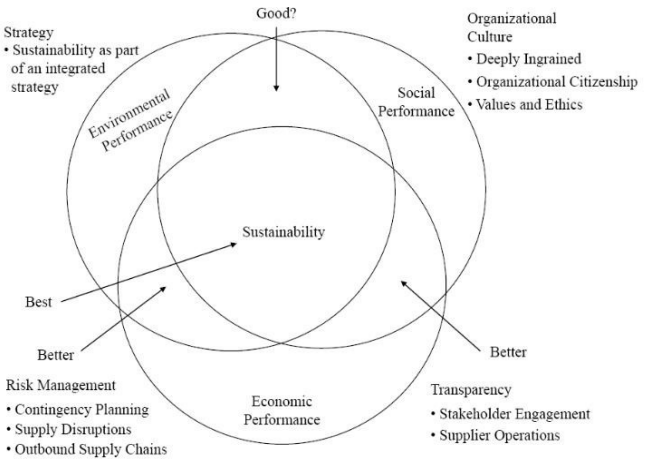

Fig. 1 Sustainable supply chain management [14]

This work is supported by Poznan University of Technology and Budapest University of Technology and Economics

Carter and Rogers define SSCM (Fig. 1) as the strategic, transparent integration and achievement of an organization's social, environmental, and economic goals in the systemic coordination of key interorganizational business processes for improving the long-term economic performance of the individual company and its supply chains [14].

In the article [15] the analysis reveals that six enablers 'Commitment from top management', 'Eco-literacy amongst supply chain partners', 'Corporate social responsibility', 'High level of supply chain integration', 'Waste management' and 'Logistics organisation ensuring goods safety and consumer health' are ranked as Independent enablers as they possess the maximum driver power. This implies that these variables are key barriers in the successful implementation of sustainability in the Supply Chain. The most important among them are 'Eco-literacy amongst supply chain partners', 'Commitment from top management' and 'Corporate social responsibility'.

Conceptualizing sustainability in three dimensions seems to be widely accepted [16, 17]. It allows an easy comprehension of the integration of economic, environmental and social issues. This also offers the justification of applying it in this paper. Most papers spend much more effort on explaining related environmental issues. In many cases, life-cycle assessment data forms the starting point for the analysis. Hence, energy demand and CO2-emissions (e.g. [18, 19, 20]) are among the frequently mentioned topics. Yet, in a number of cases, rather comprehensive lists of environmental impact criteria are taken up, such as referring to all kinds of natural capital (e.g. [21]) or resources, such as water or energy as well as waste (e.g. [22]) [4].

II. Supporting Tools of Collaboration in Sustainable Supply Chains

A. Automatic Identification, Neural Networks

In the last decade artificial intelligence (AI) methods come into prominence. The main reason is that the artificial intelligent methods are the mathematical models of human thinking and natural laws, therefore, a human-made decision support system (DSS) can behave similar way as an intelligent living being. With this ability the commonly used logistics methods can be developed in different fields such as planning and operation. In some cases the human intelligent can be swapped or complemented with artificial intelligence methods [23]. These methods could be inventory, scheduling, shortest route problems. The main purpose of [24] is to develop a time series analysis method in order to increase the demand forecast accuracy. The examined method is the Autoregressive Integrated Moving Average (ARIMA) model [23], [24], which has outstanding forecast accuracy in case of an auspicious identification. The aim is to show that the automatic ARIMA function identification can be accomplished with an artificial neural network (ANN) and with its learning ability the efficiency of identification is growing, see Fig. 2.

The automatic ARIMA (p, d, q) model identification described in [24] is a result of a continuous research and development. It was presented that the current identification methods and tests are hardly usable for "non ideal" time series and they are unable to adapt to the constantly changing characteristics of input data. On the other hand the model identification with a neural network is less sensitive to input errors through its intuitive capability, additionally after a certain number of training steps the algorithm is able to identify time series with unknown characteristics.

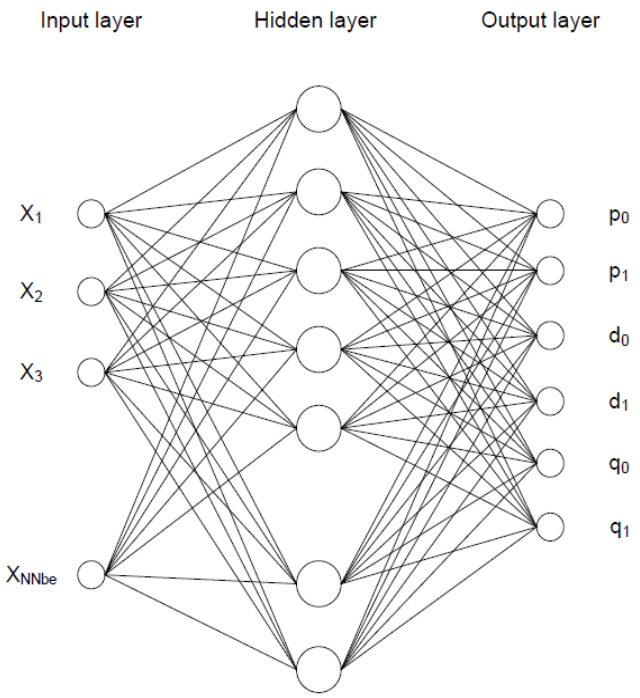

Fig. 2 Neural network [24]

These features make the method capable of integrating it into logistics processes. Of course the presented forecast method [24] is applicable to support other problems. The learning and intuitive capability of the artificial neural network is usable on any fields, where a prompt decision must be done with the support of previously acquired knowledge. It is effectively applicable solving inventory, scheduling, shortest route problems. The accuracy and efficiency of the method highly depends on the previously acquired knowledge, therefore, a great importance must be attached to the planning and operation. If the attention is made then the result is a robust, fast and flexible system wherein the unknown and random events can be treated effectively.

B. MULTI-CRITERIA SCHEDULING OF ORDER PICKING PROCESSES WITH SIMULTAN OPTIMIZATION

The flexibility of labour in a warehouse means that available personnel are redeployed during shifts to activities (storage, order picking, replenishment, etc.) where extra capacity is required. In the case when available labour capacity is not sufficient, temporary staff can be hired from specialized agencies. Order picking – retrieval of products from storage to meet customers' demand – is often the most labour-intense activity in a warehouse. The human hand as a 'handling equipment' is hard to be replaced and economical automation of retrieval of products is seldom possible. Therefore, the costs of order picking may amount to about half of the operational costs in a warehouse, so any improvement in this field may result in significant cost reduction [25, 26, 27, 28].

Both optimization and simulation are tools that support decision making. Optimization uses fixed input data, avoiding uncertainty and details. Optimization models simplify the complexity of the real system and some factors are even not considered. The simulation is not creative like optimization, but can cover uncertainty and complexity of dynamic systems in detail. The combination of optimization and simulation (simulation optimization) can be defined as the process of finding the best set of input variables without evaluating each possibility. The objective of simulation optimization is to minimize the resources spent (i.e. time) while maximizing the quality of information gained in the experiment. The model represented in [27] also uses the benefits of simulation optimization. The designed system supports operative warehouse management personnel in order to pick process scheduling and planning. By evaluating a number of scenarios, the number of the order pickers per shift, and the best sequence of releasing the pick lists to be retrieved from storage are determined [27]. It is the management's responsibility to monitor and control the order picking activities in the warehouse continuously and force the adherence to the schedule. If all order picking activities are realized according to the schedule, then the planning of the replenishment of the order picking places is also possible. The goal of [27] is to further develop the above described planning system and include the scheduling of these activities, too. The connection to the database of the WMS with the simulation model already exists so it is possible to determine when the last products will be picked from each picking place and when replenishment is necessary. By applying advanced search methods – like Genetic Algorithms – the optimal schedule for the replenishment of the picking places can be evaluated. The objective function must reflect the goal of planning the replenishment process so that the order picking processes can be executed continuously and undisturbed – products are available at the picking place and the congestion in the aisles is avoided. It is also the object of further development to improve the optimization algorithm and reach higher speed and accuracy in calculation. In this first version of the model [27], all probabilities to execute each genetic operator were constant. The proposed development (Fig. 3) will operate with variable probabilities for crossover and mutation to inherit the properties of the fittest individuals into the next population, to avoid premature convergence and to close-up the search space [27], [29].

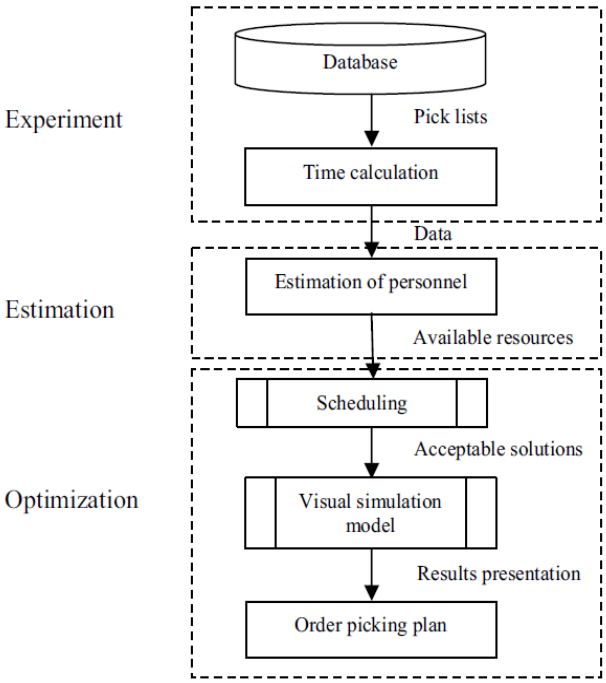

Fig. 3 Scheduling and decision support process for order picking planning [27]

C. OPTIMIZATION OF INVENTORY CONTROL SYSTEMS WITH GENETIC ALGORITHMS

The inventory control systems are responsible for the optimal operation of the inventory processes of the automotive companies. Generally, the optimization of the inventory control system manifests itself in a target conflict representing the implementation of the optimal operation in economic and reliability terms. For the process optimization, the control parameters of the regulation system should be defined. Their actual settings determine the time of placing orders of auto parts and the required quantities for the optimal operation of the processes defined above [30] presents a particular method of exploitation of the opportunities provided by the computer aided simulation and the genetic algorithms for the optimization of inventory control systems applying classical inventory mechanisms (Fig. 4).

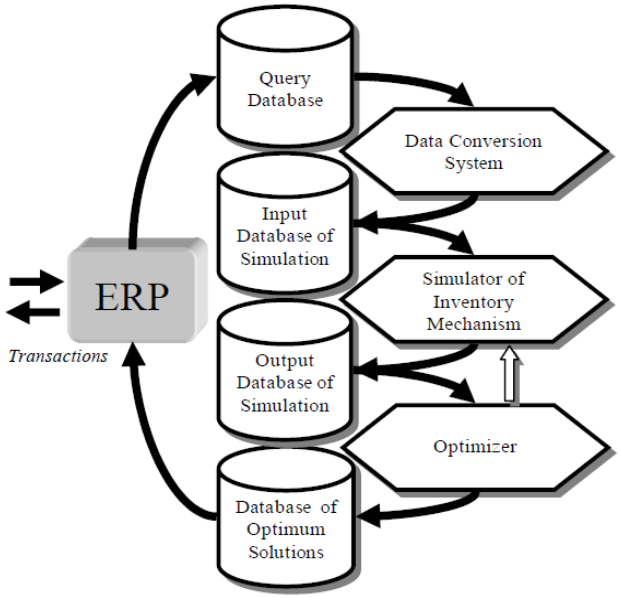

Fig. 4 Process of the dynamic inventory management [30]

The simulation inventory model presented in [30] and the binary genetic optimizing algorithm determining the control parameters showed beneficial properties in managing of stochastic inventory processes. For the establishment of proper applications, it is worthwhile to examine also the services rendered by the genetic algorithms operating with real number representation, as it is possible that this type of algorithm is able to provide the same results in a faster, more accurate way. Experiences show that the inventory processes in the future may constitute a special application field of the simulation supported optimization with genetic algorithms.

D. CITY LOGISTICS: DIFFERENT APPROACH, MODELS

The urban travel and land-use problems are not just urban problems. Their economic, social and environmental impacts extend well beyond the geographic jurisdictions of cities and towns to regions and to countries as a whole. The policies are designed to shape travel and land-use patterns to maximize the benefits of transport while minimizing their negative impacts. Given the broad spectrum of economic sectors and actors potentially impacted by urban travel and land-use activity, a package of complementary policy instruments needs to be developed that provides clear and well-targeted incentives to reduce the impacts of urban travel and land-use activities. This involves better integration of land use and transport planning. It involves finding ways to manage growth in car use and ensuring that alternative modes of travel by car – public transport, walking and cycling – are promoted. Fiscal and pricing instruments, legal and regulatory tools, currently available technology, and public information are some of the main policy tools available. A policy framework that embodies clear long-term objectives for urban travel may provide the essential parameters for implementation of integrated sustainable urban travel policies [31], [33].

By city logistics, we mean the technically, economically, organizationally efficient and environmentally friendly synchronization of goods distribution (and reverse logistics) tasks generated mainly by the secondary and tertiary sectors, and mostly retailers in downtown areas and historical city centers. There are many best practices to be found worldwide, that have already been identified and classified. Different city logistics system solutions affect the goods distribution of a city in various ways and magnitude, thus a model is desirable that helps the decision-making of stakeholders. [34] Is examining the indicators of cities housing city logistics system solutions, and some that are lacking those. The problem with the latter is that the shops, that form the demand scattered throughout the city, are not visited by their suppliers in a coordinated fashion, taking advantage of the common capacity, but rather they compete. Satisfying the demand takes place with presumably sub-optimal logistics-related costs [35]. This comes from the different suppliers transporting same types of goods to the same destinations with different – redundant – infrastructure, which could be avoided, according to [36]. Moreover, the attributes of the supply chains are adjusted to the regulation of the given municipality, but they seldom take advantage of certain possibilities (e.g. river, railways), and usually do not utilize integrated solutions, preferring road to multimodal transportation [32].

In order to assess the possibilities, [34] is developing a model that can compare various scenarios. The model is constantly evolving, but its fundamentals are: it maps an area with a graph, generates variable demand, and compares total costs. The model is basically static in structure: the different alternatives are constituted by nodes, and the transport system between each of these nodes. The demand is stochastic: the destinations and their daily demand (quantity of goods ordered) is a random variable. The total demand has to be satisfied with a – a priori unknown – number of vehicles. The common elements of the solutions are the location of the suppliers (LS), the urban consolidation centres (UCC), the urban relay stations (URS), and the urban loading points (ULP).

The number and location of these varies with each alternative. Further variable elements are the local and regional transport systems, with different vehicles and tracks. Accordingly, the model consists of a network, modelled as a graph. This structure of the model is suitable for the present and the planned systems, so they can be compared (Fig. 7).

The greatest challenge that can help the application of the model is the acquisition of more precise unit costs derived from logistics performance. External costs should later be included next to the existing ones, because a primary goal of a city logistics system solution is the reduction of the air and noise pollution and the augmentation of the standards of living. The fine-tuning of the model should produce precise

enough results that can point out an advantage of a specific alternative. The model, since it was developed generally, can be used extensively and in a wide number of cities and urban areas: the model parameters can be modified so as it can help decision-making at different locations [34].

Element	Type	Vehicle	Function
Location of suppliers (LS)	Node		Source of goods
Long-distance transport paths	Edge	Regional vehicles	Large-scale, homogeneous goods transport
Urban consolidation centres (UCC)	Node		Consolidation
Main urban transport paths	Edge	Local vehicles	Large-scale, heterogeneous goods transport
Urban relay stations (URS)	Node		Fast transhipment
Feeder urban transport paths	Edge	Last mile vehicles	Small-scale, heterogeneous goods transport
Urban loading points (ULP)	Node		Sink, points of sale

Fig. 5 Elements of a city logistics network [34]

As further possibility, in general terms, electronic freight and warehouse exchanges are virtual market places established for the harmonization of freight demand and supply. Due to their characteristics, however, these may be also suitable for the division of capacities (capacity load and storage capacity) of certain freighters and forwarders. Upon these trade directed to cities may be optimized, as groupage transport may be organized to cities, or within these to districts, considering, at the same time, the possibility of acquiring back haul, as well. In addition to this, by the division, optimal exploitation of freight capacities trade directed to the cities may be significantly reduced with the application of a transfer location in the outskirts of the city and a related warehouse exchange [36].

To effectuate a consistent methodology for urban planning – taking into consideration the viewpoints of land use and transportation – we need to approach the subject with considering complex social and economic aspects. To handle both of the mentioned urban planning areas together, we shall develop models, which are able to pay attention to all of their restrictive factors within the temporal properties as well. The efficiency of urban transportation is getting more and more important because of the increasing rate of mobility demand. To plan, control and organize urban transportation in the most efficient way, we also need to consider the aspects of land use. [37].

E. INTERMODAL LOGISTICS PROCESSES

The role of the intermodal logistic processes and related services are continuously changing and developing due to the spreading of transportation processes. One of the most frequent attribute of the service functions is the implementation parameters (for example place and material requirement) which are being changed, so the logistics system must be able to follow its flexibly. Because of the complexity, at any given time and location the implemented service requires cooperation between multiple logistics subsystems which are connected together only with the common management system and the endpoint of materials flow. One of the possible surface to satisfy the ever growing and changing claims if these services are supported by electronic freight and warehouse exchanges to perform the logistics processes.

The modified supply chain by electronic freight and warehouse exchanges is shown in Fig. 6. The main features of the modified supply chain system:

- The wholesalers are responsible for the information processes; they manage the demands of retailers.
- The logistics providers (storage providers, transportation providers, logistics centres) perform the physical freight and storage tasks, whereas they have:
  - suitable stock capacities,
  - suitable freight capacities,
  - logistics know-how.
- Electronic freight and warehouse exchanges perform the supply-demand (capacities-tasks) harmonization; the decision supporting and the optimization.
- In the case of logistics providers and electronic freight and warehouse exchanges the logistics processes are core.
- Due to the above the modified logistics system (e.g. combined transportation system) may be optimal.

Consequently, green logistics systems, e.g. green combined transportation supply chains can be realized (Example can be seen in Fig. 7). In addition, this system is beneficial not only for the individual actors (e.g. retailers, wholesalers, logistics providers, manufacturers, intermodal centres) but also for the national economy. The future plans include further development of algorithms and tests in real supply chains, e.g. supply chains of drink industry or other possible combined or complex city transportation system.

F. ROUTING (TSP, VRP) IN ELECTRONIC FREIGHT AND WAREHOUSE EXCHANGES WITH ANT COLONY ALGORITHMS

The basic function of electronic freight and warehouse exchanges is to establish connection between free freight and storage capacities and tasks [40]. In the database of such online fairs there is high number of freight and storage capacity offers and tasks, which provides good optimization opportunity for those with free capacity [42].

The Vehicle Routing Problem (VRP) is used to design an optimal route for a fleet of vehicles to service a set of customers' orders (known in advance), given a set of constraints. The VRP is used in supply chain management in the physical delivery of goods and services. The VRP is of the NP-hard type [41].

In the freight exchange the optimum search task may be formulated on the basis of the following objective function: those having free freight capacity wish to establish routes providing optimal profit from the freight tasks appearing in the freight exchange. Many freight tasks may be included into the route, but a new freight task may be commenced only after the completion of the previous one.

The ACO (ant colony optimization) is an optimizing algorithm, a method developed by Marco Dorigo based on the modelling of the ants' social behaviour. In nature ants search for food by chance, then if they find some, on their way back to the ant-hill they mark the way with pheromone. Other ants – due to the pheromone sign – choose the marked way with higher probability instead of accidental wandering. Shorter ways may be completed quicker, thus on these ways more pheromone will be present than on longer ones. After a while the amount of pheromone drops (evaporation), by this preventing sticking to local optimum [42, 43].

In the electronic freight exchange similar problem emerges as the ants' search for food: the target is the performance of freight tasks offering the higher route level profit departing from the depot of the vehicle, with taking into account the limiting conditions. The problem, therefore, is twofold: on the one hand, the freight tasks to be performed shall be selected, and, on the other hand, their order shall be defined (FB_ACO, Fig. 8).

In the electronic warehouse exchange the task is simpler but is still similar to the food search: storage tasks shall be selected by taking into account storage capacity, possibly with the best possible exploitation of capacity (RB_ACO, Fig. 8).

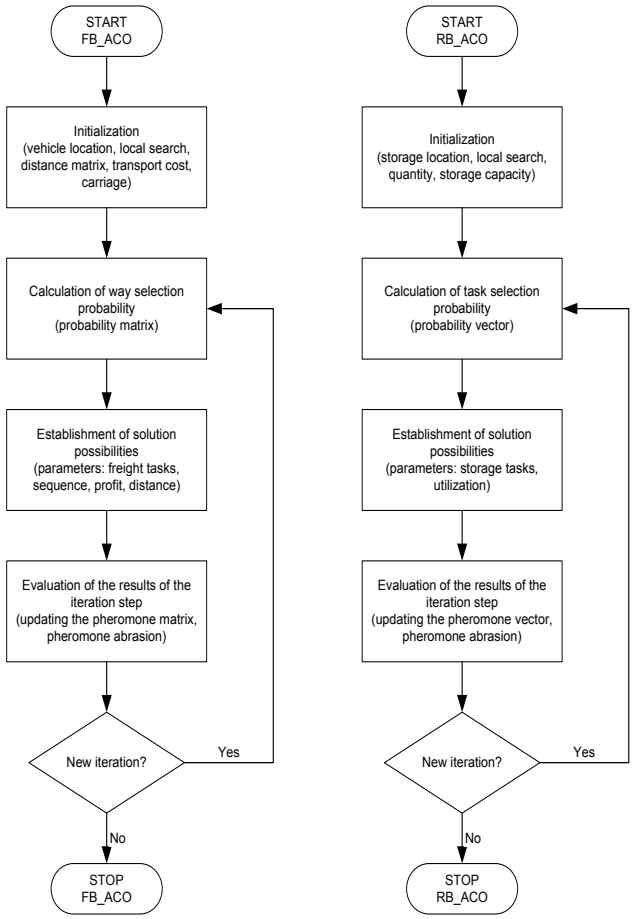

Fig. 8 The developed ant colony algorithms (FB_ACO and RB_ACO) [42]

G. SIMULATION IN EARTHWORK MODEL AND ITS LOGISTICS PROCESSES

Vehicle-based transport systems using automated guided vehicles (AGVs) are commonly used in facilities such as manufacturing plants, warehouses, distribution centers and transshipment terminals [44]. They are referred to as automated guided vehicle systems (AGVSs) [41], [45]. Early AGV systems were developed at universities and research institutes, named commonly as mobile robots. Later the industry realized advantages of autonomous transport vehicles for repeating transport tasks. One main application area for AGVs is the intralogistics or manufacturing

logistics, where the vehicles are mainly used for transporting raw materials, half-ready parts and ready products. These automated systems became moreover integral part of automated manufacturing systems as pointed out in [46]. The other important application is the automated container terminals, where AGVs transport various sized containers between the quay and the stacking area. More detailed system description find in e.g. [47]. Automation comes forward in other application areas as well [48]. Presents an automation example of a mobile excavator. The paper describes a pilot project investigates how autonomous functions could be realized on a mobile wheeled excavator. Rough terrain which characterizes construction sites however makes use of automated vehicles difficult [43]. Is aimed to help automation processes at the construction industry [43]. Concentrate on the logistics aspects, where organization of the material flow is an important task. The main of the focus of [48] to presents an automated soil transport system's simulation model which can be used to prove that intelligent systems may help construction processes as well. For the implementation agent-based approach is used.

[43] is organized as follows. First a short summary is given about the applicability of agent-based approaches. Next it describes which components or agents should be defined in different material flow systems using AGVs. In the following section detailed concept is presented for the implementation of the agent-based model for an earthmoving system (Fig. 9). Finally some remarks are made about the model's implementation in simulation environment.

The paper [43] surveyed applicability of agent-based principles for modeling material flow systems. An agent-based simulation model is also proposed. This model can be used for material flow systems' analysis not only for the case when each machine operates automatically, but due to the complex behavior for cases when the machines are operated through human workers. The proposed model is due to its modular construction can be adapted for different applications easily. Next step of the research is to build in so called information modules, which model information flow of the construction processes.

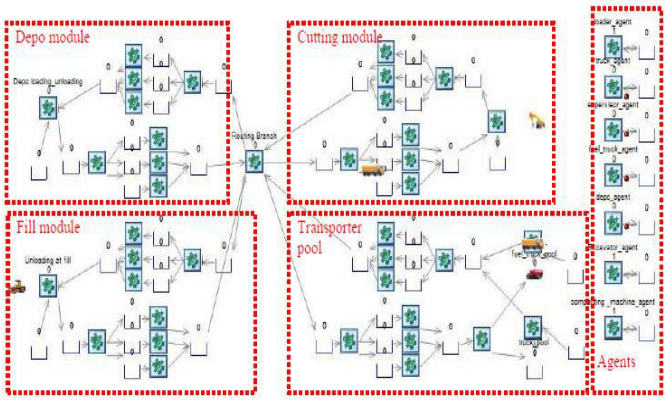

Fig. 9 Simul8 implementation of the proposed earthwork model

III. CONCLUSION

In this survey paper, there are several examples to optimizing the intra and extra logistics processes to. Automatic identification, neural networks, genetic algorithms, ant colony algorithms help find the optimal solution, and thereby to optimize the use of resources (e.g. human, material handling machines, transport machines, transport routes etc.), and to reduce the pollutants. Thus, sustainable supply chains can be realizing, that means economic and environmental efficiency too, whether it be city logistics supply chain, order picking processes or even earthwork.

We think that this topic deserves extensive additional research. Management studies and environmental science need to bridge the disciplinary distance that until now has characterized the two fields. There is a great need and urgency for further progress, and management theory must investigate the complexity of the relationship between organizations in supply chain and nature in order to support firms in the development of effective environmental strategies [49]. In this paper, we have stressed the importance of a holistic perspective in the service of sustainability. We argue that the individual firm is not the right unit of analysis for assessing environmental progress. Companies have many options to reduce their impact at the single organizational level (from clean technologies, to ecosystem restoration). But global ecological problems are not the result of a single firm's action. Ecosystem complexity over spatial and temporal scales requires close involvement and coordination across supply chains and industries as the appropriate unit of analysis for facing environmental problems [50,51].
