**Abstract**—The paper presents results of ZigBee communication tests performed in a specifically set electromagnetic environment, with the purpose to determine the applicability of ZigBee technology in non-critical messaging for vehicular communications. Known for its low energy consumption, the ZigBee technology might be used in background messaging for cooperative driving, with the purpose to reduce the overload on the main channels used for emergency message warning, or other critical applications. In the paper are presented the test bed, results and solutions for new approaches with usability to vehicular communications.

## I. INTRODUCTION

LATELY, the recent development of vehicular communications towards information exchange between moving vehicles and road infrastructure lead to a significant increase of interferences, especially in the 2.4 GHz band, where channels are shared with numerous access points and other devices outside road traffic domain. Except DSRC (Dedicated Short-Range Communications), which employs other frequencies, in several applications, such as traffic sensor wireless networks, vehicle counting/identification and vehicular communications, the use of Wi-Fi or ZigBee technologies has triggered a lot of solutions, partly tested, partly still under development. Therefore, the coexistence of many 2.4 GHz devices operating in close vicinity has become very challenging and numerous studies have been carried on in this direction.

The layers MAC (media access control) and PHY (physical) late specifications for low-rate wireless personal area networks (PAN), IEEE 802.15.4 using 2.4 GHz for the ISM (Industrial, Scientific and Medical) band has been developing in a high rhythm in the recent years. The ZigBee communications technology, based on IEEE 802.15.4, has also been deeply investigated. There can be seen an increasing demand of communications on short distance. Related to that two important industrial wireless network standards based on IEEE 802.15.4, Wireless HART, and

ISA100 have been approved. These wireless networks use the same 2.4 GHz ISM band; moreover, as a license-free radio band, 2.4 GHz ISM has also been widely employed by many non-IEEE 802.15.4 wireless networks, so coexistence among them must be also considered when developing new applications that share the same frequencies. The following section briefly presents the most recent advances in this area, based on a literature study.

## II. ZIGBEE – WI-FI COEXISTENCE – LITERATURE SURVEY

When several devices try to communicate in the same bandwidth, in different or overlapping channels, there are some important questions that a researcher should ask:

- which parameter is more adequate for investigating the electromagnetic compatibility?
- is the interference phenomenon experienced with the same intensity for both communicating devices?
- is the sense of communication (uplink / downlink) affected similarly in case of a disturbance?
- in which way position of devices, direct line of sight, reflections and refractions, antennas' position etc. do affect the coverage and quality of communication?
- is it possible to create adequate models applicable in case of studying communication quality for two or more devices?

The worst case is when communication is severely affected by interference and there is a lot of message packets loss, message delaying, and bandwidth consumption. As showed by the authors in [1], packet error rate is more than 90% when severe interference occurs. An answer to the last question put above is partly given by the authors of [2], who present the effect of different orientations of IEEE 802.11n transmission on IEEE 802.15.4 devices.

Regarding the elements that should be studied in a complete interference test, the authors of [3] gave a comprehensive solution for the input parameter, the output parameter and for the behavior sets.

As also observed by the authors of [4], the bandwidth of the IEEE 802.11b is 22 MHz, eleven times larger than the one of IEEE 802.15.4, which is 2 MHz. When Wi-Fi and ZigBee transmission coexist, usually every collision between a Wi-Fi packet and a ZigBee packet results in the ZigBee packet being lost.

□ This work has been funded by University Politehnica of Bucharest, through the "Excellence Research Grants" Program, UPB – GEX. Identifier: UPB-EXCELENȚĂ-2016 Research project title "VEHINET – Rețea cu conținut informațional adaptiv la condițiile mediului destinată deplasării inteligente a vehiculelor", Contract number 45/26.09.2016 (acronym: VEHINET).

Beneficiating of a bandwidth of only 2 MHz, ZigBee CCA captures the full power of other ZigBee transmissions in the same channel, but only 2/22th – (or -10.4 dB) – of the Wi-Fi transmitted power, resulting in a 9.6 dB higher sensitivity to Wi-Fi than to ZigBee.

Most of scientific papers' authors conclude after different experiments that ZigBee is oversensitive to Wi-Fi, while Wi-Fi is insensitive to ZigBee beyond a Heterogeneous Exclusive Clear Channel Assessment (CCA) Range, which is calculated by Zhen et al. in [5] to be 25 m with the free space path loss.

Tytgat et al. in [6] demonstrate that the deployment of a CACCA<sup>1</sup> protocol achieves substantial reduction of the ZigBee incurred packet loss, without needing any additional information exchange (and the incurred overhead), nor having a severe impact on the energy consumption. CACCA concept enables Wi-Fi to detect ZigBee presence and to reduce channel interference in different implementations.

The ZigBee technology is mainly used for low data-rate applications such as home automation, or smart-grid metering and demand response. The ZigBee Alliance defines an interference mitigation technique, named Frequency Agility mechanism [7], that can be divided into three phases: interference detection, channel evaluation and interference mitigation [8].

The authors conclude that the ZigBee Frequency Agility interference detection threshold is a crucial parameter that needs to be carefully set. In most cases, ZigBee Frequency Agility mechanism successfully switches the ZigBee network to a channel with the lowest interference level, but it can only successfully mitigate the interference that occupies a fraction of the ISM 2.4-GHz band and may be inadequate for the interference that emits signals throughout the entire band.

### III. ZIGBEE MESSAGE TRANSFER TESTS - PROCEDURE OVERVIEW

To determine the usability of low-energy ZigBee technology for vehicular communications (e.g., cooperative driving), a test setup has been deployed. The purpose of the tests is to assess the capabilities of the ZigBee link to maintain and transfer enough bandwidth to allow for a normal (non-emergency) messaging between moving vehicles and road infrastructure, in a typical Wi-Fi urban environment. The reason to employ such a setup is that on an external motorway - outside urban areas - the probability to encounter interfering Wi-Fi APs is much lower than in the cities.

Message transfer time measurements were initially performed inside the University building, in open space, with clear line of sight between the communicating modules. Interferences were created using a Wi-Fi router and a computer connected to it, both in the proximity of the

ZigBee modules, by transferring large files with speeds between 40Mbps and 70Mbps. A common environment with unknown interferences was chosen instead of an interference free one, to resemble with similar situations in a real urban vehicular environment.

If we consider the channel distribution, ZigBee channel 26 is furthest from any Wi-Fi channel overlapping, and less likely to be influenced by any Wi-Fi traffic, so it was used for message transfer time measurement.

The following scenarios were taken into consideration:

- The presence of a typical background environmental noise, produced by Wi-Fi APs with connected devices in a University;
- Heavy traffic on Wi-Fi channel 1;
- Heavy traffic on Wi-Fi channel 6;
- Heavy traffic on Wi-Fi channel 11;
- Heavy traffic on Wi-Fi channel 13;
- Heavy traffic on ZigBee channel 26.

The reason the authors decided to set up the router to use channels 1, 6 and 11 is that they are the only non-overlapping channels, and many Wi-Fi networks are using them by choice as mentioned in [9].

Wi-Fi channel 13 was chosen because is the closest one to ZigBee channel 26, and interferences because of it are most likely to appear.

For the last scenario considered, another pair of ZigBee modules was employed, set on the same communication channel as the ones used for measurements, and transmitting data with a high rate, similarly to the case where other vehicles might use the same channel.

Four XBee S2 modules were used. The criteria for selecting these modules were their affordable price and the high availability. Each module was connected to an Arduino Uno board with an XBee Shield.

Each of the two XBee pairs had one module set as a Coordinator and the other as an End-Device. One pair was employed for message transfer time measurements and the other one to generate interferences on channels 26.

The router and a computer, as well as the second pair of XBee modules were positioned in the middle, between main XBee modules, to be able to maintain constant speed when creating interference. The RF environment was considered to be similar to an average urban location, with Wi-Fi Access Points from different locations like offices, residential buildings, road infrastructure equipment or mobile devices. The distance between main XBee modules was modified between 0 and 50 meters, with a 5-meter step. A longer distance of 55 meters was also tested, but there was little to no connection between modules, even in presence of typical background environmental noise.

Results of the performed tests are presented in the following section.

<sup>1</sup> CACCA - Coexistence Aware Clear Channel Assessment

#### IV. ZIGBEE MESSAGES TRANSFER TIME MEASUREMENTS

After connecting, the Coordinator started to transmit data to the End-Device, which in return responded with the same amount of data.

The message transfer time was then measured between a clear send and a correct received response, for 100 consecutive tests. Three different cases have been approached, using messages with 256, 512 and 1024 bits per segment.

As it can be seen from Fig. 1, Fig. 2 and Fig. 3 traffic on channels 1, 6 and 11 had no influence over the message transfer time, compared with the values measured in presence of typical background environmental noise, for each of the three considered cases. This corresponds to the expectations because Wi-Fi channels 1, 6 and 11 do not overlap with ZigBee channel 26. Also, because bigger messages will require more time for them to be sent, no matter if there are interferences or not, the message transfer time increased as the size of the message increased, with average values being around 59, 149 and 188 milliseconds corresponding to a message length of 256, 512 and 1024 bits. Due to lack of interferences between these channels, the authors stopped testing these scenarios for distances greater than 25 meters, considering that values obtained in the presence of typical background environmental noise would be sufficient to describe them all.

Fig. 1. Average message transfer time (ms) for 256 bit message with traffic on specified Wi-Fi channels

Fig. 2. Average message transfer time (ms) for 512 bit message with traffic on specified Wi-Fi channels

Fig. 3. Average message transfer time (ms) for 1024 bit message with traffic on specified Wi-Fi channels

In Fig. 4, Fig. 5 and Fig. 6 it can be seen that traffic on channel 13 had the highest influence over the message transfer time for each of the three cases with an average raise of about 610, 370, and respectively 154 percent (compared with the value measured in presence of typical background environmental noise). Under the same conditions, traffic created by another ZigBee pair of devices on the same channel 26 had less influence, message transfer times having average raises of about 60, 12 and respectively 11 percent.

Fig. 4. Average message transfer time (ms) for 256 bit message with traffic on specified channels

Fig. 5. Average message transfer time (ms) for 512 bit message with traffic on specified channels

Fig. 6. Average message transfer time (ms) for 1024 bit message with traffic on specified channels

Increasing distance between devices will lead, obviously, to the situation in which communication would be impossible. As expected, it will happen first for greater message lengths.

For 1024 bit messages under typical noise conditions or with another ZigBee on channel 26 the maximum distance is 45 meters, and drops considerably to 20 meters if traffic on Wi-Fi channel 13 is present.

When using messages with 512 bits of data, maximum communication distance does not improve significantly: 50 meters with environmental noise, 45 meters with another ZigBee on channel 26, and 30 meters with traffic on Wi-Fi channel 13.

Smaller messages are transferred with more success in a perturbed environment, as for 256 bit messages the maximum distance is increased to 45 meters with traffic on Wi-Fi channel 13, and to 50 meters in the other two cases.

Regarding maximum values, for a data transfer affected by a typical environmental noise or traffic on Wi-Fi channels 1, 6 or 11, it resulted that they have reasonable values: around 65 milliseconds for 256 bit messages, 153 milliseconds for 512 bit messages and 196 milliseconds for 1024 bit messages.

For a data transfer affected by traffic on Wi-Fi channel 13, no matter the distance or length of message, maximum values for the transfer time proved to be too high to be suitable for critical applications in a vehicular environment (values between 1 and 7 seconds, mostly around 3 or 4 seconds).

In the last case, a data transfer affected by traffic on the same ZigBee channel, maximum values were lower than in the previous case, around 250 milliseconds for 256 bit messages, 320 milliseconds for 512 bit messages and 570 milliseconds for 1024 bit messages, but they may also be considered too high for some applications or vehicle speeds.

## V. CONCLUSION

ZigBee communication is heavily influenced by Wi-Fi in the proximity. As the test program measured the transfer time for a two-way non-erroneous communication, the XBee modules were unable to obtain any result as the distance

between them increased, when using data transfer on Wi-Fi channel 13, which use the closest frequency band to ZigBee channel 26.

To conclude, for distances up to 50 meters, exchange of messages between vehicle and infrastructure will be achieved in a fairly good amount of time, at reasonable travel speeds or for short time stationary vehicle, if we consider a low handshake time between ZigBee modules (which is typical for this technology) and low interferences from Wi-Fi traffic on channel 13 (situation that has a low probability of occurrence because channels 1, 6 or 11 are usually preferred) and ZigBee traffic on channel 26 (that can be avoided in non-crowded areas). As a result, implementation of ZigBee communications in a vehicular environment would be possible if one previously determines the criticalness of the desired applications and considers measuring and determination of the level of interference present in the areas where applications are to be implemented.

**Abstract**—Compressed sensing represents an interesting approach in signal processing and reconstruction. The theory involves a surprising number of branches of mathematics: linear algebra, functional analysis, convex and non-convex optimization, nonlinear approximation theory and probability. In general, the applications of compressed sensing can be found (or searched) wherever it is possible to express the signal in sparse representation in a “standard” base or in a base that was adjusted for particular signal. Core applications of compressed sensing today include image processing, signal denoising, image deblurring and inpainting. This paper addresses analysis the influence of external phenomena on the signal reconstruction using compressed sensing in wireless sensor networks. Such external phenomena include, for instance, additive white Gaussian noise (AWGN), attenuation or time shift. Three acoustic input signals sparse in frequency domain are used in experiments. The first one with significant frequency band from 500Hz up to 700Hz. The second signal with one significant frequency band from 2400Hz up to 3100Hz with considerable frequency bands between 0Hz to 1000Hz and 5000Hz to 6000Hz. The third signal used is a synthesized artificial sound invented for the experiment purposes only. It is strictly sparse in the frequency domain and has exactly three frequency bands between 400Hz and 500Hz, 2000Hz and 2100Hz, 9000Hz and 9100Hz. The results show that additive noise as well as attenuation have significant effect on the reconstruction accuracy using the selected distribution scenario and reconstruction method. On the other side, the time shift has no significant effect on the reconstruction.

## I. INTRODUCTION

A WSN is a distributed system. Having this in mind, WSNs can be used for distributing of compressed sensing task [1]. This can be achieved such that the sensor nodes perform the sampling part of the compressed sensing. The sinking node(s) perform(s) the reconstruction part (see Fig. 1).

According to the basic definition of *compressed sensing*, it is a modern method for signal representation and data compression. It is based on the assumption that some (sparse) signals can be reconstructed from such series of samples that are considered to be incomplete [2], i.e. *have insufficient information value for proper signal reconstruction through the sampling theorem*. Such reconstruction is made of small amount of samples - less than the *sampling theorem* determines.

The cornerstone of signal reconstruction using compressed sensing - the  $\ell_1$ -minimization [2], which looks for the optimal

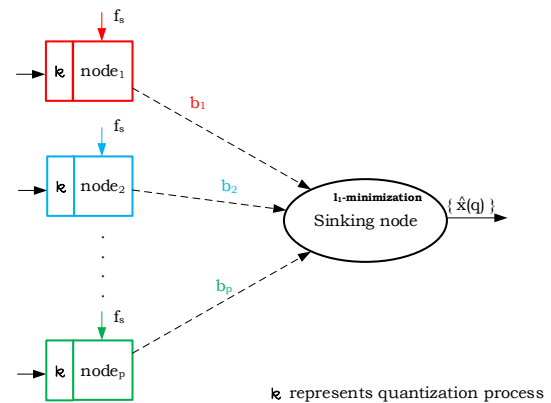

Fig. 1. Distributing compressed sensing task over the wireless sensor nodes (Compressed Sensing Method With Periodic Sampling Utilization)

representation of the signal in such base, where the signal is sparse. In compressed sensing, the measurement matrix  $A$  replaces the sampling process. This matrix determines the weight of each sample that enters the reconstruction process using  $\ell_1$ -minimization [3]. Sparse vector  $x$  represents samples of the sensed signal. The reduced vector  $b$  is a condensed version of  $x$ . The vector  $b$  is a product of multiplication of the measurement matrix  $A$  and the vector of samples -  $x$  [3].

The wireless sensor networks are deployed in the real environment. In this environment, a sensed signal is being constantly influenced by different effects. In other words, the success of the signal reconstruction depends on the influence of external factors as well [4]. In case of WSNs, these factors include mainly noise, signal attenuation, wireless nodes' asynchronous operation as well as signal time-shift due to the spacial distribution of sensor nodes. Therefore, it is important to reveal the impact of these phenomena on the *measure of accuracy of the original signal reconstruction*. The term *measure of accuracy of the original signal reconstruction* is in this paper understood as a sum of squares from the difference of the original signal  $x(i)$  and the reconstructed signal  $\hat{x}(i)$ . It is known as *mean squared error*, and in this paper it is marked as  $\mu$ :

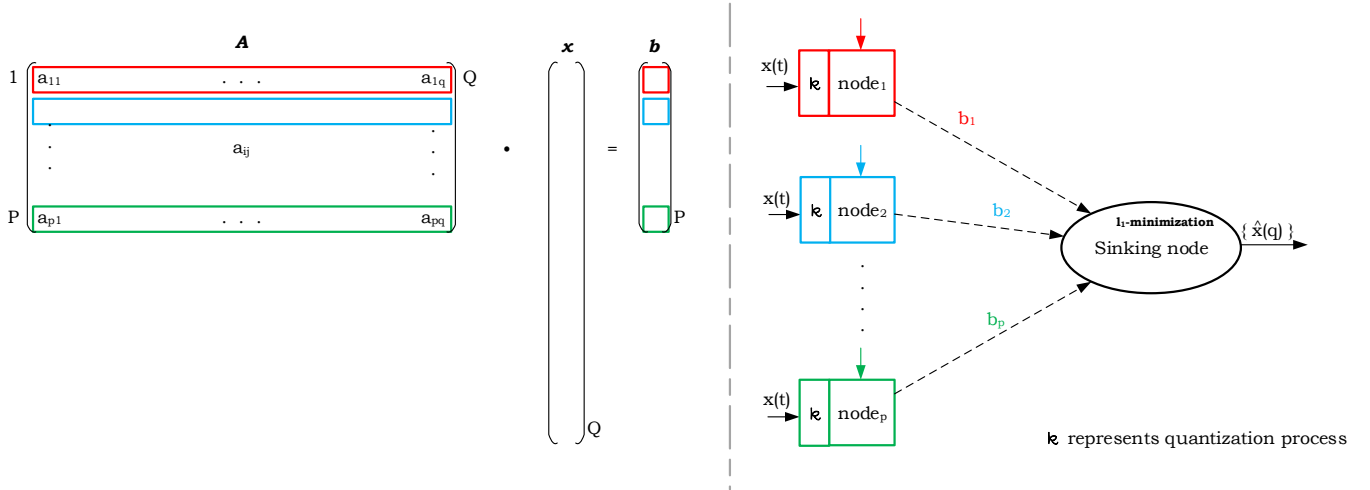

Fig. 2. Illustration of general idea of the Compressed Sensing Method With Periodic Sampling

$$\frac{1}{N} \cdot \sum_{i=1}^N (x(i) - \hat{x}(i))^2 = \mu. \quad (1)$$

The the method for WSNs (described in the further text) is based on the fundamental concept of *compressed sensing*. This includes measurement matrix  $A$ , vector of measured samples  $x$  and a reduced vector of samples  $b$ . The actual reconstruction of the original signal is based on  $\ell_1$ -minimization. This minimization is being performed on the sink node(s).

## II. COMPRESSED SENSING METHOD (WITH PERIODIC SAMPLING)

General idea of the compressed sensing is illustrated on the figure 2. Let's assume that the signal is sampled at equidistant time instants, i.e. periodically. The result of sampling of the input signal  $x(t)$  is a sequence of samples  $\{x(q)\}$  with length  $Q$ . This sequence of samples is multiplied by the measurement matrix  $A$  which has the size  $P \times Q$  where  $P \ll Q$ .

The product of this multiplication is a reduced vector of the samples  $b$  with length  $P$ . Such vector enters the reconstruction process using  $\ell_1$ -minimization. The resulting sequence  $\{\hat{x}(q)\}$  represents the reconstructed signal.

The elements of the measurement matrix  $a_{ij}$  can be randomly generated [5] as:

- Elements with Gauss coefficients (independently generated from a normal distribution with zero mean and variance  $\sigma_\nu$ , i.e.  $\mathcal{N}(0, \sigma_\nu)$ );
- Bernoulli coefficients (elements that have values  $\pm \frac{1}{\sqrt{\sigma_\nu}}$ );
- Binary values  $\{0, 1\}$  with matrix sparsity<sup>1</sup>  $S$ .

It should be noted that the choice of the measurement matrix  $A$  is itself a very difficult problem. Literature suggests that the deterministic measurement matrix for specific applications is almost impossible to construct, therefore randomly generated matrices are used in practical scenarios [5], [6], [7]. The

<sup>1</sup>Matrix sparsity indicates the ratio of non-zero matrix elements over the zero ones.

optimal choice of the statistical properties of the measurement matrices is investigated by many researches with multiple approaches [6], [7], [8], [9], [10]. In case of the Gaussian matrix, the literature states that for matrix with dimensions  $P \times Q$ , the elements should be generated from a normal (Gaussian) distribution with zero mean and variance equal to either:

- $\sigma_\nu = \frac{1}{Q}$ , i.e.  $\mathcal{N}(0, \frac{1}{Q})$  or,
- $\sigma_\nu = \frac{1}{P}$ , i.e.  $\mathcal{N}(0, \frac{1}{P})$  but also,
- $\sigma_\nu = 1$ , i.e.  $\mathcal{N}(0, 1)$ .

Now, let's suppose that each sensor node senses the same signal. General idea of the investigated method stands on the fact that each sensor node carries out multiplication of one line of the same measurement matrix with the measured samples [11]. The result is that a single node produces only a single coefficient that represents one element of the reduced vector  $b$  (see Fig. 2). This coefficient is then being sent to the sink node where the reconstruction takes place. At first, the sink node composes the reduced vector and then, this vector enters the process of reconstruction by  $\ell_1$ -minimization.

## III. CONDITIONS

In order to investigate the behavior of the mentioned method, several experiments investigating performance under external phenomena have been carried out.

The following three input signals have been used, which all of them are sparse in frequency domain:

- Simplified version of the sound of *Northern Raven*;
- Simplified version of the sound of *Bohemian Waxwing*;
- An artificial signal designed especially as sparse in the frequency domain. This signal is marked as *Artificial sparse signal*.

The first signal is one with a single significant frequency band starting at around 500Hz and ending at around 700Hz. This signal is simplified and short version of the sound of

the Northern Raven<sup>2</sup> - (*Corvus corax*). The Discrete Fourier Transform (DFT) is shown on Fig. 3.

Fig. 3. Simplified sound of the *Northern Raven* - a sparse signal in frequency domain shown in the frequency domain (a single significant frequency band, 500Hz - 700Hz)

The second signal that is used in the simulations as an input signal  $x(t)$  is a simplified and shortened version of the sound of Bohemian Waxwing<sup>3</sup> - (*Bombycilla garrulus*). The used signal has one significant frequency band starting at around 2400Hz and ending at around 3100Hz. However, there are also frequency bands that should be considered such as the ones in 0Hz - 1000Hz and 5000Hz - 6000Hz. The DFT of the signal is shown on Fig. 4.

Fig. 4. Simplified sound of the *Bohemian Waxwing* - a sparse signal in frequency domain shown in the frequency domain (significant frequency band 2400Hz - 3100Hz)

The third signal used as an input for the simulations is a synthesized artificial sound invented just for the experiment purposes only. It is strictly sparse in the frequency domain. It has three frequency bands: 400Hz - 500Hz, 2000Hz - 2100Hz and 9000Hz - 9100Hz. This signal was invented for the reference and comparison of the performance of the compressed sensing with real-world sparse signals. The DFT of the signal is shown on Fig. 5.

All three presented signals are shown in the 10kHz bandwidth. This means that a sampling scheme that can be used without significant signal reconstruction error is to sample

Fig. 5. Artificial sparse signal - a sparse signal in frequency domain shown in the frequency domain (significant frequency bands 400Hz - 500Hz, 2000Hz - 2100Hz and 9000Hz - 9100Hz)

with sampling frequency equal to 20kHz (this comes out from the *sampling theorem*). This produces 20 000 samples per second (sps). The worst case scenario is to transmit all the samples to the sinking node so that the reconstruction can be performed there. However, the highest frequency component of the Northern Raven signal is 2150Hz. In the case of Bohemian Waxwing, the highest frequency component of this particular signal is 7950Hz. The highest frequency component of the artificial sparse signal is 9100Hz. Knowing the basic information about the sampled signals, it can be concluded that the first signal - *simplified version of "Northern Raven" signal* - can be sampled as low as 4.3kHz which results in producing 4 300 samples per second (sps) only. Similarly, the second signal - *simplified version of "Bohemian Waxwing" signal* - can be sampled by sampling frequency 15.9kHz, which produces 15 900 samples per second (sps). The third signal, *an artificial sparse signal in frequency domain* that has been introduced for the simulation purposes only, has to be sampled by at least 18.2kHz sampling frequency.

Experiment of compressed sensing that utilizes periodic sampling is based on a network consisting of  $P$  sensor nodes. These nodes perform sampling at periodic intervals, i.e. with sampling frequency  $f_s$ . This sampling frequency is the same on all nodes. The sampling process generates a discrete sequence  $\{x(q)\}$  that has  $Q$  elements. This sequence  $\{x(q)\}$  is multiplied by the measurement matrix. In this experiment, the measurement matrix is based on random Gaussian values. The measurement matrix  $A_{P \times Q}$  is of size  $P \times Q$  and its elements have values from the normal (Gaussian) distribution  $\mathcal{N}(0, \frac{1}{P})$ .

Let's consider the situation where the input signal is the same for all sensor nodes. Compressed sensing task can be parallelized such as each node performs sensing such as each sensor executes operation corresponding to a single row of the measurement matrix  $A_{P \times Q}$ . There are  $P$  nodes in the sensor network. Each node ( $i$  - th node) performs a series of  $Q$  measurements:

$$\sum_{j=1}^Q a_{ij} \cdot x_j = b_i ; i \in \langle 1; P \rangle. \quad (2)$$

<sup>2</sup>The original sound of the Northern Raven is from Xeno-Canto sound database. <http://www.xeno-canto.org/124411>

<sup>3</sup>The original sound of the Bohemian Waxwing is from Xeno-Canto sound database. <http://www.xeno-canto.org/121467>

The above relation reduces the sequence of measurements into a single coefficient. The relation produces  $i$ -th coefficient of the reduced vector  $\mathbf{b}$ , i.e.  $b_i$ . These coefficients  $\{b_1, \dots, b_i, \dots, b_p\}$  from all nodes in the WSN are being sent to the sink node and in the sink node, reconstruction of the vector  $\mathbf{b}$  takes place. Afterwards, the reconstruction of the original sensed signal is performed. This reconstruction is based on the  $\ell_1$ -minimization [12]. The reconstruction based on the  $\ell_1$ -minimization produces a discrete sequence representing the original sensed signal  $\{\hat{x}(n)\}_{n=1,2,\dots,Q}$ .

In this particular case, the measurement matrix  $\mathbf{A}$  has  $1\,000 \times 20\,000 = 20mil.$  elements, i.e.  $P = 1\,000$  and  $Q = 20\,000$ . Thus, this simulates a thousand nodes performing compressed sensing in the network. The elements of the measurement matrix are randomly generated Gaussian values from the normal distribution with zero mean value and variance  $\frac{1}{1\,000}$ , i.e.  $\mathcal{N}(0, \frac{1}{1\,000})$ . Dimension  $Q$  of the matrix is chosen with respect to the *sampling theorem*.

For the experiment purposes, the measurement matrix is generated as a single entity, i.e. not partially at each node. Each sensor node performs the operations that correspond to the matrix row for the particular node. Using this row, each node performs calculation of the coefficient  $b_i$  and transmits this coefficient to the sink node.

#### IV. ACHIEVED RESULTS

For the experiment purposes and for investigation of the behavior on the influence of the external phenomena, the following phenomena are being investigated:

- Additive White Gaussian Noise;
- attenuation;
- time shift of the input signal;

In the simulation on the influence of the AWGN, the *white noise* with zero mean value and normal distribution designated as  $WN_0$  is considered. At the input of the individual sensors, there is input signal  $x_i(t)$  with mutually uncorrelated noise  $e_i(t)$  as follows:

$$x_i(t) = x(t) + e_i(t). \quad (3)$$

The conducted experiment investigates the influence of the noise on the *measure of accuracy of the original signal reconstruction*  $\mu$ . In particular, it shows the dependency of  $\mu$  on the statistical distribution of the AWGN, see Fig. 6. The statistical distribution of the additive white noise has a zero mean value and variance of normal (uniform) distribution  $\sigma_i = \frac{T_s}{i}$ ;  $i \in \langle 2, 3, 4, \dots, 10 \rangle$ . Parameter  $T_s$  represents the period of the sampling frequency  $f_s$ . Since the sampling frequency  $f_s = 20kHz$ , the sampling period  $T_s = 50\mu s$ .

The numerical results show that as the variance of the normal distribution of the AWGN grows, the measure of the accuracy of the reconstruction increases as well. Significant change of the mean squared error of the signal reconstruction is located between  $\sigma_i$  values  $\frac{T_s}{8}$  and  $\frac{T_s}{7}$ . The overall performance of this method in signal reconstruction degrades from 6.94% error rate at  $\sigma_i = \frac{T_s}{8}$  to 14.56% error rate at  $\sigma_i = \frac{T_s}{7}$ .

Fig. 6. Dependency of the measure of accuracy of the original signal reconstruction  $\mu$  on the statistical distribution of the AWGN represented by white noise variance  $\sigma_i$

TABLE I  
NUMERICAL RESULTS OF  $\mu$  [%] DEPENDING ON THE STATISTICAL DISTRIBUTION OF THE AWGN REPRESENTED BY WHITE NOISE VARIANCE  $\sigma_i$

Input signal \ $\sigma_i$	$\frac{T_s}{10}$	$\frac{T_s}{9}$	$\frac{T_s}{8}$	$\frac{T_s}{7}$	$\frac{T_s}{6}$	$\frac{T_s}{5}$	$\frac{T_s}{4}$	$\frac{T_s}{3}$	$\frac{T_s}{2}$
Artificial sparse signal	3.44	4.03	5.13	11.60	13.80	14.37	18.15	18.99	21.87
Northern Raven	5.83	6.24	6.96	15.59	16.45	18.15	22.04	23.79	26.20
Bohemian Waxwing	6.15	6.70	8.73	16.48	17.80	20.74	23.98	25.83	27.23

For AWGN variance up to around  $\frac{T_s}{8}$  the mean squared error of the reconstruction keeps under 10%, for *Artificial sparse signal* the average reconstruction error equals 4.20%. However, this is the synthetic signal. On the other hand, real-life signals perform a little worse, e.g. simplified sound of the *Northern Raven* has average value of mean squared error of the reconstruction 6.34% for in the AWGN variance up to around  $\frac{T_s}{8}$ . Simulation of reconstruction of the simplified sound of the *Bohemian Waxwing* has the average equal to 7.19% in the same variance limit.

The next conducted experiment investigates the dependency of  $\mu$  on the Signal-to-Noise Ratio (SNR), see Fig. 7. The noise level begins at 30dB and degrades to 10dB. AWGN with zero mean value and variance  $\sigma = \frac{T_s}{8}$  has been used in this simulations. Parameter  $T_s$  denotes period of the sampling frequency  $f_s$ , which equals  $20kHz$ .

TABLE II  
NUMERICAL RESULTS OF THE MEASURE OF ACCURACY OF THE ORIGINAL SIGNAL RECONSTRUCTION  $\mu$  [%] DEPENDING ON THE SNR

Input signal \ SNR [dB]	10	12	14	16	18	20	22	24	26	28	30
Artificial sparse signal	34.64	30.10	25.14	18.16	14.43	10.46	7.26	6.69	6.11	4.64	3.96
Northern Raven	36.53	32.24	29.37	22.21	16.76	13.46	8.69	7.48	7.59	5.77	4.55
Bohemian Waxwing	37.76	35.51	32.96	23.88	17.86	14.59	9.08	8.50	7.82	6.42	5.43

The results reveal that the measure of the accuracy of

Fig. 7. Dependency of the measure of accuracy of the original signal reconstruction  $\mu$  on the SNR

the reconstruction ( $\mu$ ) via mentioned reconstruction method performs good when SNR keeps above 22dB. Then, the mean squared error of the reconstruction stays below 10%. For example, the average error for *Artificial sparse signal* is 5.73% when SNR stays above 22dB. Simplified sound of the *Northern Raven* has average value of mean squared error in the same range 6.82%. Similarly, simplified sound of the *Bohemian Waxwing* has the average error 7.45% for SNR more than 22dB. The overall performance on reconstruction error of the proposed method on all investigated input signals is 6.67% for SNR more than 22dB.

This experiment as well as the previous one proves that the described reconstruction method does not suit well for reconstruction of acoustic signals in noisy environment. Advanced processing techniques for noise suppression has to be utilized. Having low noise acoustic input signals, this method provides good reconstruction performance with error up to 10%. Having environment with SNR higher than 22dB enables this method to perform with good results. Then, the mean squared error of the original signal reconstruction stays below 10%.

Another phenomenon that influences the sensed signal is called *attenuation*. In other words, the attenuation modifies the amplitude(s) of the input signal - it scales the original signal on the inputs of the nodes. This phenomenon can be expressed mathematically as the following relation:

$$x_i(t) = k_i \cdot x(t). \quad (4)$$

In this experimental scenario each of the sensors in the network senses an input signal which is scaled by the scaling coefficients  $k_i$ . These coefficient are randomly generated from normal (Gaussian) statistical distribution with mean value equal to 0.5 and with variance equal to 1, i.e.  $\mathcal{N}(0.5, 1)$ . Based on their values, several groups with different root mean square

(RMS) values have been formed. The output of this simulation is the dependency of the *measure of accuracy of the original signal reconstruction*  $\mu$  on the effective value (RMS) of the scaling coefficients  $k_{rms}$ , as shown on Fig. 8.

Fig. 8. Dependency of the measure of accuracy of the original signal reconstruction  $\mu$  on effective value of the scaling coefficients  $k_{rms}$  (performed with Compressed Sensing Method Using Periodic Sampling)

TABLE III  
NUMERICAL RESULTS OF THE MEASURE OF ACCURACY OF THE ORIGINAL SIGNAL RECONSTRUCTION  $\mu$  REGARDING THE EFFECTIVE VALUE OF THE SCALING COEFFICIENTS  $k_{rms}$

Input signal \ $k_{rms}$	0.2	0.4	0.6	0.8	1
<b>Artificial sparse signal</b>	24.12	9.68	6.75	5.83	4.68
<b>Northern Raven</b>	25.49	12.44	7.96	6.46	5.68
<b>Bohemian Waxwing</b>	29.47	13.81	8.71	7.61	6.02

The results show significant increase of the reconstruction error  $\mu$  for the effective value of the scaling coefficients higher than 0.6. Significant change of the mean squared error of the signal reconstruction is located between  $k_{rms}$  values 0.6 and 0.4. The overall performance of this method in signal reconstruction degrades from 7.81% error rate at  $k_{rms} = 0.6$  to 11.98% error rate at  $k_{rms} = 0.4$ .

Having *Artificial sparse signal*, the average reconstruction error is 5.75% for effective value of the scaling coefficients from 0.6 to 1.0. The average reconstruction error within the same interval equals 6.70% for simplified sound of the *Northern Raven*. Simplified sound of the *Bohemian Waxwing* has the average error of the reconstruction in the range 0.6 – 1.0 equal to 7.45%.

It can be concluded that the mentioned reconstruction method performs well with attenuated signals that are attenuated not less than 60% of the amplitude in average.

Major impact on the success rate of the reconstruction in the sinking node has also signal shift at individual sensor nodes. This can be expressed as:

$$x_i(t) = x(t - \tau_i). \quad (5)$$

The shift  $\tau_i$  expresses different distances of the nodes from a common source of the sensed signal. The coefficients of the time shift are for the experimental purposes generated from normal statistical distribution with a mean value equal to 0 and variance  $\sigma_i = i \cdot T_s$ ;  $i \in \langle 1, 2, 3, \dots, 10 \rangle$ . Parameter  $T_s$  represents the period of the sampling frequency  $f_s$ , which equals  $20\text{kHz}$ . Thus, the sampling period  $T_s = 50\mu\text{s}$ . The output of this experiment is the dependency of  $\mu$  on the time shift expressed by  $\sigma_i$ , see Fig. 9.

Fig. 9. Dependency of the measure of accuracy of the original signal reconstruction  $\mu$  on the time shift variance  $\sigma_i$

The results show that the accuracy of the original signal reconstruction ( $\mu$ ) performs very well for time shift up to 8 fold of the sampling period  $T_s$ .

The average error for *Artificial sparse signal* in all performed simulations is 6.29%. Simplified sound of the *Northern Raven* has average value of mean squared error for all simulations of the time shift equal to 7.53%. Simplified sound of the *Bohemian Waxwing* has the average error 8.47%. The overall performance on reconstruction error of the proposed method on all investigated input signals is 5.60% for time shift variance  $\sigma_i < 8 \cdot T_s$ .

Since the time shift of the input signal can vary in time, the results show mild resistance of the proposed method on the time shift of the input signal.

## V. DISCUSSION ON ACHIEVED RESULTS

This method, *Compressed Sensing Method Using Periodic Sampling*, requires sampling on the periodic basis on all nodes in the WSN. Therefore, sampling performed on each of the nodes was done under sampling frequency  $f_s = 20\text{kHz}$ . This produces 20 000 samples per second. However, the reduction part of the proposed method (equation 2), reduces these 20

TABLE IV  
NUMERICAL RESULTS OF THE MEASURE OF ACCURACY OF THE ORIGINAL SIGNAL RECONSTRUCTION  $\mu$  [%] DEPENDING ON THE TIME SHIFT VARIANCE  $\sigma_i$

Input signal \ $\sigma_i$	$10 \cdot T_s$	$8 \cdot T_s$	$6 \cdot T_s$	$4 \cdot T_s$	$2 \cdot T_s$	$0 \cdot T_s$
Artificial sparse signal	10.06	8.65	5.71	5.49	4.16	3.66
Northern Raven	12.67	10.39	6.56	6.28	5.26	4.03
Bohemian Waxwing	13.79	11.02	8.17	6.40	5.99	5.45

000 samples into a single one on each of the nodes. Having 1 000 nodes in all experiments, the overall compression ratio is 1:20.

The investigated method requires only 1 000 samples to be transmitted to the sink node in order to properly reconstruct the original signal with certain accuracy (in average  $\mu < 10\%$ ). Therefore, from the point of reduction of the samples, necessary to be sent over the network for reconstruction in the sink node, the proposed method is 20 times better than the case where all the samples obtained using the *sampling theorem*. This can be applied for all investigated input signals.

The aforementioned applies for the sampling frequency  $f_s = 20\text{kHz}$ . However, based on the nature of the figure investigated signals and their maximal frequency component, the input signals can be sampled by lower frequency using *sampling theorem*:

- simplified sound of the *Northern Raven*  $f_{s\_raven} = 4.3\text{kHz}$ ;
- simplified sound of the *Bohemian Waxwing*  $f_{s\_waxwing} = 15.9\text{kHz}$ ;
- *Artificial sparse signal*  $f_{s\_artificial} = 18.2\text{kHz}$ .

Following the consideration that for the simplified sound of the *Northern Raven* only  $f_{s\_raven}$  is enough, then this proposed method is just 4 times better from the point of reduction of the samples necessary to be sent to the sink node. Similarly, considering  $f_{s\_waxwing}$  and simplified sound of the *Bohemian Waxwing* as an input signal, this method gives almost 16 times better performance. Having *Artificial sparse signal* as an input signal and considering  $f_{s\_artificial}$ , this method is 18 times better regarding the reduction of the samples required to be sent to the sink node.

From the point of the sampling process, this method brings no saving of the sampled values over the *sampling theorem*. This comes out of form the method design since it uses sampling pattern based on the periodic sampling following the *sampling theorem*. This method saves only data that are being sent from the nodes to the sinking node.

## VI. CONCLUSION

The results show that the mentioned method for reconstruction of the acoustic signals does not suit well for the reconstruction of signals in noisy environment. For all three simulation scenarios and all three input signals, the dependency of the measure of the accuracy of the reconstruction  $\mu$  has increasing and nonlinear character. This is obvious where mean squared error of the reconstruction is less than 10%

only for SNR higher than 22dB. The variance of AWGN should be lower than 12.5% of the sampling period  $T_s$ . The experiments investigating effect of the AWGN and SNR show that the selected reconstruction method is sensitive to the noise. Therefore, it is more suitable for reconstructing signals in the environment with low noise levels.

The attenuation has significant effect only in case of higher attenuation level across the network. In other words, the described method can successfully reconstruct the original signal when the amplitude at most of the sensors is attenuated less than the 50% of the original signal's amplitude.

The simulations proved that time shift of the input signal does not significantly influence the reconstruction via compressed sensing methods. The mean squared error is mostly less than 10% for time shift up to ten fold of the sampling period. The time shift of the input signal can vary in time, thus, the results show mild resistance of the proposed methods on the time shift of the sensed signal.

Motivation of this work is related to the investigation of reconstruction methods for target localization WSN and distributed compressed sensing with perspective energy efficiency. The results of this paper show that Compressed Sensing Method using Periodic Sampling as described earlier can save the number of samples being sent to the sink node and thus reducing energy consumed by transmission. However, saving on signal processing does not come to effect since compressed sensing with periodic sampling requires periodic processing of the sensed values. Nevertheless, there are more compressed sensing methods for investigation, therefore, the future work includes utilization and performance comparison of Compressed Sensing Method Using Random Sampling

Generated By Measurement Matrix or Modified Compressed Sensing Method Using Random Sampling [13], [8].

**Abstract**—The paper is concerned with the application of mobile ad hoc networks to phenomena clouds boundary detection and tracking. Self-organizing, coherent networks comprised of sensors and radio transceivers that maintain a continuous communication with each other and a central operator are considered. The attention is focused on the methodology for determining the temporarily optimal network topology for detecting the boundary of a cloud that can change its shape in time. We introduce several measures for assessment a quality of a network topology and propose a computing scheme for detection topology that is the optimal one at a given time. The utility and efficiency of the proposed methodology was justified through simulation experiments.

## I. INTRODUCTION

**P**HENOMENA clouds are objects covering significant area and characterized by nondeterministic, dynamic variations of shape, size, speed, and direction of motion along multiple axes [1]. The examples of phenomena cloud can be not only environmental disasters as oil spill, toxic heavy gas cloud, flood or forest fire, but also moving group of people. In general, in case of one of the aforementioned disasters the extensive monitoring of the area of interest is necessary to manage the evacuation of people from a hazardous zone, track the propagation of a given cloud and finally, neutralize the threat.

Nowadays, mobile ad hoc networks (MANETs) are becoming increasingly popular solutions for environmental monitoring. MANET is comprised of mobile devices, which are usually equipped with GPS receivers, various detectors and radio transceivers that enable wireless communication within the network. The devices can autonomously and dynamically self-organize by changing their positions and roles into temporal networks. In general, in emergency situation MANET should not rely on external communication system as it can be damaged or congested due to the disaster. Hence, the network needs to maintain connectivity among the working set of devices and a base station. Numerous approaches to the connectivity maintenance have been proposed in the literature [2]–[6].

MANETs are widely used to cover a region of interest (*ROI*) [7], [8]. Phenomena cloud is a special type of *ROI* due to its dynamic character. Results of research on adaptation of a sensing network topology to variant phenomena cloud boundary was comprehensively described in [9], [10].

In this paper we focus on measuring quality of a network topology taking into account multiple spatial criteria. Spatial topology analysis was widely used in MANET. In [11] dense and sparse regions are identified to limit rebroadcasting packets in flooding routing protocol. Routing protocols depending on nodes' location are described in [12]. Moreover, topology analysis can support a clustering of network. Topology Adaptive Spatial Clustering that divides the network into a locally isotropic, non-overlapping clusters by creating a set of weights that encode distance, connectivity and density information within the neighborhood of each node is described in [13]. In [14] prediction of the existence of a link given the present distance between a pair of nodes and their relative speed is proposed. The prediction is based on two topology metrics: an expected link lifetime and an expected link change rate.

In this paper we define several measures (spatial parameters) that can be used to assess the quality of a current network topology. Moreover, we propose a methodology that can be used to detect the acceptable topology — the best possible configuration of a network for monitoring a given cloud at a given time step. The technique for phenomena cloud boundary detection described in [6] is extended with the analysis of a topology dynamics. The presented approach allows to increase the efficiency of detection of clouds with unknown and irregular shapes.

The article is organized as follows. First, computing scheme for detection of boundary of area covered by a phenomena cloud with mobile sensors is described. Then we introduce several measures for assessing quality of a given sensing topology and statistical tools for analyzing the variability of these measures. Next, we introduce computing scheme for detecting the temporarily optimal sensing topology. Finally, the results of applications of our method to detect the heavy

gas cloud are presented and discussed. Two more and less advanced gas dispersion models were taken into account: the box model [15] and the advance model provided in SLAB [16].

## II. PROBLEM FORMULATION

Let us consider the network  $\mathcal{G} = (\mathcal{V}, \mathcal{E})$  comprised of a set  $\mathcal{V}$  of  $N$  mobile nodes (unmanned vehicles or mobile robots)  $D_i$ ,  $i = 1, \dots, N$  operating in the workspace.  $\mathbf{o}_i = [x^i, y^i]$  denotes the reference point of  $D_i$  (e.g. an antenna location). It is assumed, that each node  $D_i$  is equipped with a punctual detector for sensing a given phenomena, radio transceiver (with radio range  $r_t$ ) and a positioning system, e.g. GPS receiver. Let us define our sensing network

$$\mathcal{V} = \{D_i, i = 1, \dots, N\}, \quad (1)$$

$$\mathcal{E} = \{(D_i, D_j), d_{ij}^i \leq r_t, i, j = 1, \dots, N, i \neq j\}, \quad (2)$$

where  $(D_i, D_j)$  is a bidirectional link between a pair of nodes  $D_i$  and  $D_j$  and  $d_{ij}^i$  is the Euclidean distance between the reference points  $\mathbf{o}_i$  and  $\mathbf{o}_j$  of nodes  $D_i$  and  $D_j$ . We assume that each node can freely change both its position and role according to its knowledge about an environment and a network. It can move with the speed  $v \in [v_{min}, v_{max}]$  in desirable direction.

Let us divide the network  $\mathcal{G}$  into  $K$  separated clusters  $\mathcal{V}_k$ ,  $k = 1, \dots, K$  of devices:

$$\mathcal{V}_1 \cup \mathcal{V}_2 \cup \dots \cup \mathcal{V}_K = \mathcal{V}, \quad (3)$$

$$\mathcal{V}_1 \cap \mathcal{V}_2 \cap \dots \cap \mathcal{V}_K = \emptyset. \quad (4)$$

We assign  $D_{H_k} \in \mathcal{V}_k$  a role of the  $k$ th cluster head,  $k = 1, \dots, K$ , and select one of cluster heads  $D_H$  to be a head of the whole network,  $D_H \in D_{H_1}, \dots, D_{H_K}$ .

It is assumed that the network can self-organize to accomplish a given task. The task considered in this paper is to sense boundaries of a given phenomena cloud to estimate a size and a shape of this cloud. The scheme for robot-assisted sensors deployment was developed and described in [6]. In this work we focus on the last phase of the deployment, i.e. *boundary detection*. We assume that at least one device detected a cloud and the cloud center  $\Psi$  was estimated by  $D_H$  based on known locations of those network nodes  $\mathcal{V}'$ , which sensors detected the phenomena (i.e. nodes located inside the cloud):

$$\Psi = \frac{\sum_{D_i \in \mathcal{V}'} \mathbf{o}_i}{|\mathcal{V}'|}. \quad (5)$$

To determine the boundary of a given cloud with high accuracy we need measurements from sensors that should be evenly deployed on the boundary (Fig. 1). Hence, our goal is to create a sensing network with evenly distributed nodes. Moreover, the permanent communication within the network has to be maintained to exchange information about topology and current measurements between nodes and report measurements to a base station.

Fig. 1: Even deployment of network clusters on the cloud boundary;

The nodes mobility model incorporates the concept of an artificial potential. The artificial potential function is constructed as a sum of repulsive and attractive potentials [17]. Every assumed time step each  $D_i \in \mathcal{V}_m$  solves the following optimization problem to calculate its new position:

$$\begin{aligned} \min_{\mathbf{c}^i} & \left[ U^i = U_c^i + \sum_{D_j \in S_i, D_j \in \mathcal{V}_m} U_j^i + \sum_{k \in IC_m} U_k^i \right. \\ & = \alpha_c \left( \frac{\bar{d}_c^i}{d_c^i} - 1 \right)^2 + \sum_{D_j \in S_i, D_j \in \mathcal{V}_m} \beta_j \left( \frac{\bar{d}_j^i}{d_j^i} - 1 \right)^2 \\ & \quad \left. + \sum_{k \in IC_m} \gamma_k \left( \frac{\bar{d}_k^i}{d_k^i} - 1 \right)^2 \right]. \end{aligned} \quad (6)$$

In the above formulation artificial potential function  $U^i$  consists of the potential  $U_c^i$  between  $D_i$  and the cloud centroid  $\Psi$ , a sum of potentials  $U_j^i$  between  $D_i$  and its neighboring nodes  $D_j$ ,  $D_j \in S_i = \{D_j : (D_i, D_j) \in \mathcal{E}, D_j \in \mathcal{V}_m\}$  and a sum of potentials  $U_k^i$  between  $D_i$  and neighboring clusters  $IC_m$ .  $\alpha_c \geq 0$ ,  $\beta_j \geq 0$ ,  $\gamma_k \geq 0$  denote weighting factors,  $d_c^i$  is an Euclidean distance between  $\mathbf{o}_i$  and estimated centroid  $\Psi$  of the cloud,  $\bar{d}_c^i = \max_{D_i \in \mathcal{V}'} d_c^i + w_1$ , where  $w_1 > 0$  denotes a distance margin (arbitrary selected),  $\bar{d}_j^i \leq r_t$  is a reference distance between two neighboring nodes  $D_i$  and  $D_j$ . In the last part of eq. (6)  $IC_m$  is a set of indexes of two closest neighboring clusters of the  $m$ th cluster that contains  $D_i$ , defined as follows:

$$IC_m = \left\{ \arg \min_{\mathcal{V}_j \neq \mathcal{V}_m} \angle(\mathcal{V}_m, \mathcal{V}_j) \right\} \cup \left\{ \arg \max_{\mathcal{V}_j \neq \mathcal{V}_m} \angle(\mathcal{V}_m, \mathcal{V}_j) \right\} \quad (7)$$

$$\begin{aligned} \angle(\mathcal{V}_m, \mathcal{V}_j) = & \begin{cases} \arccos \frac{\overrightarrow{\Psi \mathbf{c}_m} \cdot \overrightarrow{\Psi \mathbf{c}_j}}{|\overrightarrow{\Psi \mathbf{c}_m}| \cdot |\overrightarrow{\Psi \mathbf{c}_j}|} & [\overrightarrow{\Psi \mathbf{c}_m} \times \overrightarrow{\Psi \mathbf{c}_j}]_z \geq 0 \\ 2\pi - \arccos \frac{\overrightarrow{\Psi \mathbf{c}_m} \cdot \overrightarrow{\Psi \mathbf{c}_j}}{|\overrightarrow{\Psi \mathbf{c}_m}| \cdot |\overrightarrow{\Psi \mathbf{c}_j}|} & [\overrightarrow{\Psi \mathbf{c}_m} \times \overrightarrow{\Psi \mathbf{c}_j}]_z < 0 \end{cases} \end{aligned} \quad (8)$$

$$\mathbf{c}_m = \frac{\sum_{D_i \in \mathcal{V}_m} \mathbf{o}_i}{|\mathcal{V}_m|}, \quad (9)$$

where  $[\vec{q}]_z$  is z-component of vector  $\vec{q}$ .  $d_k^i$  is a distance between  $\mathbf{o}_i$  and the centroid of the  $k$ th cluster  $c_k$  and  $\bar{d}_k^i$  is an average distance between two neighboring clusters of the  $m$ th cluster (clusters with indexes from the set  $IC_m$ ) increased by a small margin  $w_2$  slightly greater than 0:

$$\bar{d}_k^i = \frac{\sum_{k \in IC_m} d_k^i}{2} + w_2, \quad w_2 > 0. \quad (10)$$

Detailed description of the mentioned above network deployment scheme can be found in [6]. The result of the *boundary detection* phase is even distribution of nodes on the boundary of an area covered by a given phenomena cloud (Fig. 1). Due to the dynamic changes of the phenomena clouds the next phase is *boundary tracking* — nodes move and follow the boundary, keeping internode and intercluster distances. The aim of the research described in this paper was to develop a methodology for detecting the temporarily optimal topology for *boundary tracking* and switch to the *boundary tracking* phase. The definitions of measures that we used to evaluate the quality of a given topology are provided in the next section.

### III. NETWORK TOPOLOGY QUALITY MEASURES

Let us consider a network defined in (1)-(4). To create a topology that allows to determine a cloud boundary at a given time and maintain the permanent connectivity we have to perform the following operation (see eq. 6):

- move all devices towards the cloud boundary (increase distance between clusters and the center of cloud);
- expand an area monitored by clusters (increase distances between nodes within cluster);
- deploy clusters on the cloud boundary (as evenly as possible).

Various measures can be used to evaluate the quality of a given MANET at a given time. Taking into account the above operations the following ones can be defined:

- distance between a centroid of the  $m$ th cluster to the estimated centroid of a cloud

$$d_c^m = \|c_m - \Psi\|_2. \quad (11)$$

The distance is increased as long as the  $m$ th cluster nodes do not reach the cloud boundary. The bigger distance is the better topology is.

- $m$ th cluster diameter

$$\phi_m = \max_{D_i, D_j \in \mathcal{V}_m} d_{ij}^i. \quad (12)$$

The bigger  $\phi_m$  is the bigger area is monitored by the  $m$ th cluster.

- standard deviation of angles between neighboring clusters

$$\sigma_{\angle} = \sqrt{\frac{\sum_{m=1}^K (\angle_m - \mu_{\angle})^2}{K-1}}, \quad \mu_{\angle} = \frac{\sum_{m=1}^K \angle_m}{K}, \quad (13)$$

where  $\angle_m = \angle(\mathcal{V}_m, \mathcal{V}_j)$  (Fig. 2) is an angle between the cluster  $\mathcal{V}_m$  and its the closest neighboring cluster  $\mathcal{V}_j$ :

$$j = \arg \min_{k \neq m} \angle(\mathcal{V}_m, \mathcal{V}_k). \quad (14)$$

For evenly distributed clusters  $\sigma_{\angle} \approx 0$ .

Fig. 2: The angle  $\angle(\mathcal{V}_m, \mathcal{V}_j)$  between a cluster  $\mathcal{V}_m$  and a cluster  $\mathcal{V}_j$  and the angle  $\angle(\mathcal{V}_j, \mathcal{V}_m)$  between a cluster  $\mathcal{V}_j$  and a cluster  $\mathcal{V}_m$ .

### IV. MEASURES VARIABILITY ANALYSIS

Changes of measures defined in (11)-(13) involve changes in the topology of a given sensing network. However, to monitor and analyze network topology dynamics we need values of the defined measures from a time interval. Let us assume that  $\mu(t_i)$  is a value of the measure  $\mu$  calculated at  $t_i$  ( $\mu \in \{\sigma_{\angle}, \phi_m, d_c^m | m = 1, \dots, K\}$ ) and  $X^\mu(t) = \langle \mu(t-M+1), \dots, \mu(t_i), \dots, \mu(t) \rangle$  is a vector of values of the measure  $\mu$  calculated at last  $M$  time steps. The goal of our analysis is to detect does a given measure

- increase (*growth*);
- decrease (*drop*);
- change slightly (*stabilization*);
- change very dynamically and chaotically (*instability*).

In brackets names of the *variability types* were introduced. It should be emphasized that detection of variability type has to be done a priori (in real time), with no information about future measurement values. Moreover, the window size  $M$  that is arbitrarily determined can influence the results of an analysis.

To analyze variability of the values of the vector  $X^\mu(t)$  following simple statistical measures were proposed:

- peak-to-peak amplitude  $A$ :

$$A = \max X^\mu(t) - \min X^\mu(t); \quad (15)$$

- Pearson's correlation  $\rho_{X,t}$ :

$$\rho_{X,t} = \frac{\sum_{i=1}^M (\mu(t-M+i) - \bar{\mu})(i - \frac{M+1}{2})}{\sqrt{\sum_{i=1}^M (\mu(t-M+i) - \bar{\mu})^2} \sqrt{\sum_{i=1}^M (i - \frac{M+1}{2})^2}}, \quad (16)$$

$$\bar{\mu} = \frac{\sum_{i=1}^M \mu(t-M+i)}{M}; \quad (17)$$

- trend direction coefficient  $tr_a$  (trend line given as  $f(x) = tr_a x + b$ ):

$$tr_a = \frac{M \sum_{i=1}^M \mu(t-M+i) i - \sum_{i=1}^M i \sum_{i=1}^M \mu(t-M+i)}{M \sum_{i=1}^M i^2 - (\sum_{i=1}^M i)^2}. \quad (18)$$

Based on these measures we can determine whether in time  $t$  the vector  $X^\mu(t)$  induces one of the previously defined variability types:

- *growth and drop:*

- Pearson's correlation; if  $\rho_{X,t} \in (\rho_H, 1]$  a measure  $X^\mu(t)$  is continually increasing with time; if  $\rho_{X,t} \in [-1, \rho_L)$  the value is continually decreasing, where:

$$\rho_H \geq 0.5; \rho_L \leq -0.5; \quad (19)$$

- trend direction coefficient; if  $tr_a \geq tr_H$  the measure is increasing significantly, else if  $tr_a \leq tr_L$  the measure  $X^\mu(t)$  is decreasing significantly, where:

$$tr_H > 0; tr_L < 0. \quad (20)$$

- *stabilization:*

- peak-to-peak amplitude; if  $A < A_L$  value of measure  $X^\mu(t)$  does not change significantly;

- Pearson's correlation; if  $\rho_{X,t} \in (-\rho_M, \rho_M)$  the measure  $X^\mu(t)$  is neither continually decreasing nor continually increasing, where:

$$\rho_M \in (0, 0.7]. \quad (21)$$

- *instability:*

- peak-to-peak amplitude; if  $A > A_H$  value of property does change significantly ( $A_H \gg A_L$ );
- Pearson's correlation — as in *stabilization*.

The simulation study was performed to determine the values of threshold values  $\rho_H, \rho_L, \rho_M, tr_L, tr_H, A_L, A_H$ . Within the study an experiment described in [6] (for  $K = 4$ ) was performed for various values of  $v_{max}$ ,  $v_{max} \in \{1 \frac{m}{s}, 5 \frac{m}{s}, 20 \frac{m}{s}\}$ . The estimated values of threshold values are presented in Table I. It was observed that values of some thresholds ( $tr_H, tr_L, A_L, A_H$ ) depend on the maximal velocity of nodes  $v_{max}$  as the higher velocity involves the bigger changes of measures every time step.

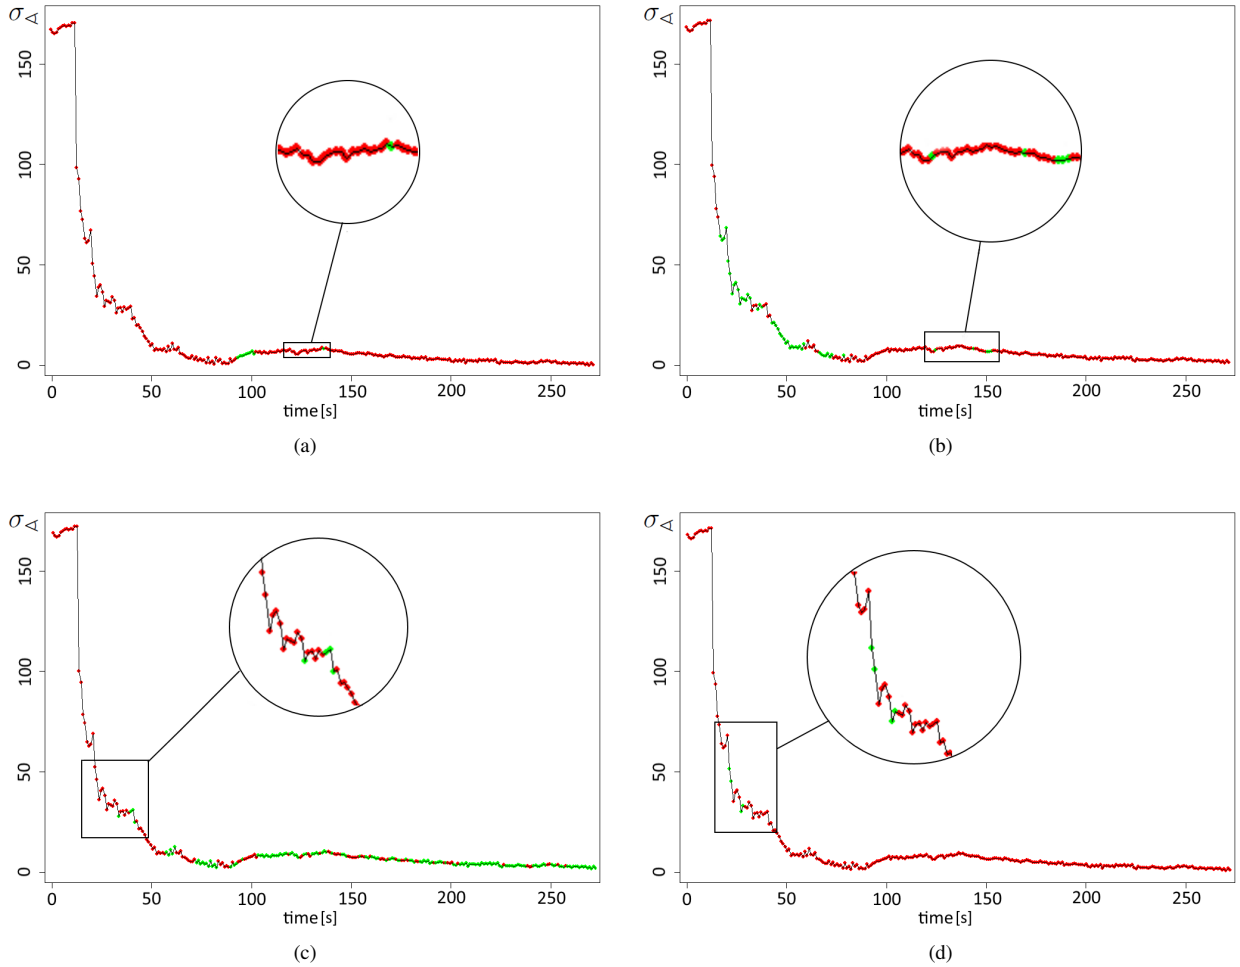

Fig. 3: Detection (green color) of (a) growth, (b) drop, (c) stabilization and (d) instability variability type of  $\sigma_A$  property during the network deployment. The less visible parts of graphs in which detection occurred were enlarged.

TABLE I: Values of threshold parameters

$\sigma_{\triangleleft}$ measure							
stabilization		drop		growth		instability	
$M$	5	$M$	8	$M$	8	$M$	5
$\rho_M$	0.7	$\rho_L$	-0.6	$\rho_H$	0.6	$\rho_M$	0.6
$A_L$	$1 + 0.1v_{max}$	$tr_L$	$-0.05 - 0.01v_{max}$	$tr_H$	$0.05 + 0.01v_{max}$	$A_H$	$3 + 0.3v_{max}$
$d_c^m$ measure							
stabilization		drop		growth		instability	
$M$	5	$M$	6	$M$	8	$M$	6
$\rho_M$	0.7	$\rho_L$	-0.7	$\rho_H$	0.7	$\rho_M$	0.5
$A_L$	$0.5v_{max}$	$tr_L$	-0.1	$tr_H$	$0.1 + 0.1v_{max}$	$A_H$	$1 + 0.8v_{max}$
$\phi_m$ measure							
stabilization		drop		growth		instability	
$M$	4	$M$	4	$M$	4	$M$	4
$\rho_M$	0.5	$\rho_L$	-0.7	$\rho_H$	0.7	$\rho_M$	0.5
$A_L$	$1.6v_{max}$	$tr_L$	$-0.4 - 0.1v_{max}$	$tr_H$	$0.4 + 0.1v_{max}$	$A_H$	$3.2v_{max}$

The results of application of the proposed variability type detection scheme for the measure  $\sigma_{\triangleleft}$  and the threshold values calculated for  $v_{max} = 20 \frac{m}{s}$  (see Table I) are depicted in Figures 3a-3d. Each figure corresponds to one variability type: *growth*, *drop*, *stabilization* or *instability*. The time steps in which a given variability type was detected are marked with a green color. It can be observed that in most cases the variability types were detected correctly. However, in some cases (see Fig. 3b,  $t = 125$ ) a variability type was detected too late. It was caused by too long observation time window.

#### V. TEMPORARILY OPTIMAL TOPOLOGY DETECTION

Summing up, the aforementioned considerations. The aim is to create the network topology that seems to be optimal to measure the boundary of a cloud at a given time. Exactly, due to the dynamic nature of the monitored cloud our goal reduces to the detection of the time step  $t$  at which we claim that the network configuration is stable or the local optimum for  $t^*$ ,  $t^* \in [t - M + 1, t - 1]$  was reached and we assume that all changes in the nearest future involve its deterioration. Such network topology in time  $t$  is called *temporarily optimal*.

Fig. 4: Time steps in which the variability type of measure  $\sigma_{\triangleleft}$  is *stabilization* or *growth*.

The decision whether the topology is temporarily optimal is made based on the observed variability types of all defined measures:

a) the topology is stable for:

- $\sigma_{\triangleleft}$  — type *stabilization*;
- $d_c^m$ ,  $m \in \{1, \dots, K\}$  — type *stabilization*;
- $\phi_m$ ,  $m \in \{1, \dots, K\}$  — type *stabilization*;

b) the topology will be worse in the nearest future for:

- $\sigma_{\triangleleft}$  — type *stabilization* or *growth*;
- $d_c^m$ ,  $m \in \{1, \dots, K\}$  — type *stabilization* or *drop*;
- $\phi_m$ ,  $m \in \{1, \dots, K\}$  — type *stabilization* or *drop*;

but not case a).

The head of  $m$ th cluster  $D_{H_m}$  detects the variability type of the measures  $d_c^m$  and  $\phi_m$ , whereas the head of the whole network  $D_H$  detects the variability type of the measure  $\sigma_{\triangleleft}$ . The calculations are performed repetitively with the repetition time equal to  $\Delta t$ . If none of the variability types is detected for measure  $\mu$  in time  $t$  based on  $X^\mu(t)$  the variability type of this measure in time  $t$  is the same as in time  $t - \Delta t$  (we assume that in the beginning the variability type of each measure is *instability*). Each of cluster heads  $D_{H_m}$  sends information about variability types of  $d_c^m$  and  $\phi_m$  to the network head. Exemplary detection of time steps in which variability type of measure  $\sigma_{\triangleleft}$  for the aforementioned example (Fig. 3) is *stabilization* or *growth* is depicted in Fig. 4.

Due to the large number of requirements regarding the number of measures ( $2 * K + 1$ ) that have to be taken into account during the decision problem and dynamics of a phenomena fulfilling all of the requirements is too rigorous. Therefore, we propose two distributed strategies.

- Strategy 1: The topology is temporarily optimal if:
  - variability type of  $\sigma_{\triangleleft}$  is *stabilization* or *growth*;
  - exists at least  $r_1$  clusters for which variability type of both  $d_c^m$  and  $\phi_m$  is *stabilization* or *drop*.
- Strategy 2: The topology is temporarily optimal if:
  - variability type of  $\sigma_{\triangleleft}$  is *stabilization* or *growth*;
  - exists at least  $r_2$  clusters for which variability type of  $d_c^m$  is *stabilization* or *drop*;

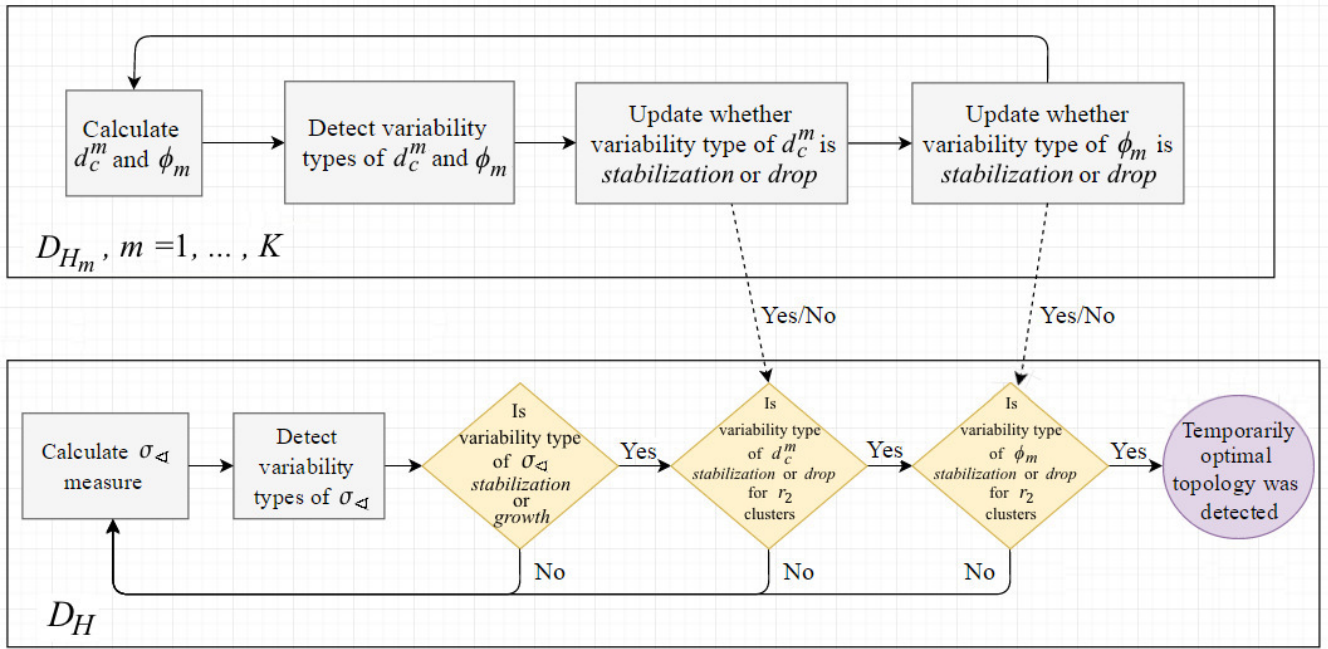

Fig. 5: Temporarily optimal topology detection — Strategy 2. With the dotted arrows communication between the cluster head  $D_{H_m}$  and the network head  $D_H$  is shown.

- exists at least  $r_2$  clusters for which variability type of  $\phi_m$  is *stabilization* or *drop*.

The scheme of making decision according to Strategy 2. is presented in Fig. 5. For  $r_1 = r_2$  the Strategy 1 is more rigorous. The results of experiments for various values of  $r_1$  and  $r_2$  are presented and discussed in the next section.

## VI. EXPERIMENTAL VERIFICATION

The performance of our methodology for cloud boundary detection was verified through simulation experiment. The task was to create a sensing MANET for monitoring uncontrolled instantaneous release of vapor LNG. Due to a low temperature of the release the created cloud was heavier-than-air. Thus, it moved close to the ground. The parameters of the released material and ambient environment are presented in Table II. The dispersion of cloud was simulated using the SLAB simulator [16]. The sensing network was built by 16 devices divided into 4 clusters. The maximal velocity  $v_{max}$  of each node was equal to  $10 \frac{m}{s}$ .

The method for detection of acceptable topology was tested for both proposed strategies and for different values of  $r_1, r_2 \in \{2, 3, 4\}$ . For both strategies for  $r_1 = r_2 = 3$  the optimal topology was detected at the same time  $t = 102$ . However, for  $r_1 = r_2 = 2$  the results obtained for both strategies were different:  $t = 100$  for Strategy 1 and  $t = 52$  for Strategy 2. In the extreme case  $r_1 = r_2 = K = 4$  (all requirements have to be fulfilled) the consensus was not reached until  $t = 220$ .

Fig. 6 shows the process of forming the network topology for cloud boundary monitoring. The results of experiment indicate that at  $t = 52$  (Fig. 6a) the topology meets basic

TABLE II: The parameters of the released material and ambient environment in the verification scenario

Name	Value	Units
Molecular weight	0.01604	$kg$
Vapor heat capacity at constant pressure	2238	$\frac{J}{kg \cdot K}$
Boiling point temperature	111.7	$K$
Heat of vaporization	509900	$\frac{J}{kg}$
Liquid heat capacity	3348.5	$\frac{J}{kg}$
Liquid density of source material	424.1	$\frac{kg}{m^3}$
Temperature of source material	111.7	$K$
Source area	900	$m^2$
Instantaneous source mass	6000	$kg$
Surface roughness height	0.01	$m$
Ambient measurement height	2.88	$m$
Ambient wind speed	1.92	$\frac{m}{s}$
Ambient temperature	306	$K$
Relative humidity	4.6	%

requirements — at least one node of each cluster is on the boundary, distance between clusters (except green and gray) are significant and nodes within clusters are rather dispersed. However, at time  $t = 100$  clusters are much more evenly dispersed on the boundary (Fig. 6b). Finally, at  $t = 220$  (Fig. 6d) the topology is slightly better (better dispersion of nodes within clusters). Furthermore there is no improvement comparing to topology created at  $t = 180$  (Fig. 6c).

According to the results of the experiment it can be induced that  $r_2 = \frac{K}{2}$  for Strategy 2 is too weak requirement and fulfilling all requirements ( $r_1 = r_2 = K$ ) may delay the detection of temporarily optimal topology unnecessarily. Thus,

Fig. 6: Topology of the sensing network:(a)  $t = 52$ , (b)  $t = 100$ , (c)  $t = 180$  and (d)  $t = 220$ . Nodes of the same cluster are marked with the same color, the cluster head is marked with darker hue.

the reasonable values for the strategies parameters  $r_1$  and  $r_2$  are:  $\frac{K}{2} \leq r_1 < K$  and  $\frac{K}{2} < r_2 < K$ . However, the future work should involve evaluation of the method performance based on simulation experiments for more complex scenarios with various number of clusters  $K$ .

## VII. CONCLUSION

MANETs can significantly enhance the capability to investigate contaminated areas, in particular detect and track phenomena clouds. In this paper we described the methodology for evaluating a quality of a network topology due to the possibility of determining a boundary of a cloud. The results of simulation experiments confirm that our approach can sufficiently support the process of detecting the temporarily optimal sensing devices configuration for cloud boundary monitoring at a given time. Unfortunately, our experimental results demonstrate that due to the dynamic nature of monitored phenomena clouds the quality of selected topology depends on the size of the observation time window and requirement of meeting all conditions for defined measurements. The trade-off between a quality of sensing network, time of calculation and fulfilling all requirements and expectations has to be assumed.

## ACKNOWLEDGMENT

This article is based upon work from COST Action IC1406 High-Performance Modelling and Simulation for Big Data Applications (cHiPSet).

**Abstract**—Despite the modern gas equipment, combustible gas leakage related emergency situations still take place and lead to building demolitions and human losses. Leak integrity failures because of anthropogenic and natural factors make impossible to prevent such emergency in other ways except providing continuous monitoring of combustible gas concentration and notification for people and special services. In this work, the design results of the Internet connected wireless sensor network for combustible gas concentration monitoring in apartment buildings is presented. The system consists of wireless autonomous gas sensors, actuators, routers and a gateway and it's connected to a web service where it posts its data and gets events to react them in WSN.

## I. INTRODUCTION

**E**VEN though modern gas equipment have flame failure control systems, combustible gas leakage related emergency situations still take place quite often. In the worst case these situations can lead to building demolitions and human losses. The main reason for those emergency situations is leak integrity failures which happen because of human factor, pipes and pipe joints quality and corrosion, etc [1]. To prevent such situations it's necessary to provide continuous monitoring of combustible gas concentration and timely notification for people and special services.

Wireless sensor networks becomes more and more popular and a lot of them were designed recently [2] - [5]. These networks consist of small nodes and are equipped with transceivers, microprocessors and sensors and can be used in different areas of life (safety, military, home automation, etc.).

Wireless sensor networks have certain advantages to perform the monitoring. Wireless autonomous devices don't need wiring and can be easily distributed inside apartment building and the network can freely be extended when needed. Established wireless network can provide additional services in home automation and others.

Wireless sensor networks are widely used in gas concentrations monitoring [6] - [9]. The main problem for wireless autonomous sensor devices is high energy consumption of combustible gas sensors [10]. This problem can be solved using special measuring algorithms [11].

According to safety standards [12] notification system of a gas detection device should include audio signal with

specified sound level and visual signals to indicate power on and alarm states. This mandatory notification system can be extended by sending alarm notification to an operator console and cell phones over cellular networks using both short message service and Internet connection.

In the case of Internet connection, data is posted to a web service and any device connected to the Internet can get access to it. The conception of devices, connected together and with their users, is known as Internet of Things [13]. This way makes possible to extend WSN automation and notification functions, for example, providing additional notifications from utility companies about maintenance period, or remote control functions to any device connected to WSN.

Therefore, the most promising approach to monitor methane leakages in apartment buildings is using electronic systems with wireless data transmission. There are several most popular technologies for wireless communication: ZigBee, Bluetooth, GSM/GPRS and Wi-Fi [14], [15]. The most important problems of the majority of such systems are the

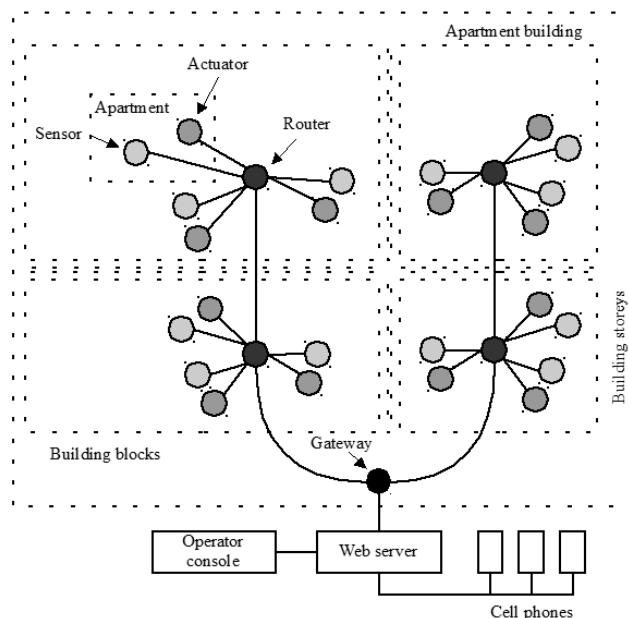

Fig 1. System diagram

Fig 2. Heating voltage

limited access to data and short autonomous lifetime of the gas sensors.

In this work, the design results of the Internet connected wireless sensor network for combustible gas concentration monitoring in apartment buildings is presented. The system consists of wireless autonomous gas sensors, actuators, routers and a gateway and it's connected to a web service where it posts its data and gets events to react them in WSN. The system is used to equip a trial apartment building in Moscow region.

The paper is organized as follows. At first we overview the system in Section II. In Section III we describe the nodes design. Section IV is dedicated to the network organization. Internet connectivity is discussed in Section V. Finally, we provide concluding remarks in Section VI.

## II. SYSTEM OVERVIEW

The system consists of the following devices: gas sensors, actuators, routers and a gateway. The system block diagram is presented in Fig. 1. Wireless communication between devices complies IEEE 802.15.4/ZigBee standards and uses unlicensed 2.4 GHz ISM band. Internet connection is performed on the gateway using cellular networks.

There is only one gateway for a building. It creates the network and acts like a network coordinator. Except that, it's also a sink device and all sensors send data to it.

Since distances in the building are relatively long, routers are used to transfer data from sensors to the gateway. They are deployed on building storeys, one per a storey in every building block.

The sensors and actuators are deployed in every apartment of the building. Sensors are placed in the kitchen. Actuators are equipped with gas valves and located at the gas pipe entrance point. Except valves, actuators can be connected to a power grid to control power of electrical devices.

The data sent to the gateway is transferred to a web service on the Internet and stored in a database. The service uses REST API to send and retrieve data for machines and a web interface for human clients.

Users of the system are presented by apartment residents and special service operators. All users have their own accounts with their own restrictions. For example, apartment residents have access only to devices in their apartments, the special services have access to all gas sensors and a valve actuator at the gas pipe entrance point of the building.

## III. NODES DESIGN

### A. Sensor

To perform combustible gases concentration measurements the node uses ATxmega16E5 microcontroller and the commercial catalytic gas sensor. The sensor is manufactured by NTC IGD (Russia) and its power consumption is 110mW in continuous measurement mode. Since, the catalytic gas sensor is very power hungry, to decrease its power consumption the measurements are performed in periodical mode and the special measuring algorithm is used.

The wireless communication is performed using Telegesis ETRX3 module. It provides the IEEE 802.15.4/ZigBee standards compatible protocol and has UART control interface with AT-style commands set.

The node is battery powered. It uses AA size lithium battery with 3.6V nominal voltage and 2600 mAh capacity. To provide maximum efficiency in voltage conversion it is performed by a TPS63060 DC-DC converter. The device generates output voltage of 3.2V from 2.5V to 12V on its input with load regulation of 0.5% with power save mode disabled.

To maintain the low power consumption the measurements are performed periodically and special multistage pulse algorithm with PWM heating is used. This method was offered and discussed in [11].

The heating profile for the pulse is shown in Fig. 2. In the first and second stages of the profile the sensor is heated up to about 200C where catalytic reaction is kinetic-controlled and there is no additional heating of sensing element from target gas combustion. During the third and fourth stages the sensor heating is continued and its temperature rises up to

Fig 3. Multistage pulse measurements current consumption

the catalysis external diffusion region (about 450°C). The heating voltage values for the stages are 3.2V, 0.7V, 3.2V and 1.4V respectively. First and third of them are forcing the heating process, second and fourth ensure the target temperature stabilization.

The measuring circuit is controlled by the microcontroller and includes two MOSFET keys to connect the sensor to the heating voltage and to the reference resistor. To heat the sensor up the microcontroller forms PWM signal with 10kHz frequency and appropriate duty cycle corresponding to specific heating voltage. Measurements are performed between the heating pulses. The reference resistor - sensor divider is connected to the microcontroller ADC, where the steady component is subtracted from the signal and the result is amplified with built-in amplifier and converted. The measurement result is the difference between sensor voltages at two different temperatures (measurement points in the heating profile diagram).

The sensor sensitivity in this case is 1.8 mV/vol%. The node operates as a two-threshold device. Threshold values are 0.5 and 1 vol%. When the sensor crosses the threshold, the node enables alarm signals and sends the data to the gateway.

To maintain the low power consumption the sensor node performs measurements periodically once in 5 minutes. Between measurements the microcontroller disables power of all components and goes to the power save mode.

The current consumption of the measuring pulse is presenting in Fig. 3. The duty cycles during the second and fourth stages are 22 and 44 percents. Therefore, the average current consumption value for the pulse is 37mA during 1.2 seconds.

To maintain online status the node sends the data every working cycle. The average current consumption in this state is 38mA during 0.35 seconds.

The average current consumption for the full cycle is 0.19mA. With the battery capacity of 2.6 Ah the node autonomous lifetime is equal to 570 days.

### B. Actuator

The main function of an actuator is to control a gas valve at a gas pipe entrance point. It also can be connected to a power grid to control power of electrical devices.

The device is line powered. The power supply generates voltages to supply a digital control circuit, electromagnetic switches and external outputs.

The digital control circuit consists of a STM32F102C6 microcontroller to process commands and a Telegesis ETRX3 module for the WSN communication. The supply voltage of the circuit is 3.3 V. To control electromagnetic switches with 12 V switching voltage the MOSFET keys are used.

The actuator provides four outputs to control external circuits. Two of them are connected to power sources with 12V/1A and regulated voltage. These outputs are originally intended to control gas valves of different types, but can be

also used to drive another electronic devices. Another two outputs can be connected to a power grid and commutate it.

### C. Gateway and routers

Even though the transmission area of the communication module is up to 350 meters without obstacles, walls and floor decks significantly reduce the distance. Coexistence with other networks, like Wi-Fi, can decrease it even more. Routers provide a steady way to transfer data between nodes.

Both routers and gateways are line powered and consist of a power supply, a STM32F102C6 microcontroller and a Telegesis ETRX3 module. The gateways have additional Telit GL865-QUAD GSM/GPRS communication module to connect to the Internet.

## IV. NETWORK ORGANIZATION

The network uses a tree topology. The main device of the network is a gateway. The gateway always creates the network and announce itself as a sink device. Other devices request the gateway address during connection process.

The gateway and routers are full functional devices. That means they are always ready to receive data, can be a parent node for other nodes and can perform routing. All other devices of the network are end devices and can't have child nodes.

All sensors send data to the gateway. The data is sent only when sensor states are changed. But every work cycle all devices should announce that they are alive and connected to the network. If a node haven't sent an alive message in predefined timeout, it's considered to be offline and the system generates alarm notification.

## V. INTERNET CONNECTIVITY

The gateway sends data to a web service on the Internet where it's stored in a database. To send the data HTTP protocol is used. To be safe the transmission is performed over TLS protocol. The protocols realization is provided by GSM/GPRS communication module.

The web service uses REST API to send and retrieve data for machines and a web interface for human clients. It is based on Apache HTTP Server and uses CMS Drupal and MySQL database server.

CMS Drupal 8 is a flexible content management software for websites and web applications. It's modular and can easily be extended. Drupal has built-in RESTful API with both JSON and XML support to integrate it with external services.

All devices are represented in the service by separate content type - Device Object. This content type have the following fields to represent its parameters: Groups, Network class, Device address, Subdevice address, Status and Value. Groups field contains information about groups associated with a device. Network class is used to create separate address space for networks with different standards and virtual devices. Device address field represents the network device

address (e.g., IEEE 802.15.4 MAC address). Subdevice address is used to distinguish different parts of a device with the same network address. Status field represents the network status of the device. And Value field contains an integer value.

Devices are connected to each other with event system. Events are also represented by a special content type - Event Object. Event Object contains the following fields: Source device, Target device, Status, Operation, Parameter, Value and Notification. Source device contains the information about a device which created the event. Target device points to a device which should process the event. Status field contains the event status. It's equal to 1 if it's a pending event, and to 0 if there is no need to process it. Operation and Parameter fields define the way the event is processed. Operation can contain one of the following actions: more, less, equal and changed. These actions are applied to the source device value. The comparison is performed with Parameter field. When Operation is "changed", the Parameter is ignored. Value field contains the data to assign to the target device. And Notification field passes the notification message to the event handler.

The event system is managed with Drupal module. All devices of the network have their own Drupal nodes. When a device node is changed, the event system looks for associated events. If it finds any, the status of that event is changed to 1 (pending event).

Gateways regularly lookup the event list for pending events. When such event exists, a gateway requests all information about it and process it. After processing the gateway modify the target device and sets the event status value to 0.

Device nodes are grouped to reflect the apartment building and the apartment it belongs. Since all devices and events are nodes, they are affected by built-in access control system of Drupal. All users have their own restrictions based on device groups. But gateways use a separate account to have write access to all records.

## VI. CONCLUSION

In this paper, a wireless system for combustible gas leakage monitoring in apartment buildings is presented. The system consists of autonomous gas sensors, actuators, routers and a gateway and is connected to the Internet. The architecture of the system allows to adjust the number of nodes depending on the number of apartments. The gas concentration data is stored in the web service database on the Internet and can be easily accessed from any mobile device (laptop, tablet PC, smartphone, etc.).

The system response time is determined by the duty cycle of methane concentration measurements and can vary in different tasks. The peculiarity of the system is in relocation of network organization, event management and data storage functions to a web service in strong interaction with WSN.

To increase the autonomous lifetime we are going to use alternative energy sources for components of the wireless system in the nearest future [16].

**Abstract**—Frequency domain features of inertial movement enables multi-resolution analysis for fall detection, yet they are computationally intensive. This paper proposes a computationally light frequency domain feature extraction method based on lifting wavelet transform (LWT) which provides computational efficiency suitable for real-time low power devices such as wearable sensors for human fall detection. LWT is combined with support vector machine (SVM) to identify falls from activities of daily living. Performance of the Haar and Biorthogonal 2.2 wavelets were compared with the time domain feature of root-mean square acceleration using a human fall dataset. Results show that the first level detail coefficients features for both Haar and Biorthogonal 2.2 wavelets achieve good overall fall detection accuracy, sensitivity and specificity.

## I. INTRODUCTION

AS many countries enter the era of aging society, they face critical elderly people's health threats which are fall and related complications caused by the injury [1]. Considering the need of real-time monitoring and ease of use, wearable sensor systems are one of the most promising systems.

Wearable sensor-based fall detection systems, inherently generate continuous monitoring of physiological measurements. Such system is usually a multi-sensor system, comprising sensors such as accelerometers, gyroscopes, pressure sensors and magnetometers. Datasets collected by such wearable sensors are thus, typically multi-dimensional and in large volumes. Such characteristics may cause hinder data processing and fall detection capabilities. Some researches therefore use feature extraction to reduce the amount and the dimensions of data [2] by extracting only necessary features. Existing feature extraction techniques include two main domains, i.e., time and frequency domains. Research such as [1], [3], [4] extracted time domain features including the mean value, maximum value, minimum value and variance, standard deviation of the patient's physiological movements and other special features such as entropy and vertical direction.

In general, time domain features are straightforward and easy to visualize which means light computational burden for feature extraction. So the system is computationally efficient in achieving a real-time fall detection. However, the time domain statistical features considers only the displayed observable trends [2]. Consequently, time domain features may not suffice for accurate fall detection.

Conversely, frequency domain features make use the spectral domain of the collected data which may not be clearly observable in the time domain. Frequency domain features were deployed for fall detection by [5] which used discrete stationary wavelet transform (SWT). In [6], a short time Fourier transform (STFT) was used for human activity recognition, whereby a fall was a subset of data in a series of continuous activities of daily living (ADLs). Ref. [7] created a prototype wavelet of typical fall pattern by using the average acceleration sum vector. The degree of similarity of the signal to the prototype was then computed through wavelet analysis. Results from the same classifier and real-world dataset revealed that the wavelet based features outperformed than other time domain features: upper and lower peak values.

Feature extraction alone only enhance the features of the data acquired by the wearable sensors. However, to detect whether a fall occurred relies on the performance of the detection mechanism. The most common and simplest fall detection is the threshold method [8]. Nevertheless, the performance heavily depends on the fixed threshold level. Hence, it is rarely used alone, and often combined with other machine learning methods such as decision tree (DT) [9], [10], artificial neural networks (ANN) [11], hidden Markov model (HMM) [12] and Support Vector Machine (SVM) [4], [14], [15] can be combined to outperform the threshold method [8], [14]. Among the machine learning methods, SVM was found the most robust for fall detection when compared to other methods such as threshold-based methods and the decision tree method [8]. However, most works which deploy SVM for fall detection use time-series features [8], [16]. It was found that SVM fall detection performance can be improved by a combination of time and frequency domain features [4]. In particular, the discrete Fourier transform

<sup>†</sup>Corresponding author

□ This work was financially supported by Suranaree University of Technology under the MOU with Huazhong University of Science and Technology, P.R. China.

(DFT) was used to determine the spectral coefficients which is computationally intensive [4]. On the other hand, the lifting wavelet transform (LWT) is an efficient, light weight frequency domain extraction method [17]. To the best of our knowledge, there is no previous work that has combined LWT with SVM for fall detection. This paper is therefore focused on the study of feature extraction based on LWT used with SVM to detect falls from ADLs using root-mean square value from a single tri-axial acceleration sensor.

The paper is organized as follows. Section II presents the proposed frequency analysis and the support vector machine scheme proposed in the paper. The time domain feature which is used for comparison is also introduced. In section III, the experiment based on a comprehensive fall detection dataset is described. Section IV presents the results and discussion and finally conclusions is given in the final section.

## II. METHOD

### A. Frequency domain feature extraction

Feature extraction based on frequency analysis of the body inertia collected from sensors has been studied in the recent literature. Discrete wavelet transform (DWT) has been proposed for mobility monitoring, posture transition and activities classification in [18] using a single chest-mounted sensors. In [19], another frequency domain feature extraction method using short-time Fourier transform (STFT) was proposed to shorten the calculation time of DWT. Despite good results, the short time windows in STFT may not always be suitable for human motion which varies greatly. If windows are too short, STFT may be unable to identify the frequency in such a short period of time. If windows are too large, more information in time domain will be lost. If the STFT window size is fixed, STFT may not be suitable for fall detection as human activities are flexible. Unlike DFT in [4], LWT can be constructed from time series signal directly. Unlike DWT in [18], LWT does not require convolution, translation or dilation of traditional mother wavelets. Furthermore, LWT allows in place calculation, with no need for auxiliary memory. Therefore, LWT provides computational efficiency suitable for real-time low power devices such as wearable sensors. In the following subsection, we describe LWT in more details.

### B. Lifting Wavelet Transform

LWT has been introduced by Sweldens in 1997 [17]. The scheme theory is often described as three steps: split, predict and update. The split step is to split a signal into two independent sequences, i.e., the even half and odd half sequences. Let  $x_i$  be the original discrete signal at time index  $i$ . Let  $even_i$  ( $odd_i$ ) denote the  $i^{th}$  index of the even (odd) sequence. We have that  $even_i = x_{2i}$  and  $odd_i = x_{2i+1}$ ,  $i \in I$ .

LWT is a recursive algorithm which splits the signal into halves at each level. If the original signal has  $2^n$  elements, then the next level will operate on  $2^{(n-1)}$  elements. Hence, if the original signal has 256 elements, there will be 8 levels with

the next level having 128 elements. The subsequent levels will have 64, 32, 16, 8, 4, 2 and 1 element. The odd values in the next level  $j+1$  is predicted from the even value at level  $j$ :

$$cD_{j+1,i} = odd_{j,i} - P(even_{j,i}) \quad (1)$$

where  $P$  is the predict function which approximates the signal,  $cD$  is the high frequency component of  $x_i$ . This is called the *Predict* phase. The even values at the next level can be found from

$$cA_{j+1,i} = even_{j,i} + U(cD_{j+1,i}) \quad (2)$$

where  $U$  is the update operation that updates on the differences from the odd values,  $cA$  is the low frequency component of  $x_i$ . This is called the *Update* phase. The multi-level lifting scheme can be summarized in Fig. 1. The averages are sometimes called approximate coefficients whereas the differences are called the detail coefficients. There are two types of wavelets used in this paper.

#### 1) Haar wavelet:

Predict :

$$cD_{j+1,i} = odd_{j,i} - even_{j,i} \quad (3)$$

Update :

$$cA_{j+1,i} = even_{j,i} + \frac{1}{2}cD_{j+1,i} \quad (4)$$

#### 2) Biorthogonal 2.2 wavelet:

Predict :

$$cD_{j+1,i} = odd_{j,i} - \frac{1}{2}(even_{j,i} + even_{j,i+1}) \quad (5)$$

Update :

$$cA_{j+1,i} = even_{j,i} + \frac{1}{4}(cD_{j+1,i-1} + cD_{j+1,i}) \quad (6)$$

Fig. 1 Forward lifting scheme

Figure 2 shows a sample fall plot of the original signal and the *first* level LWT coefficient. The number of coefficients of  $cA1$  (average or low frequency part) and  $cD1$  (detail or high frequency part) are half of the original signal according to the number of data points. By comparing  $cA1$ ,  $cD1$  and the root-mean square acceleration ( $SV_{total}$ ) in Fig. 2, it is seen that  $cA1$  greatly correlates with the original signal. Note that  $cD1$  also shows a peak similar to the original signal signifying a fall which occurred during the red highlighted window of one second. However, the baseline zero illustrated a more distinguished fall feature than  $cA1$ . Therefore,  $cD1$  was preferable than  $cA1$  for feature extraction of falls.

Fig. 2 A sample fall plot of  $SV_{total}$  and after LWT cD1 and cA1 with data points inside “fall” window highlighted

### C. Time domain feature

The tri-axial acceleration data collected contains  $A_x$ ,  $A_z$ ,  $A_y$  in x-axis, z-axis and y-axis as a function of time. All accelerometer data were in factors of gravity units (g). The accelerometer components were used to calculate the root-mean square acceleration denoted by total sum vector  $SV_{total}$ :

$$SV_{total} = \sqrt{A_x^2 + A_y^2 + A_z^2} \quad (7)$$

### D. Support Vector Machine

Support Vector Machine (SVM) is a supervised machine learning model which is commonly used for anomaly detection and classification [20], [21], [22]. As a supervised learning model, SVM requires training from datasets with “labels.” The SVM concept is to map a set of data points from the real-world to a higher dimensional space. A boundary or hyperplane is created in a high dimensional space by training datasets to classify the features into fall or non-fall. Since the fall detection system inherently generates long-term continuous monitoring of physiological measurements, such datasets are usually large. Such characteristic may cause difficulty in data processing. To reduce the amount of data and achieve a higher calculating speed, the features of the data may be extracted from these raw datasets.

To train the SVM, the data points in the dataset must be labeled. For example, in time domain,  $SV_{total}$  was directly used as input feature. We labeled all the ADLs data points with “-1” whereas falls were labeled “1.” Fig. 3 depicts a sample plot of a fall along with non-fall activities like walking around and lying on the ground. Point A shows the peak value of the dataset. A highlighted window size with point A placed at the middle of the window is constructed. Within such window, all the data points are labeled “1” and the remaining data points outside this window are labeled “-1.” The goal of SVM is therefore to distinguish the labels among the tested datasets using the model obtained from the trained data. The data points are typically non-linearly separable to classify in low dimensional space. However, if these points are projected onto a higher dimensional space, it is possible to find a hyperplane to classify the labels. Such projection is

obtained through use of kernel functions such as linear, polynomial, sigmoidal, or the Gaussian radial base functions. It is with this kernel trick that makes SVM a powerful model to classify the labels in higher dimensional space. In the next section, the experiment settings are presented.

Fig. 3 A sample plot of fall  $SV_{total}$  with data points inside window highlighted

## III. EXPERIMENT

As mentioned in the previous section, SVM requires training labeled datasets. As data input in the fall detection scenario involves both non-falls and falls data, We trained with both falls and non-falls data in Table I. We first evaluate the SVM model with a hybrid fall and non-fall activities. The objective is to evaluate a suitable training dataset for SVM to detect falls. For the sake of simplicity, only the time domain feature ( $SV_{total}$ ) is studied.

Once a SVM model is trained, we proceed to study the comparison between features in the time domain ( $SV_{total}$ ) and frequency domain (LWT using Haar and Biorthogonal 2.2 wavelets). Note that there are existing works which combined features in both time domain and frequency domain of data, the type of sensors, the number and position of sensors on human body, and in the volume of dataset for training and testing [1], [5]. From results gathered from existing literature, we focus on data collected from a single tri-axial acceleration sensor due to its low cost, reliability and efficiency.

### A. Performance metrics

To evaluate the performance, we measure the True Positives (TP) or True Negatives (TN) which refers to the number of events correctly identified or correctly rejected. False Positives (FP) or False Negatives (FN) which represent the number of events incorrectly identified or incorrectly rejected [23]. These measurements provide the following necessary metrics required to evaluate the fall detection method:

1) *Sensitivity (SE)* or true positive rate is the capability to detect a fall correctly. It is an indicator to judge whether a system will miss a fall. It is given by

$$SE = \frac{TP}{TP+FN} \times 100\% \quad (8)$$

2) *Specificity (SP)* or true negative rate is the ability to detect a fall only if a fall really occurred. It is to avoid false alarm given by

$$SP = \frac{TN}{TN+FP} \times 100\% \quad (9)$$

3) *Accuracy (AC)* or correct rate refers to the overall freedom from false. This is given by

$$AC = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \quad (10)$$

It is worth noting that SVM classifies data points individually. However, to detect a fall within a certain window as shown in Fig. 3, a set of data points must be classified rather than just a single data point. Therefore, to determine a suitable decision region to decide whether a fall has occurred, we use a simple calculation for the percentage

of predicted fall label “1” over the number of labels observed in an activity to compare with a predetermined threshold:

$$T = \frac{\text{the number of predicted "1"}}{\text{the number of testing data points}} \quad (11)$$

If  $T > \text{threshold}$ , the activity is a fall. Otherwise, else it is a non-fall activity.

### B. Training SVM Model

We hypothesize that the best type of training dataset will be the combined set of both fall and ADLs dataset. Since not only falls but also ADLs data are contained in the hybrid training dataset, the more comprehensive information contained in training dataset, the more likely the model will decide correctly.

The dataset we used to train and test the SVM models have been obtained from [24] including 70 activities (tri-axial acceleration of 30 falls and 40 non-falls collected and video recorded with Kinect camera) with details given in Table I. The tri-axial accelerometer data was sampled at 60Hz. Therefore, a one-second window for fall detection consists of

<sup>1</sup> The italic activities were used as training dataset.

60 data points. The dataset was divided into training set and testing set based on activities in the matching video of each data file. Table I consists of fall and non-fall (ADLs) activities. The SVM model has been trained with the datasets obtained in italics in Table I for a comprehensive dataset of various falls and ADL activities.

Once the data points are labeled and trained, the SVM model is obtained. The SVM model is then used to classify the testing data. The dataset remaining (non-italic activities) in Table I are used for testing. For each dataset tested, a data point is labeled “1” for data points predicted as a fall data point, or “-1” for data points predicted as non-fall data point. If the ratio of fall labels in an activity exceeds the determined threshold, then a fall has been detected. For each tested dataset, TP, TN, FP and FN is measured for the calculation of SE, SP and AC to evaluate the SVM model. Results are presented in Section IV.

### C. Comparing Time and Frequency domain features

This part of the experiment is to compare the time domain feature (based on  $SV_{total}$ ) and the frequency domain features (based on Haar and Biorthogonal 2.2 wavelets). Using the SVM model obtained in the previous experiment, a suitable level threshold level to detect a fall event for each feature is then found. For each feature, the percentage levels of threshold is tested at 10%, 20%, 30%, 40% and 50%. Then level is tested at finer threshold values. Results are shown in Table II.

We then investigate closely how multiple levels of LWT coefficients affect the fall detection performance by evaluating the first five levels of coefficients of the Haar and Biorthogonal 2.2 wavelets. Results are shown in Table III.

## IV. RESULTS AND DISCUSSION

### A. Training SVM Model

Results show that the SVM model trained and tested with *time domain* datasets of both falls and ADL activities gave a 100% sensitivity, 97.14% of specificity and 98.31% accuracy. It should be noted that the 100% sensitivity is obtained from *offline* datasets with a predetermined threshold found from observing these datasets. Furthermore, a larger dataset collected from online simulated falls is currently under investigation.

### B. Comparing Time and Frequency domain feature

Table II shows the performance comparison between time and frequency domain features at different levels of thresholds.

- 1) *Root-mean square acceleration*: Table II shows that the best threshold for the time domain feature should be between 10% to 20%. With fine threshold tuning, it is found that a threshold of 17-18% showed better preference than others (shown in bold fonts). Therefore, we chose 17% as the threshold to classify a fall or non-fall for time domain feature.
- 2) *LWT with Haar Wavelet*: The appropriate threshold for Haar LWT is found by also ranged from 10% to 50%. As

shown in Table II, the best achieved threshold should be under 10%. To fine tune the threshold levels, the threshold is varied from 2% to 10%. It is found that the threshold at 8% outperformed other levels (shown in bold fonts). Thus, we chose 8% as the threshold for LWT using Haar wavelet. In Table III, multiple levels of LWT coefficients (cD1 to cD5) are evaluated. When tested with ADLs & Falls dataset, all specificity, specificity and accuracy values of 100% was achieved only in cD1 (shown in bold fonts). This result indicated that Haar LWT CD1 coefficients achieved a goal such that no ADL has been misclassified as a fall and detected most of the falls when training and testing using finite activities in Table I

3) *LWT with Biorthogonal 2.2 Wavelet*: From Table II, the optimal threshold for Biorthogonal 2.2 (Bior 2.2) should be under 10%. With a finer threshold search, results indicate that threshold level of 6% is the best level with 100% sensitivity, specificity and accuracy (shown in bold fonts). Similar to Haar LWT, Bior 2.2 LWT coefficients also show a good performance distinguishing falls from ADLs when using most cD levels. In Table III, cD1 also outperformed other levels of coefficients similar to Haar wavelet (shown in bold fonts). The reason may be the information contained in the frequency components that is helpful to classify activities by SVM. The cD1 components contained the most distinguishable information of falls, while cD5 contained the least information. Generally, Haar was slightly better at distinguishing ADLs from falls than Bior 2.2, whereas both LWT features outperform the time domain feature of root-mean square acceleration alone. It is worth noting that these results are obtained by a comprehensive human fall dataset with video captures obtained from [24] which allow the thresholds and detail coefficients to be predetermined offline. Current ongoing work involves implementing the LWT and SVM on actual wearable sensor devices to be evaluated online for human fall detection for accuracy and efficiency.

## V. CONCLUSIONS

In this paper, we propose a computationally light frequency domain feature extraction method called lifting wavelet transform (LWT) for a wearable sensor human fall detection device combined with a fall identifier using support vector machine model. The performance of the LWT using Haar and Biorthogonal 2.2 wavelets, together with the time domain feature of root-mean square acceleration have been evaluated with raw dataset acquired from a single tri-axial acceleration sensor from an existing human fall and activities of daily living dataset.

Based on the dataset, suitable thresholds and level of detail coefficients can be predetermined. Consequently, the LWT frequency domain features are shown to have better performance than time domain features in terms of sensitivity, specificity and accuracy. Given a one-second window size under a sampling frequency of 60Hz, the best threshold in terms of the percentage of fall labels (“1”) per window is as follows, 18% for the time domain feature using the root-mean square acceleration, and 8% for Haar and 6% for

Biorthogonal 2.2 LWT wavelets when the SVM model is trained with both fall and non-fall datasets. The frequency domain feature from cD1 for both Haar and Biorthogonal 2.2 wavelets achieved 100% overall accuracy whereas 98.31% overall accuracy was attained for the time domain feature,  $SV_{total}$ . All features achieved 100% sensitivity from this dataset. In terms of specificity, the time domain feature,  $SV_{total}$ , attained up to 97.14% whereas the two LWT features attained 100%. In a final note, ongoing work involves implementing the LWT and SVM on actual wearable sensor devices to be evaluated for human fall detection accuracy and reliability in real-time.

#### ACKNOWLEDGMENT

The authors would like to thank Suranaree University of Technology for the financial support under the MoU with Huazhong University of Science and Technology, P.R. China for Ms. Hanghan Liang to conduct this research.

**Abstract**—IEEE 802.11 WLANs use carrier sense multiple access with collision avoidance (CSMA/CA) to initiate the Request to Send / Clear to Send (RTS/CTS) handshaking mechanism that solves the hidden node problem. However RTS/CTS also causes the exposed node problem where a node is unnecessarily prevented from accessing the wireless channel even when such access will not disrupt another nodes ongoing transmission. In this paper, we present continuing evaluation of a method for reducing exposed nodes in 802.11 ad hoc WLANs using asymmetric transmission ranges for RTS and CTS frames. NS-2 simulations show that the proposed method improves overall network throughput in a topology scenario of a 3-D network faced with ceiling/floor obstructions.

## I. INTRODUCTION

ALTHOUGH wireless local area networks (WLANs) provide mobility and convenience, their efficiency in today's high demand networks is unsatisfactory. WLANs generate a major portion of today's global Internet access due to their ease of use and their cost-effectiveness [1]. According to a Cisco report, wireless and mobile devices will generate 68% of all internet traffic by 2017 [2]. A factor driving the increase in use of wireless networks is the Internet of Things (IoT) currently in deployment. Devices such as household appliances, wearable devices and motor vehicles are being equipped with capabilities to connect to the Internet and to each other, wirelessly. In these scenarios, devices exist in close proximity to each other resulting in intense wireless channel contention which can lead to a severe degradation of the wireless network performance because of a high number of collisions.

The IEEE 802.11 MAC control is currently the most widely used medium access control protocol for WLANs [3]. In ad hoc networks, devices build automatic connections to other devices with no centralized infrastructure. The lack of centralized infrastructure to coordinate node activities gives ad hoc networks the advantage of simplicity but also makes them prone to collisions [3]. Since 802.11 networks do not detect collisions, frames suffering a collision will be lost in their entirety [4]. Thus, the goal in this type of networks is to avoid collisions whenever possible.

Fig. 1. The hidden node problem

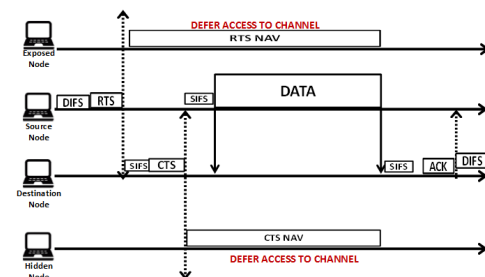

Fig. 2. The Standard RTS/CTS handshake

### A. Hidden node problem

The hidden node problem occurs when a node is visible from one intermediate wireless node, but not from other nodes communicating with that node. In Fig. 1 *B* is the intermediate node. Both nodes *A* and *C* can communicate with node *B*, however, nodes *A* and *C* cannot sense each other since they are outside each others communication ranges and this leads to difficulties in the media access control layer. If node *A* and node *C* both start transmitting to node *B* at the same time, packet collisions/loss occurs at node *B*.

### B. RTS/CTS handshake

To solve the hidden node problem, the 802.11 MAC protocol includes an optional channel reservation scheme to help avoid collisions. This scheme is implemented through a CSMA/CA technique using the four-way RTS/CTS handshake shown in Fig. 2: In Fig. 2, a node with a packet to send, the Source Node, sends an RTS packet when it senses the

Fig. 3. The exposed node problem

channel being free for a period known as the DCF Interframe Space (DIFS). If the RTS packet is successfully received by the Destination Node without suffering collisions, it replies with a CTS after a period known as Short Interframe Space (SIFS). After receiving the CTS, the Source Node sends the data and waits for an acknowledgement (ACK) from the Destination Node to indicate successful transmission of the data i.e. DATA. Although the RTS/CTS exchange helps reduce collisions caused by hidden nodes, it also introduces another problem known as the exposed node problem.

### C. Exposed node problem

Exposed nodes are nodes that are prevented from communicating with other nodes in their transmission ranges because they are close to a sending node and overhear the RTS frame [5]. Fig. 3 explains the exposed node problem. When node B initiates a transmission to node A by sending an RTS, node C overhears the RTS and is forced to defer its planned transmission to another node, i.e. node D. It is a mistake for node C to not transmit to node D just because it can overhear node B's transmission. Node C's transmission to node D would not be a problem because it does not interfere with node A's ability to receive from node B. Thus, node C is known as the exposed node in this scenario and has to hold its transmission for the Network Allocation Vector (NAV) period defined in the RTS frame. This decreases network spatial utilization and performance [6].

The CSMA/CA technique has not been improved since 1999 [7]. Although there have been several amendments to IEEE 802.11 standards since their ratification in 1997, CSMA/CA communication control technique has not caught up with the latest physical layer advancement. With the increased usage of wireless networks, it is important to optimize WLAN technology for the current and future environment.

In previous publications, we presented results for simulations based on an XY plane for grid and random distribution topologies [8]. In this paper, we introduce simulation results for an ad hoc WLAN deployed in an office building that represents an XYZ three-dimensional plane. This is in order to consider the elevation of the room and the attenuated received signal strength (RSS) in evaluating the difference in throughput between the standard RTS/CTS scheme and the proposed method.

The rest of this paper is organized as follows: Section II describes related works, Section III the proposed exposed node reduction idea and Section IV discusses the AODV routing protocol used to transport the data packet from sender to destination. Section V discusses the simulation set-up and results and Section VI concludes the paper.

## II. RELATED WORKS

Our first research of the proposed method was reported in [6]. However, the research in [6] focused primarily on multi-rate transmission of RTS and CTS frames in order to control transmission range. Our method directly adjusts the transmission ranges of the control frames without considering transmission rate. This is done for simplicity and to not cause complications with the PHY layer convergence procedure (PLCP) preamble whose transmission rate cannot be changed. Additionally, the simulations in [6] were limited to evaluating the basic performance of the method with regards to only next-hop neighbour node communication. Our evaluations go a step further to evaluate end-to-end network communication by taking into account the routing protocol used.

Another method that effectively solves the hidden and the exposed node problems is the Dual Busy Tone Multiple Access (DBTMA) method described in [9]. DBTMA uses two out-of-band busy tones to protect the RTS packets and the DATA packets from interfering stations by assuming separate channels for tones and data. Although it is technically possible for wireless devices to communicate using multiple channels simultaneously, the MAC protocol in 802.11 networks is designed for a single channel only [10]. Hence, we only consider single channel communication in this research.

Other methods proposed in literature to solve the exposed node problem are such as that described in [11]. The method called Selective Disregard of NAVs (SDN) selectively ignores certain physical carrier sense and NAVs. This method needs additional functionalities to be implemented in nodes and lacks compatibility with the IEEE standard. Other MAC protocols based on Multiple Access with Collision Avoidance (MACA) were proposed in [12] that exploit control gaps between the RTS/CTS exchange and the subsequent DATA/ACK.

## III. PROPOSED IDEA

### A. Overview

The IEEE 802.11 standard performs RTS/CTS handshaking to avoid collisions by eliminating hidden nodes. However, the RTS/CTS scheme introduces another problem referred to as the exposed node problem from nodes close to a transmitting node that overhear the RTS frame.

### B. Asymmetric transmission ranges for RTS and CTS

To mitigate the exposed node problem, the proposed method uses asymmetric transmission ranges for RTS and CTS frames. This is achieved by setting the transmission range of RTS frames to be less than that of CTS frames. We employ the fundamental method described in [6] to express the concept of asymmetric RTS/CTS transmission ranges as shown in Fig. 4.

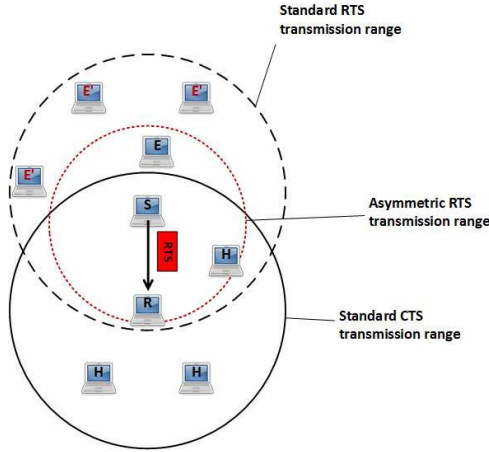

Fig. 4. Asymmetric RTS/CTS transmission

Reducing the transmission range of RTS frames means we eliminate some of the exposed nodes i.e.  $E$  that were included in the original RTS transmission range; and overhear the RTS frame from the transmitting node,  $S$ . This means that the total number of exposed nodes in the network is reduced and can even be completely eliminated if the RTS range is included in CTS range. RTS frames do not need to have such a wide transmission range, as they only need to reach the receiving node in order to provoke a CTS response [6]. Thus if the transmission range of RTS is set to the minimum distance, only reaching the receiving node, this is enough to provoke CTS from the receiver node.

#### IV. AODV ROUTE DISCOVERY

##### A. Overview

Nodes in an ad hoc WLAN cooperate in routing the data packets from the source node to the destination node since there is no centralized control. One of the most popular routing algorithms in ad hoc networks is the Ad Hoc On-Demand Distance Vector (AODV). AODV is a form of reactive routing that establishes routes between nodes only when they are requested and uses HELLO messages to discover neighbour nodes [13].

AODV uses hop count for choosing which route to use to transfer data from a source node to a destination node [13]. Because we are dealing with randomly placed nodes in our simulation, we need an efficient way to transmit the data packet from the source to the destination that incorporates the proposed asymmetric transmission ranges for RTS and CTS. In our work, we used the next-hop distance from AODV routing information to dynamically change the RTS transmission range.

##### B. Received Signal Strength

In multi-floor buildings, wireless signals can propagate through multiple floors in a phenomenon known as Inter-floor interference [14]. In such cases, a wireless node on  $Floor - X$

Fig. 5. Received signal attenuation model

will receive signals from nodes from the floors above and below, leading to interference issues.

In wireless networks, the received signal strength indicator (RSSI) can be used to estimate the distance between nodes [15]. Fig 5 shows a schematic of the received signal attenuation as it crosses the ceiling/floor. In the standard RTS/CTS method, the RSSI of RTS frames reaches adjacent floors, causing exposed nodes on those floors. RSSI decreases exponentially as the distance from the signal source increases [15]. In simulating the three-dimensional office-building scenario; we adjust the RTS transmission range considering the attenuation of the received RTS signal by the ceiling/floor. We use the RSSI attenuation model given in [15] using equations 1 and 2 below:

$$RSSI[dBm] = -10n \log_{10} \times \frac{d}{d_0} \quad (1)$$

$$d = \frac{RSSI}{-10n} \quad (2)$$

In equations 1 and 2,  $n$  is the attenuation factor,  $d$  is the distance from the node to the point of measurement and  $d_0$  is a reference point distance. These parameters were used to calculate the indoor propagation environment of the RTS frames.

#### V. NS-2 SIMULATION AND RESULTS

##### A. Overview

We use the Network Simulator-2 (NS-2) to verify the proposed method. NS-2 is an open-source; event-driven simulator commonly used for communications research [16]. We use a simple power threshold scheme to control the transmission range of RTS frames. In 802.11, the transmission range of packet is determined by the power with which the packet is transmitted from the transmitting node. At the MAC level, we set a threshold that restricts how far an RTS frame goes as described in Algorithm 1. The  $newRTSThresh$  variable is compared to a received RTS packet's power level during runtime using Algorithm 1. If the power level is found to be larger than the level defined by  $newRTSThresh$ , the incoming RTS packet is simply discarded. In this way, we are

**Algorithm 1** set RTS range

---

```

if ( $RTS_{packetpower} > newRTSThresh$  then
   $discard(p, DROPMACBUSY);$ 
  return ;
end if

```

---

Fig. 6. The simulation model

able to confine RTS packet to a certain transmission range and in turn reduce the number of exposed nodes in the network.

**B. 3-D Simulations**

For the simulations, we assumed a small four-story office building to evaluate the asymmetric RTS/CTS method. The RTS transmission range was dynamically determined during runtime based on the next-hop distance as described in Section IV. We set the X-axis and Y-axis of the office floor to 180m and the ceiling-to-floor height to 5m. The nodes on each floor were randomly distributed in such a way that each node was within 70m of another node. This was to ensure that each pair of nodes were within the proposed method's RTS transmission range of half the CTS transmission range which was set to 140m.

In Fig. 6 which shows the simplified building model, the distance from  $n1$  to  $n2$  is 50m. Based on the information received from AODV's HELLO packets, the proposed method's RTS transmission range (i.e.  $RTS'$ ) is set to 50m. From Fig. 6, we can observe that  $n0$  and  $n3$  would have been exposed nodes using the standard RTS transmission range. and Table. I presents the rest of the simulation parameters and conditions:

**C. Analysis of results**

We present simulation result comparison between the Standard and the Asymmetric RTS/CTS methods. Fig. 7 shows packet drops between the two methods for the 25 nodes simulated in our 3-D scenario. The Standard method experiences a higher number of CBR packet drops per node with the overall number of drops for the network at 1400 packets in comparison to the Asymmetric method with an overall packet drop of 507. This means the proposed method provides a 63.8% reduction in packet drops. The packet drops from unsuccessful CBR packet transmissions in the Standard method

Fig. 7. Throughput results

Fig. 8. Throughput results

are a result of secondary transmission failures as exposed nodes are prevented from communicating with other nodes in their communication ranges. Fig. 8 shows the number of dropped RTS packets between the two methods. The Standard method has an overall high number of dropped RTS packets than the Asymmetric method. RTS packet are dropped when the retry count set at the MAC layer is exceeded (after 7 failed RTS transmissions in NS-2). However; because some exposed nodes around the receiver have already received the failed RTS packet, they enter the NAV period and back-off from accessing the channel. With the Asymmetric method, even with RTS packet failures, some nodes around the sender will still be able to communicate leading to the increase in throughput presented in Fig. 9. Fig. 9 shows the throughput comparison between the Standard RTS/CTS and the proposed Asymmetric RTS/CTS methods for the 25 randomly distributed nodes using no RTS/CTS, using the standard RTS/CTS method and using the Asymmetric RTS/CTS method. Throughput was calculated using Equation 3:

$$Throughput = \frac{TotalReceivedPackets \times PacketSize}{RoundTripTime} \quad (3)$$

From Fig. 9, we can clearly see that the Asymmetric RTS/CTS

TABLE I  
SIMULATION PARAMETERS

Transmission range		
Frame Type	Standard RTS/CTS	Asymmetric RTS/CTS
RTS	140m	Next-hop node distance
CTS	140m	140m
Other parameters		
Data packet size	3000 bytes	
Propagation model	TwoRayGround	
Routing protocol	AODV	
Simulation conditions		
Simulation time	60 seconds	
Simulation frequency	x300	
Communication start time	Uniform Random	

Fig. 9. Throughput results

method has significantly higher throughput even in scenarios with obstacles such as the ceiling or floor. We attribute this throughput gain to the elimination of exposed nodes in the network.

## VI. CONCLUSION

In this paper, we present further evaluation of a novel method for reducing exposed nodes in ad hoc WLANs using asymmetric transmission ranges for RTS and CTS frames. To set the RTS transmission range, we used the next-hop node selected by the AODV routing protocol to determine the best route to the destination while keeping the RTS range at a minimum. We employ an RSSI attenuation model to consider obstacles to the wireless signal in our simulated 3-D model. Simulation results show that the proposed method has better overall network throughput than the standard method.

Future work will look at the effect the proposed method has in scenarios of mobile nodes in indoor settings. Furthermore, we will study the impact of a destination having multiple sources. These evaluations will allow us to further validate the usefulness of the Asymmetric RTS/CTS idea and propose it as an adjustment to the RTS/CTS standard in IEEE 802.11 WLANs.

## ACKNOWLEDGMENT

The authors would like to thank Dr Akihisa Matoba for his assistance with this research.

**Abstract**—In control applications, we often encounter systems that respond to the change of control signal in an undesirable way. To adjust system output, there arises the need to know system parameters, so the identification has to be performed. The aim of this paper is to compare upstanding identification error that is the consequence of dataset size, input signal type, and quantization error occurring in the signal. The experimental part of this paper presents the results measured on the real device and shows the identification results.

## I. INTRODUCTION

THE purpose of identification is to experimentally determine the structure and complexity of the model. After determining the structure and complexity of the model, an appropriate method is used to estimate the unknown system model parameters.

The first step in system identification from experimental data is modelling. The behaviour of the model is determined by the structure of the system and by the properties of the equations describing the relations of the action members. The way the individual subsystems are interconnected and how they operate is described by the overall system and its behaviour. The behaviour of the system obtained using equations describing the physical model can be described in detail by a set of algebraic and differential equations.

## II. SYSTEM IDENTIFICATION BACKGROUND

In automated control and signal processing, we understand the dynamic system model as a mathematical description of the relationship between inputs and outputs of the system. Based on this context, it is possible to determine the system transfer function and thus to identify the system. Basic methods of identification may include methods such as transition and impulse characteristics. The excited input has the character of a single jump or a unit pulse, and the output signal states the model. The application of these techniques is simple, not very susceptible to noise. Another drawback of using these techniques to identify the system is the need to introduce a unit jump / input impulse, which is undesirable for some systems [1]. For this reason, we are also addressing other systems identification approaches that are described in the following text.

The gradient method and the least squares method can be used to estimate the parameters of any linear system [2], [3],

[5]. For simplicity and clarity, consider the transport delay  $d = 1$ . Equation (1) states that

$$y(k) = \varphi^T(k-1)\theta, \quad (1)$$

where

$$\begin{aligned} \theta &= [-a_1 \dots -a_n \ b_0 \dots b_m]^T, \\ \varphi(k-1) &= [y(k-1) \dots y(k-n) \ u(k-1) \dots \\ &\quad \dots u(k-m)]^T. \end{aligned} \quad (2)$$

$\theta$  is the vector of the system parameters we are trying to determine and  $\varphi(k-1)$  is called a regression vector as it is made up of previous system inputs and outputs that affect the current system output value. When determining the correct system parameter values, it is necessary to determine the initial estimate  $\hat{\theta}(0)$ . Then the parameter values are so adjusted that the difference between the estimated system output  $\hat{y}(k) = \varphi(k-1)^T \hat{\theta}(k-1)$  and the actual output of the system  $y(k) = \varphi(k-1)^T \theta$  is minimized in time. The task of adaptation is thus minimization of the error between the difference of the expected and the actual output (3).

$$e(k) = |y(k) - \hat{y}(k)| = |\varphi(k-1)^T \theta - \varphi(k-1)^T \hat{\theta}(k-1)| \quad (3)$$

The adaptation scheme is illustrated in Fig. 1.

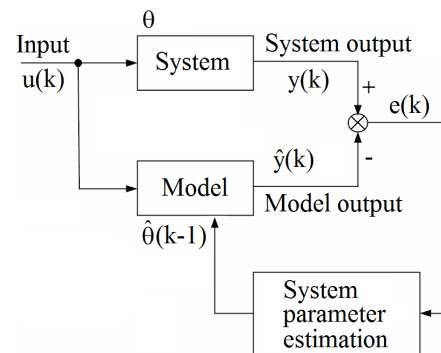

Fig. 1. The adaptation scheme of model parameters.

## III. MODELLING AND SIMULATION OF THE ACCELEROMETER BASED SYSTEM IDENTIFICATION

In order to observe the behaviour of the model, the model must first be conducted. At first, we need to define the properties of the system that we are modelling. When modelling

a weakly damped linear discrete system, it is necessary to determine the system's own frequency and the damping ratio. A relationship

$$\frac{d^2x(t)}{dt^2} + 2\zeta\omega_n \frac{dx(t)}{dt} + \omega_n^2 x(t) = f(t) \quad (4)$$

evokes that the knowledge of these parameters is sufficient to describe the second order differential equation and hence the ideal stabilized system [7]. To solve this differential equation, Laplace transform means were preferred for clarity, by means of which it is possible to shift from a mathematical model in the form of a differential equation to a system description by means of  $F(s)$

$$F(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2}. \quad (5)$$

After transforming into a z-plane we get a defined discrete model describing the system we want to simulate. The advantages of such writing include a relatively simple determination of the location of the zeros and poles based on the polynomial numerator and denominator of the system.

In order to verify the suitability of the identification method, it is adequately to generate several kinds of input signals to excite the modelling system. Selected control signals include unit pulse, unit jump, harmonic signal, or a combination thereof. Due to the fact that we model the data obtained from the accelerometer, it is necessary to set certain limitations. The simulated control signals are suitable for a certain width. We decided to represent the result by a 12-bit binary number. These signals were also affected by quantization noise. Quantum error has the character of white noise and normal distribution [7]. Based on the above, noise is generated with a normal distribution in the range determined by the sensitivity of the measurement and the range and is then added to the input and output signals.

#### IV. SYSTEM IDENTIFICATION USING THE LEAST SQUARES METHOD

To use this method for identification, it is necessary to have at least  $P$  data from the data set (6), whereby

$$P = n + m, \quad (6)$$

where  $n$  is the order of denominator and  $m$  is the order of numerator [3], [5]. Thus, the second order transfer function is in shape

$$\hat{y}(z) = \frac{b_0 + b_1 z^{-1}}{1 + a_1 z^{-1} + a_2 z^{-2}} u(z) + e(z), \quad (7)$$

where the measurable magnitudes are only the input  $U(z)$  and the output of the model  $Y(z)$ . Systems with higher order can be represented analogically. The aim is to identify coefficients of the numerator  $b$ , the denominator  $a$  of the system, but about the random error  $e(n)$ , we know only that it has a Gaussian distribution, the character of the white noise, and a zero mean

value [4]. The equation (7) can be rewritten into the analytical form

$$\begin{bmatrix} u(k) & u(k-1) & -\hat{y}(k-1) & -\hat{y}(k-2) \\ u(k+1) & u(k) & -\hat{y}(k) & -\hat{y}(k-1) \\ u(k+2) & u(k+1) & -\hat{y}(k+1) & -\hat{y}(k) \\ u(k+3) & u(k+2) & -\hat{y}(k+2) & -\hat{y}(k+1) \end{bmatrix} \begin{bmatrix} b_0 \\ b_1 \\ a_1 \\ a_2 \end{bmatrix} + \begin{bmatrix} e(k) \\ e(k+1) \\ e(k+2) \\ e(k+3) \end{bmatrix} = \begin{bmatrix} \hat{y}(k) \\ \hat{y}(k+1) \\ \hat{y}(k+2) \\ \hat{y}(k+3) \end{bmatrix}. \quad (8)$$

By stating

$$A_p = \begin{bmatrix} u(k) & u(k-1) & -\hat{y}(k-1) & -\hat{y}(k-2) \\ u(k+1) & u(k) & -\hat{y}(k) & -\hat{y}(k-1) \\ u(k+2) & u(k+1) & -\hat{y}(k+1) & -\hat{y}(k) \\ u(k+3) & u(k+2) & -\hat{y}(k+2) & -\hat{y}(k+1) \end{bmatrix}, \quad (9)$$

$$\theta_p = \begin{bmatrix} b_0 \\ b_1 \\ a_1 \\ a_2 \end{bmatrix}, e_p = \begin{bmatrix} e(k) \\ e(k+1) \\ e(k+2) \\ e(k+3) \end{bmatrix} \text{ and } \hat{y}_p = \begin{bmatrix} \hat{y}(k) \\ \hat{y}(k+1) \\ \hat{y}(k+2) \\ \hat{y}(k+3) \end{bmatrix}$$

we obtain

$$\hat{y}_p = A_p \theta_p + e_p. \quad (10)$$

The minimum number of required data is usually small. For the second order system, at least four consecutive data from the data set must be available. The complexity of the system also increases the minimum number of data points needed for sufficient accuracy. This has the effect that  $P$  is much larger (the number of rows of the  $A$  matrix grows). A larger  $P$  should provide more accurate definition of system parameters. The equation used to find optimal parameters (the smallest error) is

$$\hat{\theta}_p = A_p^+ \hat{y}_p, \quad (11)$$

where  $A_p^+$  represents a pseudo-inverse matrix to  $A_p$  (12) [6].

$$A_p^+ = (A_p^T A_p)^{-1} A_p^T \quad (12)$$

From the definition of this method, it can be deduced that choosing a larger number of input-output sample pairs leads to a more accurate system determination (Fig. 2).

Fig. 2. Comparison of the system and models obtained using different number of samples.

The error we commit when identifying depends on the number of samples used to determine the model parameters (Tab. I). However, it is important to be aware of the computational difficulty that grows with the addition of additional samples to be classified.

TABLE I  
A COMPARISON OF OVERALL ERROR OF MODELS USING DIFFERENT NUMBER OF SAMPLES.

Number of used samples	RMS error
10	295,4
20	202,4
40	196
100	172,3
200	190,9
400	3,905

When designing the simulation, we considered the appropriate choice of parameters. Based on the conducted initial experiment, we considered sampling frequency  $400\text{Hz}$ , damping ratio  $0.05$  and a resonant frequency of  $28\text{Hz}$  as the parameters of second order system.

The nature of the input signal has also an impact on the system identification. In some cases, the process of determining system parameters can not be defined as the reaction of the system to a signal in the prescribed form, which results in a limitation resulting from the suitability of the control signal being used. The response of the system to various input signals (Fig. 3) determines the parameters of the identified system differently. In our case, we chose the size of the identifying set to 20 input and 20 output data. The error that occurs in the input and output signals reaches a maximum of 1% of the range.

Fig. 3. Behaviour of selected control signals.

Adequacy of the use of different types of control signals for identification purposes may be expressed as a root mean square error (RMS error) (Table II). From the test results, it can be observed that in the least squares method it is advisable to use jump control signals for identification. Introducing an error in the input and output signal representing noise from the sensor device greatly affects the quality of the identification.

The simulation showed, that if no error occurs in the signal, this method has excellent results. By adding noise to the ideal signal, the result becomes less accurate, which in some cases has led to a poor classification of the system. White noise with normal distribution is generated and has a zero average value within a certain range and is then added to the input

TABLE II  
A COMPARISON OF OVERALL ERROR OF MODELS USING DIFFERENT CONTROL SIGNALS.

Identification control signal	RMS error
unit pulse	1,161
unit step	0,9191
ramp	1,344
harmonic aperiodic function	2,081

and output signal (Figure 4). Thus affected input and output signal are used in the identification process.

Fig. 4. Histogram and normal distribution function of generated error.

By enhancing the set of input and output signal samples, the quality of identification improves, but not sufficiently. The influence of selected noise levels at the value of the twenty inout samples used for identification is shown in Tab. III.

TABLE III  
THE IMPACT OF NOISE ON THE QUALITY OF IDENTIFICATION.

established error	RMS error
0%	0,009812
1%	2,266
2%	2,401
3%	2,484
4%	2,547
5%	2,606

Practical application has shown that when eliminating residual vibrations, it is important to determine the exact frequency of the system as accurately as possible. These results served as a basis for modifying the identification of systems in the frequency domain.

## V. EXPERIMENTAL RESULTS

Based on the need to control the coin hopper tester device, we have chosen this device as a system that needed to be identified. When identifying the dynamic properties of the system, we used printed circuit board featuring an accelerometer (Fig. 5).

As a control element, ATmega168 microcontroller was used. Its task was to provide the LSM303DLHC accelerometer configuration and send the recorded data via the RF module RFM73 to eliminate the undesirable phenomena associated with the use of wire communication. The accelerometer has been set to measure acceleration in the  $x$ ,  $y$  and  $z$  axes. The sampling rate was set to  $400\text{Hz}$ , which corresponds to the

Fig. 5. Coin hopper tester device with marked critical part.

maximum possible recording speed when the accelerometer is used.

As the receiver, we used a PCB with ATmega8A microcontroller. The role of this microcontroller was to receive the recorded data sent to the RFID measurement module via the RFM73 RF module and then to send results using the UART peripheral. In order to be able to continue working with this data on the computer, we used a communication interface converter to convert between USB and UART peripherals.

The measuring device was positioned such that the movement of the arm manifested mainly in one axis of the accelerometer (Fig. 6). On the PC, the incoming data has been aggregated into a file so it could be analyzed. We used Matlab to analyze measured signals representing acceleration in individual axes of the accelerometer.

Fig. 6. Data obtained from critical accelerometer axis.

Using the least squares method, we determined the zeroes and poles of the system. After a series of parameter estimations, when it was not possible to minimize the error below the set level (Fig. 7), a situation occurred, in which the analyzed signal represented residual vibrations (Fig. 8). When approximating such a signal, we made errors as shown in Fig. 9.

## VI. CONCLUSION

This paper presents error comparison when identification using least squares method is applied. The obtained results confirm that the error we commit by identification directly depends on the number of samples used for model parameters determination.

Fig. 7. Comparison of system and model reaction.

Fig. 8. Comparison of system and model reaction.

Fig. 9. Satisfactory identification of system parameters - identification error.

Another aspect that needs to be noticed is the control signal that is used in identification process. The deviation of model parameters results in the error on system output. It was shown that the input signal should generate adequate excitation of the system, otherwise the error significantly affects the parameter estimation.

**Abstract**—Switching power converters can achieve very high efficiency. However, they do so only for slim subset of operating conditions. Power supplies and loads with highly variable parameters do not operate at peak performance all the time. Energy harvesting and battery powered systems are typical examples. This paper studies the convenience of heterogeneous parallel DC-DC converter as a solution to this problem. The use of multiple diverse converter topologies in parallel could expand range of operating conditions with high efficiency. Such solution poses another issue of balancing workload across all topologies in system with minimal computational power. Efficiency of proposed converter is estimated by modelling converter circuits and running heuristic optimization on these models.

## I. INTRODUCTION

**E**FFICIENCY of DC-DC converters can exceed 90% for specific operating conditions. If power supply is stable and load operates at constant voltage converter design can be easily optimized. For example when powering low-voltage electronics from high-voltage grid. Battery powered devices complicate circuit optimization as voltage of the battery changes in relation to its capacity. Use of energy harvesting presents further complications due to wide range of operating voltage, available power and their variability over time. Maximum power point tracking methods can adapt operating point of the converter to extract the most from the supply. The limit of such adaptation is in the circuit design. Aim of this paper is to study the use of DC-DC converter consisting of multiple parallel lines with variable topologies. High variance of these topologies is important, so each parallel branch reaches peak performance at different operating conditions. This brings another problem, how to divide required output current among available topologies. It is important to note, that the power consumption of the converter itself needs to be minimal, as it is also considered power loss which decreases the overall efficiency of the power management system. Required computation of the balancing can use limited resources of low-power microcontroller or has to be performed elsewhere. To test both methods, we first create mathematical model of power loss of selected topologies, where brute-force algorithm running on computer with high computational power can find optimal operating distribution for given precision. Afterwards we used created models to develop heuristic optimization algorithm, capable of

running on device with limited computational power. Proposed converter can be part of power management system used in wireless sensor nodes, smart appliances or off-grid power systems.[1]

## II. LOSS MODELS OF DC-DC TOPOLOGIES

Performance of heterogeneous parallel converter is evaluated by creating electrotechnical model of loss of individual parallel paths. It is best if convertor topologies forming parallel paths are diverse. Specialization of each path for unique conditions increase overall efficiency of the system. Buck-Boost and Fly-back topologies are first candidates, due to differences by the use of simple inductor versus transformer [2]. Next evaluated is combination of two inductors and a capacitor in what is known as Zeta topology. Loss models are based on equations used by various circuit manufacturers [3] [4] [5] [6] [7] [8]. Flawless mathematical model of circuit loss would be more complex than is necessary for our purpose. Dispersion, degradation and temperature drift of component's properties make perfect model almost impossible. Models are limited to regard following losses: conduction loss on parasitic resistance, transistor gate switching and transistor linear mode. Evaluated operating frequencies are chosen in range from 10kHz to 250kHz, so properties with insignificant impact within this range can be ignored, namely: loss on inductor core, transistor drain-source capacity, parasitic properties of wiring. This will increase loss on capacitor filtering output voltage, but its impact is also ignored as it is shared by all tested converters. Narrow frequency range allows model to consider frequency dependent properties as constants - capacitor impedance, inductance value and parasitic resistance of inductors. Model assumes switching transistors operate synchronously without losses caused by imperfect timing. Due to all mentioned simplifications, created models are suitable for comparative study and not for precision tasks like control algorithm.

Important steps in calculation of loss model are :

- Calculating critical conduction current.
- Determining operating mode (continuous or discontinuous) by comparing critical and required output current.
- Calculating duty cycle for active mode.
- Calculating current flowing through each component.

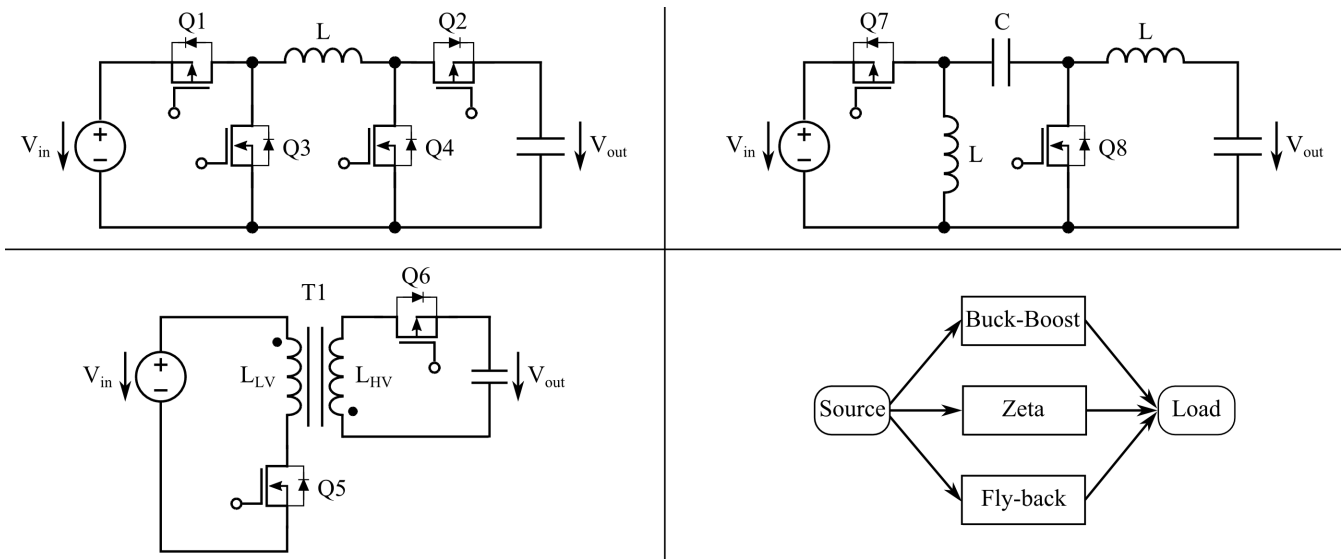

Fig. 1. Schematics of used converter circuits - (top left) four switch buck-boost, (top right) Zeta, (bottom left) Fly-back. Overview of formed mult topology converter is at bottom right.

TABLE I  
LIST OF COMPONENTS USED FOR THE TESTING

Schematic symbol	Component
L	MCSDC0805-270KU
Q3,Q4,Q5,Q8 (N-MOSFET)	SI2302CDS-T1-E3
Q1,Q2,Q6,Q7 (P-MOSFET)	SI2301CDS-TI-GE3
C	AVX 18125C475KAT2A
T1	ratio 1:100 $R_{LV}=0,1\Omega$ $R_{HV}=3,3\Omega$ $L_{LV}=51\mu H$ $L_{HV}=5mH$

Particular order of these steps depends on the form of equations describing the circuit. Other circuits may need extra steps specific to them. Model also requires parasitic values of used components. These were filled with typical values of common real world components listed in Table I. Transformer parameters were measured directly on specified part at fixed frequency 100kHz, due to lack of documentation.

For desired output voltage 3.3V and fixed switching frequency 100kHz, these models form spaces shown in Figure 2. Combinations of these spaces at three different frequencies are in Figure 3. Both these figures show different characteristics of each converter topology. Buck-Boost is the only one that can pass input voltage directly to output. This is reflected by ridge in area where input and output voltages have the same value. Loss of this topology seems to increase the least with increased frequency, which may be caused by use of just one frequency dependant component: inductor. Zeta converter topology is expected to work the best at low frequencies for the same reason. Properties of fly-back converter are heavily dependent on inductance, resistance and ratio of transformer's windings. Space of fly-back converter also contains ridge with highest efficiency, however, its position is tied to switching frequency and is limited by operating voltages and current as well as component values. The ridge represents operation in critical conduction, the border between continuous and discontinuous conduction [9].

Fig. 3. Combined spaces at various frequencies at  $V_{out}=3,3V$ 

### III. OPTIMIZATION METHODS

#### A. Exact methods

In solving combinatorial problems we encounter the issue of how to ensure that the solution is quickly achievable and as accurate as possible. The first option are deterministic methods the steps of which are always repeated in the same order. Such methods, when properly implemented, offer the exact solution.

We used a method described in Algorithm 1 that searches through all solutions. It is a relatively time-consuming method that guarantees to find an optimal solution. At data extensive tasks, however, the growing complexity of computing and time-consumption takes effect. If we need to search through all solutions for only three variables ranging from 1 to 1000, the number of iterations is about  $10^9$ . Addition of another variable will grow the number of iterations exponentially. The use of such a calculation method is purely for the verification purposes. The use in practice would be unsuitable, due to complexity. Example of this kind of method is "brute-force" or "branch and bound".

**Algorithm 1** Exact method for finding optimal solution of system

**Require:**  $freq \neq 0$  and  $n = freq.size()$  and  $precision \neq 0$  and  $BestLoss = Max.Value$

```

1: for  $i = 0$  to  $n$  do
2:    $I_o \leftarrow I_{out}/precision$ 
3:    $freq \leftarrow freq.get(i)$ 
4:   for  $j = 0$  to  $precision - 1$  do
5:     for  $k = 0$  to  $precision - j - 1$  do
6:        $lossB \leftarrow ObjB(I_o * j, freq)$ ;
7:        $lossF \leftarrow ObjF(I_o * k, freq)$ ;
8:        $lossZ \leftarrow ObjZ(I_o * (precision - j - k), freq)$ ;
9:        $lossOfSystem \leftarrow lossB + lossF + lossZ$ 
10:      if  $lossOfSystem < BestLoss$  then
11:         $BestLoss \leftarrow lossOfSystem$ ;
12:      end if
13:    end for
14:  end for
15: end for

```

#### B. Heuristic methods

Since deterministic methods do not provide a suitable solution within the required time we need to implement methods that would provide us with such solution. One type of such methods are heuristic methods. These methods are based on experience and often provide a suitable solution in a relatively short amount of time, respectively a small number of iterations. These methods do not guarantee us to find optimal solutions.

Heuristic methods are frequently used for initial finding solutions to complicated methods, for example: metaheuristic. To find the base solution we used Monte Carlo method which in a very short time will provide us with a feasible solution for the next application [10]. The next step in finding a suitable solution for system was applying heuristic exchange. Since, in our case was no threat to get stuck in a local extreme, we could simplify the method. We allowed all valid transitions between solutions as well as the transition towards a worse value of objective function. However, we only impose those

**Algorithm 2** Heuristic method for finding feasible solution of system

**Require:**  $freq \neq 0$  and  $n = freq.size()$  and  $iterations \neq 0$  and  $BestLoss = Max.Integer$

```

1:  $BestLoss \leftarrow MonteCarlo$ 
2: for  $i = 0$  to  $iteration$  do
3:    $par \leftarrow random.Double$ 
4:   if  $par > 0.5$  then
5:      $parf \leftarrow random.Int$ 
6:      $freq \leftarrow freq.get(parf)$ 
7:   else
8:      $arrayI_{out} \leftarrow randomUniformDistriboution()$ 
9:   end if
10:   $lossB \leftarrow ObjFunctionB(arrayI[0], freq)$ 
11:   $lossF \leftarrow ObjFunctionF(arrayI[1], freq)$ 
12:   $lossZ \leftarrow ObjFunctionZ(arrayI[2], freq)$ 
13:   $lossOfSystem \leftarrow lossB + lossF + lossZ$ 
14:  if  $lossOfSystem < BestLoss$  then
15:     $BestLoss \leftarrow lossOfSystem$ ;
16:  end if
17: end for

```

values into memory, for which the value of objective function gives a better solution. We have neglected all other solutions.

The method does not use the shutdown time, as is customary. Instead, it uses the number of iterations, which is introduced as a parameter and selected at the beginning. Authorized operation of this method is to exchange one for one. Since we are using global scanning, it means that we always change just one randomly selected parameter.

Each algorithm that is not exact has a certain error rate depending on factors such as time, iteration number of inputs, and others. In this case, accuracy will result in the number of iterations. During our tests this method will be analyzed on various ranges of iterations starting on  $10^4$  and ending with  $10^6$  iterations. This is important for showing differences in results because the number of iterations greatly affects their accuracy.

Other algorithms such as genetic algorithm or taboo search algorithm show different ways how to obtain good solution. Genetic algorithm uses population of solutions and mixing them with steps like crossover and mutation. On other hand taboo search uses temporary prohibition after choosing different solutions to prevent from looping. Both approaches have their strong sides and their weak sides.

Not every heuristic method is suitable for solving a specific problem. Heuristic methods are built for specific problems even though the principles of the solution can be repeated. In contrast, metaheuristic methods are considered to be generally applicable methods of solution. It is recommended to use metaheuristic methods to solve problems where there is a risk of being deadlocked in local maximum or minimum [11].

Fig. 4. Dependence of the total loss on the number of iterations.

TABLE II  
NUMERICAL VALUES OF AVERAGE FUNCTION FROM FIGURE 4

Iterations count	500	1000	2000	5000	10000	20000	50000	100000	200000	500000	1000000
Arithmetic mean [W]	0.81	0.7307	0.6956	0.64	0.6092	0.604	0.5814	0.5746	0.5693	0.565	0.5646

#### IV. SIMULATION

Performance of heterogeneous parallel converter is compared on scenarios where load requires constant supply of 2 A at 3.3V from fully charged Li-po battery at 4.2V or from Ni-MH battery at 1.2V. These values could reflect needs of wireless module inside battery powered sensor node. Simulation compares heterogeneous parallel converter with equal distribution to calculated optimal distribution. It is also compared to its homogeneous counterpart and non-parallel designs. Calculated values of the two scenarios at the most convenient frequencies are in Table III. These results show that the proposed heterogeneous parallel converter doesn't offer the lowest loss of them all, but rather low loss at wider operating conditions. This is illustrated better at the spaces created by the models. Due to all simplifications in the circuit model, absolute loss of real device would be higher. However, even distorted models allow to find best range for component values, which influence relative position of modeled spaces. Finding these values without the models would be impractical.

Optimization method used for load balancing is evaluated in Figure 4, which shows results of described heuristic method after specified range of number of iterations. To compensate for non-deterministic nature of heuristic method, every case is repeated 100 times. Optimal solution of the problem is calculated by exact "brute-force" method. Results of this simulation shows, that the number of iterations doesn't improve just average value of the solution, but also decreases dispersion of the results. Further improvements to optimization method can also decrease dispersion with minimal increase of computational requirements. One way of achieving this is to use pre-processed model data from other more powerful computer.

TABLE III  
LOSS OF VARIOUS SIMULATED CONVERTERS

System converters	f [kHz]	$V_{in}$ [V]	System loss [W]
Buck-Boost, Fly-back, Zeta ( Optimal distribution )	53	4.2	0.4457
	11	1.2	2.6731
Buck-Boost, Fly-back, Zeta ( Equal distribution )	73	4.2	0.5147
	10	1.2	2.9626
Buck-Boost,Buck-Boost, Buck-Boost	10	4.2	0.4901
	10	1.2	4.069
Fly-back,Fly-back, Fly-back	85	4.2	0.5778
	10	1.2	2.4492
Zeta,Zeta, Zeta	10	4.2	0.4161
	10	1.2	3.1504
Buck-Boost	10	4.2	1.6267
	10	1.2	12.1465
Fly-back	26	4.2	0.8348
	10	1.2	7.2589
Zeta	10	4.2	0.8949
	10	1.2	8.0541

## V. CONCLUSION

Simplified circuit models suggest heterogeneous parallel DC-DC converter has potential to be more efficient than parallel converter with homogenous power paths. While homogeneous variant can achieve lower loss at specific conditions, heterogeneous approach achieves low loss at wider operating conditions. Time characteristic of the source and load have significant impact on which of these approaches is more convenient. Load balancing of heterogeneous paths can be done by devices with low computational power at cost of precision. Use of described heuristic method leads to acceptable error within reasonable number of iterations. Optimization methods can be further improved by utilising pre-processed data from computer model.

# Information Technology for Management, Business & Society

**I**T4MBS is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to the disciplines of information technology and information systems. The IT4BMS area emphasizes the issues relevant to information technology and necessary for practical, everyday needs of business, other organizations and society at large. This area takes a sociotechnical view on information systems and relates also to ethical, social and political issues raised by information systems. Events that

constitute IT4BMS are:

- AITM'17—15<sup>th</sup> Conference on Advanced Information Technologies for Management
- ISM'17 - 12<sup>th</sup> Conference on Information Systems Management
- IT4L'17—5<sup>th</sup> Workshop on Information Technologies for Logistics
- KAM'17—23<sup>rd</sup> Conference on Knowledge Acquisition and Management

# 15<sup>th</sup> Conference on Advanced Information Technologies for Management

**W**E are pleased to invite you to participate in the 14<sup>th</sup> edition of Conference on “Advanced Information Technologies for Management AITM’17”. The main purpose of the conference is to provide a forum for researchers and practitioners to present and discuss the current issues of IT in business applications. There will be also the opportunity to demonstrate by the software houses and firms their solutions as well as achievements in management information systems.

## TOPICS

- Concepts and methods of business informatics
- Business Process Management and Management Systems (BPM and BPMS)
- Management Information Systems (MIS)
- Enterprise information systems (ERP, CRM, SCM, etc.)
- Business Intelligence methods and tools
- Strategies and methodologies of IT implementation
- IT projects & IT projects management
- IT governance, efficiency and effectiveness
- Decision Support Systems and data mining
- Intelligence and mobile IT
- Cloud computing, SOA, Web services
- Agent-based systems
- Business-oriented ontologies, topic maps
- Knowledge-based and intelligent systems in management

# Deep Learning for Financial Time Series Forecasting in A-Trader System

Jerzy Korczak, Marcin Hernes

Wrocław University of Economics, ul. Komandorska 118/120, 53-345 Wrocław, Poland

e-mail: {jerzy.korczak, marcin.hernes}@ue.wroc.pl

**Abstract**—The paper presents aspects related to developing methods for financial time series forecasting using deep learning in relation to multi-agent stock trading system, called A-Trader. On the basis of this model, an investment strategies in A-Trader system can be build. The first part of the paper briefly discusses a problem of financial time series on FOREX market. Classical neural networks and deep learning models are outlined, their performances are analyzed. The final part presents deployment and evaluation of a deep learning model implemented using H2O library as an agent of A-Trader system.

## I. INTRODUCTION

OWING to fluctuations of return rates and risk accompanying investment decisions, forecasting financial time series constitutes a very difficult problem. Currently, most trading systems are based on one or a limited number of algorithms. The proposed prediction models use, for example, genetic algorithms [1], fundamental and technical analysis [2,3,4,5], neural networks and neuro-fuzzy computing [6], behavioral techniques [7]. There are also many multi-agent approach based solutions [8,9,10,11,12]. The trend is that in most cases multiple software agents that use different methods and techniques help provide trading advice.

The problem remains unresolved. Complexity of trading problems requires the use of increasingly more sophisticated models oriented towards non-linearity of financial time series. One of these models is based on deep learning [13,14].

According to [15], deep learning algorithms have already demonstrated their ability:

- to learn complex, highly varying functions, with a number of variations much exceeding the number of training examples,
- to learn with little human input low-level, intermediate and high level abstractions of input data,
- for being computationally scalable, with linear complexity,
- to learn from predominantly unlabeled data and work in a semi-supervised setting, where examples might have incorrect labels.

In stock trading, L. Takeuchi et al. [16] carried out a study similar to the one presented in our paper using an auto-encoder and various types of networks on data extracted from S&P 500, Nasdaq Composite and AMEX lists. G. Hinton et al. [17] have used deep learning methods to build deep belief networks (DBN) based stock decision support system, with training and test data from S&P500. They found out that their system outperforms the buy-and-hold strategy. Other approaches to deep learning using regression models on chaotic time series, showing good results, are presented in [18].

Our platform, called A-Trader [19,20,21], allows for implementation of various algorithms or trading decision support methods. Recently, A-Trader is aimed at supporting trading decisions on FOREX market (Foreign Exchange Market). Currencies are traded in pairs, for example USD/PLN, EUR/GBP on FOREX. In general, a trader on FOREX can open/close long/short positions. A long position relies on "*buying low and selling high*" in order to achieve a profit. On the other hand, a short position relies on "*buying high and selling low*". On FOREX, as one currency in a pair rises in value, other drops, and vice versa [19]. A-Trader mainly supports High Frequency Trading (HFT) [20], putting strong emphasis on price formation processes, short-term positions, fast computing, and efficient and robust indicators [21].

An agents' knowledge is represented by three-valued logic (where 1 denotes open long/ close short position, -1 denotes open short/close long position and 0 denotes "*do nothing*") in A-Trader system. Also fuzzy logic is used for agents' knowledge representation, where confidence of decisions is in the range [-1..1], with "-1" level denoting "strong sell" decision, "0" level denoting "*strong leave unchanged*" decision and "1" level denoting "*strong buy*" decision. The positions can be open/close with different levels of confidence of decision. For example, long position can be open, when the level of confidence is 0.6 or short position can be open, when the level of probability is 0.7. Therefore, the timeframe for the opening/closing position is wider than in the case of three-valued logic.

A-Trader architecture and description of different groups of agents have already been detailed [19]. In order to support trading decisions, agents apply technical,

fundamental and behavioral analysis as well as different methods for knowledge integration (e.g. consensus [22,23]).

The aim of this paper is to present an application of deep learning methods for financial time series forecasting in A-Trader system environment.

The first part of the paper briefly outlines a problem of financial time series on FOREX market. Classical neural networks and deep learning models are analyzed in the next part of the paper. The final part presents deployment and performance evaluation of implemented deep learning model compared with trading strategies already implemented in the system.

## II. FINANCIAL TIME SERIES ON FOREX MARKET

Trading on FOREX relies on forecasting of opening or closing long or short positions. A long position is a situation in which one purchases a currency pair at a certain price hoping to sell it later at a higher price. This is also referred to as the notion of "*buy low, sell high*" in other trading markets. If a trader expects a currency pair to drop, he will sell it hoping to buy it back later at a lower price. This is understood as a short position, which is the opposite of a long position. A-Trader receives tick data grouped into minute aggregates (M1, M5, M15, M30), hourly aggregates (H1, H4), daily aggregates (D1), weekly aggregates (W1) and monthly aggregates (MN1).

High frequency traders are constantly taking advantage of very small fluctuations in quotation with a high rate of recurrence to arrive at significant profit margins. As many HFT experts have pointed out, traders seek profits from the market's liquidity imbalances and short-term pricing inefficiencies. Hence, minimization of time from the access to quote information, through the entry of an order right to its execution, is vital. On the whole, to be of any help to traders, systems must as quickly as possible provide advice as to the best move to be made: buy, sell or do nothing.

Fig 1 presents an example of visualization of open/close long/short positions. The green marks denote a long position, red ones denote a short position. The red dots denote open short/close long position, green ones denote open long/close short position. There are positions opened too early (example marked by yellow oval) or too late (example marked by brown oval). There also losses-generating positions (example marked by blue rectangle). Therefore, there is still a strong need to look for more efficient prediction methods or models, such as neural nets, that would generate more profitable decisions..

## III. CLASSICAL NEURAL NETWORK MODELS

Classical neural networks will be examined in order to compare and demonstrate prediction quality of deep learning model. Artificial neural networks with backpropagation learning algorithm have been widely used in solving various prediction problems and have already shown great potential for discovering non-linear relationships in time-series [e.g. 24,25,26]. Until recently, the depth of a practical neural network was mostly limited to one or two hidden layers.

In our previous paper, Multi-Layer Perceptron (MLP) model was employed to build agents of fundamental analysis. A diagram of agent operation is schematically shown in Fig 2. MLP uses sigmoid activation function and back-propagation learning algorithm. Input vector contained long term indicators and the last sequences of S&P500, FTSE 100, oil and gold tics. Long and short-term fundamental indicators were taken into account. Prediction of GBP/PLN pair return rates, shifted by  $T_n$  units in time (in our case study M5 period and USD/GBP), constituted the output. Prediction is performed as  $G(t_n+t_0)$ .

To remind the definition of an agent, below the trading agent based on the fundamental analysis is specified:

```
Input:  $q_{FTSE100} = \langle q_{ftse_1}, q_{ftse_2}, \dots, q_{ftse_n} \rangle$ 
// FTSE100 quotations,
```

Fig. 1. Example of long/short position visualization in A-Trader.

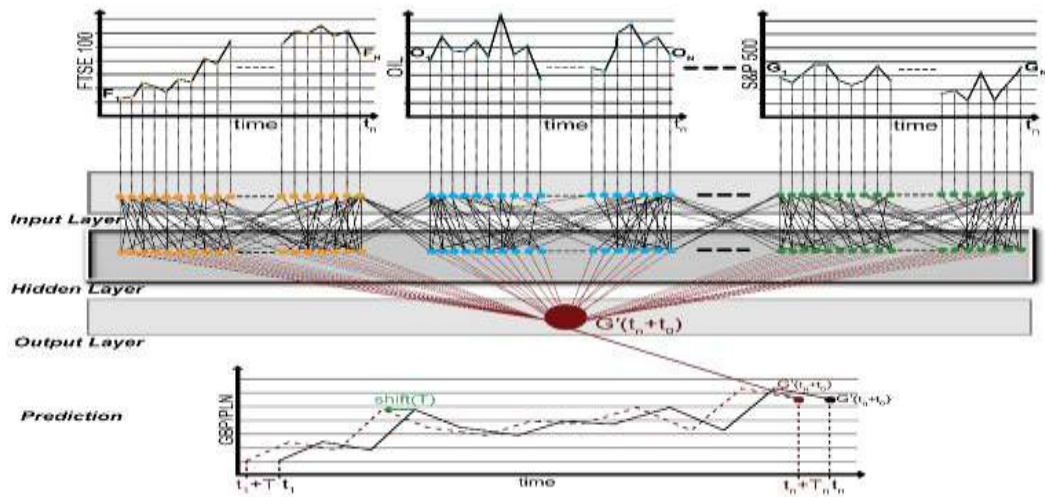

Fig. 2. MLP agent  
Source: [21].

```

q_S&P500=<q_s&p1, q_s&p2, .... q_s&pM>
// S&P500 quotations
q_GOLD=<q_gold1, q_gold2, .... q_goldM>
// GOLD quotations
q_OIL=<q_oil1, q_oil2, .... q_oilM>
// OIL quotations
i_Inflation // M/M inflation change
i_NCI // Net Capital Inflows change
i_COE // Change of employment M/M
i_IP // Industrial Production M/M change
thresholdopen //threshold level for open
//long/close short //position
thresholdclose //threshold level for close
//long/open short //position
Output: Fuzzy logic recommendation D
// (range [-1..1]).
BEGIN
  if
    CheckPerformanceLevel()
    //If financial indicators are not acceptable
    //see Tab.1
  then
    BeginLearningProcess();
    p_USD/GBPM+3 := Multi-layerPerceptron
      (q_FTSE100, q_S&P500, q_GOLD,
       q_OIL, i_Inflation, i_NCI, i_COE, i_IP);
    //Prediction of USD/GBP value change
    if
      p_USD/GBPM+3 > thresholdopen
    then
      D:= heuristic_open(p_USD/GBPM+3);
    else if
      p_USD/GBPM+3 < thresholdclose
    then
      D:= heuristic_close(p_USD/GBPM+3);
    otherwise D:= heuristic_do_nothing
END

```

From a financial point of view, fundamental analysis agent is founded on money flow interpretation. For instance, if S&P 500 is falling and FTSE 100 is rising, one can expect investors to swap their S&P shares for USD, then swap USD

for GBP, and finally buy FTSE 100 shares. Or if they bought GBP for USD, the value of GBP to USD would rise.

While performing experiments [21] using MLP network it was found out that the values of input vectors of most of fundamental analysis ratios were relatively stable. The result was that in relation to high short-time fluctuation of currencies learning process was not always convergent and the outcomes were financially very weak. These were the main reasons to look for more relevant data and more complex forecasting models.

#### IV. DESIGN OF DEEP LEARNING MODELS

Deep Learning is a set of machine learning algorithms that attempt to model high-level abstractions in data by using architectures composed of multiple non-linear transformations [27, 28]. Incidentally, MLPs with just one hidden layer are not deep because they have no feature hierarchy and they operate on original input space. Various deep learning architecture, like deep neural networks, convolutional deep neural networks, deep belief networks, recurrent neural networks are used in financial forecasting.

The network architectures used in this research are based on Convolutional Neural Networks (CNN). CNNs are variations of MLP designed to use minimal amounts of preprocessing [29]. CNNs constitute a type of feed-forward artificial neural networks in which connectivity pattern between its neurons mimics animal visual cortex connection structure. Individual cortical neurons respond to stimuli in a restricted region of space known as receptive field. The receptive fields of different neurons partially overlap such that they tile the visual field. Response of an individual neuron to stimuli within its receptive field can be mathematically approximated by a convolution operation.

Standard MLP and Deep Learning Model differ both in architecture and in the training procedure. Prior to deep learning, MLPs were typically initialized using random numbers. MLPs currently in use apply the gradient of the network's parameters related to the network's error in order to affine parameters so as to improve prediction in each

training iteration. In back propagation, it is necessary to multiply each layer's parameters and gradients together across all the layers in order to evaluate this gradient. This involves intensive computation, especially for networks with more than two layers. Often, the gradient converges to machine-zero value and training stops or explodes into a huge value; ultimately training process becomes intractable [30,31].

Deep learning offers a new learning algorithm: to find the initial parameters for deep CNN, it uses a series of single layer networks - which do not suffer from vanishing or exploding gradients. The idea of DL is illustrated in the example shown on fig. 3 where inputs are marked violet, hidden layers are marked green and outputs are marked blue. This process makes it possible to create progressively initial features of CNN input data. It can be performed in the following way [32]:

1. An auto-encoder (a simple 3-layers neural network where output units are directly connected to the neurons of the next layer – top right column on Fig. 3) is used to find initial parameters for the first layer of a deep CNN (left column on Fig 3).
2. In the same way, a single layer auto-encoder network is used to find initial parameters for the second layer of a deep CNN, and likewise for the next layers.
3. Finally, a softmax classifier (logistic regression) is used to find initial parameters for the output layer of a deep CNN.

Deep Learning is able to efficiently discover and extract new features that can be tuned with more data but there are not easy to interpret. Deep learning models are highly flexible and configurable, however, its theory is still not well understood. For example, the problem to define a number of neurons and number of layers essentially remains unresolved; nevertheless, it is a known fact that more layers means non-linearity, while more neurons translates to more features.

#### V. DEPLOYMENT AND EVALUATION OF DL MODEL

Implementation is done in H<sub>2</sub>O. H<sub>2</sub>O is an open-source distributed in-memory data analysis and modeling platform [33]. It is interactive, scalable, extensible solution consist of several machine learning models (including Deep Learning Model), oriented to exploration of Big Data. The advantage of H<sub>2</sub>O is that it integrates all programming environment and analytical platforms, e.g. Java, Python, JSON, R, Scala commonly in use [34]. In our project H<sub>2</sub>O has been integrated with A-Trader. Detailed architecture of this system has been presented in [19,20,21]. In this paper, we have outlined only those components closely related to Deep Learning Model (Fig 4).

Notification Agent of A-Trader receives quotations, distributes messages and data to various agents, and controls system operation. The main objective of Supervisor Agent is to generate profit-generating, investment risk-minimizing trading advice. A Supervisor, by using different trading strategies, coordinates computing on the basis of decisions

generated by other agents, and gives the trader the final decision. Conflicts are resolved and integration of agents' pieces of advice is performed by the Supervisor, after factoring in the decisions of all the other agents, and evaluating their performance (on the basis of performance ratios described in the further part of this paper). The Supervisor determines the agents of whom the advice is to be taken into consideration when making an investment decision and those, the advice of whom is to be ignored. The DeepLearningH2O Agent runs in two modes (controlled by Supervisor):

Fig.3. Deep learning process  
Source: [32].

1. Learning mode (continuous dots) – in this mode following steps are performed:

- Import time series to H<sub>2</sub>O platform (because H<sub>2</sub>O constitutes A-Trader's external module, data are imported indirectly from A-Trader database, it does not use the data notified by Notification Agent),
  - Specification of Deep Learning (DL) model,
  - Parametrization of DL model – (such parameters as number of hidden layers, number of training epochs, stopping rounds, stopping metrics, etc),
  - Model building – on the basis of structure of imported data and determined parameters,
  - Learning-Testing –built model is trained on the basis of training time series and testing on the basis of validation dataset.
2. Forecasting mode (dashed dot) – the time series are continuously imported from A-Trader database and trained model is used for forecasting future rates of returns.

Other agents of A-Trader support the process, among other:

- Basic Agents - pre-process time series and compute the basic indicators; agents with own knowledge base can learn and change their parameters as well as their internal states,
- Intelligent Agents include all the agents based on artificial intelligence models (e.g. genetic algorithms, neural networks – including MLP, rule-based systems, etc.), agents analyzing text messages, agents observing market behavior. A decision transferred to the Supervisor Agent

constitutes the output of Basic Agents and Intelligent Agents.

Next part of the paper details the Deep Learning Model used in DeepLearningH2O Agent.

Formally, the model can be defined as follows:

$$Y_{t+1}^i = DLM(x^i, x^p \dots x^q), \quad (1)$$

where:

$x^i$  is an input vector of rates of return related to main quotation.

$x^p, \dots, x^q$  are inputs containing rates of return related to quotations correlated with main quotation (e.g., main quotation is USD/GBP and related quotations are oil quotes and gold quotes).

Long-return rates- are used in this model, they are calculated as follows:

$$r^i(t) = \log\left(\frac{S_t^i}{S_{t-1}^i}\right) \quad (2)$$

where  $S_t^i$  is a price of quotation  $i$  at time  $t$ .

Long-returns rates are normalized and projected by H<sub>2</sub>O in the range from -1 to 1.

Formula of input vector related to main quotation:

$$x^i = \{r^i(t), r^i(t-1), \dots, r^i(t-k)\} \quad (3)$$

where  $k$  is a number of past quotations used as inputs – in this experiment we assume  $k=30$ .

$Y_{t+1}^i$  assumes a value in the range  $[-1, 1]$  (generated as fuzzy logic output) and it predicts a log-rates-of-return at time  $t+1$  (normalized value).

Training set consists of input vectors  $x^i$  and inputs

Fig. 4 Schema of processes.  
Source: Own work

$x^p \dots x^q$  at time  $t$ ,  $t - 1$ , etc. (in this experiment have been used about 1400 inputs quotations) and output at time  $t + 1$  (the learning process is performed on the basis of historical time series, hence log-rate-of-return at time  $t + 1$  is known).

On the basis of DeepLearningH2O Agent's output, the Supervisor Agent is able to use different strategies to generate opening/closing positions, for example by using genetic algorithm or consensus strategy. Supervisor takes into consideration thresholds for open/close positions determined by genetic algorithm. Supervisor also determines the mode of DeepLearningH2O Agent operation. Learning mode is started if performance (performance ratios are presented in further part of this paper) of this agent is low. If performance is high, then only forecasting mode is run using previously generated model.

The agent's performance analysis was carried out for data within the M5 period of quotations from FOREX market. For the purpose of this analysis, test was performed in which the following assumptions were made:

1. USD/GBP quotes were selected from randomly chosen periods (each - 1440 quotations), notably:
  - 15-03-2016, 0:00 am to 15-03-2016, 23:59 pm,
  - 16-03-2016, 0:00 am to 16-03-2016, 23:59 pm,
  - 22-03-2016, 0:00 am to 22-03-2016, 23:59 pm.
2. At the verification, the trading signals (for open long/close short position equals 1, close long/open short position equals -1) were generated by the Supervisor on the basis of DeepLearningH2O Agent and MLP agent.
3. It was assumed that decisions' probability levels for open/close position are determined by the genetic algorithm (on the basis of earlier periods).
4. It was assumed that pips (a pip is equivalent to the final number in a currency pair's price) constituted the unit of performance of analysis ratios (absolute ratios).
5. The transaction costs were directly proportional to the number of transactions.
6. The capital management - it was assumed that in each transaction the investor commits 100% of the capital held

at the leverage 1:1. The investor may define another capital management strategy.

7. The results obtained by tested agents were compared with the results of *Buy-and-Hold* benchmark (a trader buys a currency at the beginning and sells a currency at the end of a given period).

The DeepLearningH2O Agent was run in stand-alone computer with 4 processors Intel Xeon E52640 v3 2.6GHz 8C/16T, and 32GB memory with the following parameters:

- input: 30 return rates USD/GBP, oil and gold quotes, (sliding window),
- hidden layers [100,100,100,100] trained for 200 epochs,
- output 1 predicted,
- overwrite\_with\_best\_model = true,
- stopping\_rounds = 5,
- stopping\_metrics = "MSE",
- stopping\_tolerance = 5e-2,
- score\_validation\_sampling = "Stratified",
- score\_duty\_cycle=0.1,
- to reduce overfitting we have specified RectifierWithDropout, and the default values for Hidden\_dropout\_ratio = 0.15.

The final deep learning contained 4 hidden layers of 78, 64, 87, and 63 neurons respectively. The learning time of model is about 1 minute. The computing time of forecasting was approximately 0.14 sec.

Table 1 presents the results obtained in given particular periods. In general, it should be noted that not all decisions generated by agents were profitable. However, in A-Trader, performance evaluation does not compute rate of return alone, there are other ratios of significance, among them risk involved in trading (these measures have been described in detail in [20]).

The evaluation function provides the fast choice of the best agent. It may be noted that the values of efficiency

TABLE I.  
PERFORMANCE ANALYSIS RESULTS

Ratio	DeepLearningH2O			MLP			B & H		
	Period 1	Period 2	Period 3	Period 1	Period 2	Period 3	Period 1	Period 2	Period 3
Rate of return [pips]	27	127	24	9	-66	28	-143	89	-160
The number of transactions	11	14	9	4	7	5	1	1	1
Gross profit [pips]	21	110	43	11	61	43	0	89	0
Gross loss [pips]	14	63	38	17	37	28	-143	0	-160
The number of profitable transactions	7	9	6	3	3	3	0	1	0
The number of profitable consecutive transactions	3	3	2	2	2	2	0	1	0
The number of unprofitable consecutive transactions	2	2	1	1	3	2	1	0	1
Sharpe ratio	0.83	1.64	1.17	0.55	1.8	0.78	0	0	0
The average coefficient of volatility [%]	1.12	0.74	1.92	1.66	0.86	1.94	0	0	0
The average rate of return per transaction	2.45	9.07	2.67	2.25	-9,43	5,6	-143	89	-160
Value of evaluation function (y)	<b>0.45</b>	<b>0.51</b>	<b>0.42</b>	<b>0.38</b>	<b>0.17</b>	<b>0.53</b>	<b>0.06</b>	<b>0.32</b>	<b>0,03</b>

ratios of particular agents differ in each period. Values of this function oscillate in the range [0.03, 0.53]. Therefore, use of this function makes it possible to reduce divergence of the values of the ratios.

The results of the experiment allow us to state that the ranking of agents' evaluation was different for different periods. In the first and second period, the DeepLearningH2O was the best agent, in the first period MLP Agent was ranked higher, but was ranked lower than B&H benchmark in the second period. In the third period MLP Agent was ranked the highest, with DeepLearningH2O being ranked higher than B&H.

The highest value of evaluation function of DeepLearningH2O Agent (in first and second period) results from the highest *Average Rate of Return per Transaction* and low values of risk measures. The B&H benchmark was ranked lowest in all periods, it generated losses in the first and third periods. It should be noted that an upward trend was observed in the second period, hence B&H's *Rate of Return* was positive. The first and the third periods show a downward trend, implying negative *Rate of Return* for B&H. Taking all the periods into consideration, it may be stated that DeepLearningH2O Agent was ranked highest the most time. DeepLearningH2O Agent always was characterized by greater number of transactions than MLP Agent. DeepLearningH2O is characterized by higher *Rate of Return* than MLP Agent. Both, DeepLearningH2O Agent and MLP Agent are characterized by low level of risk.

## VI. CONCLUSION

The deep learning model implemented as agent in A-Trader is used for supporting trading decision on FOREX market. Deep Learning proved to be a powerful, efficient and robust financial time series forecasting model. This model helps achieve better performance than MLP model. Experiments have shown that the error rate of time series forecasting has dropped significantly with CNN compared to other models. An important advantage of deep learning applications that makes them attractive to stock trading practitioners and researchers is the wide availability of high quality open source software, libraries and computation facilities.

Learning mode constitutes the main disadvantage of using Deep Learning Model, it is a time consuming process with a negative effect when near real time trading is applied [31]. It can be reduced, for example, by using a distributed cloud computing architecture. It was also interesting to observe the ability of deep learning model not only to dynamically adapt to network architecture but also to discover unknown features in raw financial time series.

The further research works may be related, among others, to optimization deep learning model by tuning values of parameters, and evaluating its performance. Additionally, models with different inputs vector structure could be developed, e.g. by using another number of log-rates-of-return or using weighted inputs.

# Implementing ERP Systems in Higher Education Institutes Critical Success Factors Revisited

Christian Leyh; Anne Gebhardt; Philipp Berton

Technische Universität Dresden; Chair of Information Systems, esp. IS in Manufacturing and Commerce  
Helmholtzstr. 10, 01069 Dresden, Germany  
Email: Christian.Leyh@tu-dresden.de

**Abstract**—The aim of our study is to investigate ERP project critical success factors (CSFs) with a focus on higher education institutes (HEIs). We conducted a systematic literature review to identify specific CSFs affecting HEIs' project outcome. Building on these results, we led several interviews within selected German HEIs. Overall, there is little literature dealing with the HEIs' CSFs, but nearly all factors found in the literature were also mentioned by the interviewees. However for HEIs, factors like ERP system tests or ERP system configuration are even more important than Top management support or Project management that are the most important CSFs in general studies. Our study shows that in spite of the maturity of the field, revisiting CSF research for specific types of organizations/institutions is still worthwhile.

## I. MOTIVATION AND BACKGROUND

NOWADAYS, companies need to be able to efficiently and effectively react to rising globalization as well as changing markets and economic conditions. However, public bureaucracy and especially higher education institutes (HEIs) such as universities and universities of applied sciences are facing similar challenges as private enterprises. They not only have to respond to far reaching changes in government and society but also have to compete nationally and internationally. Challenges include declining financial support from state-level governments, unpredictable fluctuation of student numbers, globalization, and global competition among universities as well as increasing competition on the national level for students, scientists, and third-party funds. Therefore, as a result of these changing conditions, universities need the highest possible efficiency and effectiveness in their administrative processes as stated by several researchers (e.g., [1]–[6]).

Given these numerous and varied challenges, the task is to find organizationally and technologically suitable solutions to these requirements. In order to create effective and efficient management and administrative processes and to bundle resources and databases, universities (mostly large HEIs) have started to implement integrated application systems (e.g. ERP systems) beginning in the mid-1990s, and especially during the 2000s. Attention is given to similar concepts that have been effective in integrated information processing in the corporate world [3], [7]. Several benefits

result from the implementation of ERP systems for universities [4], [8]:

- improved information supply and flow for planning and controlling processes of the university;
- improved service for faculties, students, and staff;
- lower business risks;
- reduced expenditures through increased process efficiency.

The implementation of integrated application systems such as ERP systems is a complex and time-consuming project during which organizations face both great opportunities and enormous risks. Furthermore, these implementations often require significant organizational changes. Implementation at universities represents a doubly difficult task as these systems influence both the academic and administrative fields. Here, approaches that have proven successful during the last decades for the implementation of application systems in private companies cannot be transferred equally to projects in HEIs [2]. This must be taken into account when implementing ERP systems at HEIs. In addition, vendors have less experience with the implementation of application systems in universities than in enterprises. To take advantage of the potential opportunities rather than get caught by the risks of these implementation projects, it is essential to focus on those factors that support a successful implementation of an information system. By being aware of these factors, an organization (private enterprise or HEI) can positively influence the success of the implementation project and effectively minimize the project's risks [9]. Recalling these so-called critical success factors (CSFs) is of high importance whenever a new system is to be adopted and implemented or a running system needs to be upgraded or replaced.

In recent years, several studies have been published in which specific information system implementation projects at selected universities are considered and analyzed (e.g., [4], [6], [7], [8]). However, none of these studies provide insight into the CSFs of those implementation projects at universities. The existing ERP system success factor research (e.g., [10]–[14]) has focused mostly on the selection and implementation of ERP systems in private enterprises. Less or even no attention has been paid to the implementation projects in HEIs.

In our opinion CSFs are useful and a fruitful path to increase understanding of the complex organization-IT

relationship. Therefore, it is worthwhile to continue research in the area. For example, it is valuable to revisit old frameworks to check their validity and also their adoption by practice. Moreover, the use of ERP systems in “new types” of organizations, such as HEIs, motivates our research. Identifying and recalling, as well as considering the CSFs for ERP projects at HEIs can still be seen as an important issue.

Therefore, the central objective of our research project was and still is the detailed investigation of ERP implementation project CSFs for HEIs. To achieve this goal, we set up a study with a specific focus on the implementation of ERP systems in HEIs’ administrations. Overall, our study was driven by the following research questions:

- **Q1:** *What are the critical success factors of ERP system implementation projects in HEIs?*
- **Q2:** *What similarities and differences exist between critical success factors for ERP implementation projects in HEIs and private enterprises?*

To answer those questions, as a first step in our study, we conducted a systematic literature review in order to detect already identified CSFs for HEI ERP implementations. On the basis of the CSFs identified, we conducted multiple interviews within German HEIs to obtain insights into the CSFs for their ERP system implementation projects. We focused on German HEIs in this step as an initial starting point for our investigation due to our cultural background.

Selected results of this first step will be presented within this paper. Therefore, the paper is structured as follows. The following section deals with the results of our literature review. Next, our data collection methodology is described and the results of the interview study are presented. Finally, the paper concludes with a summary of the results and discusses the limitations of our study.

## II. LITERATURE REVIEW – CRITICAL SUCCESS FACTORS FOR HEI ERP IMPLEMENTATIONS

### A. Procedure of the Literature Review

A critical success factor for an ERP project is defined according to [13] as a reference to any condition or element that is seen as necessary in order for the ERP implementation to be successful. However, not every CSF has the same impact on the success of every project. Therefore, we are also referring to the definition of [11] who see CSFs as “a number of factors that may affect the ERP implementation process and the probability of conversion success.”

With regard to our research questions, we conducted a literature review by systematically reviewing articles in five different databases, as well as papers drawn from several international conference proceedings. The literature review was performed in several steps, similar to the approaches suggested by [15], [16]. More specifically, we had already conducted several literature reviews with a focus on the CSFs of ERP implementations at private enterprises (e.g., [14], [17]) and thereby, we have adapted our review approach according to the experience we gained during those reviews.

**Step 1:** The first step was to define the sources for the literature review. Therefore, five databases (Academic Search Complete, Business Source Complete, Science Direct, SpringerLink, and WISO) and conference proceedings (AMCIS, ECIS, HICSS, ICIS, and Wirtschaftsinformatik conference) were identified.

**Step 2:** In this step, we had to define the search terms for the database-driven review. Keywords selected for this search were mostly derived and adapted from the keywords supplied and used during our previous CSF reviews (e.g., [14], [17]). Example search terms that we used are listed in Table I. Since the WISO database also includes German papers, we additionally used the German translation of the search terms. For the conference papers, only inappropriate search fields were provided. Hence, we decided to manually review the abstracts and titles of the papers in this step.

TABLE I.  
SEARCH FIELDS AND SEARCH TERMS

Database + search fields	Examples of search terms / keywords
<b>Academics Search Complete:</b> “TI Title” or “AB Abstract or Author Supplied Abstract”	ERP + university + success* ERP + university + failure ERP + university + crit*
<b>Business Source Complete:</b> “TI Title” or “AB Abstract or Author Supplied Abstract”	ERP + higher education + CSF ERP + higher education + CFF ERP + higher education + fact*
<b>Science Direct:</b> “Abstract, Title, Keywords”	“Enterprise system*” + university + success*
<b>SpringerLink:</b> “Title” or “Abstract”	“Enterprise system*” + university + failure
<b>WISO:</b> “General Search Field”	“Enterprise system*” + university + crit*

**Step 3:** During step 3, we performed the initial search according to step 1 and step 2. The initial search provided 6,963 papers from the databases. From the conference search, 34 papers remained. Altogether, 6,997 papers were identified during this initial search step.

**Step 4:** Step 4 included the identification of duplicates and irrelevant papers. During the initial search, we did not apply any restrictions. The search was not limited to the research field of IS; therefore, papers from other research fields were included in the results, too. Thus, these papers had to be excluded. This was done by reviewing the abstracts of the papers and, if necessary, by examining the papers’ content. The elimination of duplicates was done by using the literature management software *Mendeley* (<https://www.mendeley.com/>) where duplicates are automatically identified during the literature import process. Of the papers, 185 stemming from the database search and all 34 conference papers remained. Altogether, this step yielded 219 papers potentially relevant to the field of CSFs for ERP system implementations at HEIs.

**Step 5:** The fifth step consisted of a detailed analysis of the remaining 219 papers and the identification of the CSFs. Therefore, the content of all papers was reviewed in depth. Emphasis was placed not only on the wording of the CSFs

but on their meaning. Following this step, only eight relevant papers that suggested, discussed or mentioned CSFs in the context of HEI ERP implementations remained.

**Step 6:** Because of the small number of relevant papers, we applied (contrary to our previous reviews) a sixth step during which the references of the eight relevant papers were searched to identify suitable papers. With this method, we could identify seven additional papers addressing the field of ERP projects at HEIs. Therefore, we had a list of 15 relevant papers for further investigation. The identification of the additional seven papers also shows that papers focusing this topic are not all published in the “main” publication channels. Those papers often stemmed from smaller conferences or journals not indexed in the used databases.

### B. Results of the Literature Review

The identified 15 papers were again reviewed in depth in order to determine the various concepts associated with CSFs. For each paper, the CSFs were captured, along with the publication year, the type of data collection used, and the HEIs (i.e., the number and size) from which the CSFs were derived. Overall, 30 different factors were identified. In most previous literature reviews of other researchers with a focus on private enterprises, the CSFs were grouped more coarsely so that a lower number of CSFs was used (e.g., [11], [13]). The grouping was neither done within our review nor within our own previous reviews ([14], [17]). With 30 factors, we used a larger number than earlier researchers had because we expected the resulting distribution to be more insightful.

While identifying the CSFs within the papers, no special weighting of the factors was used. This means that each success factor that has been addressed within a paper will be considered with “1” in our result list. Afterwards, we counted these numbers. Table II lists the identified success factors according to their frequency.

TABLE II  
CSF'S IN RANK ORDER BASED ON FREQUENCY OF APPEARANCE IN  
ANALYZED LITERATURE

Factor	No. of instances
Top management support and involvement	8
Communication	8
User training	8
Balanced project team (cross-functional)	6
Involvement of end-users and stakeholders	6
Change management	6
Project management	6
Organizational Culture	5
Interdepartmental cooperation	5
ERP system acceptance / resistance	5
Organizational fit of the ERP system	5
External consultants	5
Clear goals and objectives (e.g., vision, decision strategies)	5
Vendor relationship and support	4
Project leadership / empowered decision makers	3
Skills, knowledge, and expertise	3
IT structure and legacy systems	3
Business process reengineering	3
Environment (e.g. language, culture)	3
Data accuracy (analysis and conversion)	3

Organizational structure	2
Available resources (e.g. employees, budget)	2
ERP system configuration	2
ERP system tests	2
Error management and troubleshooting	1
Monitoring and performance measurement	1
Knowledge management	1
University (Company's) strategy / strategy fit	1
Project champion	1
Vendor tools and implementation methods	1

We will not describe each factor in detail in this paper. However, to provide a comprehensive understanding of the different CSFs and their concepts, we previously described most of the 30 factors (since most are also affecting ERP implementations in private enterprises) in [14].

The differences in the CSF frequencies are only minimal and are related to the small number of identified papers. Therefore, deriving CSFs and their differences in importance on HEIs ERP projects based on a literature review was just the first step in our research project. Thus, our follow up study (2<sup>nd</sup> step) addresses this little amount of identified papers and their CSFs by investigating ERP projects at HEIs and the respective successes and/or problems.

## III. QUALITATIVE APPROACH – INTERVIEW STUDY

### A. Study Design – Data Collection Methodology

To gain a deeper understanding of the differences and importance of the CSFs for ERP system projects at HEIs, we used a qualitative exploratory approach within German universities and universities of applied sciences. As mentioned in the motivation we selected, to get initial insights, German HEIs due to our cultural background. The units of analysis in our study were the ERP implementation projects carried out within the HEIs' administrations. For the data collection, we conducted several interviews with members of the ERP implementation project teams or with the projects' responsible persons to identify the factors that they found to be relevant for the projects' success. In this process, we interviewed employees of nine HEIs located in Germany: one HEI with more than 40,000 students, three HEIs with 30,000 to 40,000 students, one HEI with 20,000-30,000 students, three HEIs with 10,000 to 20,000 students, and one HEI with less than 10,000 students.

Within these HEIs, due to the low number of ERP systems available for the specific requirements of universities, we have a low range of ERP systems (which cannot be named directly within this paper due to data protection). However, it can be stated that most of the HEIs have implemented a system from the same ERP manufacturer. Most of the implementation projects took place in the early or mid-2000s. The interviewees were indeed active in various areas of the administration, but they were also deeply integrated into the project and therefore could well provide information about the project. Five of those interviewees were ERP project managers, three were administrative IT managers, and one was a key user.

To gain a deep and detailed view of the HEIs and their

structures as well as of the interviewees' experiences, we chose direct structured interviews as our method of data collection. The interviews were conducted in retrospect to the ERP projects in summer and autumn 2015. The interviews were designed as partially standardized interviews using open to semi-open questions as initial starting points for the conversation. An interview guideline was developed, based on the questions of [18], who conducted a similar study with an enterprise focus, as well as on the basis of our previous CSF studies, which had also an enterprise focus [10], [19]. We changed the questions to align with our identified CSFs (see Table II) in order to ensure that all of the factors were discussed in the interviews. The interview guideline consisted of five topic sections with 61 main questions and further sub-questions:

- **Section A:** Background information on the interview partner and the university
- **Section B:** Project management in the context of the selection and implementation of the ERP system
- **Section C:** Procedure, tools and methods used for the ERP implementation
- **Section D:** System analysis, system selection, technical implementation
- **Section E:** Final assessment of the ERP implementation

These questions were formulated in an open way so that it would be possible to identify "new" CSFs that were not currently identified in the literature review. This questionnaire was sent to interviewees before the interviews took place, to allow them to prepare for their interviews.

Due to the large physical distance, telephone interviews were conducted by the authors. For a more thorough analysis of the results, we recorded all interviews (the interviews typically took between 60 and 240 minutes) and transcribed them afterwards (resulting in about 160 pages of written text). The calls were recorded by the app *TapeACall* (<https://www.tapeacall.com/>). To evaluate the CSFs, the transcribed interviews were analyzed with reference to each CSF question block. All in all, the evaluation and assessment of the interview results followed the approach of [20]. The coding itself was carried out using the MAXQDA software (<http://www.maxqda.com/>).

### B. Results of the Interview Study

After the coding, we again matched the answers and statements of the interviewees to the respective factor. Then each CSF was ranked according to a four-tier scale (see legend of Table III). This rating was done regarding the respective statements of the interviewees (similar to our approach used in [10]). After setting up this ranking of CSFs, we discussed the factor rating with other researchers in this field to reduce the subjectivity of the rating. Finally, this procedure resulted in a ranking of 30 CSFs according to the interviewees' statements and answers (Table III).

Compared to the results of the literature review (Table II) four new factors could be identified during the interviews (marked yellow within Table III): *Key users*, *Requirements*

*specification*, *Use of a steering committee*, and *Call for tenders*; whereby four factors found in the literature review were not mentioned by the interviewees: *Clear goals and objectives*, *Involvement of end-users and stakeholders*, *Environment*, and *Project champion*. However, most of these new and not-found factors were only on medium ranks in both lists. Only the factors *Involvement of end-users and stakeholders* as well as *Clear goals and objectives* were among the top ten factors of the literature review.

TABLE III.  
CSF'S ACCORDING THE FOUR-TIER-SCALE RATING

Rank	Factor	Factor rating (4-tier-scale)
1	Culture of the HEI	25
2	User training	24
3	Communication	23
4	ERP system configuration	22
	ERP system tests	22
6	Go-Live approach / vendor tools and implementation methods	21
7	External consultants	20
	Organizational fit of the ERP system	20
9	Monitoring and performance measurement	19
10	Error management and troubleshooting	18
	Balanced project team (cross-functional)	17
11	Business process reengineering	17
	Project management	17
14	Key users	16
	Requirements specification	15
15	IT structure and legacy systems	15
	Data accuracy (analysis and conversion)	15
	Top management support and involvement	15
	Vendor relationship and support	15
20	Change management	14
	Skills, knowledge and expertise	14
22	Project leadership / empowered decision makers	13
23	Use of a steering committee	11
	ERP system acceptance/resistance	11
25	Call for tenders	9
26	Available resources (e.g. employees, budget)	8
27	Knowledge management	7
28	University (Company's) strategy / strategy fit	4
	Organizational structure	4
	Interdepartmental cooperation	4
3 – the factor was intensively considered during the project and influenced the project significantly 2 – the factor was stated and did have observable effects on the project 1 – the factor was stated but did not have any observable effects on the project / was not seen as an important factor 0 – the factor was not mentioned at all maximum possible rating on basis of 9 interviews = 27		

## IV. CONCLUSION AND LIMITATIONS

The aim of our study was to address the research field of CSFs for ERP implementation projects, with a specific focus on ERP projects at HEIs. Another objective was to compare the identified factors with the CSFs of ERP implementations in private enterprises.

As a first step, we carried out a systematic literature review to identify CSFs affecting HEIs' ERP projects. Our review turned up very little variety of papers focusing on those specific CSFs. All in all, we identified only 15 relevant

papers dealing with the CSFs of ERP system projects at HEIs. From these existing studies, we derived 30 different CSFs (see Table II). Compared to a similar literature review that we conducted focusing on CSFs at private enterprises' ERP projects [14] – here, we identified 320 articles with this explicit focus – those 15 papers with an HEI focus reveal that this can still be seen as a clear lack of research.

To this end, we set up an empirical interview study with a specific HEI focus. We found that nearly all factors found in the literature review were mentioned by at least one interviewee. However, four CSFs were not mentioned, and we could identify four additional CSFs that were not found within the existing literature. Here, contrary to the ranking resulting from the literature reviews, we identified factors with a more technological focus as also important for those ERP projects. The factors *ERP system tests* and *ERP system configuration*, as top 5 factors, refer to more technological aspects. Hence, factors with an organizational characteristic could also be identified as part of the top 5 factors in our study (*User training*, *Culture of the HEI*, *Communication*).

Regarding our research questions, our study could show that most factors that influence the success of ERP system implementation projects in large-scale enterprises also influence ERP projects at HEIs. However, we found that the importance of the factors differs remarkably and that HEIs and also the ERP manufacturers have to be aware of these differences in the factors' characteristics. They should also focus on the technological aspects of the ERP implementations rather than focusing mainly on the organizational factors, as they are more important for the large-scale private enterprises.

Overall, we conclude that the specificities of different types of organizations/institutions and domains make it worthwhile to identify and rank CSFs within these fields instead of simply relying on what is known from other studies. Thus, revisiting CSF research from time to time, especially with a specific focus, still reveals new findings in this mature research field.

A few limitations of our study must be mentioned as well. For our literature review, we are aware that we cannot be certain that we have identified all relevant papers published in journals and conferences since we limited our selection to five databases and five international conferences. Another limitation is the coding of the CSFs. We tried to reduce the subjectivity by formulating coding rules and by discussing the coding of the CSFs with several independent researchers. However, other researchers may code the CSFs in other ways. For the interview study, the interviews conducted and data evaluated represent only an investigation on sample ERP projects in German HEIs. These results are limited to the specifics of these organizations and the experience of the interviewees. In light of this, we will conduct further case studies and some larger surveys to broaden the results of this investigation.

# Project Management and Communication Software Selection Using the Weighted Regularized Hasse Method

Karolina Muszyńska, Jakub Swacha

University of Szczecin, Faculty of Economics and Management

ul. Mickiewicza 64, 71-101 Szczecin, Poland

Email: {karolina.muszynska, jakub.swacha}@usz.edu.pl

**Abstract**—This paper addresses the problem of selecting the most appropriate project management and communication software for a project having specific requirements. A four-stage procedure featuring the weighted regularized Hasse method is used to compare and rank the candidate tools. The ranking of the tools takes into consideration the importance of the functional and non-functional features of the project management systems with their respective weights based on the results of a questionnaire conducted among members of a dispersed international project team.

## I. INTRODUCTION

REALIZING projects in dispersed teams is a complicated and demanding task. In any project it is vital to follow a project management methodology or set of best practices to manage its different areas including scope, schedule, costs, quality and human resources. Yet, in dispersed, multinational teams, additional communication and collaboration issues may arise, as a result of linguistic problems, limited trust, scarce direct contact among team members and less influential leadership. Moreover, the physical distance in dispersed teams augments the importance of the software systems supporting project managers in planning and monitoring project progress and whole teams in communicating, collaborating and documenting the results.

The project management and communication software differs in offered features, complexity of handled information, ease of use, and price per user. Choosing one for a specific project should take into consideration its scope, size, management model, workflows and users' expectations.

With tens of available project management suites, and tens of criteria to consider, the choice of the right tool is not trivial. Moreover, such choice should be repeated for every project undertaken, as the specificity of a given project may render unusable a tool used successfully in multiple other projects. Hence the need for an easy-to-use technique capable of supporting such type of decisions.

The aim of this paper is to propose a selection procedure using the weighted regularized Hasse method [1] as an effective solution for this purpose. This method is not only

simpler than the most widely used methods supporting multi-criteria decision process (such as PROMETHEE, the ELECTRE family methods, or the Analytic Hierarchy Process – see [2] for a comprehensive review), but also has a number of other benefits (primarily, highly informative and highly readable form of results – see section VI).

As a proof of concept, this method is applied to evaluate and rank project management systems with regard to the criteria and their weights defined for the case of an international project consortium, consisting of seventeen partners from eight countries. Due to its territorial dispersion and the multiplicity of communication channels among the project team members, the project represents a valid exemplification of a situation in which a deliberately selected project management and communication system is needed to ensure effective and successful project realization.

The paper is structured as follows. Section II explains the nature of issues related to project management in an international dispersed team, also stressing out the significance of the project management software. Section III provides an insight on the chosen approach, introducing the concepts of partial ordering and Hasse diagrams. Section IV provides basic information on the case project. Section V describes the applied selection procedure, whereas Section VI presents its results. Section VII concludes.

## II. PROBLEM BACKGROUND

Realization of any kind of project in a dispersed international team is a challenging task. Different research studies show that geographic dispersion may impede effective information sharing, coordination, problem solving, building trust, and constructively resolving conflicts with others on the team [3,4]. Project delivery risks with distributed teams tend to be greater when compared to co-located teams [5]. This is mainly due to the lack or high limitation of face-to-face contact, which hinders interpersonal relations, trust and commitment and causes misunderstandings.

In dispersed global project teams, most communication and the building of relationships is performed through information and communication technologies (ICT), and the ICT support becomes one of critical success conditions [6].

The current trend in project management is to find technology that allows the creation of a professional

The publication was financed from the funds of the Department of Engineering of Information Systems at the Faculty of Economics and Management of University of Szczecin for maintaining research potential.

environment for dispersed teams, similar to the one expected if these teams were collocated [7].

Project management software is a very broad category [8]. Selecting the right tool has therefore a significant effect on the success of the project and effectiveness of teamwork [9].

### III. CHOSEN METHODOLOGY

It is a significant challenge to analyze data and make a decision taking into account many different aspects and criteria. The fact that many different indicators must be included simultaneously means that the so-called multi-indicator system or multi-criteria analysis must be used [10].

One way to handle a multi-indicator system is a mathematical mapping of the single indicator values to get a one-dimensional scalar, eventually to be used as the ranking indicator [11]. However such a mapping process, e.g. by using a weighted sum, hides all background information and may also cause unwanted compensation effects [12].

There are well-known outranking methods to obtain a linear order from a multivariate data matrix [2]. A less known yet attractive alternative to the above-mentioned methods is the partial order method. It allows not only to rank objects but also to obtain information to what extent a given object is better than another.

In partial ordering, to acknowledge object  $X$  as better than object  $Y$  (written as:  $X \geq Y$ ), there must be at least one indicator value for object  $X$  which is higher than the corresponding indicator value for object  $Y$ , and no indicator for object  $X$  is lower than the corresponding indicator value for object  $Y$ . If some indicators for object  $X$  are higher and others are lower than the corresponding indicators of object  $Y$ , then the objects are recognized as incomparable. A set of comparable objects is called a chain, whereas a set of mutually incomparable objects is called an antichain. If all indicator values for two objects are equal, the objects are considered as equivalent, having the same rank [13].

Partial orders can be visualized with Hasse diagrams, in which comparable objects are connected by a sequence of lines, while incomparable objects are not connected. The levels give approximation to a weak order of the objects from “bad” (bottom) to “good” (top). Before constructing a Hasse diagram, it is essential to make sure that all indicators have a uniform orientation. Partial order method provides a weak order, where tied orders are not excluded. This is obtained by calculating the average order of the single objects, as e.g. described by Bruggemann and Annoni [14].

Partial order methodology has been used in many different research studies in environmental sciences, chemical industry, poverty analysis and many others (see [15]). It has also been successfully applied to software selection problem in the case of digital assets management systems [16].

That approach has, however, a significant weakness. In the case of problems with many criteria, such as the one researched here, often a large number of incomparabilities are observed which leads to a less meaningful representation.

Moreover, the original Hasse method considers all criteria as equally relevant in determining the final data structure, and that is not always desired. A comprehensive solution to both these shortcomings has been proposed by Grisoni et al. [1] in the form of the weighted regularized Hasse method. It is this improved method that has been chosen to solve the discussed problem. The details of the performed procedure will be provided in section V; before that, however, the project selected for the exemplification will be described.

### IV. THE CASE PROJECT

The case project is an international cooperation project titled *BalticMuseums: Love IT!*, realized within the Interreg South Baltic Programme 2014-2020 and supported by the European Union from the European Regional Development Fund. The project team comprises three scientific partners, five museum or cultural institution partners and one partner specialized in creative IT-related events. Apart from the nine partners, taking part in all project activities, there are also eight associated partners, involved only in selected activities. The partners are based in eight European countries.

The main aim of the project is to develop new IT-enabled tourism products for natural and cultural heritage tourist destinations in the South Baltic Region in a form of multilingual BYOD-guided tours providing an enhanced visitor experience during and after the visit featuring multimedia content and gamification techniques.

The case project has the following characteristic properties:

- there is no single project management system used a priori by all or most of the partners (the users have different experiences and expectations);
- the partners have very different levels of IT fluency, hence the need for a very easy to use, but still highly functional solution;
- the project is scheduled for three years (there is enough time to learn the new software);
- the financial management is done in a separate system prescribed on the European Union programme level (that is why no financial features should be taken into account in the evaluation).

### V. SELECTION PROCEDURE

The procedure of selecting the best project management and communication software included four stages. The first one comprised two phases – selection of criteria against which the potential project management systems will be ranked and obtaining weights reflecting the importance of each criterion. The weights were set on the basis of a questionnaire answered by the project partners’ representatives. For each criterion, they were asked to assess its importance on a five grade scale. For each value on the scale, a number has been assigned: not important – 0, of little importance – 1, desired – 2, important – 3, absolutely crucial – 4. The weights of the

respective criteria were calculated by summing up the numbers obtained from the respondents and then normalizing them to make the sum of weights of all the criteria equal to 1.

In stage two, a set of project management systems to be evaluated was chosen. Because of the huge amount of that type of tools available, a pre-selection phase was needed. The pre-selection was based on the following assumptions: the software is recognized as popular on the benchmarking lists [17,18], the annual cost of using the tool by 25 users does not exceed the threshold of 600 euro, the available disk space (in case of cloud solutions) is not less than 20 GB, and a demo/trial version of the tool is freely available for testing.

In the third stage, the pre-selected project management tools were evaluated with respect to the criteria – features of the system which were defined in stage one. Fourteen of the criteria could be rated using a binary scale: with 1 assigned if a certain criterion was met, and 0 if it was not. Other criteria

needed a larger evaluation scale (0 to 2 or even 3), because their scope strongly differed among the tested tools. All functions and features which were evaluated using a non-binary scale are listed in Table I (see Table II for a full list).

As a result of stage three, the original Hasse matrix and the corresponding diagram (see Fig. 1) were obtained.

The goal of the final stage was to determine the complete ranking of the project management and communication systems for the BalticMuseums: Love IT! project team, taking into consideration the weights of the respective criteria. To accomplish that, the approach proposed by Grisoni et al. [1] was followed.

In its first phase, the weighted count matrix  $t^W$  was obtained using the following formula [1, eq. 1]:

$$t_{ij}^W = \sum_k w_k \cdot \delta_{i,j,k} \quad (1)$$

TABLE I.  
EVALUATION RULES FOR THE NON-BINARY FEATURES OF THE PROJECT MANAGEMENT SYSTEMS

Feature (scale)	Levels (points awarded)
sharing and co-creating docs (0-3)	no sharing/co-creating (0), place to store and share files (1), place to store and share files with version control (2), sharing files and co-creating documents (3)
email integration (0-3)	no email integration (0), notifications to external email (1), possibility to send to/receive from external email (2), own mailbox/internal messages (3)
instant messenger (0-2)	no chat (0), one-on-one chat (1), group chat (2)
notifications (0-2)	no notifications (0), automatic, but poorly configurable notifications (1), highly configurable automatic notifications (2)
project schedule (0-2)	no schedule (0), schedule only defined in tasks (no visualization) (1), schedule displayed on a Gantt chart (2)
managing tasks (0-2)	flat or two-level task hierarchy (0), at least three level tasks hierarchy (1), multilevel task hierarchy, task dependencies (2)
dashboard (0-3)	no dashboard (0), dashboard with only recent activities (1), dashboard with tasks, activities, calendar (2), dashboard with graphical visualization of project status (3)
shared calendar (0-2)	no shared calendar (0), calendar with no integration with external calendars (1), calendar with integration with external calendars and/or meeting planner (2)
access control (0-2)	no user access management (0), basic user access management (1), advanced user access management (2)
mobile version (0-2)	no mobile app (0), basic functions mobile app (1), full mobile app (2)
interoperability (0-2)	no interoperability (0), basic export/import possibilities (1), integration with many different tools (2)

TABLE II.  
NORMALIZED WEIGHTS OF THE PROJECT MANAGEMENT SOFTWARE EVALUATION CRITERIA

Symbol	Criterion (feature of the system)	Normalized weight	Symbol	Criterion (feature of the system)	Normalized weight
C1	sharing and co-creating documents	0.053493	C14	risks register	0.034934

C12	dashboard	0.046943	C25	ability to withdraw and delete data	0.033843
C13	issues register	0.039301			

where:

$$\delta_{i,j,k} = \begin{cases} 1 & \text{if } x_{ik} \geq x_{jk} \\ 0.5 & \text{if } x_{ik} = x_{jk} \\ 0 & \text{if } x_{ik} \leq x_{jk} \end{cases} \quad (2)$$

and:  $w_k$  denotes the weight of criterion  $k$ , and  $x_{ik}$  the evaluation of object (software system)  $i$  with regard to criterion  $k$ .

In the second phase, a weighted regularized Hasse matrix  $H^R$  was obtained from the weighted count matrix using the following formula [1, eq. 2]:

$$[H^R(t^*)]_{ij} = \begin{cases} 1 & \text{if } t_{ij}^W \geq t^* \\ -1 & \text{if } t_{ij}^W \leq 1 - t^* \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

where  $t^*$  has been set to the minimum allowed value of 0.55 – i.e. it is enough for object  $i$  to be better than object  $j$  in 55% of the criteria to set an ordering between the two.

Although Grisoni et al. [1, p. 97] suggested one more phase to obtain a total ordering, in our case it was unnecessary as the chosen value of  $t^*$  for the construction of the weighted regularized Hasse matrix was sufficient to eliminate all the incomparability between evaluated tools and to construct the complete ranking.

## VI. RESEARCH FINDINGS

The first stage of the research procedure resulted in specifying 25 criteria – features of project management tools whose importance was evaluated by the respondents of the questionnaire – the representatives of the project partner organizations. Note the simplicity of the data gathering process as compared to, e.g., the AHP method requiring pairwise comparisons [19].

Table II presents the criteria together with corresponding normalized weights (the normalization consisted in dividing each weight by the sum of all weights so that the sum of all normalized weights is 1). The values reflect which criteria were indicated as the most important by the majority of the respondents; the five top-ranked were: email integration, sharing and co-creating documents, managing project tasks,

project schedule, and dashboard.

The second stage of the research concentrated on the pre-selection of project management and communication tools for the final evaluation. As a result of the pre-selection process, the following nine project management systems were chosen: Zoho Projects Premium (T1), Freedcamp Lite (T2), Moovia (T3), Proofhub Start up (T4), AdminProject (T5), Teamwork Projects Small Office (T6), Trello free (T7), 2-Plan Team free (T8) and Open Project free (T9).

In the third stage, each of the pre-selected systems was evaluated with regard to each of the 25 criteria, what resulted in creation of a source matrix for the Hasse diagram. Note that at this stage the criteria weights were not yet taken into account.

Fig. 1 The original Hasse diagram  
(source: own elaboration, obtained using [20]).

The Hasse diagram, presented in Fig. 1, reveals the dependences among the evaluated project management systems. There are five chains showing the order among some of the systems:  $T6 \geq T4 \geq T3$ ,  $T6 \geq T7$ ,  $T6 \geq T2$ ,  $T1 \geq T2$  and  $T1 \geq T7$ . Apart from the listed chains, other tools are incomparable with one another. Due to the existence of incomparable objects, the Hasse diagram does not provide the complete ranking of the evaluated software.

In order to accommodate the criteria weights, in the first phase of the final stage, the weighted count matrix  $t^W$  was calculated (see Table III). The weighted count matrix was then used to calculate a weighted regularized Hasse matrix  $H^R(0.55)$ . The Hasse diagram resulting from this matrix (not presented here as it has an obvious form of a degenerate tree) revealed the complete ranking of the project management systems (see Table IV).

TABLE III.  
WEIGHTED COUNT MATRIX FOR THE SELECTED PROJECT MANAGEMENT TOOLS

TABLE IV.  
THE FINAL RANKING OF THE SELECTED SYSTEMS

Rank	Id	Project management tool
1	T6	Teamwork Projects Small Office
2	T1	Zoho Project Premium
3	T4	Proofhub Start up
4	T2	Freedcamp Lite
5	T8	2-Plan Team free
6	T9	Open Project free
7	T5	AdminProject
8	T3	Moovia
9	T7	Trello free

## VII. CONCLUSION

The selection of the most appropriate project management system is one of the most important decisions which influence the realization, communication, collaboration and documentation processes throughout the project. It is, of course, only one of many important factors which determine the success of the project, but using the right IT tools makes all other processes easier to realize.

In this paper, it was shown how the selection of the most appropriate software can be supported using a procedure consisting of four stages: (1) definition of the evaluation criteria and their importance for the project team members, (2) pre-selection of the project management software tools, (3) evaluation of the pre-selected tools against the defined criteria, and (4) establishing the complete ranking of the evaluated tools, using the weighted regularized Hasse matrix (which is much simpler than AHP or outranking methods).

The proposed procedure has been validated using the case of an international project, realized by a consortium of 17 organizations from 8 countries. The applied procedure led to the final ranking of the project management tools, listing the systems under consideration in the order of preference based on the fulfillment level of the 25 defined evaluation criteria and the criteria weights set by the consortium members.

Selection of the project management and communication software is an important element of setting up an effective project realization environment. It must be, however, taken into consideration that using even the best software tools for project management and communication is not enough to ensure project success. Appropriate procedures and processes must be defined and observed by the whole team to let the software be utilized in the best possible way [21].

It should be noted that the procedure applied in this research for evaluating and ranking the project management systems can as well be applied to other software selection problems having similar context (many candidate solutions, multiple criteria, criteria having distinct weights).

**Abstract**—Collaboration in business environments is an ongoing trend that is enabled by and based on cloud computing. It supports flexible and ad-hoc reconfiguration and integration of different services, which are provided and used via the internet, and implemented within business processes. This is an important competitive advantage for the participating stakeholders. However, trust, policy compliance, and data privacy are emerging issues that result from the distributed data handling in cloud-based business processes. Up to now, several architectures and technical systems that enable the cloud-based collaboration within business processes have been developed, but the selection of an appropriate business process management system (BPMS) is missing. An implemented BPMS has to meet certain requirements that result from the cloud-based characteristics and from the other implemented systems. This paper derives requirements for BPMSs in cloud-based environments, currently available BPMSs are evaluated against the derived requirements and the selected one is implemented subsequently.

## I. INTRODUCTION

COLLABORATION is one of the essential mechanisms in business environments that follow the trend of outsourcing and concentration on core competencies in order to create customized business processes. Foundation and enabler of this development is the technology of cloud computing (CC) [1], [2]. Next to benefits such as facilitated collaboration, flexibility, and ad-hoc reconfiguration, there are certain challenges arising from the virtualization of resources and the decentralized data handling within the CC paradigm. Especially, the cloud based planning, operation and monitoring of business processes incorporates sensitive data. Hence, data privacy and the related policy compliance results in a crucial challenge for affected companies that participate in such a cloud-based business environment [3]. Recent publications deal with the issues of data privacy in cloud-based business processes [4], based on the so called collaborative business process as a service (BPaaS) [4], [5]. Several components of a comprehensive

The work presented in this paper was funded by the German Federal Ministry of Education and Research within the project 'Logistik Service Engineering und Management' (LSEM) under the reference BMBF 03IPT504X and within the project 'Privacy-preserving Methods and Tools for cloud-based Business Processes' (PREsTiGE) under the reference BMBF 16KIS0082K. More information can be found on the websites <http://lsem.de> and <http://prestige.wifa.uni-leipzig.de>.

architecture and their interfaces have been described in several papers [4], [6], [7]. The only missing core component of the presented architecture is the Business Process Management System (BPMS), which the paper focuses on.

The BPMS has to meet several requirements from the perspective of business and privacy policies. Further, the already implemented components of the architecture impose additional requirements based on the given ways of communication and the underlying logic. In summary, the paper answers the following research question: *How is a privacy preserving BPMS to be designed and implemented in order to grant data privacy for collaborative BPaaS?*

The paper is structured as follows: After the introductory motivation, section 2 focuses on the theoretical background. Section 3 briefly introduces the applied methodology, which comprises the deriving of the requirements for privacy-driven cloud-based BPMS, the introduction of several alternatives and their evaluation. After section 4 that briefly introduces the implementation of the selected BPMS, the paper is concluded in section 5.

## II. THEORETICAL BACKGROUND

Business Engineering (BE) is the approach of the methodical implementation of new business solutions as well as company's organization design, especially of business processes comprising its modeling, strategy and information systems usage [8]. Alphar et. al. [9] refer to St. Gallen's business architecture and define BE as the method of integrated design based on process orientation focusing on the link between business strategy and IT. The key aspects of BE are the optimization of existing and the design of new customer-oriented processes. The design should ensure substantially completed processes and that activities are presented ordered chronologically and logically with regards to the business objectives [9], [10]. The outputs of the activities have an essential impact on the process execution as they serve as input for the particular subsequent activity. The most important challenges and main objectives of business engineering are execution time, promotion of customer loyalty as well as reduction of process faults and errors [8].

There are two fundamental approaches used for process design: top-down and bottom-up. The first one proceeds from business strategy down to its IT-implementation and comprises vision, initial diagnose, redesign, development

as well as evaluation phases. The benefits of this approach are the systematic consideration of customer orientation, business strategy, and its objectives. Moreover, it allows to build end-to-end processes starting at customer needs and ending with its achievements [11]. However, [9] argues, that the criticized bottom-up project implementations are frequently applied due to rare possibility of top-down's greenfield approach integration.

The need of proper process design and its preparation results from the information models' complexity and their high quality requirements [12]. A methodical approach supports the handling of complex business model design, as those models consist of multiple, standardized, and modular components and dependencies. Hence, systems and modules can be reused in other business models to accelerate the design process [9]. With the help of reference models, during BE particular business IT architectures can be developed [13]. There is a variety of solutions, notations, and approaches for process modeling such as ARIS (Architecture of Integrated Information Systems), BPMN (Business Process Model and Notation), EPC (Event-driven Process Chain) etc. [8].

Business strategy and business objectives are the foundation and purpose of business process modelling [11]. Business process modeling is part of business process management, which encompasses the whole lifecycle of business processes. This comprises design, modeling, execution, monitoring, and optimization [14]. Business process management systems (BPMS) comprise tools, methods, and concepts to support business process management for the whole business process life-cycle [11], [12].

The result of business process design is a machine-readable process description, which can be executed by process engines of the BPMSs. Languages for this purpose are e.g. XPD (XML (Extensible Markup Language) Process Definition Language) and BPEL (Business Process Execution Language). The major drawback of those languages is the lack in graphical process representation [10], [15], [16]. In order to overcome this problem, the language BPMN was developed. Nowadays, it is the most common notation in business process management due to its multiple advantages: the processes created in BPMN are executable, machine readable, and further a special graphical representation was created to enable human readability. Consequently, the BPMN has prevailed against BPEL and other languages and has become a standard in process modeling. BPMN is based on structured layers, each of those consists of different elements. The most fundamental ones, that make it possible to construct BPMN diagrams are Process, Choreography and Collaboration [17].

Due to the rapid growth of information system's modularity by the implementation of technologies such as SOA and Web Services, BPM is an integrator for coupling and connection of independent components with the help of the process level. This helps to deliver personalized and specialized processes to customers, in order to provide

a mix of responsive products and services, that work together in value chains. The cloud provides a flexible and scalable environment for such integration tasks. Hence, the realization of BPMS in the cloud is a consequential step. Benefits of the cloud paradigm's implementation are e.g. reliable performance on demand, scalability, and predictive analytics for process tasks. Usually cloud services are distinguished into Infrastructure as a Service, Platform as a Service, and Software as a Service, which are different levels of abstraction of services from virtualized hardware to whole ready to use software products [18], [19]. Reference [18] defines the three following diverse system categories of BPMS, that could be implemented on the particular cloud level: Interconnecting Systems for information exchange through all accessible channels on IaaS and PaaS; Adaptive Systems for internal process and customer monitoring based on SaaS; Specialized customer-oriented Systems at SaaS level. When it comes to BPMS in the cloud, another layer, the Business Process as a Service (BPaaS) is added to the stack. The mentioned benefits of the cloud paradigm are also valid on BPaaS layer.

Considering how functionality of BPM architecture spreads across the cloud, [20] defines the four following levels: Infrastructure Service Layer, which comprises Service Bus with File Storage System; Platform Service Layer for business process engine and pre-built business process rules libraries with diverse middle-ware core elements; BPMS-as-a-Platform layer, which provide full BPM-life-cycle management support, especially process design and monitoring; and finally, Software and Service Layer with the tools for information analysis on the highest abstract cloud computing level. According to [5], the transformation of BPMS paradigm from domain-specific business process to executable work-flow in Cloud consists of five levels to be fulfilled as follows. Knowledge Externalization comprises the representation of cloud service features in a human and machine readable way, can be achieved by clear semantics and language. BPaaS design maps the activities of business process to cloud services. The third level of transformation is BPaaS allocation, where each business process in the cloud can be understood as a service, which can be deployed to the cloud. The BPaaS execution level provides the orchestration of such cloud service on a higher abstraction. Finally, the level of BPaaS evaluation collects all information from the BPaaS deployment in multi-cloud environments to provide conceptual analytics on business level. Through all those levels security and privacy has to be guaranteed.

The public access as well as multi-tenancy provided by cloud computing have a tremendous impact on information security and privacy. Reference [21] defines the five following perspectives based on high level security requirements of business processes, in order to guarantee integrity, consistency and completeness:

- *Information Perspective* refers to the structure and relationship of information units

- *Function Perspective* is the mapping of and the dataflow between process activities
- *Dynamical Perspective* concerns the representation of all states for each information unit as well as its status transformation during information unit lifecycle
- *Organization Perspective* provides information about who executes which activity at which point of time
- *Business Process Perspective* represents the business process as activity and information stream from the perspective of the whole process.

Apart from the process security, also security on the cloud environment itself should be considered. Reference [22] argues the communication of components based on Trusted Third Party (TTP) Services as the ideal solution for integrity, confidentiality, and credibility in the cloud. TTPs are operationally connected certificate paths, that provide a notion about Public Key Infrastructure (PKI) and support strong process authentication, authorization for an access to resources, data banks and informative systems as well as data confidentiality.

Summarizing, BPaaS provides a suitable approach for business process management in cloud-based collaborations. One of the major challenges in this field is the compliance of privacy policies due to decentralized handling of sensitive data. This challenge has already been met for some parts of BPaaS architectures [4]. However, the evaluation and selection of a suitable BPMS is still missing. The following section derives requirements for privacy preservation in collaborative BPaaS and evaluates existing BPMS.

### III. EVALUATION AND SELECTION OF BPMS

In this section, a method for BPMS evaluation and selection [23] is introduced and applied in the field of collaborative BPaaS. Requirements of a BPMS in collaborative cloud environments are derived from business perspective and from the existing architecture's perspective. Afterward, existing BPM tools are identified and evaluated with the help of the derived requirements and eventually an appropriate tool is selected for subsequent implementation.

The method of [23] comprises the three steps that are depicted in Figure 1: identifying the the organizational requirements, identifying BPM tools, and selection of appropriate BPM tool with the help of the requirements. The common and specific requirements help to improve the decision of tool selection. According to [23] both first steps are executed in parallel. In the identification of BPM tools during second step, there are some weak spots in the method because of its proposal to identify *all* available market tools without any restriction. This leads to comprehensive and extensive list, that should be elaborated completely. One of the options here is to reduce the list by identifying common criteria both for software and BPM tools with regards to common evaluation practices. During the last step, each BPM tool from the list is evaluated by

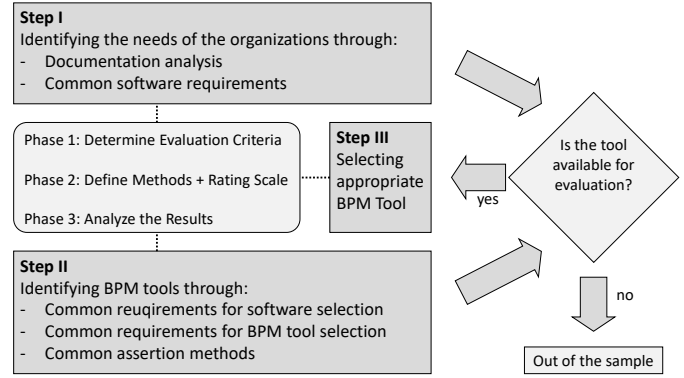

Fig. 1. Methodology for BPM Tool selection (referring to [23], [24])

particular criteria in order to evaluate the tools' suitability to meet the requirements. Moreover, a tool cannot be evaluated, if at least one criteria cannot be applied and evaluated.

#### A. Identifying Organizational Requirements

According to [24] there are two types of organizational requirements, that are described in functional specifications. First type comprises a compilation with the scope on delivery and performance. The second type describes the implementation. Further, a distinction can be made between functional and non-functional requirements [24]. According to [25] there are various document types for documentation such as use case and class diagrams, software glossary, sequence diagrams, domain models, performance and interface description, etc.

An interview among companies from the logistics sector revealed that privacy is one of the most important concerns of companies when it comes to collaborative BPaaS. Also the application of SOA (Service Oriented Architecture) principles for the whole system has been emphasized by the interviewees.

The central outcomes of the architecture's development [4] are structures for design, execution and monitoring of privacy preserving business processes. The focus is laid on the customer-specific declaration of privacy rules. They are monitored with strategic, operative and tactical KPIs (Key Performance Indicator) with the focus on price, time as well as quality. The quality aspect is verified through test cases development, evaluation and continuous improvement. Through functional and non-functional requirements as well as description of desired conditions, a requirements catalog has been developed, which comprises five architecture-specific criteria. The architecture's functionality is defined through component diagrams and descriptions as well as interface descriptions.

The functional requirements are briefly introduced:

1) *Service Selection*: The first requirement is the ability of reusing process activities from a (IT) Service Catalog, e.g. as proposed in [26]. It can both accelerate and facilitate the process design. However, it is not to think

about a general service repository in the sense of SOA context such as WSDL (Web Service Description Language) directory, but as repository for structuring and retrieval of customized business process activities, that in BPMS context are known as Work Items.

2) *Remote invocation*: This criteria comprises interface and functionality for remote process administration and control. For instance, one of the architecture's main components is able to start the process per remote invocation, while another component should be capable of the process' deployment. Moreover, one important feature is the parameter delivering and its acceptance by process during its execution, as well.

3) *Process Activity Logging*: In enterprise systems, transaction are executed and persisted for compliance as well as for monitoring reasons. The logging of each step during process execution is a challenging task. There is a need for so-called Safe-Points within the process because of real-time process tracking, which is done by parts of the architecture's external components for process monitoring. Safe points save the state of the process instance during process execution. The logging support is required for the process execution engine, as well as for the trigger performance for remote control.

4) *Security Provider*: The environment of architecture's components should be homogeneous and privacy preserving. Processing with the Single-Sign-On technique can guaranty confidentiality and ease of use for its clients. As a result, one of the requirements on BPMS is the support and integration with OpenID systems.

5) *Cloud Readiness*: As the architecture's business processing is managed in the cloud, a crucial requirement is the BPMS' support of various features such as support of a CLI (Command Line Interface) for process administration, in order to ease project management. Multi-tenancy feature support is another requirement because of the necessity of process virtualization. This enables independent execution and design for each particular user or groups of users according to particular roles. It comprises also the possibility to use e.g. customized data sources, or customized persistence configurations.

The trust evaluation index system proposed by [27] was used in order to define non-functional requirements. The three chosen criteria are: reliability, security, and maintainability. The BPM tools will be further evaluated towards meeting the requirements usability and system architecture. Altogether, five non-functional criteria with the following key points to be supported have been defined:

- 1) Reliability: process monitoring, simulation and design as well as process mining
- 2) Security: data security and confidentiality as well as process roles and access
- 3) Maintainability: testability as well as product support and service
- 4) System Architecture: SOA/Enterprise-components, repository, audit/history logs, human task, work-

bench

- 5) Usability: both installation complexity and GUIs (Graphical User Interface) for modeling, process and project administration

Summarizing the first step, there are five aspects determined for the BPMS evaluation that outline the functional requirements.

### B. Identifying BPM Tools

The architecture's objectives are being used to derive organization types and use cases in accordance with particular aspects of the decision framework proposed by [28] in order to choose the best fitting BPMS. According to [24], there are some common analytical methods for software tools identification, which comprise market review, rough selection as well as gathering of price offers. For the current paper, the market review and online sources were used. Multiple BPMSs were detected. However, the majority of the BPMSs did not provide the capability of process execution, but only the capability of process design. As a result, common BPMSs are distinguished from BPMN-Engines, which do offer the capability of process execution. Consequently, the list with BPMN engines from [29] was used and extended with the BPEL-Engines from the list of [30] that support BPMN 2.0 language. The list comprised more than 30 BPMN 2.0 engines. Derived from the architecture's setup, the features of BPMN 2.0 Core are determined as essential for the evaluation and selection. Consequently, the list was reduced to seven BPMN 2.0 engines, i.e. Edorasware, Camunda BPM, Imixs Workflow, jBPM, Stardust, W4 BPMN+, and inubit BPM.

By now the BPMN engines have been evaluated based on the BPMN 2.0 Core characteristics. However, reliability and similar aspect such as process monitoring, simulation, and deployment are not part of the BPMN specification [17] but should be considered for evaluation, as well.

### C. Selecting BPM Tool

With the aforementioned non-functional requirements, the seven identified BPMS are evaluated. Final results of this assessment are presented in Figure 2. Harvey Balls are chosen as the rating scale. Only jBPM resulted to fully meet all non-functional requirements. However, through interviews with project managers, there was defined an importance of each particular non-functional requirement. The highly weighted are reliability, system architecture as well as security (en-framed bold). Hence, three BPMN engines were chosen to be thoroughly examined concerning the functional requirements in the next step.

The BPM tools are being pre-chosen according to the non-functional requirements. The remaining three are now evaluated concerning the extent to which they meet the functional requirements. The weight of the sub-requirements are presented in the following list:

- Service Selection: Work Item Task (50%), Work Item Repository (50%)

Weight			jBPM	Imixs-Workflow	Stardust	Edorasware	Camunda BPM	inubit BPM
high	I	Reliability	●	●	●	●	●	●
high	II	System Architecture	●	●	●	●	●	●
high	III	Security	●	●	●	●	●	●
low	IV	Maintainability	●	●	●	●	●	●
low	V	Usability	●	●	●	●	●	●

Fig. 2. Evaluation of BPMS against the developed requirements.

- Remote Invocation: Remote API for process administration (50%), parameter mapping (50%)
- Process Activity Logging: Signal Events with Remote API (Application Programming Interface) (50%), parameter mapping (50%)
- Security Provider: Support and its full integration (100%)
- Cloud-Readiness: CLI (50%), Virtualizing (50%)

Regarding the executed evaluation, there is only one BPMS fulfilling all functional requirements, i.e. *jBPM*. The tool *jBPM* is open a source product supporting BPMN 2.0 since 2013. It comprises a huge community and provides a comprehensive and well written documentation. Further, product maturity and integrity can be assumed as it is available in the sixth stable release (currently: 6.5). In the next section, the implementation of the *jBPM* and the integration with the other existing parts of the collaborative BPaaS architecture is described.

#### IV. IMPLEMENTATION OF BPMS

The following section presents the general implementation of *jBPM* in the context of a collaborative BPaaS and the implementation of the architecture-specific functional requirements in particular. Further, performance optimization methods for BPMS processes are described. To increase the comprehensibility, some short code snippets are presented.

The integration of privacy evaluation into each activity of the business processes can be achieved by evaluating the privacy at the start of the activity and annotating the data produced by the activity with the appropriate privacy policies. This functionality is not provided by *jBPM* originally, but it is implemented by creating customized *Work Items* which represent the activities of the business processes. Such *Work Items* have to be kept extremely flexible. This *Work Item* is called "Execute\_Generic\_Task" and is the core element of the privacy extensions added to *jBPM*.

##### A. Service Selection

The first functional requirement is the service selection from a service catalog. Two out-of-the-box services are

provided by *jBPM*, which can be used for external communication between the components from within the process. However, there is not much flexibility provided by them, as their data fields and behavior are predefined and cannot be adapted easily. The most adaptive design provides the interface *AbstractWorkItemHandler* that can be used within customized *Work Items*. Its implementation is realized as a plug-in into the process modeling palette. There are two interfaces available: *WorkItemHandler* with only two methods to be implemented and the abstract class of *AbstractWorkItemHandler*, which implements *WorkItemHandler*-interface. Multiple useful methods are provided and are further discussed in the following. The abstract class that takes over *StatefulKnowledgeSession* object as the parameter is responsible for the extended functionality that has to be integrated. It provides a common way for interacting with the process engine through the following methods: *getProcessIntance(WorkItem wi)*, *getNodeIntance(WorkItem wi)* together with *getSession()*.

First of them provides an access to meta-information about the current process or its parent process, while the second one provides the meta-information about the particular node. Finally, *getSession()*-method gets no parameter and returns the global session that comprises the current session and further various ones being instantiated within the particular project. Further, the above described methods provide also the access from within the node to process variables through the *input/output*-interface. The procedure of registering the customized *Work Item* and to inform the process engine about the customization and registration during process execution, comprises three following steps:

- 1) *Work Item artifact upload*: After compiling the *Work Item* as jar-file, it should be uploaded into the process repository which is managed by the maven dependency tool. There are several options available: direct upload through *jBPM Workbench* with subsequent referencing to it as project dependency in the project management console. The other option is pointing to the deployment ids i.e. *groupId*, *artifactId*, and version from the company's external maven repository in the setting.xml file. The *Work item* will be loaded from the maven repository.
- 2) *Work Item registration by Runtime Manager*: The *AbstractWorkItemHandler* has to be registered in the *kie-deployment-descriptor.xml* file. In code snippet1 line 4 points to the class as well as to its constructor with the *ksession* as parameter being taken over, where *ksession* is the global variable registered automatically by *jBPM Engine* and points to *StatefulKnowledgeSession* object.
- 3) *Work Item registration by Work Definition*: *WorkDefinitions.wid* file provides all important information of *Work Item* that is being displayed in the design palette as well as its reference to

the Work Item artifact through its name. The list of parameters in code snippet 2 refers to the input elements, that will be taken over by Work Item. This particular Work Item returns no output parameters. Otherwise, they could be listed through results keyword as a list that is similar to the list of input parameters.

---

**Code Snippet 1** Registration of WorkItem by Runtime Manager

---

```

1 <work-item-handlers>
2   <work-item-handler>
3     <resolver>mvel</resolver>
4     <identifier>org.example.
        ExecuteGenericTask(ksession)</
        identifier>
5     <parameters/>
6     <name>CustomWorkItem</name>
7   </work-item-handler>
8 </work-item-handlers>

```

---

---

**Code Snippet 2** Registration of WorkItem by WorkItemDefinitions.wid

---

```

1 [ "name" : "ExecuteGenericTask",
2   "parameters" : [
3     "elementId" : new StringDataType(),
4     "ip" : new StringDataType(),
5     "email" : new StringDataType(), ],
6   "displayName" : "ExecuteGenericTask",
7   "icon" : "defaultservicenodeicon.png"
8 ]

```

---

For the WorkItemHandler interface registration the first and the third steps are the same. However, as an interface provides no constructor, it cannot be registered via kie-deployment-descriptor.xml file, but it should be registered in kmodule.xml file, where the session as well as its setups should be provided manually. Having Work Items being uploaded as well as registered in the project, they are displayed in the modeling palette on the left side as shown in fig. 3. Both work items "Get\_Initial\_Request\_Data" and "Service Selection" are instances of "Execute\_Generic\_Task" being renamed according to their purpose. This is possible because of the generic implementation being written with AbstractWorkItemHandler interface.

### B. Remote invocation

The possibility to run the process by remote invocation is provided by the jBPM Remote API (Application Programming Interface). From the multiple use cases which are provided by this interface, there are suitable ones for the project-specific requirements to be used by some of

the project's components. Remote process invocation from within the privacy management system taking over the user's IP address and email address as well as remote process deployment by the configurator are crucial interface of the architecture. To realize the first use case, there are two components to be known, namely process definition id as well as deployment name. Code snippet 3 shows the web service call which is necessary to start the process with process definition id "main:project:1.0" and deployment name "project.generic-process". The process definition id is created by stringing together repository, project name, and version delimited by colons, while the deployment name comprises repository and process name which are delimited a dot. While creating the URL it is crucial to take care of data types and automatic type recognition of the application server and framework because of e.g. the IP address which contains dots is not interpreted as a floating point number. This can be ensured by masking critical characters of the values. After request is received and the process is started, the variables are being assigned to the global process variables as shown in code snippet 4. This way their values can be accessed in all Work Items of the whole business process.

---

**Code Snippet 3** The URL for starting the process

---

```

Http post = new HttpPost("https://<host
>:8443/jbpm-console/rest/runtime/main:
project:1.0/process/project.generic-
process/start?map_ip=user_ip&map_email
=user_email")

```

---

---

**Code Snippet 4** Assigning taken over variables to process global ones (kcontext is jBPM's global variable being instantiated by default and points to ProcessContext object)

---

```

kcontext.setVariable("email_var",
    kcontext.getVariable("email"));
kcontext.setVariable("ip_var", kcontext.
    getVariable("ip"));

```

---

### C. Process Activity Logging

One of the most important project requirements to be implemented is the Safe Points one. It's main objective is to provide process logging after each activity while the process is executed. On the one hand, Signal Events in jBPM are provided via a REST API (Representational State Transfer API) and execution can be resumed programmatically through the BPMS-controller after the log file is read off and all its content is sent to Log-Collector (i.e. the architecture's logging database collecting all operational logs during process execution). On the other hand, as already mentioned, all the logic of the process being packed

Fig. 3. Business process with custom Work Items being plugged in jBPM Workbench

within the Work Item, each Work Item should control privacy compliance, and, if the privacy rules are violated, the process should be stopped. If the privacy violated could be resolved by the user the process needs to be continued<sup>1</sup> from the node at which the process was stopped. For this purpose XOR-gateways (see Fig. 1) were implemented,<sup>2</sup> which consume boolean values being supplied by Signal Event after a process resume request. If the value is false, the process continues its execution. Otherwise, the Work Item creates a link to a web service which enables the process to be continued manually and sends it to Log Collector. The Cockpit retrieves the link from the Log Collector and presents it to the user indicating the node where the process was suspended. When the user clicks on the link the process is resumed from the activity which failed the privacy evaluation.<sup>3</sup>

#### D. Security Provider

As discussed earlier an important step in terms of privacy and security of BPaaS can be achieved by securing the cloud environment itself. This can be done by selecting and implementing secure components. E.g. keycloak is an open source identity and access management system, that provides the easy to integrate and secure single sign on mechanism OpenID connect. By providing a minimal configuration, it is possible to provide fully integrated process security with the service provider and user information being known. After keycloak's deployment to the application server and the server adapter (part of the architecture's gateway) being installed, the setup parameters for integration with client and for identity provider can be provided through web-based GUI. Moreover, there is a list of parameters being used during client's integration e.g. type of ssl being required, principle-attribute selection as well as basic authentication enabling, which provides flexible setup of the system. Altogether, keycloak is an easy to implement tool to provide security integration for jBPM environments which is also very reliable.

#### E. Cloud-Readiness

Due to the multi-tenancy of clouds the data of each business process have to be kept separated from each other. Following this, the unintentional data transfer between

#### Code Snippet 5 Distinguishing properties in pom.xml to be changed

```
<groupId>#{groupId}</groupId>
<artifactId>#{artifactId}</artifactId>
<version>#{version}</version>
```

two business processes is avoided. To ensure such a strict separation of the business processes each business process is packaged in an individual project. This project is then deployed to the jBPM server. Then the process can be started independently by each user. This steps of this approach are as follows.

1) *Preparing Project Artifacts:* Since projects in jBPM are managed in a maven repository, a pom.xml has to be created for each project in order to deploy it to the jBPM server. To simplify the generation of the pom.xml for the processes a template has been generated. The template is copied to the project folder and the process ids, i.e. groupId, artifactId, and version, are filled in automatically. This way each deployment's id is different from each other. The relevant section of the template is depicted in code snippet 5.

Business processes which have been designed in the Configurator are uploaded to an XML database (see sixth criterion's implementation) as xml files. The BPMS provides an API to the Configurator to upload the newly designed process to the database and to send a request to the BPMS-controller containing all relevant variables as described above. The necessary steps to replace the variables in the template and to prepare the deployment of a business process are shown in code snippet 6. The variables are extracted from the http request and are used in line 3 to replace the placeholders in the template pom.xml file. In line 4 the BPMN file for the business process to be deployed is retrieved from the XML database.

2) *Process deployment:* Having all artifacts being appropriately prepared for project deployment, it is important to check, whether a deployment with the same id already exists. jBPM provides a REST API for both project deployment and un-deployment. Hence, both methods can

---

**Code Snippet 6** Generation of process specific pom.xml and bpmn file
 

---

```
Path path = Paths.get(System.getProperty(
    "user.home") + "/standalone/generic-
    project/pomToGenerate.xml");
String pomContent = new String(Files.
    readAllBytes(path));
String pomContentReplaced = pomContent.
    replace("#{groupId}", groupId).replace(
    "#{artifactId}", artifactId).replace(
    "#{version}", version);
String processContent = baseXService.
    getXMLContent(groupId + ":" +
    artifactId + ":" + version + ".xml");
Files.write(Paths.get(System.getProperty(
    "user.home") + "/standalone/generic-
    project/project-to-deploy/src/main/
    resources/generic-process.bpmn2"),
    processContent.getBytes());
```

---

be used consecutively to guarantee the deployment of the project will execute without any conflicts. Line 1 of code snippet 7 shows the implementation of project's un-deployment, while line 5 shows the deployment of the project. Line 3 invokes the maven script in order to compile the project and upload it to the external artifact repository.

---

**Code Snippet 7** Deployment phase
 

---

```
restService.trigger(groupId, artifactId,
    version, Trigger.UNDEPLOY) //see
    method's implementation in the code
    snippet 8
...
Runtime.getRuntime().exec("mvn -f" +
    System.getProperty("user.home") + "/"
    standalone/generic-project/project-to-
    deploy" + " clean install deploy");
Thread.sleep(30000);
restService.trigger(groupId, artifactId,
    version, Trigger.DEPLOY); //see method
    's implementation in the code snippet
    8
```

---

#### F. Process operational data's external storage

As Work Items consume various multiple operational variables, the number of I/O mappings grows linear to the number of consumed variables. Hence, the possibility of errors grows as well. This results in a big performance issue which will be addressed in further research. In order to solve this problem, variables are stored to the external XML database. The following criteria are defined for

---

**Code Snippet 8** Implementation of the method in order to un/deploy the project
 

---

```
public int trigger(String groupId, String
    artifactId, String version, Trigger
    trigger) {
    ...
    HttpPost post = new HttpPost(hostname + "
    :8443/jbpm-console/rest/deployment/" +
    groupId + ":" + artifactId + ":" +
    version + "/" + trigger.toString().
    toLowerCase());
    //evoke request
    //return status code }
```

---

---

**Code Snippet 9** Retrieving values from XML-DB with BaseX API
 

---

```
public Map<String, List<String>>
    getDataByAttribute(String
    processInstanceId, String element,
    String attribute, String value) {
    HttpGet get = new HttpGet(hostname + "
    :8443/" + processInstanceId + "?
    query=//" + element + "[@" +
    attribute + "=" + value + "]");
    //execution
    }
```

---

their selection: REST interface support, GUI provision as well as compliance to standards. The selected application BaseX provides the usage of both XPath and XQuery via REST API. Thus, documents' content can be queried flexibly by the possibility to query either XML nodes or specific values of attributes. Code snippet 9 provides one of the methods used during project implementation to achieve a decision by querying attribute's value. ProcessInstanceId is the id of the current process instance. It also names the referring table which is created during the process' execution. In order to ensure privacy, the XML file with the all operational data is deleted at the end of each process. The implementation as well as the creation was provided through Work Items. Fig. 4 contains a general view of the business process being designed to meet all requirements. As already mentioned, Work Items provide the activity's full range of functionality. The first activity of each process is not a Work Item, as the first activity is always "Get Initial Values". This activity gathers the initial process input data and stores them in global variables. Those global variables are then consumable by the following tasks.

#### V. CONCLUSION

Collaborative BPaaS is an innovative and important approach in order to plan, execute and monitor business

Fig. 4. Evaluation example process.

processes with several involved companies in the cloud. Next to benefits such as increased flexibility and easy reconfiguration, however, the decentralized handling of sensitive data implicates the crucial challenge of companies' individual compliant privacy preservation. In order to meet this challenge, an IT architecture and several of its components have already been developed. This paper presents the implementation of a business process management system as one of the essential components of this architecture. After deriving the requirements for this component, existing BPM tools have been roughly sorted and the remaining one have been evaluated against the requirements. As a result, jBPM is evaluated as the most suitable BPM tool that is able to handle the BPMN 2.0 Core specification and thus, jBPM is implemented into the existing architecture.

Limitations result from the implementation in one exemplary programming language, i.e. Java, as well as from the selection that is influenced by the research induced requirements. Requirements and programming language preference may vary in other contexts of application.

Implication for research is, to the best of our knowledge, the first scientific approach of selecting and implementing a BPMS for cloud-based collaborative business processes in the context of BPaaS. Thus, companies are enabled to collaborate through the cloud while ensuring the privacy preservation of sensible data complying to individual companies' policies. Enabling and realizing the cloud-based collaboration while preserving data privacy, participating companies obtain a decisive comparative advantage.

The system has already been evaluated in several experiments and in interviews with experts from research and practice. Currently, the system is being evaluated in the context of real life use cases within the business environments of several companies. One crucial point for developing the system towards applicability is the optimization of its performance. Starting points for this are the parallelization of privacy evaluations or the parallelization of differing process paths' evaluation.

In summary, the acceptance of cloud computing in general and collaborative BPaaS in particular can be increased by ensuring the preservation of individual customizable data privacy as an important precondition in order to build up trust in the cloud paradigm.

**Abstract**—The aim of this article is to analyze the use of basic e-government elements by individual users in Poland in 2017. Article presents the results of research highlighting popularity, use and influence of e-government functions that support such application in reality. Seventeen core e-government functions, most popular among respondents, were selected based on prior consultation, being the baseline for following analysis. Authors conducted the CAWI analysis to evaluate the distinguished e-government functions on a selected sample of university students. A group of over two hundred and fifty randomly selected people from the university environment was examined. This approach was guided by the structure of the article consisting of the presentation of the research hypothesis, the description of the methodology and the research sample, and the analysis of obtained results and their discussion, together with the conclusions. The results can be used by people involved in the creation and development of e-government systems.

### I. INTRODUCTION

THERE is no definitive and complete definition of the e-government in the literature. According to the European Commission, e-government states for the use of digital tools and information systems to deliver better quality public services to citizens and businesses [1]. Polish equivalent – e-public administration - suggests narrowing this concept to public administration [2] only, while e-government also includes services offered by the budget sector, that go beyond the scope of the commonly understood public administration [3]. This is the reason why the Central Statistical Office has defined this as the use of information and communication technology (ICT), organizational change and new competences in public administration to improve public services and planned democratic processes [4]. Public administration is understood not only as an executive apparatus of the state, but also expressed as activities targeted to organize the conditions and principles of social relations, culture, urban transportation, environmental protection, etc. [5]).

In the meantime, according to other definition, this is more electronic system of information and public services. It would therefore be more appropriate to define e-public administration as an opportunity to exploit the complexity of telecommunication tools and techniques to streamline common administrative and civil services. Gathering in one -

virtual space, time and a single public administration portal all matters related to a specific category of users (citizens, business) facilitates and expands the ability to handle that [6].

In the European Union, public services are identified as guidelines for citizens that can be used via the Internet [7]. For individuals such services are: income tax, job search, social security, personal identity cards and document, vehicle registration, construction permits, police admissions, access to resources of public library, birth and marriage certificates, college registration, change of place of residence and access to health services. In Poland above presented list is slightly modified and according to project „Wrota Polski” it looks as follow: tax registration, job search and help finding a job, getting a social pension for unemployed, handicapped and retired, obtaining a student scholarship, obtaining a personal ID, obtaining a driving license, obtaining a passport, registration of a vehicle, obtaining a building permit, reporting to the police negative events such as theft, access to public library catalogs and searching them, filing Civil status forms and acts and obtaining required copies of those, college registration, change of place of residency and sign up for a doctor's visit [8].

Citizens of the European Union more often use the electronic method of contact with governmental agencies than Polish citizens. If we consider digital interaction of citizens with public institutions (excluding e-mail), Poland with the share of 31% of persons of age 25-64 (in 2015) holds 25th position in the ranking. Behind Poland are only three countries with lesser level of electronic interaction: Italy, Romania and Bulgaria. E-government services are divided into three groups: downloading forms, uploading of filled applications, and searching for related to service and service processing information. In this area Poland is away from leading European standards. In groups: downloading and uploading of forms and applications Poland is worse about 15% than average result for all European countries and about 26% worse in the group of gathering information about the matters realized via e-government systems. While in the top fifteen most developed European countries the percentage of filing tax returns is 32%, in Poland it amounts to only 14.2%; percentage of claims for social benefits in Western Europe is 11% while in Poland 0.7%; use of public

libraries in Poland is 3.1% compared to the average of 10% in Western Europe, etc. [9]. The above results indicate that Polish citizens despite filling tax declarations, don't use more advanced services of the e-government e.g. fulfillment of e-forms. The most common reasons for this state of use of e-government interaction is lack of sufficient competence to do that online (11%), concerns about personal data security (11%) problems with digital signature or digital ID (3%) and lack of specific functionality (2%) [10].

Considering above, the main purpose of this study was to determine whether this adverse status noticed 3-4 years ago was maintained. In addition, it was attempted to find out whether the current state of e-government in Poland satisfies people who are willing to use it and to what extent. Identifying the current status of functionality provided by the e-government systems may become the basis for the proposed changes in this area.

## II. RESEARCH METHODOLOGY

Provided in the introduction statistical analysis are not optimistic. Those indicate rather low interest of potential users of electronic administration systems in the current form. The article neither perform characteristics of those services, nor critical analysis of accompanied functionality. The authors faced the difficult task of selecting, a priori, the range of e-government services that are the most popular for the analyzed population and on the one hand, are consistent with the findings and definitions of the e-government used in definition of the European Union recommendations.

Research method consists of following steps: creation of list with all services that are possible to be provided via e-government systems; conducting the "popularity test" of used public services on a limited group of twenty-five people of the surveyed population; creation of survey questionnaire based on returned from "popularity test" answers, adjusted in its essential part and the language and scope of the question to the respondents' understanding of the basic functions of e-government; sending notifications to potential respondents and analysis and discussion of the results; the conclusions of the survey and the consequences therefrom.

Research was executed based on Computer-Assisted Web Interviewing (CAWI) method [11] on selected sample of university students at the end of February 2017. CAWI is an Internet surveying technique in which the interviewer follows a script provided in a website [11]. 254 respondents from academic environment took part in the survey. 197 participants provided full response to the survey, that is 76% of the whole survey population. Despite pre-consultation, questions still were reported as difficult for respondents. Survey contained following parts: introductory questions on the frequency and technology of access to the Internet and frequency of access to e-government; the main part consisting of: questions about another e-government service, resulting from the European Commission's assumptions, together with the question of the quality of the service in relation to the same service performed in the traditional way and the results and the degree of satisfaction resulting from it;

open questions addressing the future of e-government and demographic and social data questions.

The survey was distributed online via servers of Faculty of Management Of University of Warsaw. Participants were limited only to academic environment and were recruited from students of all types studies at Faculty of Management, University of Warsaw, Academy of Finance and Business Vistula. The survey completed over 250 respondents, who evaluated the whole issue. 76 percent of participants submitted correctly completed full questionnaire. Among the respondents there were 78,17% of women and 21,83% of men. An average age of the respondent was 21,39 years (out of range 19-23 years).

Among respondents 4,06% already finished the Bachelors studies and 0,75% finished Masters level. Approximately 69% of the respondents were students and 30% were working students. Almost 28% of respondents declared the origin of the city with the number of over 500 thousand of inhabitants, 12,18% lived in of the cities of 100-500 thousand inhabitants, over 13% lived in the cities with 50-100 thousand inhabitants and almost 24% of the respondents declared to live in the cities up to 50 thousand inhabitants and 22,34% declared origin of the rural area.

Selection of the sample group was decided after analysis of D. Batorski research [12], who proved that the highest level of Internet activity is within the age group of 16-24 and 25-34 (almost 70%), following the newmarketing.pl [13] service data, where 34% of all beneficiaries of all online services (including mobility) - were coming from the age group of 18-34 (similar values are given by other sources, e.g. MarketingAutomagic.pl [14]). The accepted assumption about the age of customers is at the same time an advantage of the choice that reduced the potential for generalization and also increase the positive results of the analysis.

## III. ANALYSIS AND DISCUSSION OF RESULTS

The most essential findings of the research are presented below.

A significant number of interviewees (97.97%) responded to the question about the frequency of use the Internet, that they use it several times a day, and additionally not less than once a day answered 1.51%. Only 0.51% of respondents use it rarely - a few times a month. In the meantime, the answer to the question whether respondents often use functions of the e-government is clearly disappointing. Most of people (39.59%) use such functions very rarely or not at all (18.78%), and additionally 15.23% respondents handle public matters traditionally, which is a testimony to the fact that almost 75% of respondents does not participate in the benefits of the functionality of this area.

The first question concerned the most popular function of e-government – on-line tax settlement. Almost 45% of respondents have confirmed that they have used often (or have used from the beginning of such availability) or several times. 8.63% of respondents never used such features. The traditional way of doing taxes is declared by nearly 30% of respondents. Almost 60% of those who declare to use this

system, admit that on-line tax settlement is better method than visiting a Tax Office, while the opposite opinion shows 8,12% of respondents.

At a similar level, was rated the opportunity to use the Internet for job placement. In this case 41% of respondents used this advantage several times, and 16.24% used at least once. Unfortunately, more than half participants did not use it at all, and 8.12% used traditional methods of job-seeking. This resulted that only slightly more than 19% of respondents who use such form of contact rated online employment searching as better than traditional methods, and almost the same number claimed to be equal. By contrast, over 56% have no opinion on this subject. From the other hand, only 3% believe that online job searching produce worse results than traditional.

Generally, similar distribution of responses was obtained in response to the question related to participation in the on-line social security service for individuals. More than a quarter of respondents declared that they used this form of contact at least once. But almost the same - 2% - claims to handle such cases in a traditional way, and as many as 52.28% do not use at all such services available on the Internet.

Much better proportions are noticed in the process of using online services related to driving area. More than 58% of respondents used this service at least once, 28% did not use it. Almost 20% used traditional methods. More than 56% of respondents consider it to be equal to the traditional, and only 2.5% assess it worse. 38% have no opinion on this subject.

Only slightly over 25% of respondents participated in the online process of passport service, more than 38% of respondents handle passports traditionally, 3% of respondents do not use this online service. Only 14% believe that online methods are better than traditional, more than 10% recognize those services as equivalent, but 66.50% do not have any opinion.

Even worse were the results of online personal identification services. At least once, 37% of respondents used this possibility out of those two thirds only once. On the other hand, 4% of the respondents used traditional methods. Those who used on-line services, claimed that this was a better way than traditional methods (26%), but more than half (54%) did not have an opinion on this.

Almost 48% of respondents don't use the registration and de-registration of vehicles process, 34% of participants handle it traditionally. Only 18.28% of respondents supported these activities using ICT techniques. Only 18% believe that the results were better or equal to traditional ones. Nearly 75% have no opinion on this subject.

76% of respondents do not use online services to obtain construction and demolition permits and 20% handle it traditionally. Only 4% participants use the facilities in this regard. 87% respondents have no opinion about the primacy of online methods, and almost 80% think that the results of the systems used in this field are almost none.

Approximately 19% of respondents used the Internet to obtain the required documents from the Office of Civil Status. Only one quarter deals with this matter traditionally, and

55% have never had a need to use those services at all. However, less than 10% think that online methods are better than traditional, and 7% recognize the equivalence between traditional and web supported. But still 74% have no opinion on this subject. Two thirds believe that currently the results of use of such systems are almost nonexistent.

The opposite is the situation with the use of on-line health service. At least 66.7% of respondents used it at least once, and almost all of them considered it at least enough, and only 23.9% handle it traditionally. Therefore, 66% consider such services to be better than traditional, and only 29% of respondents have opposite opinion. Even when treating medical services in the general way as were used in the survey (contact with health services over the Internet), it is not possible to notice that they are at low level.

There is also an advantage of using online public opinion polls and public mailing lists - 53% over the people who don't use such services - 47%. On the other hand, on line reading is positioned very well, almost 81% of the respondents experienced this form of communication with culture via the Internet, while 78% consider it to be at least equivalent to traditional methods and 100% are glad with it.

Additionally, due to the selected research sample, students were asked about the possibility to apply online for admission to the university, and over 94% of the respondents used this form of communication and considered it better or at least equivalent to the traditional forms as well as they confirmed that participants were satisfied with this form.

#### IV. CONCLUSION

To sum up the above considerations it should be noted that average results of use of the e-government systems in 2016 do not differ much from the results described in the survey carried out in Poland and Europe in 2013-2015. The fact is indicated by nearly 35% of users of e-government systems in 2016, compared to 31-33% in other studies [9], [15] and similarly 30.% for the tax settlement (compared to 31% in the European Commission databases [7]). The resulting differences may be caused by the methodological discrepancy or characteristics of the selected test group.

In summary, conducted surveys, supplemented by comments from respondents, give the following conclusions:

- the level of electronic services in e-government area in Poland is considerably lower than in most of European countries. In the official sphere this situation has not changed since the last three years,
- some revival can be noted in the social sphere (culture, public opinion, public health services, etc.), but the opinion expressed by respondents shows that respondents do not always distinguish public administration services from private services,
- the basic problem in using of e-government services is lack of ability to handle the whole matter from start to finish via the Internet. The small range of available services are often limited to the ability to print out a document, which is even more disconcerting than attracting potential users,

- another element that deduces the benefits of the e-government is a need to appear personally in the office despite the settlement of some cases over the Internet,
- there is serious level of a mistrust to the local and central administration as well as perception of a potential lack of internet security,
- for the respondents the decision to use the e-government function is also balanced with the security of their personal data while handling the matter,
- there are gaps in information how to handle a given matter or the information is not clear for the user and he lack of proper marketing and information about possibility to handle public administration issues over the Internet and education about related benefits,
- there are technical problems and e-government services are incorrectly designed from the user's point of view and are described in an incomprehensible language,
- sometimes there is no response from the officials or lack of answer to the question and the low competence of officials informing how to fill out the web forms
- in this situation it is not surprising the large share of traditional methods in dealing with official matters.

The above conclusions show a number of potential postulates for e-government, the most important considered by authors are:

- the ability to provide universal functionality to fill applications and documents without the need for an electronic signature as is in its current form, accompanied with feedback on whether the document has been properly filled out, or reverse information how to correct errors,
- the dissemination of information regarding e-government, as many people simply do not know about the possibility of settling official affairs and education on how to use online services and forms to convince unconverted to use this method to contact with the public offices or institution,
- proper design of e-government services, making them in a user-friendly language, not necessarily professional, maximizing the simplification of forms and minimizing of information taken from

the citizen, especially when already present in the databases of the office or institution,

- and above all, the unification, simplification and integration of numerous legal and organizational regulations and restrictions that hinder contact with public administrations and the use of e-government.

The presented study has preliminary character and was concerned on the distinguished population. Its nature was based on the results obtained from test group and should therefore be extended to include a broader social cross-sectional survey and focus more on the use of e-government by citizens rather than on the current state of its activity and acceptance.

**Abstract**—Survey is the most common way to gather information for research purposes. Gathering information is usually provided in the early stage of research procedure. The information create the basis for further activities which lead to scientific research results. The problem is that information gathered as a result of survey is exposed to the high risk of errors. Following factors generates mostly errors: the way of survey carrying out, the survey content and just by simple human factors. Researchers very rarely pay their attention to the data quality taking as an obvious that gathered information describes properly studied case. In the end of the process they get results, which are becoming basis for the conclusions. Taking that into account the questions is about the quality, of research results, which were based on the surveys. What is important, usually most publications do not contain any information about source data on the basis of which results came out. It disables the independent evaluation of the results. The goal was to investigate the scale of survey data errors, using the scientific experiment. To achieve it, authors used their own survey system, which helped them in instant verification of the respondents' answers.

### I. INTRODUCTION

**S**URVEY is probably the most popular method of data gathering for research purposes [1]. It is used as a supporting tool not only for science but for political and business aspects of life as well [2] [3] [4]. Surveying consists in gathering data from respondents using dedicated tool. Data collected that way should form the standardized set, mapping reality being examined. People to be surveyed form the target of previously prepared questions. Questions can refer to themselves or to theirs' opinions about the subject being examined [5]. During survey the answers are being collected into a set, that forms the source data, which is a basis for the further steps of research procedure. Using appropriate research methods [6] previously gathered data is then analyzed.

The issue that can occur is big possibility of errors in gathered set of data. The most important is that even single errors in gathered data can have negative effect on all set [7]. The low quality of the set, of the source data, affects the further research procedure. That can cause wrong analysis results and false complex process results. It is important to mention that a mistake made in the beginning phase of

research procedure, becomes more difficult to be discovered while executing the furthers steps. The next problem is lack of possibility to undermine answers given during survey. That is because the answers are individual convictions of the respondents, who represent tested reality [8] [9]. It is difficult to prove that answers given by respondents are wrong and that they do not represent theirs real preferences.

Considering the above-mentioned issues, there comes the question about the quality of source data that is used as a basis for the scientific research. As we can find in the different sources, the problem of errors in source data is known and is being current since many years. Assuming that most research is conducted on the basis of such data sets, their results may be incorrect.

### II. THE ANALYSIS OF THE PRESENT SITUATION

The problem of the errors in surveys' data and low quality of data are being mentioned since long time. Unfortunately large group of researchers don't pay appropriate attention to the quality of used by them data. This is also confirmed by studies published in 1996 [10]. The results of these studies suggest that errors in the source data are not perceived as a significant factor affecting their poor quality. Scientists often ignore the issue of source data errors.

There are many proven causes of low quality survey data. Such a situation is caused by many factors [11] [12], which are often ignored by the survey authors. Unfortunately, most of them cannot be eliminated if the survey data collection method is used. Rapid development of ICT, caused that standard surveys are replaced by electronic ones. Such technology made possible reaching faster more respondents. The main advantage of collecting data through electronic surveys is that data are ready for analysis, immediately after survey is finished [13]. The biggest disadvantage of online public surveys is the lack of a representative sample [14]. The interviewer can't verify the affiliation of his respondents to the desired target group. It seems that optimal way is to conduct electronic surveys, under the supervision of an interviewer. The group of respondents can be verified and collected data are stored into the database.

In data quality research, attention is also paid to the lower involvement of the respondent, in the case of a web survey [15]. The problem with the respondent's involvement is also due to the volume of survey. Keeping the respondent's attention becomes more difficult, the longer the time it takes to respond. An interesting solution for that problem may be mobile technology where survey questions are sent periodically to the respondent's mobile devices [16]. That shows that the development of information and communication technologies significantly increases elimination of survey errors.

It is also very important, in the discussed subject, that the majority of published research results do not contain any source data. Verification of the result is almost impossible, without access to the source data that was used. Sharing data is a natural in custom areas such as: astronomy and genomics [17]. Publishing the source data together with the research results, gives the proof of data good quality [18]. Authors of those publications choose their research to be publicly verified. Publishing source data also gives opportunity for other researchers, to use them in their own work. It has also been proved to have a positive effect on the author's citation rate [19]. In science we can observe a trend in which sharing source data is promoted. Some researchers support that path and some don't [20] [21] [22] [23] [24][25].

### III. THE EXPERIMENT

Present knowledge suggests that the data collected from the surveys very often contains errors. Using such a data cause that received results may be incorrect. The aim of carried out experiment was to diagnose the scale of the problem. The goal was to verify possible amount of errors in the set of data gathered from survey. During the acquisition of data for the research, an electronic survey was used. It was filled under the supervision of an interviewer. The specificity of the experiment required establishing own individual survey system. That is why own author's ICT system was prepared and used. This was due to necessity to enter data as a respondent's declaration and their immediate practical verification. This activity allowed to check the quality of declared responses. Immediate verification of the respondent's declarations was possible thanks to the QR code technology (Quick Response). QR code works similar to the bar code, which is the basis for automatic identification [26]. The graphic form of the code stores data that can be read by optical input devices, such as a digital camera.

The scenario of the survey assumed the following stages: the exclusion of respondents who don't have the technical capabilities to join the survey, placing the survey question and receiving the respondent's answer in a declaration form, the practical verification of the previous declaration. 216 persons participated in the experiment. People aged 19-23 were invited to the study. It was assumed that this age group consists the most people that should be able to solve the

problem presented in the study. The sample group included people connected with technical and non-technical studies fields.

After people who didn't have technical capabilities for survey participation were eliminated, 197 qualified for the second stage. That group has been tested and questioned with two questions concerning the same issue. The feedback coming from the first answer was in a form of declaration. That question contained the graphic shown in Figure 1 and the question: "You walk into the shop to buy some electronics and you see the poster shown above. Would you be able to get this discount?" The respondents declared whether they would be able to use the promotion. The second question was concerning the same issue, but feedback was based on the real use (scan) of the QR code. Correct scanning of the displayed code formed a practical verification, of the previously declared ability. The design of the author's survey system allowed to count how many people confirmed their declaration during the practice part of the test. Each respondent received individual code and only the real scan, saved the response to the survey database.

Fig. 1 Graphic of the survey question

The next step in the research procedure was to compare the answers given to both questions. That was a comparison of the declaration, with the real replies given by respondents. By comparing the results from both elements, you can discover possible scale of errors in respondents' declarations.

### IV. DETERMINANTS OF FORMAL EVALUATION OF THE MULTICRITERIAL DECISION PROBLEM

An important phase was studying the error formation, based on data coming from examination of the preferences of a particular group. In order to eliminate factor of the "Digital exclusion", technical and economic fields students attended the study. In the research author used the method of multidimensional functional analysis - the scoring method [27]. The scoring method is based on a specific hierarchy of elements and their distance from the maximum possible achievable value. In the method, hierarchy is characterized by an increasing or decreasing, indicating the level of global criteria realization, which contains all sub-criteria [28]. Using the point method collects the information about criteria. The information receives assigned value according

to a comprehensive scale of values (Table 1) and the results are listed in the summary table [29].

It should be pointed that the criteria used in the elaboration are treated equal and values of factors are designated to the scale of preferences. In the assumed and accepted method, in assessing the preferences of the surveyed students, the following actions were considered:

- appointing an expert group of representatives of users and potential users of QR technology, selected from a rated group (university students);
- defining detailed criteria for QR codes assessment, their hierarchy and the relationships between the evaluation factors which means creating a detailed survey;
- compiling results in the form of individual tables and in the form of aggregate tables;
- final results analysis and conclusions (preferences of survey respondents and AHP decision support method)

In the point method, experts assign ratings to the criteria according to the scale consistent with the Table 1.

TABLE I.  
SCORING RULE EVALUATION OF EACH OF THE TEST CRITERIA

Grades range	Explanation
0	Represents lack of a given feature
0,25	A low (satisfactory) level of a feature
0,5	An average (sufficient) level of a feature
0,75	High (fair) level of a feature
1	Exceptionally high level of a given feature

The point method that was selected for the assessment allows partial evaluation for each of tested criterion. That method does not specify the criterion as the worst / the best, it is only derived from the normalized distance. On the basis of the results coming from the point rating of respondents' preferences, the Analytical Hierarchy Process (AHP) method was used [30]. The relevance in the AHP method for transforming the scores obtained from the expert marks each criterion and factor in the hierarchical model, gained from the pairwise comparison. The result of comparing two elements from the same hierarchy level is reflected by the existing domination between them. For the domination description we use nine-step preference scale. Then all elements values in the row are summed [31] [32] [33]. The sums are normalized according to the formula (1) in further steps of the method we determine the coherence of the ratings (4), which is the same as the transitions of the criteria weights. It should be emphasized that in order to assess the validity of the criteria to be considered consistent, the value of the calculated conformity factor should not be greater than 0.1.

$$an_i = a_i / \sum_{n=1}^i a_n \quad (1)$$

The divergence factor is derived from the formula (2):

$$CI = \frac{|n - \lambda_{sr}|}{n-1} \quad (2)$$

Where:  $n$  is the number of criteria where (matrix rows) and  $\lambda_{sr}$  is the consistency factor.

The compliance indicator is derived from formula (3):

$$CR = \frac{CI}{R} \quad (3)$$

Where, CR is the compliance rate, CI is the coefficient of discrepancy and R is the factor random compliance.

The cohesion factor is determined using formula (4):

$$\lambda_{sr} = \frac{1}{n} \sum_{i=1}^n \lambda_i \quad (4)$$

Where, in  $\lambda_i$  is described by the formula (5):

$$\lambda_i = \frac{\sum_{j=1}^n A_{ij} * w_j}{w_i} \quad (5)$$

Where,  $w_i$  is the weight of the criterion  $i$ ,  $A_{ij}$  is the matrix element  $A$ .

The coefficient of randomness of R is dependent on the number of criteria being taken into account. The value of this factor according to the number of criteria is shown in Table 2.

TABLE III.  
VALUES OF CONFORMITY  $R$  FOR SPECIFIC QUALITY OF CRITERIA

n	1	2	3	4	5	6	7	8
R	0	0	0,52	0,89	1,11	1,25	1,35	1,4
n	9	10	11	12	13	14	15	
R	1,45	1,49	1,51	1,54	1,56	1,57	1,58	

Similarly, the consistency of the preferences of the choice options can be determined in relation to each criterion. We should adopt  $n$  not as the number of criteria but as the number of variants. The synthesis of the criteria importance and alternatives preferences according to each criterion consists in multiplying the weight of a given criterion by the value of the variant evaluation for that criterion. That action is done for all criteria, and the results received for each criterion are summed up. As a result, we obtain the generalized alternative quality measure. Those actions are repeated for each variant and then variant ranking is created. The highest quality value means the best considered variant [34]. As the result of the AHP method we receive the ranking of variants created according to the quality measure coming from each decision alternative. That method determines whether the user is able to use the QR code correctly.

## V. EMPIRICAL VERIFICATION

The presented research is based on results of an online survey - more in Chapter III: The Experiment. Through the survey all phenomena related to the survey errors formatting,

based on data from the respondents' preferences were categorized. Results are classified by 4 characteristics (conditional criteria). The studies used variables, which had adopted integers value from the range [0-1]. Data characterized the status of variables as:

K1 Are you using a mobile phone?

K2 Do you use an Internet access in your mobile?

K3 Entering the electronics store with a decision to make a purchase, you see the poster as shown below. Do you know what to do to get a discount?

K4 Now, scan the code shown below and see what it is hiding.

It should be noticed that the choice of the criteria did not solve the problem of decision selection. It was necessary to determine the preference vector for those criteria. Due to the gained results, questions arise. What were the preferences of respondents who responded to the survey questions? What did they pay the most attention to? And did the students not cheat while answering survey questions? The last key question is whether respondents answered all questions correctly? Receiving an answer and determining the preference vector for the selected criteria requires a point method (single or group context). Results of the point method of scoring the preferences of respondents are presented in Table 3.

TABLE III.  
ESTIMATION OF RESPONDENTS' PREFERENCES ACCORDING TO  
CRITERIA

	Preferences	Point scale	Explanation
K1	0,91	1	Very good level of features
K2	0,95	1	Very good level of features
K3	0,74	0,75	Good level of features
K4	0,25	0,25	Satisfactory level of features

After receiving ratings from the survey and pointing the respondents' preferences, the next step was AHP method use. The AHP method identifies in dialog mode, not very clear statements of a selected group of experts (respondents answering the survey questions). The characteristics of QR codes according to the evaluation criteria, indicated by the AHP method and the preferences of the respondents are shown in Table 4.

Table III.

QR CODES ACCORDING TO THE INDICATED EVALUATION CRITERIA

Criteria	K1	K2	K3	K4	Scales
K1	0,17	0,17	0,16	0,19	0,171
K2	0,18	0,18	0,16	0,19	0,179
K3	0,31	0,31	0,28	0,25	0,288
K4	0,34	0,34	0,40	0,37	0,362

In order to assign each criterion's weight according to the AHP procedure, the criteria were compared in pairs and the preference of the decision maker was assessed. The next step was the matrix of the relative criteria importance construction. Based on the matrix's own value, the generalized relevance of criteria were determine. Shown in Table 5.

TABLE V.  
GENERALIZED VALIDITY OF CRYTERIA

Criteria	Sum of grades	Scales	$\lambda_{max}$
K1	5,82	0,171	1,00
K2	5,57	0,179	1,00
K3	3,57	0,288	1,03
K4	2,73	0,362	0,99

The AHP method uses the 1-9 scale. The goal is to find out the advantage of one variant over another, according to a particular criterion. Quantitative data were used in that study.

As a result of the AHP procedure, we received the W1 preferences matrix (declared data) and W2 (practically verified data), according to all criteria and containing generalized preferences. That matrix is shown in Table 6 and the distribution of results in Figure 2.

TABLE VI.  
VARIANT PREFERENCE MATRIX

	K1	K2	K3	K4	Scales
W1	0,476	0,487	0,425	0,200	0,364
W2	0,524	0,513	0,575	0,800	0,636

Fig 2 Variant Preference Matrix according variants W1 and W2

In the preferences matrix distribution according variants W1 and W2 shown above, we can observe clearly dominance of W2. The difference between variants 1 and 2 was the first element recorded standard survey declaration and the second one examined the actual situation. Thanks to the presented results received using author's survey system, we could investigate the phenomenon of survey data error formation. In the experiment we combined declared values with data practically verified. That study showed the probable scale of the low quality data coming from survey research. The collected data indicate that part of respondents were wrong about their competence in the examined subject. Thanks to the QR and other IT technologies that phenomenon was discovered and described in the above research.

## VI. CONCLUSION

The result forms the basis for the analysis of the current respondents behaviour. It concerns the area of justification and the subsequent efficiency using survey as a method of obtaining data for research. The presented approach to multicriteria evaluation of the decision problem allowed us to use the point method for the evaluation of the respondents' preference designation and the AHP. Thanks to the used survey tool, the data obtained for the experiment include not only the declared responses, but also their practical verification. A comparison of the data from two sources showed that the theoretical data obtain to be significantly different from the real. Using such data sets in research may lead to wrong results and cannot be verified.

The current state of ICT development allows step by step resignation from survey data acquisition methods. We have presently more and more opportunities to use modern mobile devices and data-communication technologies for data collection [35]. Those technologies can be used successfully to conduct research procedures and they can eliminate respondents' involvement in the survey process.

**Abstract**— The paper aims at 1) finding the most important factors influencing positive customer reactions and purchasing merchandises after seeing online social media advertising and 2) identifying characteristics of customer clusters having positive reaction, as well as of purchasing customer clusters, after seeing online social media advertising. Data from 370 respondents are collected by questionnaires using convenience sampling method. Attribute selection and clustering techniques are employed in data analysis to find important factors and identify customer clusters, respectively. It is found that there is a strong correlation between the reason for clicking advertisement on social media and the satisfaction with merchandise, and between purchasing merchandise online and saving information for further consideration. The findings also indicate the characteristics of “Product conscious” and “Price Conscious” clusters for customer's reaction and purchasing after seeing online social media advertising.

## I. INTRODUCTION

WITH high popularity of social media, several social media websites have been developed such as Line, Facebook, Twitter, etc. and the usage rate has increased every year. Social media has become a fast and easy way to reach people in almost every group categorized by age, occupation, and education etc. with less cost. The usage of social media is widespread in private and public environments. In the highly competitive business world, social media has become a source of large amounts of data that is extremely useful when data are analyzed properly. The results from analyzing data properly can be useful in variety of disciplines including education, business, politics, social, science, technology, etc.

Marketing campaigns with online advertising are one of the methods that businesses use for increasing purchasing motivation. Finding target customer characteristics and customer reactions to social media advertising helps to reach more customers and is useful information for a marketing campaign. Data mining is one of the known techniques to analyze data to find hidden information from a large amount of available data without having prior hypotheses. Data

mining provides a variety of methods such as association, classification, clustering, etc. for analyzing data, but selecting a method to match with the objectives is a challenge.

The purposes of this study are to 1) find the most important factors influencing positive customer reactions after seeing online social media advertising, 2) find the most important factors influencing purchasing products advertised online, 3) identify customer clusters characteristics that have positive reaction after seeing online social media advertising, and 4) identify customer clusters characteristics that purchase merchandise after seeing online social media advertising.

The rest of paper is organized as follows. Section II gives a review of literature. Section III describes methodology. Results are given in Section IV. Section V concludes the paper and gives discussion.

## II. LITERATURE REVIEW

Data mining has been defined as the process to extract knowledge from large quantities of data in order to discover meaningful patterns and rules [1]. Reference [2] defines data mining as the analysis of (often large) observational data sets to find unsuspected relationships and to summarize the data in novel ways that are both understandable and useful to the data owner. Reference [3] defines data mining as a process of knowledge discovery. Reference [4] summarized that data mining contains three key stages: finding patterns, interpreting them in order to check their usefulness, and finally using the patterns to solve business problems. The ultimate goal of data mining is to discover knowledge and it will be useful in several disciplines. In business, data mining is used for strategic benefit such as direct marketing, trend analysis, etc. In direct marketing, data mining is used for targeting people who are most likely to buy certain products and services. For trend analysis, data mining is used to determine trends in the marketplace [5].

Reference [4] explains that there are two main types of DM models as follows: 1) Predictive model: This model is constructed to predict a particular outcome or target variable. Commonly used predictive modeling techniques

This work was supported by King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand.

include multiple regression (for predicting value data), logistic regression (for response prediction) and decision trees (for rule-based value or response models). 2) Descriptive model: This model gives a better understanding of the data, without any single specific target variable. Commonly used descriptive techniques include factor analysis (to extract underlying dimensions from multivariate data), cluster analysis (for grouping a customer database into segments), and association analysis (for discovering relationships between items such as retail products).

A marketing campaign is a specifically defined series of activities used in marketing a new or changed product or service, or in using new marketing channels and methods. Marketing activities are efforts to increase awareness for a particular product or service. Social media is one of the most popular marketing channels due to the ability to reach large numbers of customers with low cost. Social media advertising helps businesses find new potential clients by using the users' own shared information to identify interest. Rather than re-actively targeting users who search for a certain term, social media advertising proactively targets relevant users before they even begin their searches.

Prior research that relates to the study topics were reviewed as follows: Reference [6] researched the factors that influence the recipients to open direct emails and make an action desired by the company and also studies whether and what elements in the email would influence them to buy the products or services promoted. The results are obtained based on a data mining analysis which includes clustering and classification processes and offer a guide on how organizations should design their email marketing communications in order to have higher response rates. Reference [7] researched on the value of social technologies in organizations based on the 'value focused thinking' approach. The findings highlight innovation of internal processes, creation of organizational identity and new business models, integrated business functions, as well as employee support to be important values of social technology enabled innovation in organizations. Reference [8] researched on the segmenting of consumer reactions to social network marketing. The purpose of the study is to understand how consumers may be segmented with respect to their reactions to social network marketing. The results identified five segments – Passive, Talkers, Hesitant, Active, and Averse – along with significant covariates such as information search, convenience, entertainment, age, and gender that predict membership.

### III. METHODOLOGY

Several aspects related to the factors that influence a respondent to react and purchase a product or service after seeing social media advertising are explored from the literature review. Based on the literature review, the questionnaires are developed and distributed to people who used to purchase product or service through social media such as Facebook, Line, Instagram, etc. The questionnaires

are composed of the three parts; the first part is about the demographic data of the respondents, the second part is about the respondent's reaction when seeing social media marketing campaigns, and the third part is open-ended questions about the respondent's opinion. The data has been gathered at the level of samples including 370 respondents aged less than 60 and being employees, freelancers, entrepreneurs, managers, and students. The data has been collected between January and April 2017 through an online survey by using the convenience sampling method.

The research directions include: determining the most important factors that influence the customers to have a positive reaction after seeing social media advertising; determining the most important factors influencing purchasing products that advertise online in social media; identifying the customers characteristics that have positive reaction after seeing social media advertising; and identifying the customer clusters characteristics that purchase merchandises after seeing social media advertising. The software used to analyze data is WEKA data mining software. The research employs an attribute evaluator called "CorrelationAttributeEval" for determining the most important factors with respect to class attributes. It also uses the "SimpleKMeans" clustering algorithm for grouping customers.

### IV. RESULTS

The analysis results indicate that most of the respondents are students, females, aged 21-30, single, and educational level of Bachelor's degree, and average income less than 15,000 THB. Highest percentage on the usage of social media is Facebook, followed by Line and Instagram. The most purchasing are in fashion merchandise, followed by IT and software, and beauty and health merchandise. Spending per transaction is between 500 to 1,000 THB.

In order to identify the most important factors that influence the customers to have a positive reaction after seeing social media advertising, the class attribute called ReasonForClickingAdvertisementOnSocial Media is selected. The relation between the class attribute and the others is determined using CorrelationAttributeEval. The results present that for the customers, there is a strong correlation between the reason for clicking advertisement on social media and the satisfaction with merchandise (0.12727), special rewards (0.08522), not buying (0.0852), and link for searching on more details (0.08507). Other attributes are ranked below 0.07.

The class attribute PurchasingMerchandiseOnline is selected to determine the most important factors influencing purchasing products with social media advertising. The relation between the class attribute and the others is determined using CorrelationAttributeEval. The results present that for the customers, there is a strong correlation between purchasing merchandise online and saving information for further consideration (0.13879),

merchandise logo (0.10179), and immediately purchase if satisfied (0.09747). Other attributes are ranked below 0.09.

The EM (Expectation Maximization) and “SimpleKMeans” clustering algorithms are used for grouping similar customers based on positive reaction after seeing social media advertising. The EM algorithm is used to identify the approximated cluster numbers. In this case, the result is 2 clusters. This value is used as a parameter for the “SimpleKMeans” algorithm. The algorithm results are presented in Table I.

Cluster 0: Most customers in this group save information for further consideration (74%) and are interested in high percentage of discount (64%) after seeing advertising in the social media. For this cluster, the advertising should emphasize on merchandise quality as well as price to create more positive reaction.

Cluster 1: Most customers in this group save information for further consideration (70%), are interested in high percentage of discount (64%) after seeing advertising in the social media, and are also interested in seeing text, image, and clip advertising (65%). For this cluster, clip advertising may increase the customer's interest and create more positive reaction.

Clustering customers based on purchasing merchandises after seeing social media advertising is similar to clustering based on positive reaction after seeing social media advertising. The results are presented in Table II.

Cluster 0: This group of customers can be called “Product conscious.” Most customers in this group save information for further consideration (74%) after seeing advertising on the social media and purchase when satisfied with merchandise or services (55%). Seeing text, image, and clip advertising is also interesting for this group (53%). For this cluster, the advertising should emphasize on quality and brand to justify the price.

Cluster 1: This group can be called “Price conscious.” Everyone in this group is concerned about price before purchasing merchandise. Interesting price (100%) and high percentage of discount (71%) will get these customers' attention. Customers in this group also like to save information for further consideration (65%) and are interested to see text, image, and clip advertising (58%). For this cluster, the opportunity to purchase at a low price should be emphasized on the advertisement online.

## V. CONCLUSION AND DISCUSSION

Based on the findings from this research, e-commerce business should draw attention to the content that is emphasized in the advertisement online, due to some clusters

Table I. Customers cluster based on positive reaction after seeing social media advertising

No.	Attributes	Cluster 0 (94, 25.4%)	Cluster 1 (276, 74.6%)
1	Interested in Seeing Advertisement on Social Media: merchandise logo	0.2128	0.0725
2	Interested in Seeing Advertisement on Social Media: text, image, and clip	0.266	0.6522

23	Marketing Campaign Influence Buying: having after sales service	0.2255	0.1037
24	Marketing Campaign Influence Buying: others	0.017	0

that are product conscious while others are price conscious. For the product conscious group, price does not matter as

much for them and they decide to purchase based on satisfaction with the merchandise after thoroughly considering. Merchandise quality alone can get the product conscious group to purchase or have positive reaction after seeing online advertising in social media. For the price conscious group, they are looking for an interesting price and a high percentage of discount. Presenting interesting price will draw high attention from the price conscious group. However, both groups are interested in the advertisement online, and the advertisement that can draw customer's attention should provide interesting text, image, and clip advertisement. The advertisement should be attention-getting about the pricing so that it would convince the customers to click on the advertisement and continue to purchase the merchandise. The advertisement should also emphasize the high percentage of discount, which can draw attention from customers in both clusters that derive from positive reaction and lead to the purchasing of merchandise after seeing online advertising in social media.

The major limitation of the research consists in the low number of respondents (only 370), so this exploratory research should be followed by a conclusive one to verify the conclusions of the present research. Also, the majority of the respondents were students, aged 21-30, with low income and low spending per transaction, which may have influenced the positive reaction after seeing online advertising in social media.

Future directions of research may include: (1) using association techniques to determine rules related to positive reactions and purchasing, (2) adding some other information about respondents like time spent in front of the computer and time spent in using social network, and analyzing the influence of those factors on positive reactions and the purchasing of merchandise.

<sup>§</sup>corresponding author

**Abstract**—This paper investigates the problem of the sustainable ammonium nitrate transport. The significance of this problem is increasing, considered the occurrence of the worldwide agricultural production boost. The existing international regulations for the transport of the dangerous chemical substances are not sufficient to obtain a satisfactory solution for the sustainable transport. The main reason for that is the fact that the safety criteria can easily become dominated by the economic factors.

In this paper, the authors use the COMET method to identify a decision making model for the selection of the best scenario of sustainable transport. The COMET method is a new multi-criteria decision-making technique that is free of the rank reversal phenomenon. The identified model provides information about the global and local significance level of each of the criteria. The proposed approach can be easily expanded by using a greater number of criteria, depending on the particular problem analyzed. The proposed methodology is an efficient and highly accurate solution to make decisions based on experts' knowledge.

## I. INTRODUCTION

THE ammonium nitrate is one of the most popular mineral fertilizers in Poland and in Europe. It supports a highly developed agricultural industry [1], [2]. The carriage of the ammonium nitrate is regulated by international legal standards due to its dangerous nature [3]. The process of the registration of the transport of the ammonium nitrate and its classification to a group of hazardous materials determines a number of guidelines on its transport [4]. The obligation to ensure the compliance of the carriage of the ammonium nitrate with international laws and regulations for transporting dangerous materials by rail (RID - Règlement concernant le transport International ferroviaire des marchandises Dangereuses) and road (ADR - L' Accord européen relatif au transport international des marchandises Dangereuses par Route), affects the final time and cost of the transport of the product [4], [5].

The sustainable transportation systems should not only be efficient, robust and economical, but also friendly towards the environment, which is the requirement of the modern times [6]. They should minimize the impact on the environment, such as air pollution, noise, etc [7]. The evaluation and selection of the best scenario for the transportation system

is a big challenge. Many popular evaluation methods, such as Economic-Effects Analysis (EEA), private investment analysis and CBA, are considering mainly the economic effects [8], sometimes neglecting the ecological, spatial or social aspects of the transport scenario [9]. Even if those latter aspects are taken into account, for example in a Social Cost-Benefit Analysis (SCBA), it remains difficult to obtain a monetary assessment of all the criteria [10]. This challenge can be solved with a usage of appropriate multi-criteria decision making (MCDM) methods, which are frequently used in transportation systems' management problems [11], [12].

Generally, the MCDA methods can be divided into two groups: American and European schools. The former are based on a functional approach – a utility or value function is used [13], [14]. Two types of relationship among the alternatives are used in these methods, namely, the indifference and the preference. The incomparabilities of the variants are skipped. The pronounced downside of these methods is the fact that they do not consider the expert judgements' variability and uncertainty [15]. The methods from the latter group are based on a relational model. The relations of weak or strong preference, indifference or incomparability are used most commonly [16], and the outranking relation is used in the aggregation process to provide the final rankings of the studied alternatives [17]. Unfortunately, although the ranking of alternatives is produced in the European school methods, the quantitative information on the differences between alternatives is often lost.

Apart from the aforementioned groups of methods, there has also been some research that connects the MCDA approach of both of them [18]. Additionally, methods based on a rule sets exist. A range of the MCDA methods, along with their assignment to the American, European, mixed or rule set approach, is presented in Table I.

The MCDA methods from all the aforementioned groups have been successfully used to facilitate decision making in various kinds of transport management: land [49], [50], [55], maritime [47], [54] and air [27] transport. Some of the researched transport management decision problems also included the carriage of hazardous materials [55]. A comparison

of selected approaches of the MCDA methods' application in the transport management decision-making is presented in Table II. A further literature review can be found inter alia in [6], [57] and [58].

Unfortunately, the classical MCDM methods are often criticized for their possible shortcomings, such as the rank reversal phenomenon [59]. Therefore, new MCDM approaches have been developed to avoid the identified flaws. One of the issues considered is the fact that the decisions are often being made on the basis of multiple conflicting information sources. Based on these premises, a new MCDA method, Characteristic Objects METHod (COMET) has been developed, which is

completely free of the Rank Reversal phenomenon [60].

The rest of this paper is organized as follows: in the next section, the Fuzzy Set Theory preliminaries are outlined. The third section describes the COMET method as a tool to identify the decision models. Subsequently, in section IV, an experiment to build a decision model for an exemplary ammonium nitrate transport is described and the results are presented. The conclusions and the possible future directions are presented in section V.

## II. FUZZY SET THEORY: PRELIMINARIES

The development of fuzzy set theory was initiated by Lofti Zadeh, who presented the idea and the first conception of fuzzy sets in his "Fuzzy Sets" paper [61]. Today, the fuzzy set theory is a very important approach to the control and model creation in various scientific fields. Modeling with the usage of the fuzzy sets has proven to be an effective way to formulate the multi-criteria decision problems [62], [63], [64]. The basic notions and concepts of the Fuzzy Set Theory are defined below [65], [66], [67]:

**Definition 1** The fuzzy set and the membership function

The characteristic function  $\mu_A$  of a crisp set  $A \subseteq X$  assigns a value of either 0 or 1 to each member of  $X$ , as well as the crisp sets only allow a full membership ( $\mu_A(x) = 1$ ) or no membership at all ( $\mu_A(x) = 0$ ). This function can be generalized to a function  $\mu_{\tilde{A}}$  so that the value assigned to the element of the universal set  $X$  falls within a specified range, i.e.,  $\mu_{\tilde{A}} : X \rightarrow [0, 1]$ . The assigned value indicates the degree of membership of the element in the set  $A$ . The function  $\mu_{\tilde{A}}$  is called a membership function and the set  $\tilde{A} = \{(x, \mu_{\tilde{A}}(x))\}$ , where  $x \in X$ , defined by  $\mu_{\tilde{A}}(x)$  for each  $x \in X$ , is called a fuzzy set [68], [69].

**Definition 2** The triangular fuzzy number (TFN)

A fuzzy set  $\tilde{A}$ , defined on the universal set of real numbers  $\mathbb{R}$ , is told to be a triangular fuzzy number  $\tilde{A}(a, m, b)$  if its membership function has the following form (1) [68]:

$$\mu_{\tilde{A}}(x, a, m, b) = \begin{cases} 0 & x \leq a \\ \frac{x-a}{m-a} & a \leq x \leq m \\ 1 & x = m \\ \frac{b-x}{b-m} & m \leq x \leq b \\ 0 & x \geq b \end{cases} \quad (1)$$

and the following characteristics (2), (3):

$$x_1, x_2 \in [a, b] \wedge x_2 > x_1 \Rightarrow \mu_{\tilde{A}}(x_2) > \mu_{\tilde{A}}(x_1) \quad (2)$$

$$x_1, x_2 \in [b, c] \wedge x_2 > x_1 \Rightarrow \mu_{\tilde{A}}(x_2) < \mu_{\tilde{A}}(x_1) \quad (3)$$

An example of triangular fuzzy number  $\tilde{A}(a, m, b)$  is presented on Figure 1.

**Definition 3** The support of a TFN  $\tilde{A}$

The support of a TFN  $\tilde{A}$  is defined as a crisp subset of the  $\tilde{A}$  set in which all elements have a non-zero membership value in the  $\tilde{A}$  set (4):

$$S(\tilde{A}) = \{x : \mu_{\tilde{A}}(x) > 0\} = [a, b] \quad (4)$$

**Definition 4** The core of a TFN  $\tilde{A}$

The core of a TFN  $\tilde{A}$  is a singleton (one-element fuzzy set) with the membership value equal to 1 (5):

$$C(\tilde{A}) = \{x : \mu_{\tilde{A}}(x) = 1\} = m \quad (5)$$

**Definition 5** The fuzzy rule

The single fuzzy rule can be based on the Modus Ponens tautology [68], [69]. The reasoning process uses the *IF – THEN*, *OR* and *AND* logical connectives.

**Definition 6** The rule base

The rule base consists of logical rules determining the causal relationships existing in the system between the input and output fuzzy sets [69], [70].

**Definition 7** The T-norm operator: product

The T-norm operator is a  $T$  function modeling the *AND* intersection operation of two or more fuzzy numbers, e.g.  $\tilde{A}$  and  $\tilde{B}$ . In this paper, only the ordinary product of real numbers is used as the T-norm operator [68], [69], [70] (6):

$$\mu_{\tilde{A}}(x) \text{ AND } \mu_{\tilde{B}}(y) = \mu_{\tilde{A}}(x) \cdot \mu_{\tilde{B}}(y) \quad (6)$$

### III. THE CHARACTERISTIC OBJECTS METHOD

The COMET method is completely free of the Rank Reversal phenomenon. The basic concept of the COMET method

was proposed by prof. Piegat [69]. In the previous works, the accuracy of the COMET method was verified [71]. The formal notation of the COMET method should be briefly recalled [65], [66], [67].

**Step 1.** Definition of the space of the problem – the expert determines the dimensionality of the problem by selecting  $r$  criteria,  $C_1, C_2, \dots, C_r$ . Then, a set of fuzzy numbers is selected for each criterion  $C_i$ , e.g.  $\{\tilde{C}_{i1}, \tilde{C}_{i2}, \dots, \tilde{C}_{ic_i}\}$  (7):

$$\begin{aligned} C_1 &= \{\tilde{C}_{11}, \tilde{C}_{12}, \dots, \tilde{C}_{1c_1}\} \\ C_2 &= \{\tilde{C}_{21}, \tilde{C}_{22}, \dots, \tilde{C}_{2c_2}\} \\ &\dots \\ C_r &= \{\tilde{C}_{r1}, \tilde{C}_{r2}, \dots, \tilde{C}_{rc_r}\} \end{aligned} \quad (7)$$

where  $c_1, c_2, \dots, c_r$  are the ordinals of the fuzzy numbers for all criteria.

**Step 2.** Generation of the characteristic objects – The characteristic objects ( $CO$ ) are obtained with the usage of the Cartesian product of the fuzzy numbers' cores of all the criteria (8):

$$CO = C(C_1) \times C(C_2) \times \dots \times C(C_r) \quad (8)$$

As a result, an ordered set of all  $CO$  is obtained (9):

$$\begin{aligned} CO_1 &= C(\tilde{C}_{11}), C(\tilde{C}_{21}), \dots, C(\tilde{C}_{r1}) \\ CO_2 &= C(\tilde{C}_{11}), C(\tilde{C}_{21}), \dots, C(\tilde{C}_{r2}) \\ &\dots \\ CO_t &= C(\tilde{C}_{1c_1}), C(\tilde{C}_{2c_2}), \dots, C(\tilde{C}_{rc_r}) \end{aligned} \quad (9)$$

where  $t$  is the count of  $CO$ s and is equal to (10):

$$t = \prod_{i=1}^r c_i \quad (10)$$

**Step 3.** Evaluation of the characteristic objects – the expert determines the Matrix of Expert Judgment ( $MEJ$ ) by comparing the  $CO$ s pairwise. The matrix is presented below:

$$MEJ = \begin{pmatrix} \alpha_{11} & \alpha_{12} & \dots & \alpha_{1t} \\ \alpha_{21} & \alpha_{22} & \dots & \alpha_{2t} \\ \dots & \dots & \dots & \dots \\ \alpha_{t1} & \alpha_{t2} & \dots & \alpha_{tt} \end{pmatrix} \quad (11)$$

where  $\alpha_{ij}$  is the result of comparing  $CO_i$  and  $CO_j$  by the expert. The function  $f_{exp}$  denotes the mental judgment function of the expert. It depends solely on the knowledge of the expert. The expert's preferences can be presented as (12):

$$\alpha_{ij} = \begin{cases} 0.0, & f_{exp}(CO_i) < f_{exp}(CO_j) \\ 0.5, & f_{exp}(CO_i) = f_{exp}(CO_j) \\ 1.0, & f_{exp}(CO_i) > f_{exp}(CO_j) \end{cases} \quad (12)$$

After the  $MEJ$  matrix is prepared, a vertical vector of the Summed Judgments ( $SJ$ ) is obtained as follows (13).

$$SJ_i = \sum_{j=1}^t \alpha_{ij} \quad (13)$$

Eventually, the values of preference are approximated for each characteristic object. As a result, a vertical vector  $P$  is

obtained, where the  $i$ -th row contains the approximate value of preference for  $CO_i$ .

**Step 4.** The rule base – each characteristic object and its value of preference is converted to a fuzzy rule as follows (14):

$$IF \ C(\tilde{C}_{1i}) \ AND \ C(\tilde{C}_{2i}) \ AND \ \dots \ THEN \ P_i \quad (14)$$

In this way, a complete fuzzy rule base is obtained.

**Step 5.** Inference and the final ranking – each alternative is presented as a set of crisp numbers, e.g.,  $A_i = \{a_{1i}, a_{2i}, \dots, a_{ri}\}$ . This set corresponds to the criteria  $C_1, C_2, \dots, C_r$ . Mamdani's fuzzy inference method is used to compute the preference of the  $i$ -th alternative. The rule base guarantees that the obtained results are unequivocal. The bijection makes the COMET completely rank reversal free.

#### IV. THE AMMONIUM NITRATE TRANSPORT

The development of the production of the ammonium nitrate, which is one of the most popular fertilizers on the European market, entails the problems of its transport. Poland is one of the five world largest producers of the ammonium nitrate, realizing about 5.5% of the total world production. The biggest Polish plant producing ammonium nitrate – Zakłady Azotowe "Puławy", plans to expand its production lines by 2020, thus increasing the production of the fertilizer to the level of 1,200 tons per day.

The paper presents the sustainability model of decision making for transport management scenario where ammonium nitrate is transported from Puławy to Gdańsk. Based on the RID [5] and ADR [4] regulations, a set of 16 possible scenarios of ammonium nitrate transport,  $A_1$ - $A_{16}$ , was prepared. The alternatives  $A_1$ - $A_8$  represent the rail transport scenarios, whereas the alternatives  $A_9$ - $A_{16}$  represent the road transport scenarios. The scenarios within each of the rail and road groups differ in the type of the container used during the transport. The COMET method and the expert's knowledge was used to create the decision model.

##### Step 1: Definition of the space of the problem

Based on the expert's knowledge, the dimensionality of the problem was determined to be equal to  $r = 3$ . The expert pointed out the three most important criteria for the evaluation of the hazardous materials' carriage:

- $C_1$  – time required for the transport, including loading and unloading time (in hours);
- $C_2$  – transport safety (a value from the range from 0 to 10, where 0 means low and 10 means high safety);
- $C_3$  – the cost of the transport of a single ton, including the cost of loading and unloading (PLN/ton).

The performance table of the alternatives  $A_1$ - $A_{16}$  and the criteria  $C_1$ - $C_3$  is presented in Table III. It can be observed, that the rail alternatives are slightly cheaper, but significantly slower than the road ones. Regardless of the method of transport chosen, the alternatives using steel crates are characterized

TABLE III  
THE PERFORMANCE TABLE OF THE ALTERNATIVES  $A_1$ - $A_{16}$ .

Alternative	Method	Container	Time [h]	Safety		Cost [PLN/ton]
				Linguistic	Numeric	
A1	RID	cistern	79	High	9	320
A2	RID	in bulk, closed container	78,5	High / Medium	7	262
A3	RID	in bulk, open container	78	Medium	5	252
A4	RID	steel crates	87	High	9	1837
A5	RID	cardboard boxes	86	Medium / Low	3	352
A6	RID	rigid DPPL	84	High / Medium	7	932
A7	RID	elastic DPPL	85	Medium	5	262
A8	RID	plastic canisters	96	High / Medium	7	498,6
A9	ADR	cistern	14,2	High	9	426,4
A10	ADR	in bulk, closed container	13,6	High / Medium	7	388
A11	ADR	in bulk, open container	13,2	Medium / Low	3	366
A12	ADR	steel crates	22,2	High	9	1917
A13	ADR	cardboard boxes	21,2	Low	2	432
A14	ADR	rigid DPPL	19,2	High / Medium	7	1012

A16	ADR	plastic canisters	31,2	Medium	5	579

by the highest price per ton, as opposed to the alternatives where the cargo is transported in bulk, in an open container.

Subsequently, the expert's knowledge was used to divide the domain of each of the criteria to three triangular fuzzy numbers. The obtained division is expressed by (15):

$$\begin{aligned} C_1 &= \{10, 40, 100\} \\ C_2 &= \{0, 5, 10\} \\ C_3 &= \{200, 600, 2000\} \end{aligned} \quad (15)$$

The triangular fuzzy numbers for the criteria  $C_1$ - $C_3$  are presented on Figures 2-4. The membership functions for the triangular fuzzy numbers *short*, *medium* and *long* for the criterion  $C_1$  are defined in the equations (16)-(18) respectively. The membership functions for the TFNs for the criteria  $C_2$  and  $C_3$  can be defined in a similar manner.

$$\mu_{short}(C_1) = \begin{cases} 1 & C_1 = 10 \\ \frac{40-C_1}{30} & 10 \leq C_1 \leq 40 \\ 0 & C_1 \geq 40 \end{cases} \quad (16)$$

$$\mu_{medium}(C_1) = \begin{cases} \frac{C_1-10}{30} & 10 \leq C_1 \leq 40 \\ 1 & C_1 = 40 \\ \frac{100-C_1}{60} & 40 \leq C_1 \leq 100 \end{cases} \quad (17)$$

$$\mu_{long}(C_1) = \begin{cases} 0 & C_1 \leq 40 \\ \frac{C_1-40}{60} & 40 \leq C_1 \leq 100 \\ 1 & C_1 = 100 \end{cases} \quad (18)$$

### Step 2: Generation of the Characteristic Objects

The characteristic objects  $OC_1$ - $OC_{27}$  were generated as a Cartesian product of the fuzzy numbers' cores of each of the  $C_1$ - $C_3$  criteria. The obtained characteristic objects are presented in the first four columns of Table IV and depicted on Figure 5.

Fig. 2. The set of three triangular numbers for the transport time criterion ( $C_1$ ).

Fig. 3. The set of three triangular numbers for the transport safety criterion ( $C_2$ ).

### Step 3: Evaluation of the Characteristic Objects

Subsequently, the expert performed a pairwise comparison of the characteristic objects. As a result, the Matrix of Expert Judgement ( $MEJ$ ) was determined, where each  $\alpha_{ij}$  value was calculated with the usage of (12). The  $MEJ$  matrix is depicted on Figure 6, where the  $\alpha_{ij}$  values of 0, 0.5 and 1 are represented by white, black and grey boxes respectively.

Next, the vertical vector of the Summed Judgements ( $SJ$ ) was calculated with the usage of (13). The  $SJ$  vertical vector is presented in the fifth column of Table IV. Eventually, the  $SJ$  vector was used to approximate the values of preference, which rendered the  $P$  vertical vector of preference (see the sixth column of Table IV).

Fig. 4. The set of three triangular numbers for the transport cost criterion ( $C_3$ ).

TABLE IV  
THE RESULTS OF THE COMET METHOD.

$CO_i$	$C_1$	$C_2$	$C_3$	<b>SJ</b>	<b>P</b>
$CO_1$	10	0	200	16.5	0.65
$CO_2$	10	0	600	14.5	0.55
$CO_3$	10	0	2000	5	0.15
$CO_4$	10	5	200	22	0.90
$CO_5$	10	5	600	20.5	0.85
$CO_6$	10	5	2000	13	0.45
$CO_7$	10	10	200	26.5	1.00
$CO_8$	10	10	600	23.5	0.95
$CO_9$	10	10	2000	15.5	0.60
$CO_{10}$	40	0	200	14	0.50
$CO_{11}$	40	0	600	11	0.40
$CO_{12}$	40	0	2000	3	0.10
$CO_{13}$	40	5	200	20	0.80
$CO_{14}$	40	5	600	15.5	0.60
$CO_{15}$	40	5	2000	7.5	0.20
$CO_{16}$	40	10	200	23.5	0.95
$CO_{17}$	40	10	600	19	0.85
$CO_{18}$	40	10	2000	10	0.35
$CO_{19}$	100	0	200	8	0.25
$CO_{20}$	100	0	600	7.5	0.20
$CO_{21}$	100	0	2000	0.5	0.00
$CO_{22}$	100	5	200	14	0.50
$CO_{23}$	100	5	600	10	0.35
$CO_{24}$	100	5	2000	2.5	0.05
$CO_{25}$	100	10	200	17.5	0.70
$CO_{26}$	100	10	600	15.5	0.60
$CO_{27}$	100	10	2000	8.5	0.30

#### Step 4: The rule base

In the next step, each characteristic object and its performance was converted to a fuzzy rule with (6). A sample rule is presented below (19):

$$\begin{aligned}
 R_1 : \\
 \text{IF } C_1 \sim 10 \text{ AND } C_2 \sim 0 \text{ AND } C_3 \sim 200 \\
 \text{THEN } P \sim 0.65
 \end{aligned}
 \quad (19)$$

#### Step 5: Inference and the Final Evaluation

In the last step of the model creation, each alternative was presented as a set of crisp numbers corresponding to the  $C_1$ - $C_3$  criteria. Mamdani's fuzzy inference method was used to

compute the preference  $P_i$  of each of the alternatives. The obtained  $P$  vertical vector, along with the resulting ranks of the alternatives, are presented in Table V.

According to the ranking generated by the COMET method, the  $A_9$  alternative (i.e. ADR, cistern) is the best method of ammonium nitrate transport. It is fast, relatively cheap, and yet very safe. The second position was assigned to the  $A_{10}$  alternative, i.e. ADR, in bulk, closed container. This type of container renders the alternative only slightly less safe, but the time of the transport is shorter and the price is lower than in the  $A_9$  alternative. The  $A_1$  alternative is the best one from the RID alternatives and has the fourth position in the ranking. It provides high safety and a lower price than the aforementioned alternatives, however the time of transport is significantly longer. The  $A_{12}$  alternative, having the thirteenth position, is the worst one from the ADR group, and the  $A_4$  alternative is considered to be the worst solution in the ranking. This is probably caused by the very high cost associated with the the steel crates' container type.

#### Sensitivity analysis

To verify the robustness of the obtained decision model, a sensitivity analysis was performed. Values of each of the  $C_1$ - $C_3$  criteria were increased by 1%. The numeric and percentage difference between the original and the new  $P_i$  values for each  $A_1$ - $A_{16}$  alternative were calculated. Table VI demonstrates the highest and the lowest changes of the  $P$  value for all the  $A_1$ - $A_{16}$  alternatives. The absolute values of the percentage change vary from 0.0503% to 1.4602%, thus confirming the stability of the obtained decision model.

#### Comparison to a Linear Model

In the last step of the research, a linear model was created on the basis of the characteristic objects, to verify how the simplification of the model would affect the results. The linear model results were compared to the COMET method results. The formula from equation (20) was used to calculate the  $P'_i$  value for each of the  $A_1$ - $A_{16}$  alternatives. The coefficient of determination  $R^2$  is presented in equation (21) and its value suggests that the linear model fits the COMET model very well. The seventh column of Table V contains the  $P'$  vertical vector, and the eighth column presents the difference between the preference calculated by the linear model and by the COMET method. As it can be noted, the difference between  $P$  and  $P'$  for the  $A_{12}$  alternative is equal to 6.91%, which shows, that despite the  $R^2$  value being very close to 1, the linear model does not fit the COMET model perfectly well.

$$P = 0.5111 - 0.1453 \cdot C_1 + 0.1618 \cdot C_2 - 0.1966 \cdot C_3 \quad (20)$$

$$R^2 = 0.9644 \quad (21)$$

## V. CONCLUSIONS

The development of the agriculture and the increase of the demand for mineral fertilizers, ammonium nitrate being one of them, results in the intensification of the fertilizers' transport. Since the ammonium nitrate is classified as a hazardous material, there are many factors to consider when transporting it.

While many of the prior studies focused on the economic aspects of the problem, the MCDA methods allow to build transport management models that include the other, often conflicting, factors. The authors' contribution in this paper was to

create a sustainable transportation management decision model that incorporates some of the aforementioned criteria, yet is not prone to the rank reversal problem. Furthermore, it was demonstrated that the COMET method can be successfully employed in the ammonium nitrate transport management decision problems scope.

The problem of ammonium nitrate transport management was described in the paper. A methodology of sustainable decision model creation with the usage of the fuzzy set theory and the COMET method was presented. Eventually, an experiment was performed to evaluate sixteen alternative

Fig. 6. The Matrix of Expert Judgement (MEJ).

modes of the fertilizer transport on the route from Puławy to Gdańsk, based on the three most dominating ammonium nitrate transportation management criteria and the expert's knowledge.

In the first step of the experiment, the space of the problem was defined. Subsequently, the characteristic objects were generated. Next, the Matrix of Expert Judgment was created. In the fourth step, the rule base was defined, to allow to perform the inference and creation of the final ranking in the last step of the experiment. The robustness of the obtained ranking was then verified by the sensitivity analysis execution. Additionally, a linear model was created and its results were compared to the COMET ranking.

The research has identified possible areas of improvement and future work directions. This study was based on a set of the three dominating criteria, i.e. transport time, safety and cost. It would be beneficial to extend this set with additional criteria and thus create a complete hierarchy of ammonium nitrate transport management sustainable decision-making criteria. Furthermore, the hesitancy factors could be considered and a hesitant fuzzy version of the model could be created.

# 12<sup>th</sup> Conference on Information Systems Management

**T**HIS event constitutes a forum for the exchange of ideas for practitioners and theorists working in the broad area of information systems management in organizations. The conference invites papers coming from two complimentary directions: management of information systems in an organization, and uses of information systems to empower managers. The conference is interested in all aspects of planning, organizing, resourcing, coordinating, controlling and leading the management function to ensure a smooth operation of information systems in an organization. Moreover, the papers that discuss the uses of information systems and information technology to automate or otherwise facilitate the management function are specifically welcome.

## TOPICS

- Management of Information Systems in an Organization:
  - Modern IT project management methods
  - User-oriented project management methods
  - Business Process Management in project management
  - Managing global systems
  - Influence of Enterprise Architecture on management
  - Effectiveness of information systems
  - Efficiency of information systems
  - Security of information systems
  - Privacy consideration of information systems
  - Mobile digital platforms for information systems management
  - Cloud computing for information systems management
- Uses of Information Systems to Empower Managers
  - Achieving alignment of business and information technology
  - Assessing business value of information systems
  - Risk factors in information systems projects
  - IT governance
  - Sourcing, selecting and delivering information systems
  - Planning and organizing information systems
  - Staffing information systems
  - Coordinating information systems
  - Controlling and monitoring information systems
  - Formation of business policies for information systems
  - Portfolio management,
  - CIO and information systems management roles

**Abstract**—Small companies have the potential to be agile, flexible and informal because they are usually formed by few members. This usually creates more synergy among these professionals because they tend to have more than a single role inside the company. With such role versatility, it is understandable that those professionals have to multitask/split their working hours among different kinds of demands: that may cause difficulties in planning, development, verification and improvement of internal processes. This article brings a case study where the COBIT 5.0 toolkit (Process Assessment Model) was used to identify internal processes that needed improvement within the studied company. In order to improve the selected processes, ABNT NBR ISO/IEC 12207 was tailored concerning the company's needs. Additionally, it was applied the PDCA cycle of continuous improvement and it was also proposed the adoption of an agile method, SCRUM, to integrate internal activities and processes.

investigate the application viability of COBIT, ISO/IEC 12207 and SCRUM in the context of a small company (up to 9 people, statistic average in Brazil) [1]. COBIT, ISO/IEC 12207 and SCRUM should be tailored considering a small company's resources limitation, where it is common to find human resources assuming multiple roles while working on different projects at the same time. The small IT Brazilian company analyzed in this case study, identified as “studied company” had reported the following main problems: rework due to scope change, consecutive delays due to lack of stakeholders' commitment, stakeholder's change and/or multiple stakeholders with inadequate communication. If not well managed, such problems can imply in financial loss, lack of productivity, frequent re-negotiations, and negative impact in other projects and human resources reallocation. Therefore, affecting commercial, development, creation and quality assurance areas – company's key areas.

## I. INTRODUCTION

THIS article presents a viability case study for the application of an Information Technology (IT) corporative governance program in a small software development company. [2] shows metrics about Apps development projects – about 56% concluded within agreed deadlines and 68% within agreed budget. In order to meet deadlines and have better budget control, IT area must be efficient, aligned with business goals, and solutions must not only meet quality requirements but also have low cost and adaptability[19][2]. IT alignment with business goals can be achieved adopting a Governance model. COBIT (Control Objectives for Information and Related Technology) is a De-fact standard used to provide IT area with a governance model and it helps understanding and managing its associated risks [17]. IT efficiency can be improved with well-defined processes and standardization, using ISO/IEC 12207[8], the international standard for software life cycle processes[19]. Process should be easily adaptable as business' needs change. The adoption of agile development is increasing due to the need of fast adaption to changes. The most used agile method nowadays is Scrum [17][18][23]. Considering the Governance context (COBIT), the development model (ISO/IEC 12207) and SCRUM method, this article aims to

## II. RESEARCH GOAL

The goal of this study is to assess the application viability of COBIT 5.0 and consequent verification, analysis and proposition of improvements in a small companies' context, providing a viability analysis of the challenges and benefits observed when applying COBIT, ISO/IEC 12207 and SCRUM in a small company context. The primary analysis will be done with COBIT toolkit version 5.0. The application of this framework aims to verify which are the main processes influenced by the cited problems – knowing such processes will enable the application, within the right adherence level, of standards and/or techniques based in good practices of IT governance and software engineering.

## III. EXPECTED CONTRIBUTIONS AND METHOD

It is possible to cite as expected contributions of this study internal processes and governance improvement, and the fact that this study is related to a less studied domain: small companies – Showing the application viability of such practices in this context. The method used in this study has the following activities: (1) Collection of information and problematic situations; (2) Analysis of collected data; (3) Application of COBIT 5.0 framework; (4) Bibliographic

survey for possible solutions; (5) Analysis and proposition of hypothetical solution; and (6) Development of paper that documents adopted procedures and obtained conclusions.

#### IV. RELATED WORK

Several researchers have investigated the harmonization of Governance models with agile models of development. [16] used concepts of COBIT, PRINCE2 and SCRUM to propose the addition of security tests requirements and penetrations tests into the agile development lifecycle. [14] proposed a software acquisition model aligned with COBIT, ITIL, PDCA concepts for continuous improvement, adding concepts as daily meetings from Scrum and portfolio management from SAFe. [22] observed the migration of a company to agile models from Waterfall, while complying with COBIT – listing challenges and adopted solutions, while losing the big picture in design, a problem solved with the addition of a zero sprint step following a formal approval process. Similarly to such studies, this work has combined COBIT, PDCA and SCRUM, however using a different approach, adding COBIT to identify which processes should be improved on a context of small to medium enterprises, using ISO 12207 for the full software development life cycle and PDCA for continuous improvement. In order to combine Governance control over the agile model, researchers had worked on mapping COBIT process with SCRUM activities. [7] mapped COBIT controls with the development processes of understanding requirements, designing, building, testing and implementing solutions to make agile projects comply with Sarbanes Oxley regulatory requirements. [24] validated their proposed model AGIT (AGile software development), which includes measurement of Scrum-based software development, with information systems auditing criteria, as described in COBIT. [4] observed the impact of applying control over the project context and over the team communication either using formal control, based on performance evaluation strategy and Informal control, based on social and people strategies. [3] researched metrics that could provide IT management with information regarding progress of scrum-based software development process not harming SCRUM's agility. This work has also mapped COBIT process with the ISO/IEC 12207 processes and SCRUM model.

#### V. CASE STUDY

##### A. Problems analysis – causes and effects

It was necessary to collect information and understand the processual problems shown by this company in order to enable its analysis and consequent improvements/solutions proposition. The method used to analyze all problems consisted of:

**1. Brainstorm:** Informal meetings with the board of directors (2 members responsible for the management of the Marketing, Sales, Operations, Finances) and the technical team (3 members that work assuming multiple roles during

software's lifecycle) in order to detect the main problems affecting company's management and operations;

**2. Data Collection analysis:** All the main topics discussed during the brainstorm were analyzed and the main problematic situations detected were:

A: Rework due to scope change;

B: Delays due to lack of stakeholder's commitment;

C: Stakeholders change and/or multiple stakeholders;

D: Money loss due to delays in projects and company's unavailability to work in new projects;

E: Lack of productivity due to extra work caused by unexpected scope changes;

F: Frequent renegotiations due to inadequate process and communication, and scope change;

G: Negative impact in other projects;

H: Human resources reallocation.

**3. Brainstorm:** Meetings with the board of directors to identify the possible root causes and the effects of each problematic situation detected;

**4. Cause-effect matrix:** Problematic situations were classified into causes or effects of other problems and distributed in a cause-effect matrix. The following matrix shows causes (C) and their effects (E):

TABLE I. CAUSE-EFFECT MATRIX<sup>1</sup>

CAUSE EFFECT	A-2	B-2	C-2	D-2	E-2	F-2	G-2	H-2	TOTAL CAUSES
A-1	-	E	E	C	C	C	C	C	5
B-1	C	-	E	C	C	C	C	C	6
C-1	C	C	-	C	C	C	C	C	7
D-1	E	E	E	-	C	E	E	C	2
E-1	E	E	E	E	-	E	E	E	0
F-1	E	E	E	C	C	-	C	C	4
G-1	E	E	E	C	C	E	-	C	3
H-1	E	E	E	E	C	E	E	-	1

<sup>1</sup> Read the matrix as follows: e.g. A-1 is cause/effect of B-2. Grey cells represent the selected main causes.

After building the cause-effect matrix, an established criterion was applied to allow the identification of the main causes among all problems. The criterion was: the problematic situation should cause at least 70% of problems. The goal was to define root problems/major causes: "A", "B" and "C" were found as such. The actual development model is based on the waterfall model. The process is defined as follows: initial scope analysis and alignment between it's internal manager and stakeholder; characterization of necessary documentation, development, tests and delivery - in modular increments. When a module is delivered, the stakeholder might not be the same who did the initial request, his need might have changed or due the lack of alignment during the module development, it might not be what he was expecting (problematic situations "B" and "C"). This will cause the problematic situation "A".

Additionally, whenever an alignment is needed, meetings are scheduled without any pre-determined periodicity as there are no formalized alignment milestones. Considering the need to generate more commitment from stakeholders, the previously proposed adoption of an agile method can be cogitated as an essential part of the solution. This may help

focusing on scope's alignment and delivery validations due to frequent alignment during development process.

### B. COBIT 5.0 framework application

This framework was conceived for technology information management. Its application involves business requirements analysis considering: effectiveness, efficiency, integrity, availability, compliance and trustability. Its results bring a panoramic view on the general maturity level of the company's IT area, helping to understand what needs to be done to reach higher levels.

COBIT 5.0 framework was applied addressing the previously cited problems - the assessment was done for every process described in the framework. It establishes 6 maturity levels, on a 0 to 5 scale.

There was an initial process of governance being executed to ensure the governance setting and maintenance (EDM01 – Rated: Level 1), but it was not being properly managed/maintained - resulting in a lower maturity level.

Value optimization governance (EDM02 – Rated: Level 3) was being managed and had a defined process, but needed well-defined quality attributes to measure its effectiveness.

Risk optimization governance (EDM03 – Rated: Level 2) was being managed at the start and end of projects, but lacked management and measurements during its life cycle.

The budget and costs management process (APO06 – Rated: Level 4) establishes measuring points during the process, to provide costs monitoring and control for the full life cycle of the project.

The positive aspect regarding quality management governance (APO11 – Rated: Level 3) lies in the establishment of more rigorous processes during software development (direct or indirectly).

A bigger level of quality control should be assured by verifying, validating and making revisions in partnership with stakeholders. This would mitigate uncovered problems in quality metrics that were found during COBIT's application.

Risk management governance (APO12 – Rated: Level 2) should be continuous, during the entire project's life cycle. There is a established process, but it's not managed. Each risk must be analyzed and proper actions should be taken (avoiding, assuming, reducing or transferring risk) and documented.

Requirement's definition governance (BAI02 – Rated: Level 2) can be improved by using a well-defined acquisition process, suggesting a process to the acquirer (if he does not have it already). Other project's phases will also suffer impact such as: provision, development, maintenance, documentation, quality assurance, verification, validation, joint review and management.

Upon the establishment of a clearer and more well-defined process, operations management governance (DSS01 – Rated: Level 3) can be more complete, by controlling and monitoring more crucial aspects about projects. To improve these processes - requirements, risks and costs must be traceable and documented. To reach this goal, it was suggested the adoption of an ALM (Application Life Cycle

Management) tool that automatically registers these steps. A small company's team cannot spend time with bureaucracy that can be automated.

## VI. ANALYSIS AND SOLUTION HYPOTHESIS

Many studies were considered [4][5][6][20][21] for the choice and proposition of a viable solution for the studied company. It was found as a viable solution the definition of an adherence level to the ISO/IEC 12207 standard[8]; the incorporation of SCRUM [9][10][13][15] and the implementation of continuous improvement cycle with PDCA [11][12]. Cycle-based processes, based in a study that shows how to apply ISO/IEC 12207 with SCRUM and Agile Methods [15]. Please, view Appendix for full details in this section.

## VII. RESEARCH AND SOLUTION PROPOSITION: ISO/IEC 12207, PDCA CYCLE AND SCRUM

As a technical standard reference, it was adopted the ISO/IEC 12207 [8]. The decision for SCRUM was taken based on study [6]. To reach an agile process, it was also recommended to follow the Agile manifesto and its key principles[9].

In order to properly adapt the ISO/IEC 12207 [8], it was used some criteria that is fully explained in the full article. ISO/IEC 12207[8] sub-processes were selected considering the previously mentioned criteria and adaptations were made to it, relating to it SCRUM activities and the affected COBIT processes. Please, view Appendix for full details in this section.

## VIII. CONCLUSION

In this case study of a small company, it was applied the COBIT 5.0 framework in order to identify which IT goals impacting processes needed improvement.

After improving selected processes, ISO/IEC 12207 was adapted according to the company's needs, and it was also suggested the adoption of PDCA cycle for continuous improvement along with SCRUM to organize company's development process.

The application of COBIT 5.0 in this company was complex, because small companies usually don't have specific departments to manage their internal processes. Every roles and attributions, in general, are treated by a reduced amount or people, that accumulate roles, mixing activities in different processes.

It was also noticed that some activities and processes such as the monitoring of costs and risks (during the project's life cycle) were not being formally executed.

Although the company was aware of the consequences and impacts of scope changes in the project, there were no formalized processes to tackle this problem in order to standardize decisions in such scenarios. During the development of this case study it was verified that COBIT 5.0 governance framework when applied in a small company's

context, might be challenging, because it requires some adaptations (given the deepness of its analysis) such as: lowering of its high complexity (may be hard to understand and use it), having enough time and human resources on getting it to a reduced scope (for analysis) and bringing together the high volume of information/necessary resources for a precise diagnostic.

It's possible to imply that these might be challenging situations, because in a small company context, there is a reduced amount of people to execute certain tasks, and they end up accumulating responsibilities regarding some processes, that may have different maturity levels.

This research's goals can be defined as attained: It was verified as viable the diagnostic of a small company's IT governance using COBIT, identifying processes that impacted strategic goals and proposing solutions as the definition of formalized processes, based on ISO/IEC 12207. The PDCA cycle along with SCRUM contributed to the improvement process and it will be useful enabling the company to adopt a continuous delivery tactics, gaining more competitiveness in the market.

This study was limited to processes related to software engineering in ISO/IEC 12207 and IT governance impacting solutions were proposed. These propositions of improvement on processes involved the establishment of a set of controls and processes with positive impacts in company's management, helping it achieving higher maturity levels.

Concluding, an objective and selective process view is obtained by the application of COBIT framework and it's possible to adopt standards and patterns in a tailored level of adherence and complexity within processes, enabling better processes and reduction of efforts/costs – mainly in the studied context.

#### APPENDIX

This paper and the study that was made is extensive. Due to paper's space restraints, the full paper was published in the following internet address for further reading with more details regarding problem analysis, solution hypothesis and paper's contributions:

[http://www.fei.edu.br/~plinio.aquino/cobit\\_scrum/](http://www.fei.edu.br/~plinio.aquino/cobit_scrum/)

#### ACKNOWLEDGMENT

Special thanks to professors Antonio Rigo, PhD. and Gianni Ricciardi, MSc. that conducted the IT governance classes and helped providing important information and insights on IT governance for this article. We thank FAPESP (São Paulo Research Foundation) for financial support.

**Abstract**—The main aim of this article is to analyse the collected opinions on the use of electronic banking tools by individual clients in Poland, at the end of 2016. The research has been carried out using a CAWI method. The survey questionnaire, which was verified by finance experts, was made available to respondents on the servers of the Faculty of Management at the University of Warsaw. The following article structure has been adopted: after a brief introduction, the authors presented the assumptions of the conducted research and the research method, and subsequently the authors have carried out an analysis and discussion of the obtained findings and conclusions, which may be seen as supplementary in relation to previous studies conducted in the summer of 2016.

## I. INTRODUCTION

ELECTRONIC banking is an economic sector which is developing in the most consistent and sustainable way. In relation to the third quarter of 2015, in the same time in 2016 the number of individual clients with potential access to account increased by 21.71% (which amounted to 4.94% more than in corresponding period in 2014/2015) reaching over 33.009 million users; the number of active individual clients in the same period increased by over 5.44% [13]. Thus, undoubtedly, due to mobile banking phenomenon, this is the fastest and simultaneously, the most spectacularly developing banking sector. The growth in the number of clients with potential internet access to account is accompanied with the continuous increase in the number of active clients (at least one banking operation a month); nevertheless, the share still fluctuates around up to 55%. From year to year, the population of new users taking advantage of the opportunities created by the Internet to handle banking transactions is growing. Last year we could observe a continuous growth in the number of active individual clients from 14.468 million people to 15.300 million [5]. Thus, it is a significant, greatly diversified market, which may be seen as a wide area for research analyses.

The main aim of this article is to analyse the opinions on the use of electronic banking tools by individual clients in Poland at the end of 2016. IT banking system is a conglomerate of traditional and modern computer and Internet/network communication systems [1]. Among the modern systems, as indicated above, electronic banking enjoyed the greatest popularity. E-banking is frequently divided according to the tools which are used to carry out transactions into particular areas such

as: internet banking, mobile banking, payment cards systems, ATM and POS systems. The most popular kind of internet banking is here understood as the realization of business enterprises which uses the Internet to conduct banking operations. The realization consists in obtaining access to account by means of the Internet. The said access to the Internet may be obtained in two ways: by means of various devices/hardware and applications/software. The first is the access via a browser and a website. It may be carried out by means of traditional devices such as a laptop or a desktop computer or mobile devices such as a smartphone/tablet. The second one, which relates only to mobile devices, offers an additional possibility to perform banking functions using mobile applications [2].

## II. ASSUMPTIONS OF THE STUDY

The discussions on the evaluation of the access to internet e-banking services are presented in an extensive body of the literature on the subject and based on considerable and valuable practical and research experience. However, there is no single evaluation approach which would determine a set of evaluation criteria which would be objectively regarded as the best and most suitable indicators from the point of view of individual clients [8], [9], [10], [11], [12], [14]. On the basis of the literature review one may conclude that e-banking websites/services may be analysed from the point of view of: their usefulness/usability (e.g.: site map, directory), interactivity (e.g.: availability and responsiveness), functionality (e.g. search engine, navigation and contents), visualisation (colour scheme, background, graphics, text, etc.), effectiveness (e.g.: cost of purchase, transport, the differences in prices in traditional and online shops), reliability and many others.

The available methods of websites evaluation do not fully cover the research problems associated with using the e-banking services [4]. They need to be accompanied by further studies which would complement the findings obtained additional studies. And it is difficult to compare with comprehensive survey surveys in this field included eg. in [6], [7]. The prototype of the survey was created in a traditional form and it was tested on a selected group of professionals, specialists in the area of finance and banking, and following the verification and modification of the questionnaire, the authors created an electronic version of the survey and made

it available online to be completed by respondents. In the fact it was pilot study for more specified research of the chances for using of using m-banking in Poland tailored to the level of the user group. In December 2016, the authors carried out a study with the application of a CAWI (Computer Associated Web Interview) method examining the opinions of 193 respondents presenting their views on the use various manifestations of electronic banking, and the research may be seen as supplementary in relation to previously conducted studies. The sample was a case of purposeful sampling — the participants of the study were students of post-graduate studies at the Faculty of Management at the University of Warsaw and Vistula University in Warsaw, in the age of 19-25, in randomly selected lecture groups. On the one hand, the study included only one, specific age group. On the other, this is a group consisting of the most active users of modern technologies and - in this case - directly connected with the sector of finance (employees of banks, insurance agencies, accounting offices, etc.), who may be regarded as specialists in the field. Among the respondents there were 79.79% of women and 20.21% of men. This time, the greatest share of respondents (29.53%) came from rural areas; the second place (21.24%) was taken by people from towns below 50,000 residents (23.83%); the third place from cities with over 500,000 inhabitants, mainly from Warsaw and surrounding areas. The remaining part, one fourth came from towns with 50,000-500,000 residents. The majority of the sample were people holding a Bachelor's degree, about 5% declared having secondary education, 72.02% were students, and 27.98% were working students.

### III. ANALYSIS AND DISCUSSION OF THE FINDINGS

In the study the authors conducted a survey consisting of a few main parts: the evaluation of the knowledge concerning electronic banking services; evaluation of the electronic payments capacity; specification: social and demographic characteristics of the sample.

Among the 193 respondents who correctly completed the survey, only one person did not use electronic banking tools (taking the form of e.g. websites - internet banking, mobile applications of banks, ATMs, payment cards, contactless transactions, mobile payments, POS payments or money transfers). It was established that the respondents most frequently use access channels such as a combination of a laptop and a desktop computer (using websites) - 33.47% of the responses, ATMs - 27.02% and a combination of a smartphone and a tablet (using websites and mobile applications) - 22.18%. The remaining combinations of access tend to be more and more marginalized. Clients of electronic banking most frequently use the standard services such as checking the account balance and history of transactions in the account (42.96%) as well as making transfers (42.26%). The latter is frequently connected with making e-payment transactions. The remaining services are most frequently used by fewer than 15% of clients, out of which the greatest share (over 10%) indicated topping-up mobile phones. In this particular age group there are few operations which are usually regarded as most commonly

applied in e-banking such as opening fixed-term deposits (2.31%) and establishing standing orders (1.15%). Submitting online applications for these products is a very rare phenomenon (0.69%). Over 16.58% of respondents have a few payment cards, and 81.87% one payment card. Only 1.55% respondents do not use any payment card. Interestingly, 6.62% of the respondents do not know what type of card they own. However, almost all survey participants (99.48%) know whether their card has a proximity functionality. And thus 86.53% of the respondents own only proximity cards, 4.66% state that most of their cards are proximity cards, and only 8.29% do not own such a card. Out of the share of the sample holding proximity cards, an overwhelming majority — 84.46% use them whenever they have such a possibility, and 4.66% only in selected, safe and reliable points of sales. The same group does not use such payments cards because they are concerned about the security of their transaction, and 6.22% of the sample do not own a contactless card at all. Attention should be given to a 2.24% discrepancy in plus between the holders of proximity cards, and their use (according to the respondents's claim there are more people who do not own proximity cards than those who use them). ATMs are used by the respondents in a traditional way mainly to withdraw cash (46.44%) and to check the account balance (23.59%), and 41.97% do not use them at all. Unfortunately, as many as 22.80% do not know if their smartphone offers a mobile payment options, and in consequence, they do not use them for such purposes. Few clients have used multimedia kiosks — 2.08% in total, to contact the banks and to withdraw cash. The remaining 97.93% of respondents have never used the multimedia kiosks.

Nevertheless, the respondents claim (76.17%) that they have confidence in the various electronic banking tools. The remaining 3% either have no opinion on the subject or they are not convinced of the usefulness or reliability of these tools. Even ten years ago the problem of the lack of confidence in electronic banking was an obstacle discouraging over 35% of clients from using it. Despite the high level of trust in electronic banking, 48.72% of the respondents, if they use a different Internet access/network than their own Internet connection, then usually - 48.72% of the share use it at home, and 27.84% at the university. Using the Internet at work is less popular (14.65%), and the least popular option (8.79%) is using the Internet access in restaurants or at the airports. Generally, the issue of security is still important for users of e-banking. The greatest number (43.53%) use a password to access the website and a text message with one-time password (38.84%). It is important to note that the so-called "scratch card" (12.95%) and a token (4.13%) are losing its popularity. The "scratch card" owed its popularity to the fact that this is one of the cheapest forms of ensuring transaction security; however, at present it is being replaced with one-time SMS passwords. A token, by contrast has always been regarded as one of the most effective solutions guaranteeing transaction security. The above described aspect gains in importance since many users state that they have experienced situations

which posed a threat to the safe use of e-banking tools. The greatest share of the respondents (45.68%), which is also indicated in the analyses carried out by the authors in a [3], have encountered problems associated with hardware failures or software errors in websites. Half of the previous share (24.07%) experienced problems related to the lack of sufficient knowledge with regard to using hardware. 14.20% of respondents recall receiving email messages containing requests to disclose the login or password they use to access e-banking services. The second part of the questionnaire was devoted to the respondents' use of e-payments. The survey findings show that the banking services which were most frequently used by the clients were on-line payments in the Internet (22.06%) and ATM cash withdrawals (17.36%). Other services which enjoy considerable popularity are the purchases of tickets (train, municipal transport fares) — 15.27%; slightly less popular are card payments in a shop (POS) - 14.36%. The high position in the ranking (10.84%) was taken by paying bills and invoices as well as purchasing tickets for cultural or sporting events (9.79%). In this group of users, other services, such as: topping-up mobile phones (6.01%), purchase of digital content (2.35%), e-wallet used for payments and settlements (1.04%) and parking fees (0.78%) are less popular. Among the respondents, 65.28% of individuals owning a smartphone or a tablet made a payment via a mobile device using a browser (website) or a mobile application at least once. The remaining share of 34.72% stated that they are ready and willing to do it in the nearest future. Among the respondents, the factors contributing to the popularity of using mobile devices were mainly (56.78%) convenience, perceived savings and simply curiosity (22.34%). The abovementioned curiosity with regard to the differences between using the services of Internet banks via mobile devices (smartphone/tablet) and traditional devices (laptop/desktop computer) or the differences between handling transactions in the case of mobile banking application and browser-based tools contributes to the increase in the number of transactions and the development of the mobile banking sector. Other relatively significant factors were attractiveness in financial terms (10.99%) and fashion (6.59%). In the users' view, the bank's marketing campaign was the aspect which affected them the least (3.30%). The subsequent questions included in the survey concerned the users' opinions on the payment technologies, which are not widely used at present, but believed to become very popular in the future. The clients were also asked about their expectations and predictions concerning the future development trends. The first query concerned the clients' approach towards the Blik system. It is a mobile payment system which enables making payments both in the Internet and retail outlets (product and service POS), ATM cash withdrawals and money transfers between smartphone users. A prerequisite for its use is owning a smartphone running an e-banking mobile application which is compatible with the systems. 36.54% share of the respondents agreed with the statement that this method of payment will probably gain in popularity among young smartphone users and indicated that this method is

similar to a payment with a proximity card (25.59%). The third place with regard to clients' opinions (19.93%) was taken by the convenience of the transaction. Nearly 7% of the respondents claimed, however, that this new technology is not sufficiently secure, and nearly about 3% - were of the opinion that it is too complicated for an average user. Simultaneously, almost 10% had no opinion on the subject. The transfers between Blik users was the most recently introduced service on the market. In the case of this service, there is no need to enter the account number containing 26 digits, the user may use the telephone number of the recipient of the transfer. The condition for making an instant transfer is using the banking system which is compatible with the system and a prior registration of the phone number. If the user's number is not registered yet, he/she receives a text message (SMS) with an instruction on how to collect the money which is transferred according to KIR (National Clearing House) session. 43.41% of respondents believe that in the future such transfers will be a generally applied, fast method of settlement of one's financial obligations. An almost equally large group of clients (41.95%) believe that, even though they are not using this method of payment, these solutions will become popular soon. Almost 5% of the sample claim that such transfers are not secure, they do not seem reliable and that they will not be adopted, and nearly 10% admit that they do not know such solutions at all. Another kind of payment, micro-transfers (where the maximum value of a single transaction is PLN 50) via Facebook to a friend's account, represents yet another manifestation of modern technology applications in banking services. This functionality was first provided by AliorSync, a worldwide pioneer in this regard, and it is made possible thanks to an account being linked to the user's Facebook account. However, this requires some initial steps to be taken: first, the user needs to log in to AliorSync electronic banking, create a special account and install a dedicated application on his/her smartphone. The recipients of the money transfer must be on the list of our Facebook friends, and the auto-identification procedure is carried out via the code sent by SMS. More than half (54.21%) of the respondents have never heard of this method of payment - perhaps, it has not been widely promoted or used so far. Almost 22% of the sample state that they have never used it; still, they believe that it may be commonly applied in the future due to the general popularity of Facebook and its influence on its users. However, as many as 23.36% of the respondents are of the opinion that this may be very dangerous, does not inspire confidence and probably will not be accepted in everyday life. A very similar distribution of opinions may be observed in the case of the views concerning money transfers made to an email address. In order to make such a transfer, one simply needs to know the email address of the recipient. Due to the simplicity of the procedure, most banks have introduced a one-time transfer limit for security purposes. However, this is not a very popular method — 52.66% of the survey participants stated that they have never heard about this solution, and as many as 26.57% believe that this method is not secure and it raises some

concerns. Only the remaining over 20% sees its great potential for future development.

#### IV. CONCLUSIONS

The presented analysis points to considerable diversity in the opinions of individual clients on the issue of using e-banking systems, associated with the selection and use of websites for banking operations which would meet their everyday needs in this regard. In relation to previously conducted research [3], the present study indicates also the changes with regard to clients' awareness and activity, which have taken place in recent years. An individual client of e-banking services has changed from the user of its basic functions into a conscious customer being aware of the advantages and disadvantages of this modern form of communication and electronic payment functionalities associated with it.

The recapitulation of the authors' considerations and research findings leads to the following conclusions:

- in recent years, the most significant phenomenon which occurred in the e-banking market is mobile access to banking services. It can take two forms: access via banking websites and via banking applications running on mobile devices such as smartphones and tablets. At present, the access via mobile applications is estimated at over 22%,
- increase in banking fees announced and expected to be implemented in 2017 may bring about changes with regard to owning and using payments cards. In 2016, we were witnesses to increases in fees for account maintenance and ATM cash withdrawals e.g.: ING, Pekao, BPH. Currently, other banks are planning to introduce the changes in the charges: Bank Handlowy (account maintenance, using a debit card, money transfers and cash withdrawals from ATMs), Citi Bank (using cards, charges for selected money transfers, withdrawals from the ATM of another bank, rise in account maintenance charges in the case of selected accounts (e.g. City Priority)). A complex and confusing way of increasing charges for banking services may discourage users to own one or more than one payment cards. At present, nearly 17% of respondents own more than one payment card,
- among the payment cards owned by the respondents, debit cards constitute the majority of the share (71.16%), the campaign promoting credit cards have not changed the
- users' habit of many years consisting in using the debit cards which are generally regarded as safer; nevertheless, over 86% of survey participants own proximity cards,
- a similar traditional approach may be observed in the case of using ATMs mainly for cash withdrawals,
- the security of using e-banking services and e-payments is still very important from the point of view of users, but to a smaller extent than a few years ago. The most frequently used security method (nearly 44% of the share) are passwords enabling the users to log into the system

and one-time SMS passwords entered to confirm the transaction (nearly 39%),

- the distribution of the kinds of transactions being conducted is almost uniform. Most frequently, the survey participants make payments using Internet banking (over 22%) or ATMs (more than 17%). Subsequently, they buy public transport tickets and pay with a card in a traditional shop,
- more than 65% of the respondents have made at least one payments via a mobile device, and they were usually influenced by factors such as convenience and cost-effectiveness (nearly 57%),
- the users are still cautious with regard to new and innovative systems. 36.54% of the survey participants agreed that Blik payments is a technology which has great potential for development and in the nearest future it may be used more and more commonly; however, they had certain reservations related to ensuring the security of the system. Similar results have been obtained in the case of micropayments which may be realised via Facebook or transfers made to an email address. In addition, a large group of people, that is 40-50% in each of the mentioned cases, claim that they have not heard about such methods.

The diversification and dynamics of the evaluations seem to confirm the thesis related to the necessity to conduct ongoing analyses of this sector, with particular attention being paid to the usefulness and cost-effectiveness of services as well as the tendencies concerning the design and usability of websites from the clients' point of view. This also justifies the need to further investigate the development trends in order to construct a multi-dimensional, multi-criteria, hierarchical and multi-aspect system for the evaluation of e-banking, which in addition to the presently considered aspects would incorporate detailed criteria such as e.g. customer profile. This particular area may be the object of research in the future; however, at present it appears that electronic banking, which combines various tools, technics and methods used in its operations, constitutes the complex structure in itself, and does not necessitate the studies of such a vast scope. One may notice a new trend consisting in the fact that the position of mobile access is increasingly prominent, and browser-based tools and mobile applications running on mobile devices seem to take over the part of the market traditionally served by access to account using personal and desktop computers. It is also increasingly evident that the development irreversibly changes clients' requirements, assumptions and habits concerning operations conducted in the banking sector, and conversely — it also necessitates faster changes of the medium, which would take into account the users' expectations and demands.

# Conceptualization of an Abstract Language to Support Value Co-Creation

Christophe Feltus, Erik HA Proper

Luxembourg Institute of Science and Technology,  
5, avenue des Hauts-Fourneaux,  
L-4362 Esch-sur-Alzette, Luxembourg  
{firstname.name}@list.lu

**Abstract**—Companies willing to survive the numeric economy are forced to collaborate with each other in order to maximize their co-creation of value. This co-creation exists for many reasons: to sell and acquire information, goods and services, to optimize the quality of procedures, to improve security and privacy, etc. In this paper, we analyze and model value co-creation through three dimensions: the value's nature, the method of value creation, and the business object impacted by the value. By combining these dimensions, we afterwards suggest different types of co-creation schemas, and we propose an abstract language to communicate them. The latter is finally validated by applying the “The Physics of Notations” guidelines.

## I. INTRODUCTION

Companies willing to survive the web economy must collaborate with each other to maximize their co-creation of value. For long, information system (IS) design and engineering has been motivated and inspired by the need to optimize value design and value delivery (e.g., e3value [1], ArchiMate® [2], Demo [3], the value delivery metamodel from the OMG [4]). In this context, two or more companies engaged in value co-creation (VCC) have to define, create and manage the value they co-create. Therefore, they must use appropriate tools to support and manage the co-creation, amongst them, models and dedicated languages that support communication and information sharing between involved parties. Unfortunately, designing such a unique language, with a concrete syntax, to express all the VCC dimensions remains challenging for three reasons:

The 1<sup>st</sup> reason is that value may be of different natures (e.g. security, quality, privacy,...) and each type of nature uses its own type of language (e.g., ISSRM [5] relates to security, Quality Model relates to quality [6], or Privacy metamodel relates to privacy [7], [8]). Moreover, this nature is only significant in the context in which the relevant value exists. For instance, the value of privacy is more important in the healthcare sector than in bookstores. The value of a pecuniary type has more relevance for a profit organization than for a non-profit one. Or the value of a well-being type is more important in a SME than in an international company.

The 2<sup>nd</sup> reason is that value is often created using different methods, in a function of the sensibilities and preferences of the companies, and each method is defined using its own syntax (e.g., method by design [9], method chunk [10], or model-driven approach [11]).

The research is supported by the National Research Fund, Luxembourg (<http://www.fnr.lu>) and financed by the ValCoLa (VCC Language) project.

The 3<sup>rd</sup> reason is that objects concerned by the value are not necessarily the same for each company and, as a result, these objects may have different functions for the enterprise. In parallel, these enterprises are generally modelled using different frameworks depending on the sectors they belong to. That means that each company's context may be described with a dedicated language (e.g., ArchiMate® [2], Aris [12], or CIMOSA [13]). Additionally, value is sometimes co-created at different layers of the company. For instance, in some cases, the value is created by the IT service, and in other cases, by business developers. In this case, two different languages are necessary: one to be understood by IT specialists, the other to be understood by business men.

In this paper, we focus on VCC at the IS level and provides a new perspective on the traditional one-dimension VCC. Indeed, the co-creation of value that considers that a firm is invited by a customer to make a value proposition offer only in exchange of money is too short-sighted. Our idea is that (1) VCC is built upon multi-dimensions because it supports the co-creation of value for all the parties (business entities) involved, (2) it is co-created using different methods in accordance to the parties engaged and these methods have to be integrated with each other, and (3) the object of value is potentially of a different nature in a function of the sector implied.

In the next sections, we review VCC state of the art through different disciplines. In Section III, the three value dimensions are presented and based on the latter, we introduce VCC schemas in Section IV. In Section V, we present the VCC abstract language that we validate in Section IV. Finally, we conclude and present future works in Section VII.

## II. STATE OF THE ART

VCC discipline originates from the marketing theory. It aims to define and to explain the mechanism for the co-generation of value during business exchanges amongst two or more companies [15]–[17]. Vargo et al. [16], [17] formalized it using a framework for defining VCC in the perspective of the service dominant logic (S-DL). According to the authors, service is the *basis of all exchanges and focuses on the process of value creation rather than on the creation of tangible outputs*. As a result, a service system is a *network of agents and interactions that integrates resources for VCC*.

[16]. On that basis, Vargo et al. further elaborate on the idea that value is *derived and determined in use rather than in exchange*. That means that value is proposed by a service provider and is determined by a service beneficiary. Hence, the firm is in charge of the value-creation process and the customer is invited to join in as a co-creator [16]. For Grönroos et al. [14], this interaction is defined through situations in which the customer and the provider are involved in each other's practices. Consequently, the context (social, physical, temporal and/or spatial) determines the value-in-use experience of the user in terms of his individual or social environment. Another conceptual framework for VCC has been proposed by Payne et al. [8]. This framework is composed of three processes: *customer value-creating*, *supplier value-creating*, and *value encounter* for which goals are defined in a customer learning perspective and may be of a type that can be *cognitive*, *emotive*, and *behavioral*. The idea behind being that the more the customer understands about the business opportunities, the greater the value. Hastings et al. [19] also define a set of six concepts to design the practice-driven service framework for value creation, to know: customers co-create value with providers, value is created in service systems, modular business architecture, scalable Glo-Mo-So (global, mobile, social) platforms, continuous improvement via learning, and multi-sided metrics. At the analytical level, Storkacka et al. [20] have complementarily proposed to analyze the actors' engagement as a micro-foundation (explanation on a low analytical level) for VCC and Frow et al. [21] propose a framework to assist firms in identifying new opportunities for value co-creation. Therefore, the authors provide a strategically important new approach for managers to identify, organize and communicate innovative opportunities.

Recently, Chew [22] has argued that, in the digital world, service innovation is focused on customer value creation and he proposes an integrated Service Innovation Method (iSIM) that allows analyzing the interrelationships between the design process elements, including the service system. The latter being defined as an IT/operations-led cross-disciplinary endeavor. At the information system domains level, Gordijn et al. [23] explain that business modeling is not about process but about value exchange between different actors. Accordingly, in [1], Gordijn et al. propose e3value to design models that sustain the communication between business and IT groups, particularly in the frame of the development of e-business systems. In [24], Weigand extends e3value language for considering co-creation. Therefore, he defines the so called *value encounters* which consist in spaces where groups of actors interact to derive value from the groups' resources. In the same vein, Razo-Zapata et al. propose visual constructs to describe the VCC process [25]. These constructs are built on requirements from the service dominant logic and software engineering communities. They aim is to express three co-creation types (co-ordination, co-operation and collaboration) following the three elements of the customer relationship

experience: *cognition*, *emotion* and *behavior* [18]. According to [26], the co-creation may happen through different processes (B2C, B2B, C2B or C2C) and may refer to different types of value (for the company or the customer).

Two of the existing states of the art in the field of VCC are particularly interesting. The first one reviews the existing literature through both following perspectives: co-production and value-in-use [27], and the second one through two dimensions: theoretical dimension of the co-creation, and collaboration and co-creation between firms and customers [28]. Despite the undeniable need for designing an effective language to support the VCC management [1], [24], [25], the review of the state of the art demonstrates that, up to date, no approach fully considers all the dimensions necessary to cover the VCC domain.

### III. VALUE DEFINITION AND PERIMETER

In this section, value is defined according to the following three dimensions (Fig. 1): the nature of the value, the method of VCC, the object concerned by VCC. In the next sub-sections, each dimension is conceptualized, modeled and illustrated with real cases.

Fig. 1. Three value dimensions

At a methodological level, the research that we tackle concerns the improvement of value management in the field of interconnected societies. Accordingly, we have conceptualized and defined the abstract language to support the value co-creation on the basis of the three value dimensions mentioned here above. Through this research, we aim to strengthen the organizational capability to improve the design of the information system which sustains VCC. Accordingly, Hevner et al. [29] explain that the Design Science Research (DSR) paradigm seeks to extend the boundaries of human and organization capability by creating new and innovative artefacts. Practically, provided that we aim to design a new artefact (abstract language for VCC) to support the design of the information system, we acknowledge that this research may plainly be considered in the scope of DSR [30]. As advocated by the DSR theory [29], [30], the method that we use to design these value dimensions is an iterative approach consisting first of analyzing different instances of the domain under scope, second of extracting the relevant concepts from the instances, and third of designing elementary domain models. E.g., to model the nature of the value, we have analyzed some instances of this nature like security, privacy, quality, we have extracted the more relevant concepts of these domains in Table II, and we have designed the nature of the

value model (Fig. 2). For the sake of pragmatism, only the last version of the iterations are presented in the next sections.

#### A. Nature of the value

Value is an abstract concept that expresses a measureable information of a determined nature and which is associated to a well-defined object. According to Zeithaml, value implies some form of *assessment of benefits against sacrifices* [15]. Most researches that focus on depicting the semantic of value agree on the abstract character of the latter, mostly generated by the different types of existing value nature [26]. Whatever, two main categories of value nature emerge depending on the context: value at provider side vs. value at customer side. When value is perceived at the provider side, economists largely argue that the latter is *created (manufactured) by the firm and distributed in the market, usually through exchange of goods and money* [31]. This nature of value has for a long time traditionally been represented by the possession of wealth and money. However, it is also worth to note that considering the provider in the context of the digital society expands this narrow mind meaning to the consideration of other value elements, like the information collected on the customers which, afterwards, fills the bill of economic increase [32]. On the customer side, value generated by a transaction never refers to money but consists in other wealth, which contributes in sustaining and supporting the customer's own business.

Let us take the example of a SME that outsources the privacy management of its assets to dedicated enterprises, in order to remain being focused on its core business. In this case, the privacy nature of the value is traditionally expressed with well-defined characteristics (e.g., pseudonymity, anonymity, consent, etc. (see Table I) that are specifics for privacy). Moreover, two types of value are created by this outsourcing: a direct value (privacy of the assets) and an indirect value (more time for core activities). Over and above that, this transaction happening with a customer being a citizen also contributes to the latter's improvement of his well-being as observed in [33] that asserts that *value for customer means that after they have been assisted by a self-service process or a full-service process, they are or feel better off than before*.

As summarized in Table I, our analysis to understand and to define the nature of the value has been performed by tackling a set of frameworks in different areas like security, quality, compliancy, privacy, responsibility, and so forth. For instance, we have analyzed the Information Systems Security Risks Management (ISSRM [5]) framework that addresses the IS security. ISSRM characterizes security through integrity, confidentiality, non-repudiation and accountability, availability, and the latter concerns business asset of the company. Moreover, according to [34], we acknowledge that the above mentioned characteristics also constitute complementary types of value.

Based on our review, we have observed that value is an abstract concept defined by a well precise nature with well

determined characteristics, that it is measureable and that it concerns a well-defined object.

TABLE I. NATURE OF THE VALUE

Value reference framework	Nature of the Value examples		
	Nature of the value	Characteristics of the nature of the value	Concerned object
ISSRM [5]	IS Security	Confidentiality, Integrity, Availability, Non-repudiation, Accountability	Business Asset
ReMMo [35]	Responsibility	Accountability (e.g., RACI)	Actor
Web Quality Model [6]	Quality	Functionality, Reliability, Usability, Efficiency, Portability, Maintainability	Web feature
EA Compliance Model [36]	Compliance	Correctness, Justification, Consistency, Completeness	Acts of software developers
Privacy Metamodel [7] and [8]	Privacy	Notice, Choice and Consent, Proximity and Locality, Anonymity and Pseudonymity, Security, and Access and Resource [13]	Sensitive Information [9]
VDML [4]	Generic Value	Factor of benefit, Factor of interest	Business item [24]
HCI [37]	Usability	Learnability, Flexibility, Robustness	Design rules, design knowledge
...			

The concepts composing the nature of the value model are:

- **Nature of the value.** The nature of the value expresses a domain of interest and a context that characterize an element of the information system. (e.g., security of the IS, the cost of a transaction, or the privacy of personal data)
- **Characteristics of the Nature of the Value.** This concept expresses the different elements that characterize the nature of the value, or the pillars that found this nature. (e.g., availability, confidentiality, portability, etc.)
- **Object.** The object concerned by the value is the IS element that will be better off after that value is delivered (e.g., an actor, a process, a data)
- **Measure.** The measure corresponds to a property on which calculations can be made for determining the amount of value generated.

Based on the above definitions, the nature of the value has been modeled in Fig. 2.

#### B. Method of value creation

A method of value creation is a formalized activity which contributes to the generation of value. Traditionally, value is acquired by exchanging goods or services and it emerges out of its use [2]. Methods for value creation are the body of techniques and series of steps necessary to create value. This corresponds, at the corporate level, to a bundle of approaches including processes, audits, controls, decisions, etc.

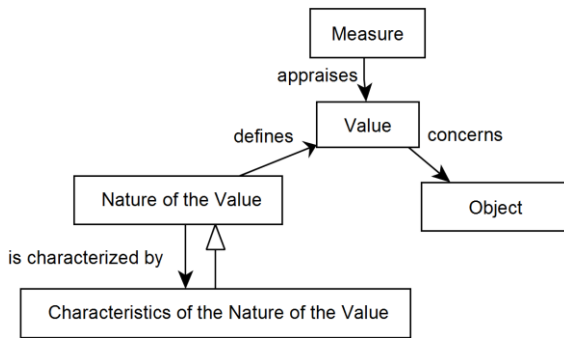

Fig. 2. Nature of the Value

Likewise, as for the nature of the value, in order to depict the elements relevant for the creation of value, we have reviewed a set of value creation methods amongst a plethora of them (Table II). The methods that we analyzed so far are the impact assessment [38], the method by design [9], the process based [39] and the risk based method [40], the model driven approaches [11] and the “method chunk” [10]. By looking more closely to all of them, we observe that these methods have each a dedicated goal, that they are composed of method elements and that the latter are organized in ordinate steps. For instance, by investigating the model driven approach, we notice that it has for goal to *improve interoperability of enterprises information systems*, that it is composed of *models*, and that three steps are required for model driven interoperability, to know: *models design, models integration and models instantiation*.

TABLE II. METHOD OF VALUE CREATION

Method reference	Method of Value creation examples			
	Method	Goal of the method	Method elements	Steps of the method
[11]	Model-driven	Improve interoperability of companies information systems	Model	Models design, model integration and model instantiation
[38]	Impact assessment	Explore social consequences for social security policies	Scenario, Strategy, Impacts, Implementation	Scenario design, Design of strategies, Assessment of impacts, Ranking of strategies, Mitigation of negative impacts, Reporting, Stimulation of implementation, Auditing and ex-post evaluation
[10]	Method chunk	Method creation	Chunk of existing methods	Decomposition of existing methods into method chunks and definition of new method chunks from scratch
[40]	Risk-based	Security strategy development	Risk, Costs, Benefits	Analysis of the methods elements and identification of the options that exist in investment decisions

[39]	Process-based	Risk management for global supply chain	Process, Step, Dependency	Step-by-step execution in a function of the dependency amongst them
[9]	By design	Prevent privacy risk from occurring	Project	Project-by-project approach realization
...				

Amongst the other methods reviewed, it is interesting to highlight that one of them (method chunk) has for particular objective the *creation of method* themselves, using, as method element: *chunk of existing methods*, and as method steps: *the decomposition of existing methods into method chunks and the definition of new method chunks from scratch* [10]. As a summary and according to our analysis, the concepts which compose the method of value creation are:

- **Method.** The method is an abstract concept that gathers a set of method elements ordered in steps (e.g., process based approach...)
- **Goal.** The goal corresponds to the expected operation on value created by the method (e.g., create value, assess or evaluate value generated, optimize the value)
- **Method element.** The elements of the method correspond to unitary tasks that constitute the method. (e.g., analysis, collect of information, reporting...)
- **Method step.** The method steps consist in the organized and coherent articulations of the method elements (e.g., if then else, process elements ordination...)

Based on the above definitions, the value creation method has been modeled in Fig. 3.

Fig. 3. Value creation method

### C. Object concerned by the value

The object concerned by the value corresponds to the elements (mostly existing at the information system level, e.g., information, process, tool, actor) that have significance for a company to achieve its goal. This object exists in a determined environment represented at the information system level by the context, the latter having an influence on the type and the amount of value associated to this object. For instance, a *customer browsing history* is an object of a data type that has a particular pecuniary value for an airline travel agency which can estimate the value ascribed to a flight ticket for a customer. This value is calculated based on the number of times this flight ticket was viewed on the company website by

the customer. At the opposite, this *customer browsing history* is not an object of value on a drugstore website with fixed prices. Complementarily, it is also worth to note that this context has no impact on the nature of the value. E.g., privacy in the healthcare sector is defined the same way as in the industry, meaning, with the same characteristics.

To collect and to deal with the concepts that are necessary to model the object of value, we assume that each sector of activities, should it be the manufacturing, the finance, or the healthcare sector for instance, is associated with a specific information system. The latter models the objects composing them and the relationships between these objects, using a dedicated language. In order to focus on the right object of value when defining a business model or when analyzing the co-creation of value, it is important to have an understanding of, and an alignment between, the objects of value of all stakeholders involved. The sector specific information systems and enterprise architecture (EA) models and languages are therefore good approaches because they semantically define generic objects and sometimes concrete languages to express the latter. Numerous frameworks have been designed to model IS and EA of various sectors, e.g., Cimosà [13], ArchiMate® [2], HL7 [41], DODAF [42], BSE [43], etc.

Table III provides a review of some metamodels and languages to depict: the context targeted, the IS under scope, and some examples of objects addressed.

TABLE III. OBJECT CONCERNED BY THE VALUE

Reference/ Language	Object concerned		
	Context - Sector	Information system	Example of objects
CIMOSA [13]	<i>Production Industry</i>	Industrial information system	Business process, flow, step, function, information, resource and organization aspects, business user, control, capability...
ArchiMate® [2]	<i>Enterprise</i>	Enterprise information system	Service, Actor, role, process, function, contract, software, data, capability, role, device, node...
HL7 [41]	<i>Healthcare</i>	Clinical document architecture	Organization, Clinical document, Author, Legal Authenticator, Person, product, consumable...
Demo [3]	<i>Enterprise</i>	Business Process, Information Systems	Models (Interaction, Business Process, Action, Interstriction, Fact), Actor, Action...
DODAF [42]	<i>Military</i>	DoDAF Meta-Model (DM2)	Guidance, activity, capability, resource, performer, location, information, project materiel, system, service, organization...

ARIS [13]	<i>Enterprise</i>	Business process management	Data, Function, Organization, Material, IT resources, or Machine resources...
BSE [43]	<i>Enterprise</i>	Business Service Ecosystem	Service, Capability, Resource, Process, Actor...
...			

As a summary and according to our analysis, the concepts which define the context and the object concerned by the value are:

- **Information system.** The information system that encompasses the objects concerned by the value.
- **Context.** The context represents the surrounding of the IS (e.g., the sector and the sector purpose of the business entity that is concerned by the IS, the rules and regulations related to the sector or the IS, etc.)
- **Language.** The language represents the vocabulary used to express the information system of a specific context.

Based on the above definitions, the context and the object concerned by the value have been modeled in Fig. 4.

Fig. 4. Object concerned by the value

#### IV. TOWARD A CONCRETE VCC LANGUAGE CONSIDERING THE 3 VALUE DIMENSIONS

As reviewed in the state of the art, value co-creation has always been analyzed at a high abstraction level and mainly with the objective to explain the co-creation of the value without describing what value it precisely stands for.

In traditional dyadic co-creation models, one firm collaborates with a customer in order to understand how value could be generated for this customer in exchange of money. In return, the latter has some obligations like sharing information with the firm and co-creating new value propositions which, afterwards, can be embedded in services sold by the firm. The existing co-creation processes focus on the nature of the value for the customer but does not consider the value generated back for the firm. Current approaches roughly consider that the firm benefits from the co-creation process by being afterward paid for the service delivered, and hence, by getting money from the customer.

This section aims to demonstrate that the three dimensions explained in Section III influence the established VCC models (e.g., [14], [16], [17]). Indeed, considering combinations of some dimensions from the tuple (value nature, method of value creation, and object concerned by the value) allows

extending and enriching the notion of VCC and value-in-exchange. Acknowledging the three value dimensions allows better understanding the VCC, and more especially the VCC processes between companies: (A) by considering the context of the object of value for stakeholders, (B) by considering different nature of the value for each party involved and, (C) by considering different VCC methods at each party's side.

Having observed that value may be described following three dimensions, we also acknowledge that value may be co-created depending on the level of the dimension at which enterprises collaborate. I.e., the collaboration may happen following three basic schemas: (1) at the methodological level, because the enterprises engaged in co-creation share some methodological elements, (2) at the physical level, because companies evolve in the same environment and share common objects concerned by the value, or (3) at the nature of the value level, because companies create the same type of value nature. At a modeling point of view, this means that depending on the type of collaboration, one or more concepts of the three value dimension models (Fig. 2, 3 and 4) are common to the companies.

Table IV illustrates possible combinations when 2 actors are engaged in VCC. When one actor creates value for its own and does not collaborate with another, schema 1 applies. These schemas are represented by, and include, the nature of the value concerned (Circle), the method of value creation (Triangle), and the business object impacted by the value (Rectangle). The company is represented in a dash-line circle, e.g., *Company A* and *B* on Table IV.

#### A. Co-creation of different objects of different values

This co-creation happens at the methodological level and is represented by the schema 2a in Table IV. On this schema, the concept of method (in blue) is shared by the companies but the nature of the value and the object of value created are different. In this co-creation case, VCC activities achieved by two companies may generate different types of value nature and that, concerning different objects evolving in different contexts. As a result, the co-creation described in this first schemas happens because enterprises share and achieve activities together that contribute to value creation.

For instance, in the financial sector, to monitor the level of privacy, a bank performs regular privacy impact assessments (PIA). In parallel, to monitor the quality of the service delivered, the bank's data-center performs gap analysis processes (GAP) that allow estimating the level of compliance between the real level of quality and the expected one. Both methods, the PIA and the GAP, are different and have for objective to generate two values of different nature in two different contexts. However, it may happen that in some cases, some steps of both methods overlap and, as a result, may be conducted jointly by the bank and its data center, and be mutually enriched or optimized. For instance, regarding the case here above, to perform the PIA and the GAP, the data

center and the bank have to audit the efficiency of the secure lease line.

TABLE IV. SYNOPSIS VIEW ON VALUE CO-CREATION SCHEMAS BASED ON THE 3 VALUE DIMENSIONS

Number of Actors	Id	Schema	Description
1 actor	1		Value Creation
2 actors	2a		Co-creation of different objects of different values
	2b		Separated creation of different objects which create the same value
	2c		Separated creation of a unique object which creates different values

This audit may be co-realized through a collaboration of experts from both entities who decide to co-achieve some tasks, to synchronize during dedicated meetings, and so forth. Another option is that some parts of this audit may be co-acquired from a sub-contracted third party.

#### B. Separated creation of different objects which create the same value

This co-creation concerns the nature of the same value and is represented by schema 2b presented in Table IV. In this schema, the concept of nature of the value (in red) is shared by the companies but the object of value created and the value creation method are different.

VCC activities from two companies may be achieved by using different methods and may concern different types of objects from different contexts, however, these different activities concern the co-creation of value of the same nature. This could be the case, for instance, in the healthcare sector, where the accounting department of a hospital sends invoices to the patients, with the name of the doctor visited but using a codification for medical treatments. Having received the invoice, the patient forwards it, to the insurance company for refund. The latter uses the same codification to calculate the amount to be paid back and transfers the cash to the patient's bank account without any reference to the doctor having provided the treatment. In this simple case, the privacy of the patient (nature of the value) is co-created by the hospital using

a codification on the invoice, and by the insurance company using a disclosure of the doctor's reference.

The context represents the internal and external environment of the company. The external context represents the laws and the rules that constraint the organization, the company's business partnerships, etc. The internal context represents the internal organization of the company, including its structure, hierarchy, information system etc. As illustrated in the case above, the same VCC process happens in two different contexts and it is necessary, to be the most relevant as possible, that each of the parties is aware of the context that characterizes the IS of the other party. For instance, it is important that the assurance company knows about the codification rules of the treatments. Additionally, regarding the external context, in order to foster the VCC, it is also relevant that each of parties knows about the other party's context. For instance, the assurance company should know about the legal requirement of the hospital to identify the right type of value (e.g., the privacy of the patients) that the hospital expects and vice-versa.

#### C. Separated creation of a shared object which creates different values

This co-creation concerns a unique object that creates value of different natures in different contexts. It concerns schema 2c presented in Table IV.

Two or more companies may require to collaborate to co-create value but this value may be of different nature for each of them. Classically, one service provider co-creates value with a customer in exchange of money. For the customer, the nature of the value is a function of the service delivered by the service provider (it may be for instance the delivery of a report, the deployment of a security tool, etc.) and for the service provider, the value is of a pecuniary value (e.g., the customer pays for the service).

Another example is the case of a retailer who receives an order from a supermarket through a just in time integrated process. In this case, the supermarket collaborates with the retailer to improve the rapidity of the process, and in return, the retailer collaborates with the supermarket to improve the quality of the service offered. In this case, two types of nature of value are generated through the same value co-creation activity: rapidity of the process for the supermarkets and quality of the service for the retailer.

#### D. Integrated VCC

Understanding and considering the three dimensions of the value allows improving and optimizing the definition of the value creation at company level. This is also the case when VCC occurs between two companies, as illustrated through the three different value schemas presented in previous section.

In practice, it is worth to note that co-creation is not limited to the basic schemas presented in Table IV. Two complementary co-creation variants exist. The first one happens when more than two companies are involved in one

dimension of the VCC. E.g., in the case of the healthcare sector, a third company could also act to protect the privacy of the patient like for instance an independent audit company or second healthcare practitioner who accesses the information from the doctor and writes a second report while also guaranteeing the patient's privacy. This case should be represented according to the schema on the left side of Fig. 5 that expresses that *Companies A, B and C* create value of a privacy nature (red circle). A second possible co-creation could happen when co-creation of value between two companies concerns more than one dimension, as represented on the right side of Fig. 5.

Fig. 5. Co-creation variants

A stronger integration of both companies is observable in this schema due to the fact that *Companies A and B* co-create value of the same nature and use some shared methodological elements. This is, for instance the case, in the financial sector, where co-creation happens when both the bank and its data center achieve activities in common to generate the same value nature. E.g., the bank achieves a PIA to generate privacy value, the data center achieves a GAP of its business processes in comparison with the GDPR (General Data Protection Regulation – [44]), and both collaborate to achieve some identical tasks of the PIA and of the GAP.

Finally, a complete system of VCC activity may also be represented based on different existing schemas (Fig. 6).

Fig. 6. Integrated VCC view

Optimizing VCC is now feasible because, based on the models defined in Section III, it is possible to identify in the three dimensions the elements that are common to the different values co-created at each side of the traditional dyadic VCC. E.g., it is possible that step x of the method for VCC in the first company (e.g., method 1) is the same as step Y of another method (e.g., method 2) for VCC in the second

company. E.g., the analysis of the risk and benefit of the VCC process can be achieved jointly by both companies.

It is also possible that an element  $x$  of the context in the first company (e.g., context 1) is the same as element  $y$  of another context in the second company. E.g., two companies from two different sectors co-create value in order to face a unique regulation that applies in both contexts.

Finally, while two companies co-create values that have two different natures, it is possible that some characteristics are common and may be handled jointly. E.g., company 1 and 2 work and co-create value together, but for company 1 the value means more privacy and for company 2, the value means more security of the information. In both cases, both natures of value have a common characteristic which is to set up the confidentiality (given that confidentiality is a characteristic of privacy and of security).

It is also conceivable to have a more integrated approach like for instance, one step of method 1 contributes to 1 characteristic of nature 2, one element of context 1 is addressed using one step of method 2, or one element of nature 1 is a requirement of one element of the context 2...

## V. TOWARD A CONCRETE VCC LANGUAGE

As explained in the introduction, two or more companies engaged in VCC must know each other and communicate in order to detect, design, and manage the collaborations where value is/could be co-created. Therefore, these companies need to be supported by a single language in order to share a common understanding of the concepts' semantic and meaning. Unfortunately, designing one unique concrete language to express all the dimensions of the VCC remains utopian for many reasons like, as explained in the introduction, the habits of a company, the different natures of value, the enterprise context in which the objects concerned by the value exist, the different layers of VCC, etc. Accordingly, the three value dimensions introduced in Section III (and based on their corresponding model) can be considered as a valuable intermediary language to support the relationships amongst different languages, from different layers, with different concrete syntaxes, tailored to express different value natures. The language interoperability using the abstract value co-creation language is made possible on the basis of chains of conceptual mappings between language concepts. Depending on the VCC schemas (see Table IV) and both co-creation variants (see Fig. 5), a plethora of chains may potentially be designed. For instance:

- In the case of schema 1 of Table IV, the conceptual mappings chain may be the following: Domain language enterprise 1  $\rightarrow$  Value dimension 1 (abstract language)  $\rightarrow$  Value dimension 2 (abstract language)  $\rightarrow$  Domain language enterprise 2. E.g., an operation manager who wishes to assess the process at risk must communicate with the risk manager. At a language level, the conceptual mapping is the following: Process reference model  $\rightarrow$  Object concerned by the value  $\rightarrow$  Value creation method  $\rightarrow$  Risk domain.

- In the case of schemas 2a, b, c, the conceptual mapping chain may be the following: Domain language enterprise 1  $\rightarrow$  Unique value dimension (abstract language)  $\rightarrow$  Domain language enterprise 2

- In the case of more than two companies involved in one dimension of the VCC, the conceptual mapping chain may be the following: Domain language enterprise 1  $\rightarrow$  Unique value dimension (abstract language)  $\rightarrow$  Domain language enterprise 2, 3... n.

- In the case of value co-creation between two companies concerning more than one dimension, the conceptual mapping chain may be a function of the required integration, and different possibilities arise.

In most cases, more than one value dimension is concerned by the conceptual mapping. The conceptual mapping between more domain languages (from one or more companies) is, as a result, potentially based on the integration of the three value dimensions. This integration, illustrated in Fig. 7, constitutes the core of the conceptual mapping. It is elaborated on the concept of value which concerns the concept of object. Both concepts are existing in the three dimensions of the value and constitute, hence, the appropriate trade-off amongst the latter.

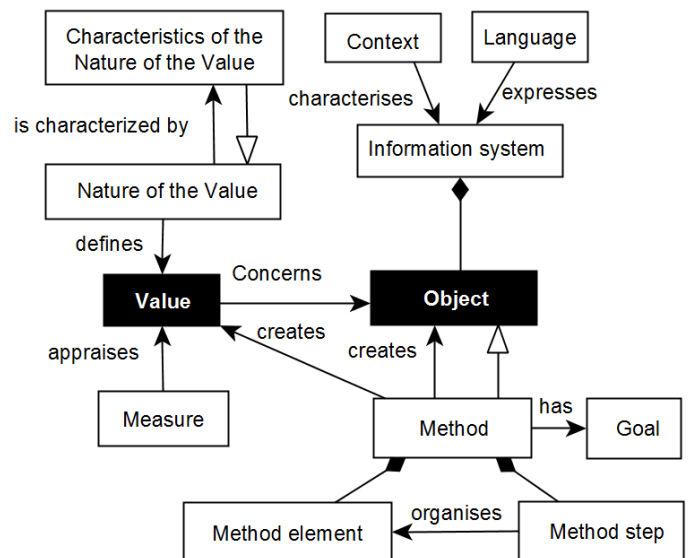

Fig. 7. Integrated three value dimensions

## VI. VALIDATION BY APPLYING MOODY GUIDELINES

The evaluation of the three dimensions-based abstract language to support VCC is performed at the level of cognitive effectiveness, i.e. the effectiveness of the language to convey information to a group of specific persons (e.g., enterprise analysts, experts of the value modeling, managers...).

This assessment of the cognitive effectiveness of the language is based on the work of Moody that establishes the foundation for a science of visual notation design called "The Physics of Notations" [45]. Moody has defined a set of nine principles for designing "cognitive effective visual notations". These principles are based on the theory and empirical evidences about cognitive effectiveness of visual

representation. They constitute what Moody calls the prescriptive theory for visual notation and they allow shifting from unselfconscious into a subconscious process of visual notation design. Table V summarized the analysis of the compliance of the VCC abstract language in regard to the nine principles defined by Moody. The table reminds the definition of the principles and how the language is compliant to the latter.

As a conclusion of the evaluation, we observe first that the majority of the principles are respected, second that the principles of complexity management and cognitive fit are irrelevant provided the abstract characteristic of the designed language, and third that the principles of complexity management and dual coding are partially respected. These principles should be improved in future works.

TABLE V. LANGUAGE VALIDATION

Principle	Definition	VCC abstract language
Principle of semiotic clarity	There should be a 1:1 correspondence between semantic constructs and graphical symbols	This principle is respected. Each semantic dimension of the value, the company, and the value created in the company is represented by a symbol.
Principle of complexity management	Explicit mechanisms for dealing with complexity should be included, such as modularization or hierarchy.	This principle is more relevant for complex languages. As we propose an abstract language, we do not have to deal with the complexity of concrete instantiations.
Principle of semantic transparency	Visual representations whose appearance suggests their meaning should be used.	This principle is partially respected. The relations between the companies that co-create value clearly appear, however, the value dimension is not deductible enough.
Principle of cognitive fit	Different visual dialects should be used for different tasks and audiences.	This principle is not relevant provided that we propose an abstract language. The principle of cognitive fit will be meaningful at the instantiation level, respectively, when languages from different audiences are integrated on the basis of the abstract language.
Principle of cognitive integration	Explicit mechanisms to support integration of information from different diagrams should be included.	The principle of cognitive integration is the core of the abstract language which aims at establishing the bases for languages mappings and integrations.
Principle of cognitive fit	Different visual dialects should be used for different tasks and audiences.	This principle is not relevant provided that we propose an abstract language. The principle of cognitive fit will be meaningful at the instantiation level, respectively, when languages from different audiences are integrated on the basis of the abstract language.
Principle of dual coding	Text should be used to complement graphics	This principle is partially respected. Text could support the principle of semantic transparency for distinguishing between the value dimensions.

Principle of graphic economy	The number of different graphical symbols should be cognitively manageable	This principle is respected.
Principle of perceptual discriminability	Different symbols should be clearly distinguishable from each other.	This principle is respected. The shapes are clearly different from each other.

## VII. CONCLUSION AND FUTURE WORKS

Two or more companies engaged in a VCC must be supported by a dedicated language. Unfortunately, designing a unique concrete syntax to express all the dimensions of the value creation remains utopical. Therefore, in this paper, we have presented the foundation of the three value dimensions which aims at defining an abstract language to support VCC: the dimensions that constitute the pillars of the language to express the nature of the value (e.g., privacy, money, security, quality...), the object concerned by the value (information, process, business asset...), and the method for value creation (risk management, gap analysis, model-driven, method chunk...).

Based on these dimensions, a set of schemas for value (co)creation has been proposed and illustrated in different sectors. In parallel, two value co-creation variants have been explained, respectively: when more than two companies are involved and when VCC between two companies concerns more than one dimension. Afterwards, the paper has presented some clues on the way conceptual mapping chains may be designed, using the three dimensions-based abstract language in order to support the value (co)creation management amongst enterprises from different sectors, considering different value nature and using different value creation methods. Finally, the designed abstract language has been evaluated in regard with Moody's nine principles for designing "cognitive effective visual notations".

Concerning future works, as argued by the DSR theory [29], [30], additional iterations are continuously required to improve and validate the designed abstract language, at the model level and at the visual notation level. In that regard, we intend in the next months, to exploit the language to support the co-creation of the value in the context of business exchange between road operators. Secondly, the abstract language needs to be enriched with complementary symbols in order to sustain the definition of chains of conceptual mapping related to some classical and frequent value dimensions, e.g., security, privacy, but also specific sectors, e.g., healthcare or public administrations.

**Abstract**—The article presents an approach to integrate a business process knowledge of Decision Support Systems. It concerns two major aspects of the system, i.e. the formalization of processes predefined in Business Process Modeling Notation, the reuse of a domain ontology, and the analysis of economic and financial information. The described approach is a continuation of the construction of the intelligent cockpit for managers (InKoM project), whose main objective was to facilitate financial analysis and the evaluation of the economic status of the company in a competitive market. The current project is related to the design of smart decision support systems based on static (structural) and procedural knowledge. The content of the knowledge is focused on essential financial concepts and relationships related to the management of small and medium enterprises (SME). An experiment was carried out on real financial data extracted from the financial information system.

## I. INTRODUCTION

MANAGING an enterprise requires access to the appropriate Decision Support System (DSS) that must always go hand in hand with the methods and tools of financial analysis. The problem is that managers of SMEs often do not possess a solid background in financial analysis and IT technology to strengthen their competitive position on the market and maintain financial credibility. The problem is often caused by the lack of the knowledge required to correctly interpret economic indicators. Moreover, these studies have shown difficulties for the knowledgeable use of information systems that contain too many functions and tools that exceed the manager's competencies.

The essence of financial analysis is to address various problems of the current short-term decision making as well as long-term strategic planning. Both types of the decisions made refer to the appropriate level of debt. Liabilities include necessary sources of business financing, however, are also an important cause of financial risk, and may lead to bankruptcy [1]. The main factor associated with financial obligations is the lack of internally generated funds allowing for their repayment.

Taking into consideration all managerial requests and the complexity of business problems, solutions are needed that integrate managerial knowledge in DSSs and support intelligent analysis and decision making [2]. One of the

main obstacles for automation of analytical processes within current DSS is the lack of a formal representation of the procedural knowledge within models of business processes. In most of the systems, the operations within the processes are defined diagrammatically, in natural language or pseudo Pascal notation which makes this representation very informal and ambiguous. In consequence, the reasoning tasks and computation are very limited.

The aim of the paper is to propose an approach that integrates financial knowledge, analytical models, and business reasoning. In the project, it is assumed that the financial knowledge is formally defined by the domain ontology. The analytical models as well as business reasoning rules are known in the literature and can be easily encoded. The essential part of the work is to develop the system that enables automated analysis of information available in financial databases and reports. The idea of the project is partially inspired by works on modelling business process knowledge, notably F. Smith and D. Proietti [3], A. De Nicola, M. Lezoche and M. Missikoff [4]. The process of analysis is to be defined using the Business Process Model and Notation (BPMN) extended by the domain ontology in OWL and a process knowledge encoded in Business Process Abstract Language (BPAL). Ontology, representing structural and procedural knowledge, seems to be a key element in the DSS that will support a manager to make correct business decisions, oriented toward company prosperity.

The paper is structured as follows. The first part briefly introduces the economic and technological background of financial analysis. The analytical activities are described as a business process diagram in BPMN, extended by the financial ontology. In the next section the design methodology of process-oriented ontology is briefly discussed. The presentation is focused on formal aspects of procedural knowledge specification. In Section 4 the use case is detailed using real life data extracted from a financial information system. The analytical activities are specified formally in a language close to BPAL and illustrated by the analysis of financial data. The whole analytical process is decomposed to subprocesses, activities, and tasks, and completed by the required information resources. The specifications focus on one of the key issues of financial

analysis related to the processes of emergency policy. Finally, in the last section, some conclusions are drawn and the future of the project discussed.

## II. FOUNDATIONS OF AUTOMATION OF ANALYTICAL PROCESSES

The problems associated with assuring on-going continuation of business operations in their current form and size are very common in practice. Managers are obliged to evaluate on a constant basis the ability of a company to operate in the future. Thus, lack of meeting this requirement may result in legal sanctions against managers. One of the most common reasons for solvency problems and the inability of a company to continue its operations is an excessive amount of liabilities in relation to equity or total assets. Among the most common restructuring activities is to strive for eliminating excessive financial liabilities. Business practice has developed many ways to reduce liabilities [5, p. 995].

Key Performance Indicators (KPI) analysis is a comprehensive method used by financial analysts to evaluate the financial standing of a company and support managers in the decision making process. This is due to the fact that the set of financial indicators and metrics allows for multifaceted evaluation of the validity and effectiveness of the financial obligations. While building financial ratios, it is possible to compare liabilities with various items included in the balance sheet, and profit and loss account, as well as cash flow statement. The most commonly used indicator in assessing company equity is *Debt to Equity Ratio* (computed as relation between *Total Liabilities* and *Equity*). The lower the ratio the better financial position of the company. This ratio is used not only by banks, but also by potential investors. This is why managers want to maintain company equity in excess of the financial obligations or want to systematically decrease liabilities while simultaneously increasing capital.

The process of financial analysis can be represented as a workflow graph describing the correct sequence of operations, where each operation described involves concepts, data items, and the relations between them. To model the analytical operations, Business Process Modeling and Notation (BPMN) will be applied (<http://www.omg.org>). Usually, a BPMN model is defined through a Business Process Diagram (BPD), which is a kind of flowchart incorporating constructs to represent the control flow, data flow, the work to be assigned to the participants, and handling of exceptions. In the project, a process of analysis is composed of an interrelated set of subprocesses or activities, where an activity is formed by sub-activities or tasks. A task is an atomic element that cannot be decomposed. Fig.1 illustrates an example of BPD referring to the analysis of financial situation of a company.

The presented BPD describes the order of analytical processes and the related financial concepts. The process

starts with the request for financial data. The detailed information about the sources and market signals will be explained in Section 4. After having received the data of the subprocess of KPI's evaluation starts, among other things, the task of assessing *Debt to Equity Ratio* discussed in the paper. The presentation focuses only on processes to be executed within Emergency Policy (shown on the left side of Fig. 1). On the right part of the analytical, three key subprocesses end the whole process, namely:

- Financial Recovery Program through increasing sales revenues and decreasing debt ratio;
- Conversion of Liabilities into Equity,
- Commencement of Bankruptcy Procedure.

The specifications of all subprocesses will be detailed in section 4.

Each of these key subprocesses is based on information derived from the financial statements, projections of future performance on the cost of debt, and the scale of business operations in the future. A full explanation of these complex financial issues is beyond the scope of the article.

The workflow model of financial analysis describes the process enactment but does not contain information on the domain knowledge. Therefore, in the project, the financial ontology has been added. The ontology provides semantic annotations of the entities, objects, items and pre- and post-conditions involved in the sub-processes. In order to define the semantics, the Ontology Web Language (OWL) was used. A part of the ontology related to the solvency threat is illustrated on the top left of Fig.1. The Description Logics used in OWL represents the domain concepts in a form of TBoxes and the assertions as ABoxes. For instance, TBox may describe a concept of hierarchy, (e.g., *Balance\_Sheets*  $\subseteq$  *Financial\_Reports*  $\wedge \exists$  *report-edBy.Company*). An example of ABox is an assertion about an individual can be written as follows: *Bal-ance2016.Company* : *Balance\_Sheets*. OWL is syntactically layered on RDF. The underlying data model (derived from RDF) is based on statements (or RDF triples) of the form  $\langle$  *subject*; *property*; *object*  $\rangle$ , which allow us to define a resource (subject) in terms of named relations (properties). Values of named relations (i.e. objects) can be URIs of Web resources or literals, i.e. representations of data values.

In the project, the financial ontology has been encoded using the Protégé platform (<http://protege.stanford.edu/>). It is important to note that the given ontology describes only static structures, namely the financial concepts and their relationships. The ontology presented in Fig. 1 shows a few concepts related to *Key\_Performance\_Indicators* analysis (marked by a green border). On the screen-shot, the *Solvency Threat* area is encircled by a red solid line. In this screen-shot there are two types of lines between topics: (1) the solid line represents a relation *Subclass-of* and (2) the dashed line represents the experts' defined relationship (for example: *depends on*).

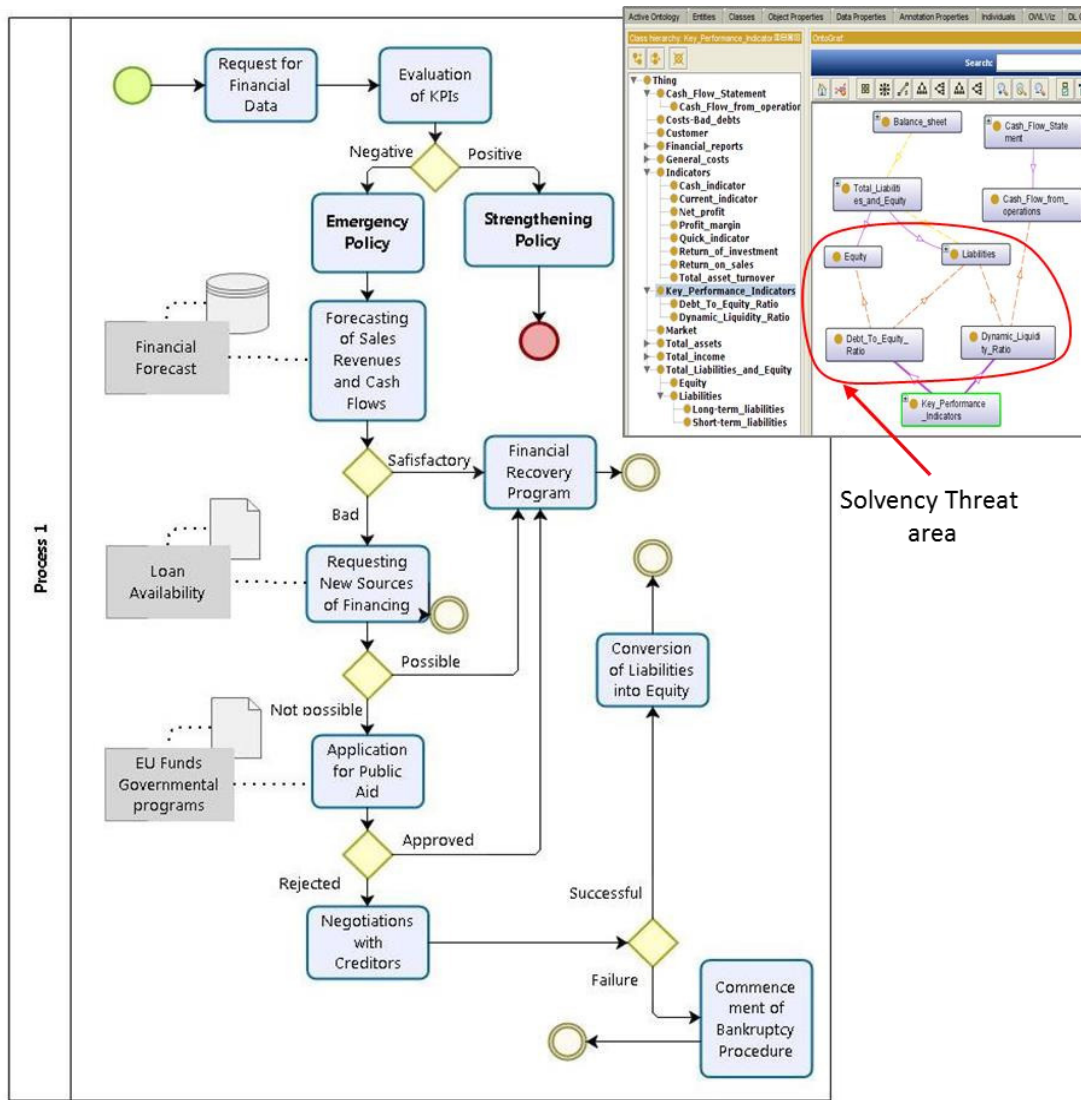

Fig. 1. Diagram of processes of financial data analysis

Source: own elaboration.

The created ontology illustrated on fig.1 can be presented as OWL code as follows:

```
<!DOCTYPE Ontology [
...
<Declaration><Class IRI=
    "#Debt_to_Equity_Ratio"/></Declaration>
<Declaration><Class IRI=
    "#Dynamic_Liquidity_Ratio"/></Declaration>
...
<Declaration><Class IRI=
    "#Key_Performance_Indicators"/></Declaration>
<Declaration><Class IRI="#Liabilities"/></Declaration>
...
<Declaration><ObjectProperty IRI=
    "#contains"/></Declaration>
<Declaration><ObjectProperty IRI=
    "#depends_on"/></Declaration>
...

```

```
<SubClassOf>
<Class IRI="#Debt_to_Equity_Ratio"/>
<Class IRI="#Key_Performance_Indicators"/></SubClassOf>
<SubClassOf>
<Class IRI="#Debt_to_Equity_Ratio"/>
<ObjectSomeValuesFrom>
<ObjectProperty IRI="#depends_on"/>
<Class IRI="#Equity"/>
</ObjectSomeValuesFrom>
</SubClassOf>
<Class IRI="#Debt_to_Equity_Ratio"/>
<ObjectSomeValuesFrom>
<ObjectProperty IRI="#depends_on"/>
<Class IRI="#Liabilities"/>
</ObjectSomeValuesFrom>
</SubClassOf>
...
</Ontology>

```

In this fragment of OWL code, the three parts can be distinguished: the declarations of concepts (for example: *Debt to Equity Ratio*, *Liabilities*), the declarations of types of relations (for example: *contains*, *depends\_on*), and the declarations of instances of relations (for example: *Debt to Equity Ratio depends\_on Liabilities*). The definitions of topics, relationships and instances are used by the above mentioned processes.

Usually business data contains a lot of explicit and hidden relationships that make their usage difficult. To interpret correctly the values of financial indicators, many measures and ratios need to be examined that either directly or indirectly influence the final result. Explicit visualization not only makes the interpretation of indicators easier, but it also contributes to finding explanations of current values of indicators.

### III. DESIGN OF PROCESS ORIENTED ONTOLOGY

The design of process oriented ontology has to provide not only a concise, comprehensive description of business processes but also express the semantics of processes in a formal way to be understood both by humans and the computer. In the project, a methodology of creating an ontology of financial knowledge, described in [6; 7], has been applied. To obtain a complete view of financial knowledge, the specification of dynamic and procedural structures has to be added. The diagrammatic representation of BPD is insufficient to be translated into a system that will be able automatically to execute all these analytical processes. Many other tasks, such as retrieval, verification, or process composition, have to be done manually.

There are several languages to describe business processes such as UML, BPMN, BPEL, PSL, OWL-S, WSMML, WISMO, etc. [8; 9; 10; 11; 12]. Taking into consideration a rigorous mathematical basis, close links with BPMN, and modelling facilities, Business Process Abstract Language (BPAL) has been chosen to specify procedural knowledge in processes of data analysis [13; 14].

BPAL contains a number of modelling concepts, symbols and rules to define so called abstract processes. The syntax and semantics of BPAL constructs can be found in [13; 14]. Looking at specifications of BPAL processes, one may say that there are many similarities to the constructs in BPMN, but BPAL is not a diagrammatic notation. In general, BPAL Application Ontology is a collection of validated BPAL processes with respect to the BPAL Axioms, where Axioms represent the rules and constraints related to application processes. Business concepts in an application are defined using unary and relational predicates, called BPAL Atoms.

The process illustrated previously with BPMN can be defined as BPAL abstract specification as follows:

```
act (request_for_financial_data),
act (analysis_of_KPI),
act (evaluation_of_KPI),
act (strengthening_policy),
```

```
act (emergency_policy)
prec (request_for_financial_data, analysis_of_KPI),
prec (analysis_of_KPI,
assert: adec (evaluation_of_KPI),
prec (evaluation_of_KPI, strengthening_policy),
prec (evaluation_of_KPI, emergency_policy)
msg (reporting_of_KPI_ratios),
msg (policy_recommendations)
part_of (Balance_Sheet, Assets),
part_of (Balance_Sheet, Equity)
isa (KPI, Debt_to_Equity_Ratio)
```

The key words in the specification mean the following [4]: **act** represents a business activity, **prec** indicates a precedence relation between activities, **assert** an assertion, **msg** a message sent and received. **isa** is a specialization relation, **part\_of** – aggregation relation. An exclusive branch **adec** leads to the execution of exactly one successor, while an inclusive branch leads to the concurrent execution of a non-empty subset of its successors. The set of successors of exclusive or inclusive decision points may depend on conditions that usually take the form of tests on the value of the items that are passed between the activities.

The specification describes also the physical and the information items that are produced and consumed by the various activities during the execution of a process.

Formally, the created model of business processes has to contain not only a set of ground facts, predicates, but also a set of rules. The rules define among other things hierarchical relationships among the BPAL predicates, relationships among BPAL elements, properties, and item flow relations. The model of a process should respect a number of constraints related to the representation of activities, events, conditions, and exception handling [14]. The design of the analytical processes that illustrates these concepts will be detailed in the next section.

### IV. USE CASE

Improvement of the financial situation should be a dominant objective of any manager. In the use case, the analytical process of emergency policy will be presented and illustrated by the real data from financial information systems. The example is based on the general schema of processes related to the analysis of financial data (Fig.1).

For the purposes of the study, the decision making process supported by the i system was divided into six subprocesses as shown in Fig. 1.

Each of the indicated subprocesses will be described, including input, preconditions, activities, exception handling, postconditions, and output. Due to the limitations of the article length, only selected aspects of process modeling will be described.

The first subprocess concerns the request for financial data, in particular the data which is available in the financial statements. To illustrate the case, the basic information describing the financial situation of the company over three years is shown in Table 1.

TABLE I.  
SELECTED FINANCIAL INFORMATION (IN K PLN)

Specification	2014	2015	2016	2017	2018
Share capital	600	600	600	600	600
Supplementary capital	600	430	30	0	0
Net Income	-170	-400	-90	-260	-370
Long-term debt	400	360	320	280	240
Short-term debt	500	900	1 300	1 380	1 500
Short-term receivables	400	600	800	800	700
Investments and cash	600	200	80	80	20

Source: own elaboration.

After the requested information is obtained, the second subprocess is related to the evaluation of critical KPIs. The most important measure used in this analysis is *Debt to Equity Ratio* (see Fig. 1). Additionally, the liquidity ratios and other measures de-scribing corporate financial stability can be applied.

The system provides an internal report which serves as the input to the process 'Evaluation of KPIs'. The data included in the report refers to the most important measures of financial stability. Each manager can individually determine the content of the report or take advantage of the default solution. Assessment of KPIs is a very important component of the decision making process, but various common-size analysis and percentage change analysis may be also applied.

Subprocess 'Evaluation of KPIs' can be specified as follows:

**input:** Financial Data (share capital, supplementary capital, net income, long-term debt, short-term debt, short-term receivables, and short-term investments including cash)

**preconditions:**

*debt structure ratio = total liabilities/total assets*

*debt structure ratio > 70%*

*quick ratio = (accounts receivable + cash) / short term liabilities*

*quick ratio < 1*

**activities**

*assessment of current financial standing of the company based on debt structure ratio, debt to equity ratio, liquidity ratios*

**exception handling:** lack of data values

**postconditions:** negative or positive assessment of debt to equity ratio

**output:** Emergency policy or Strengthening Policy

The most important outcome from this process is the recommendation with respect to the financial standing of the company. In the analyzed company, *Debt to Equity Ratio* of 200% indicates extremely high financial leverage. Thus, the situation of a company is definitely perceived as highly unfavorable, because the company is likely to have serious problems with servicing its financial obligations in the future.

Taking into account the necessity to complete the process, the manager has two options. If *Debt to Equity Ratio* is on the satisfactory level, the company should go back to normal activities. If the ratio exceeds 200%, then the procedure for reducing financial risk should be initiated. Such a high level

of debt to equity ratio is a clear sign of the extremely unfavorable financial situation of the company. The system based on *Debt to Equity Ratio* analysis generates a signal indicating excessive debt. This suggestion prompts the carrying out of the subsequent subprocess called 'Forecasting of sales revenues and free cash flows'.

Sales forecasting as well as the company's ability to generate excess cash are both essential elements of overall company management. A company forecast to encounter excessive debt needs to search for corrective measures. The basis for this subprocess is a report containing financial data and KPIs as described in the previous subprocess.

Subprocess *Forecasting of sales revenues and free cash flows*

**input:** Financial statement data, KPIs values

**preconditions:**

*debt to equity ratio > 200%*

**activities:**

- preparation of the forecast financial statements: the amount of future liabilities, potential minimum amount of free cash flow (linear forecasting model)

- estimation of the debt to equity ratio on the forecast financial statement

- assessment of forecast ratios

**exception handling:** registration of new contracts aimed to increase sales revenue

**postconditions:** forecast debt to equity ratio < 200%

**output:** Financial recovery program or Requesting of new sources of financing

The forecast can be used to provide warning signals. The values presented in Table 1 (last 2 columns) indicate that the forecast *Debt to Equity Ratio* (> 200%) significantly exceeds the safety level.

Information included in the forecast does not permit the introduction of a financial recovery program and its normal operation. It is necessary to look for new solutions created in the subprocess 'Requesting of new sources of financing'. This sub-process requires a response from the manager. Thus it is necessary to obtain information on banking offers. The key information refers to the terms and conditions of bank loans.

Sub-process: *Requesting new sources of financing*

**input**

*Bank and Credit Institution list of offers and financing conditions*

*Report on corporate credibility*

**preconditions:** unsatisfactory financial forecast

**activities:**

- analysis of offers and financing conditions

- checking of financial standing of company

- selection of the best offers

- request of manager decision (accept or reject)

**exception handling:** obtain of short-term credit lines (3 months)

**postconditions:** acceptance or rejection from bank or credit institution

**output:** financial recovery program or suggestion necessity applying for public aid

Before granting a loan, each bank shall determine the loan conditions concerning the interest rate, loan period, additional charges, and safety. Analysis of bank offers is conducted against the financial situation of the company. It is necessary to verify the terms of loan in the context of the company's credibility. If there is more than one suitable offer, a manager has to choose the most favorable loan and send the application to the selected bank.

In the case of a negative decision from the bank, the system initiates the next process '*Applying for public aid*'. As in the previous subprocess, it is necessary to check all available aid funds. Specification of this subprocess is as follows:

*Sub-process Applying for public aid*

**input:**

*EU programs list, governmental funds and programs list,  
local government funds and programs list*

*Application criteria to be met*

*Financial data report*

**preconditions:** *available financing from banks and other financial institutions*

**activities:**

*- analysis of public aid*

*- checking of application criteria*

*- request for manager decision to choose public aid program*

*- preparing and submitting a project application form*

**exception handling:** *financial aid to adapt the company equipment to meet the needs of people with disabilities.*

**postconditions:** *acceptance or rejection of submitted application*

**output:** *suggestion for financial recovery program or necessity for negotiations with creditors*

Financial aid is a solution dedicated only for selected companies. External institutions offer additional aid funds on the basis of very strict criteria. The manager has to analyze the available opportunities after providing the system with the required data related to public assistance. If the system generates a support program tailored to the needs of the enterprise, the manager will be asked to prepare and submit applications. If the application is rejected, then it is necessary to execute the next subprocess.

Unfortunately, due to the poor financial situation, it may be that the company cannot receive an external financial aid. Thus, the last step will be focused on negotiations with creditors to improve the financial situation of the company. Negotiations with creditors are the last chance for the company to survive. The subprocess can be specified as follows:

*Subprocess: Negotiations with creditors*

**input:**

*list of creditors*

*list of creditors' requirements*

*proposal of financial restructuring*

**preconditions:** *not available aid funds*

**activities:**

*- analysis of creditors' requirements,*

- *preparing and submission of restructuring program*
- *negotiations with creditors*
- *preparing the contract on conversion of liabilities into equity*

**exception handling:** *ownership changes of creditors*

**postconditions:** *acceptance or rejection*

**output:** *suggest necessity of converting liabilities into equity or the commencement of bankruptcy procedure*

The starting point in the negotiation process is to recognize the creditors' requirements. Creditors may expect to obtain a specific number of shares instead of debt reduction. Creditors generally expect the managers to conduct the restructuring program for the company. These two elements serve as the basis to begin the process of conversion of liabilities into equity. If the conditions for conversion are accepted by both parties, then the relevant agreement is processed. Negotiations with creditors are the last chance to avoid bankruptcy. The creditors' agreement for the conversion of liabilities into equity can be the only possibility for the company to survive. If there is no opportunity to reduce excessive debt, then the company is likely to go bankrupt in a legal sense. As shown in the example, the conversion of liabilities into equity should be immediately negotiated even if this is unfavorable for the current owners.

The presented use case illustrates an approach to the automation of the process of decision making support. The integration of external sources of information with the contextual internal data is a way of reducing uncertainty in the decision process. The identification of analytical activities as well as assigning a minimum set of information is a relatively new approach to analytical work automation. The conducted preliminary study may serve as the basis for the use of a process-oriented methodology in the decision-making analysis. The use of process-oriented knowledge-based systems allows managers to make better business decisions.

## V. CONCLUSION AND FUTURE WORKS

The idea of the paper to enrich the financial knowledge by presenting formally specified business processes has been achieved. The approach was applied to real-world scenarios coming from financial analysis. In the design, it was made possible to merge the procedural and ontological perspectives and to express process-related knowledge by using standard modeling languages such as BPMN, OWL, and, for reasoning and execution, BPAL and BPEL. The use of formal notations assured a mathematical rigor in process descriptions and the precise definition of concepts and relationships in the domain knowledge. In providing the formally written financial ontology, the sources of ambiguity and confusion were considerably reduced.

Currently there are many process modeling notations, e.g. BPMN, EPC, XPDL, and Petri nets. From the functional viewpoint, they should be interoperable, in order to

overcome heterogeneities of different formalisms and map them to one common, machine-interpretable, process ontology. In addition, the solutions should provide interrelations to existing domain ontologies, and enable query and search facilities.

Giving consideration to a formal account of BPMN, BPAL seemed to us an appropriate choice to automate the use of business process knowledge. BPAL remains at an abstract level, since it relies on BPMN for its concrete diagrammatic representation and on BPEL for its actual execution. The formally written BPAL specifications can then be automatically translated into executable programs BPEL and perform the reasoning and interpretation of financial information.

We are convinced that the abstract language of process specification provides a declarative and procedural semantics that can be interpreted, processed, and executed as a BPEL.

The experiments we have conducted are encouraging and revealed practical usability and its acceptance by business experts.

From the financial viewpoint, the presented use case leads to the conclusion that the conversion of liabilities into equity should be carried out when there is a dominant owner with high potential for raising capital. The reduction of financial liabilities is highly desirable in order to improve financial standing, but it cannot be done at any price. The considerations contained in this paper underline the need for in-depth analysis of the conversion of financial liabilities into equity.

Further work should be focused on a comprehensive process-oriented approach to problem solving in enterprises. Each decision-making problem should be decomposed to subprocesses and activities, and associated with relevant information. This would not be possible without the use of knowledge possessed by experienced managers and financial analysts. The process oriented approach implemented in the decision support system helps one to achieve a competitive advantage for the company. The use of process-based knowledge may also contribute to increasing the financial stability of corporates.

# Industry 4.0 and Lean Production – A Matching Relationship?

## An analysis of selected Industry 4.0 models

**Abstract**—The increasing digitalization of business and society has led to drastic changes within companies. Nearly all enterprises are facing enormous challenges dealing with topics such as Industry 4.0/Industrial Internet. With the goal of supporting companies to handle these challenges and “move” in an Industry 4.0 environment, several frameworks or reference models already exist. Here, we share the results of a detailed analysis of selected Industry 4.0 models. In particular, we foster in our analysis Lean Production aspects since the basic principles of Lean Management/Lean Production in existence since the 1980s have yielded appropriate measures to optimize production. These principles can and should be addressed and included by Industry 4.0 models as well. Our study provides a classification of 31 Industry 4.0 models/frameworks as well as the identification of needs for further research to enhance existing Industry 4.0 models more holistically.

### I. MOTIVATION AND OBJECTIVES

Considering the evolution of technology, digitalization/digital transformation provides manifold opportunities to support or even renew business processes by using technological solutions. These advanced technological opportunities, especially the merging of the physical with the digital world, result in new fundamental paradigm shifts that affect all sectors of industry. Companies must handle global digital networks, improve automation of individual or even all business processes, and reengineer existing business models to gain momentum in digital innovation. [1]-[3].

To appropriately deal with this adjusted management, communication concepts have become or will become highly important. In many parts of society, the Internet of

Things (IoT) has already established itself as an interlinked communication network to connect value chains. Examples include package tracking and vital data logging via Smartwatch or Smart Home control within domestic environments. This development is accompanied by increasingly short and individual life cycles of products that consequently lead to new production requirements. Transferring the approaches of the IoT to companies resulted in the concept of Industry 4.0 by connecting production with the internet, leading to an increasing digitization of products and systems associated with their interconnectedness [4]-[6].

An analysis using the "Google Trends" tool (see Figure 1) shows that interest in the field of Industry 4.0 has never been stronger than in the last few years. However, especially for those companies willing to use/integrate Industry 4.0 in their production, this integration is not a trivial task. Different reference models, frameworks and Industry 4.0 architectures have emerged to support companies acting in the field of Industry 4.0. Using these tools should enable companies to structure their business process appropriate regarding Industry 4.0 requirements.

Therefore, aim of this study was to analyze selected architectural/reference models of Industry 4.0. We characterized these models according to the basic principles of Lean Management/Lean Production since these approaches have existed since the 1980s and offer appropriate measures to optimize production. In our opinion, these approaches should be addressed and included by Industry 4.0 models as well.

Fig. 1. Search queries for the terms “Industrie 4.0” and “Industry 4.0” on Google since 2012

This study is guided by two research questions:

**Q1:** What organizational and technical reference models exist for Industry 4.0?

**Q2:** What relationship can be established between the reference models and Lean Production?

In order to answer those questions, we set up a study based on a systematic literature analysis. The aim of the literature analysis was to describe, summarize, evaluate, clarify and integrate aspects focusing Industry 4.0 and/or Lean Production. Selected study results will be presented in this paper. The paper is composed of four sections: 1) an introduction, 2) an overview of the conceptual background of the key terms “Industry 4.0” and “Lean Production,” 3) our literature analysis (its methodology and selected results) and 4) a summary and aspects for future research.

## II. CONCEPTUAL BACKGROUND

### A. Industry 4.0

The term Industry 4.0 or the Industrial Internet is characterized as the fourth stage of the industrial revolution and consists of an increasing interconnectedness of products and systems. Focusing on the enhancement of the automation, flexibility, and individualization of products, production, and the connected business processes [7], Industry 4.0 aims to connect the physical and virtual worlds.

From a production perspective, Industry 4.0 is understood as the movement of intelligent workpieces that independently coordinate their paths through a factory. Machines are able to “realize” these tracks and communicate in real time with the corresponding warehouse. Information is primarily used to assess and control current processes [8]. However, a universal definition for the term Industry 4.0 does not exist. Therefore, we defined a working definition to serve as the foundation for our research, and we also used this definition in other related Industry 4.0 articles (e.g., [1], [5]): *Industry 4.0 describes the transition from centralized production towards production that is very flexible and self-controlled.*

*Within this production, the products, all affected systems, and all of the process steps of the engineering, are digitized and interconnected to share and pass information and to distribute this information along the vertical and horizontal value chains and beyond in extensive value networks.*

The fact that companies have not yet implemented many parts of Industry 4.0 is shown in Table I. Based on these data, independence is to be promoted at all levels; such independence can only be achieved through better communication (an essential part of Lean Production).

### B. Lean Production

Lean Production/Lean Management already existed prior to the introduction of the concept of Industry 4.0. This form of production management was first seized on by Taiichi Ōno in 1978, who was responsible for the production of the Japanese automotive manufacturer Toyota [9]. After the end of World War II, Toyota noticed that American car manufacturers were able to produce nine times as much as Japanese car manufacturers over the same time period because they manufactured large batch sizes in order to compensate for long set-up times. Such manufacturing was not possible for Toyota, however, because its production volume was too small. Therefore, Toyota implemented measures to achieve a leaner production (see [10]). In total, this concept led to a paradigm shift: Lean Production is now defined as a third production system design since it is neither mass production nor manual work [11].

The basic principle of Lean Production is based on the avoidance of eight causes of waste. These causes are summarized by [10] as *transport, storage, accessibility of processes, unnecessary movement, waiting times, overproduction, tight tolerances, defects* and, above all, *unused skills of the employees*. In addition, [12] classifies three central principles of Lean Production: *Kaizen, Total Quality Management (TQM) and Business Process Reengineering (BPR)* (for a detailed description of this principles see [12]).

TABLE I.

COMPARISON OF A FACTORY TODAY AND AN INDUSTRY 4.0 FACTORY [14]

		Today's Manufacturing	Industry 4.0 Manufacturing
<b>Component</b> (e.g., sensor)	Key attributes	precision	independent action based on own predictions
	Key technologies	smart sensors and fault detection	degradation monitoring and remaining useful life prediction
<b>Machine</b> (e.g., controller)	Key attributes	producibility and performance (quality and throughput)	independent action based on own predictions and comparison with inventory data
	Key technologies	condition-based monitoring and diagnostics	operating time recording with predictive health monitoring
<b>Manufacturing System</b> (e.g., manufacturing execution systems)	Key attributes	productivity and overall equipment effectiveness	Independent configure, maintain and organize
	Key technologies	lean operations: work and waste reduction	low-maintenance, self-adapting production systems

### C. Lean Production - Lean Automation - Industry 4.0

Kolberg and Zühlke describe Industry 4.0 as a further development of Computer Integrated Manufacturing (CIM) and therefore as a network approach, which is complemented by CIM via communication and information technology. This approach is supported by the integration of Cyber Physical Systems [13]. These systems are a combination of two essential elements, which are the control of processes with the help of integrated software systems and the network of these software systems. With these systems, Lean Automation can be implemented in order to support and expand the approaches and concepts of Lean Production. The objectives of short lead times with minimal costs and the highest quality remain unchanged. Consequently, it is possible to provide a company-wide representation of the actual situation in real time and to enable simulation-based optimization measures based on decentralized control systems. Each workpiece is therefore clearly identifiable. Optimization measures and new services can be created from the resulting data.

In addition, the employee becomes the smart operator of production. The smart operator is, for example, notified by means of e-mail or SMS in the event of a fault reported by sensors, therefore reducing the time that elapses between the occurrence of the error and a fix being implemented. At the same time, the enterprise system makes suggestions for troubleshooting. [13].

## III. LITERATURE ANALYSIS

As shown in Section II, Industry 4.0 and Lean Management/Lean Production are complex concepts that appear to possess similarities. To investigate these aspects, we set up a study approach to contrast those two concepts. Since Lean Production is a mature concept and Industry 4.0 is an emerging topic, we conducted a systematic literature review to identify current papers dealing with the area of Industry 4.0. After identifying and analyzing the Industry 4.0 papers, we compared and contrasted identified Industry 4.0 frameworks and models with important aspects and approaches of Lean Production/Lean Management.

### A. Methodology

This systematic literature analysis is based on four steps according to [15], [16].

**Step 1 – Selection of databases and search terms:** To obtain a broad overview of the topic, we selected the databases *ScienceDirect* as well as *Academic Search Complete* and *Business Source Complete*. In addition, we used *Google Scholar* to identify articles may be not listed in scientific databases. The search fields for the database search were limited to the abstract, title and keywords. The search terms stemmed from a short preliminary search according to [16], resulting in the following search string:

TITLE-ABSTR-KEY("industrie 4.0" OR "industry 4.0" OR "fourth industrial revolution" OR "smart factory" OR

"digital factory") and TITLE-ABSTR-KEY("framework" OR "scheme" OR "structure" OR "model").

**Step 2 – Implementation of practical screening criteria:** In step 2, we classified journal papers, conference papers and reports. We did not apply any temporal restrictions to our searches. We sought a general reference model for Industry 4.0 or, at least, Industry 4.0 concepts, frameworks, and approaches to a large extent. Therefore, articles were excluded that dealt only indirectly with Industry 4.0 or only with a single partial aspect of Industry 4.0 such as *Big Data*. All of the identified papers were transferred in the literature management software *Zotero*. Next, we used the *Zotero*'s functionality to perform a duplication check.

**Step 3 – Implementation of methodological screening criteria and Step 4 – Synthesis of the results:** In these steps, a deeper analysis of the papers that were not excluded during the practical screening was conducted. First, the papers were classified according to basic criteria:

1	Manufacturing environment: Does the model/the paper focus on the manufacturing industry?
2	Industry 4.0 concept: Does the paper present/discuss/evaluate a reference model that covers all aspects of Industry 4.0? Or are only partial aspects of Industry 4.0 addressed?
3	Does the model address software and/or hardware aspects of Industry 4.0?
4	To what extent are Lean Production principles included and addressed in the reference model?
5	To what extent are business applications or enterprise systems explicitly fostered in the model?
6	Can the paper be classified as narrative article or merely as examining statistical and mathematical aspects?
7	Is an evaluation presented and discussed regarding the suitability and fit of the model in terms of Industry 4.0 requirements?

To rate the papers according these criteria/questions, we used Harvey Balls with the differentiation shown in Table II.

TABLE II.

CRITERIA CLASSIFICATION

Symbol	Description
○	Criterion is not addressed
◐	Criterion is addressed indirectly
◑	Criterion is mentioned
◒	Criterion is partially addressed
●	Criterion is fully addressed

In addition to the seven merely general criteria, we also assessed the models using the four concrete implementation requirements of Industry 4.0 postulated by different German national associations (e.g., VDMA: Mechanical Engineering Industry Association; Bitkom: Federal Association for Information Technology, Telecommunications and New

Media; ZVEI: German Electrical and Electronic Manufacturers' Association) (see [6]):

8	The extent of horizontal integration across value networks
9	The extent of vertical integration in the company
10	The extent of product lifecycle management (PLCM) and consistency of engineering
11	The extent of the "human factor" – the employee as a conductor in the value networks

### B. Selected Results

The search in the aforementioned databases with the presented search string yielded a total of 166 papers. Nine out of the 166 papers were duplicates and listed in more than one database. Therefore, those papers were excluded from the deeper screening. After practical screening of the remaining 157 papers, 31 papers were identified as fostering an Industry 4.0 framework or model according to our criteria. All of the papers that passed step 2 and were included in the methodological screening were published no earlier than 2010, which again emphasizes the relevance and topicality of this topic. We then screened these 31 articles carefully to assess the criteria of step 3. An example of the assessment of three selected papers is provided in the Appendix in Table IV. Selected results will be discussed in the following paragraphs. However, a complete assessment of all articles as well as the entire reference list of these papers will not be part of this article, but will be provided by the authors upon request or can be downloaded as supplementary material (see Table IV).

Twenty-seven out of the 31 articles focused on the manufacturing industry. The remaining articles dealt with, for example, the service sector, the construction sector and issues of cooperation in the value chain. During the deeper analysis, it became clear that 15 of the 31 articles presented or discussed an Industry 4.0 approach with a holistic focus and that 16 papers addressed specific partial aspects of Industry 4.0. In addition, it was striking that a discussion of software architectures prevailed in many of the articles. Hardware issues and aspects were not solely discussed and appeared in combination with software aspects.

Considering Lean Production, only three articles (Table IV, no. 4, 6, and 12) actively addressed and incorporated Lean Production in an Industry 4.0 setting to a full extent (in regard to our criteria). Although Lean Production was often noted (as discussed in Section II) to be one of the foundations for Industry 4.0, most related concepts in the identified 31 articles touched on only marginal aspects of Lean Production or did not focus on this principles in combination with Industry 4.0. Regarding the Industry 4.0 implementation requirements (criteria 8–11), we noted that vertical integration was the main subject in 13 out of 15 articles that provided a holistic Industry 4.0 model. On the other hand, the integration of employees was least often noted as the main paper topic. Table III gives a short summary of these the articles assessment.

TABLE III.

SHORT CATEGORIZATION OF THE IDENTIFIED ARTICLES

Category of articles	No. of papers
Relevant in the sense of the research questions	31
↳ No holistic Industry 4.0 reference model included	16
↳ Holistic Industry 4.0 reference model included	15
↳ Lean Production principles addressed as a main topic	3
↳ No Lean Production principles addressed as a main topic	11
↳ Lean Production principles are addressed in a medium to large extent but not as a main topic	1

## IV. DISCUSSION AND CONCLUSION

In summary, we identified several models and frameworks addressing the complex field of Industry 4.0 and have provided a first answer to research question Q1. However, not all models dealt with this topic in a holistic way; some instead focused on specific aspects or requirements of Industry 4.0. Hence, a common goal could be identified throughout all of the papers. The (explicit or indirect) stated goal was always to reduce the cost per unit produced. It was also crucial for all models and often discussed in the papers that communication (in three relationships: man-man, machine-man and, above all, machine-machine) was viewed as especially important for the further development and appropriate implementation of Industry 4.0. Machine-machine communication has an even larger impact because in Industry 4.0 communication and information sharing forms an essential foundation for autonomous machine decisions. A primary conclusion from this analysis is that the use of appropriate information and communication technology (ICT) is a crucial factor in Industry 4.0 environments, as has been also stated by several authors (e.g., [2], [3], [5]).

Regarding research question Q2, it became obvious that the Lean Management/Lean Production principles were not often addressed in Industry 4.0 models. Despite the fact that those aspects are often viewed as a basis for Industry 4.0 implementation, they were not integrated in the respective models nor were they discussed in connection with these models. Vertical integration was the main aspect in the identified models, and it also appeared in combination with horizontal integration aspects. This result also supports the fact that appropriate ICT is essential for Industry 4.0.

Those results motivate further research. First of all, it will be a challenge for enterprises to move in the field of Industry 4.0 and identify and implement the appropriate ICT. Therefore, in addition to the identified models more general ICT maturity models are needed (focusing Industry 4.0 requirements) and approaches for an appropriate master data management in the entire value networks. Several models re-

In summary, despite the fact that there are already several existing frameworks and reference models considering Industry 4.0 environments there are still issues that can be viewed as unsolved or at least not adequately addressed. Therefore, further research is necessary to combine existing approaches with additional key aspects of Industry 4.0.

**Abstract—** The term gamification is a relatively new concept, but the use of games for solving a variety of problems is not a new phenomenon. Gamification is used in many industries such as marketing, politics, health, environment. In education, gamification is used as a tool to strengthen e-learning systems, motivate students to learn more effectively and engage more in the learning process. Moreover, games provides new insight on learning materials

The concept of orchestration is defined by methods that allow the management of educational activities in such a way that a pedagogical effect is achieved. Orchestration relies on graphs that describe educational scenarios from different viewpoints - structure of activities, pedagogical ideas, workflow.

The main aim of the article is to show the possibilities of orchestration graphs as a tool for supporting gameducation.

## I. INTRODUCTION

Gamification is the use of mechanics known from role-playing and computer games to modify people's behavior in non-gaming situations to increase their engagement [1][2]. Technique is based on the pleasures that come from pursuing the next achievable challenge, competition, collaboration, etc. Creation allows people to engage in activities that are in line with the author's expectations, even if they are considered boring or routine [3]. The method is mainly used in marketing, science/training, market research and in motivating the company's employees [4]. Although the use of rewards, loyalty programs, and game schema elements has been used in business for a long time, the gamification itself has been described and detailed in the United States only in 2010. Then they began to appear websites such as Bunchball and Badgeville, which introduced elements familiar from games to their sites in order to diversify and attract customers.

Dillenbourg and others define the process of orchestration as a real-time management of multi-layered activities in a multi-constraints context[11]. Orchestration graph visualizes the teaching scenario consisting of learning activities [12]. Dillenbourg uses orchestration graphs in most cases as a tool to facilitate the functioning of the Massive Open Online Courses (MOOC) [13].

In this article we would like to propose a different form to use it - as a tool to support gamification.

## II. THE ESSENCE OF GAMIFICATION

Education using a game methodology is a new field, but the games themselves are involved in the life of mankind since the dawn of time. Motivation and engagement are usually seen as a prerequisite for completing a task or encouraging a particular behavior.

At this point we should explain differences between gamification and serious games There are some terms and concepts that have similarities - gamification, game inspired design, serious games, simulations and games. The boundaries between them are not clearly defined [5]:

- Game inspired design is the use of ideas and ways of thinking that are inherent in games. Game inspired design does not express in adding game elements, but rather in using of playful design.

- Gamification is the use of game metaphors, game elements and ideas in a context different from that of the games in order to increase motivation and commitment, and to influence user behavior.

- Serious games are games designed for a specific purpose related to training, not just for fun. They possess all game elements, they look like games, but their objective is to achieve something that is predetermined.

- Simulations are similar to serious games, but they simulate real-world things and their purpose is user training in an environment resembling real life.

- Games include everything mentioned above and they are designed for entertainment.

All the above-mentioned concepts have one thing in common – they use elements that are inherent in games and their purpose is to support learning and to improve users' engagement.

In education, the main causes of poor performance are boredom, lack of commitment, and deconcentration caused by widespread access to new mobile technologies [6].

Effective game must have a clear goal, constant feedback messages, the pleasure of achieving small victories, winning small artifacts, the company of other participants in the game

[7]. While the concept of gamification may be simple, effectively gamifying a concept isn't. However, it can be simplified, by following a five-step process.

#### **Understanding the target audience and the context**

The decisive factor for the success of the educational program is appropriate recognition to whom it is addressed. This combined with the context in which the program is being delivered, will help in designing a program that empowers the student to achieve the objective of the program. Audience analysis can help you determine factors such as age, skills, and knowledge, analysis of the context can provide detailed information on the size of the group of students, the environment, determining skill and timing.

#### **Defining learning objectives**

Defining educational objective is based on the answer to what a student will achieve by implementing an educational program. These goals can be divided into three groups:

- General Instructional Goals such as having the student complete an assignment, a test/quiz/exam, a project, etc.
- Specific Learning Goals which could include the student understanding a concept, being able to perform a task after the training, or completing the learning program.
- Behavioral Goals which may require the student to concentrate in class, complete assignments faster, minimize distractions in class, etc.

#### **Sequence learning process**

Structuring the experience via stages and milestones enable instructors to sequence knowledge and quantify what the students need to learn and achieve by the end of each stage or milestone. These milestones work well for students as well, as it makes the ultimate objective seem more achievable and measurable, while ensuring that obstacles within and between each stage are easily identifiable. Breaking down the education program into different stages gives the instructor the opportunity to judge the objectives, context, and pain points, and prepare a more effective overall gamified process for education.

#### **Defining game elements**

After identification of stages and milestones we can decide which stages, if any, can be gamified, and how. Considering the gamification we should answer the following questions:

- can we apply tracking mechanism?
- what currency we would use and how much we need to level-up?
- are the implemented rules transparent to participants?
- does the overall system give the student and/or instructor feedback?

When designing the section being gamified, a currency can help determine levels within a stage and it is possible for a level to be a whole stage in the education program. It also gives the instructor the opportunity to use currency-based levels and rules to receive and give feedback. Feedback is an important ally, as studies show that students do better when

given more opportunities to complete a task [8]. This is exactly what makes games appealing, as students are given quick feedback if they do a task wrong and have the chance to try it again.

#### **Applying game elements in education**

Gamification in education is based on the implementation of game elements into the teaching content. Game mechanics can be classified as self-elements or social-elements [9].

Self-elements can be points, achievement badges, levels, or simply time restrictions. These elements get students to focus on competing with themselves and recognizing self-achievement. Social-elements on the other hand, are interactive competition or cooperation, like for example leaderboards. These elements put the students in a community with other students, and their progress and achievements are made public.

Keeping other factors constant, social-elements can motivate students in a community setting.

Applying gamification strategies and/or technology to curriculums may often do a better job of teaching. However, it does not mean it should be a replacement for a comprehensive curriculum or face-to-face instruction. Instructors must be careful not to depend on extrinsic motivators in the game to modify student behaviour, as the habit created during the gamified process may not sustain once the extrinsic reward is gone [10].

### **III. CONCEPT OF ORCHESTRATION**

The term orchestration can be defined as real time management of multilayered activities in a multi-constraints context [13]. The concept of orchestration defines the role of the teacher as a person defining the forms of student interaction, management of available resources and technology.

In 2015, Dillenbourg [11] introduced the idea of orchestration graphs (fig.1) in the form of timelines with social granularity on the y-axis (ranging from individual work, to small groups, whole class, and the world) and time along the x-axis (fig.1). It is a structured view of a learning scenario, consisting of learning activities (nodes). Activities take place at different social planes, have a start and an endtime.

On an individual plan students work independently on the assigned task (gathering information, writing summary, reading text, etc.).

On the set of group students work in small teams (up to 10 people) focused on solving a given problem.

Within the team, individuals may be assigned different roles, but, at the end, they need to converge on a joint product.

On the class plane, the activity involves all the students in the class: they do activities such as listening to lectures, participating in discussions, presenting posters, or visiting a museum together.

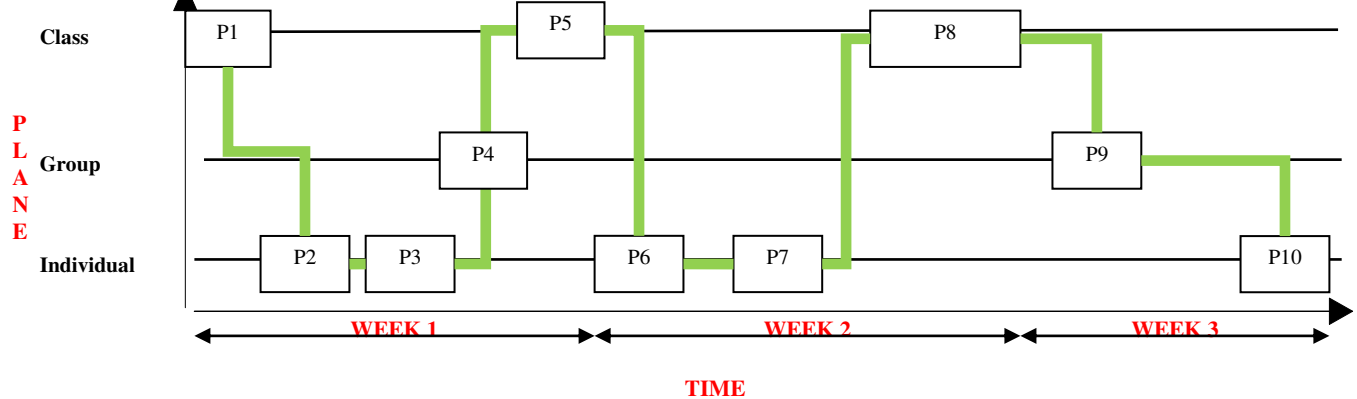

Fig.1 Example of orchestration graph.

The term activity defines what students should do to achieve the goal established by the teacher. Activities do not have a specific duration, can last 2 seconds or 2 months. Some activities performed by learners cannot strictly be qualified as “learning activities” - students are not exactly learning anything, but they have to perform an activity required for continuing the learning scenario (i.e. finding teammates). Therefore term “learning activity” can be considered as synonymous with “learner activity” [11].

Activities can be described by parameters such as:

- objects
- products
- competencies
- traces
- metadata.

In orchestration graphs, activities are connected by edges.

These can contain pedagogical justifications (e.g., activity 1 is an advanced organiser for activity 2), learning analytics information (e.g., student success in activity 1 is 34% correlated with/predictive of success in activity 2), and operators [13].

Operators receive data from student activities (products), and generate input for subsequent activities. Operations can include aggregation, disaggregation, assignment, translation and transformation of the student product. Operators are also used to generate social structures based on input data, such as organizing students into groups based on their previous answers [12].

Operators are classified into categories [12]:

- Aggregation operators gather data for subsequent activities (listing, classifying, sorting, synthesizing, visualizing),
- Distribution operators split data for subsequent activities (broadcasting, user selection, sampling, splitting, conflicting, adapting),
- Social operators modify the social structure of activities (group formation, class split, role assignment, role rotation, group rotation, dropout management, anonymization),
- Back-office operators enrich data with external information, including information manually provided by human actors (grading, feedback, anti-plagiarism, rendering, translating, summarizing, converting, updating).

In gamification you may attempt to use the following operators which capture the spirit of the game: real time feedback, tracking mechanism, leveling, currency, teaming, plot twisting, loss aversion, challenges, discovery and exploration, countdown.

The use of graphs and operators to illustrate the implementation of games in education will be presented in the next section.

#### IV. POSSIBILITY OF USING ORCHESTRATION GRAPHS IN GAMIFICATION

In order to judge the effectiveness of gamification scientists of University of Cape Town (UCT) decided to apply it to an existing Computer Science course focusing on 2D games design and development a traditional computer game [14]. The game had a Steampunk theme. Steampunk is a science fiction sub-genre set in an alternate past similar to the Victorian era, but with advanced technology. Students are introduced to a secret “Order of the Curmudgeons”. This order is a club of mad scientists, each with their individual quirks and expertise. A device called the “Crowther Engine” has gone missing and the students must solve the mystery of its theft. This is accomplished by earning clues by completing tasks. Once the students unravel the final set of clues, they have solved the mystery.

The long-term goals of the second year Games Course are to teach development concepts and skills relevant to 2D games design. Gamification is intended to aid in meeting this long-term goal by [14]: improving the students review of course material, increasing meaningful class participation, fostering problem solving skills, increase lecture attendance, encouraging creativity in practical tasks.

Each of these sub-goals in design was linked explicitly to a reward structure, through an experience point (XP) system. The students were given short timed assessments, in the form of quizzes, once a week. The quizzes were based on lecture material taught in the previous week and promoted a review of course material after lectures. Students were awarded experience points (XP) for achieving various levels of success: 10 XP were given for 70-79%, 20XP for 80-89%, 30XP for 90-100%.

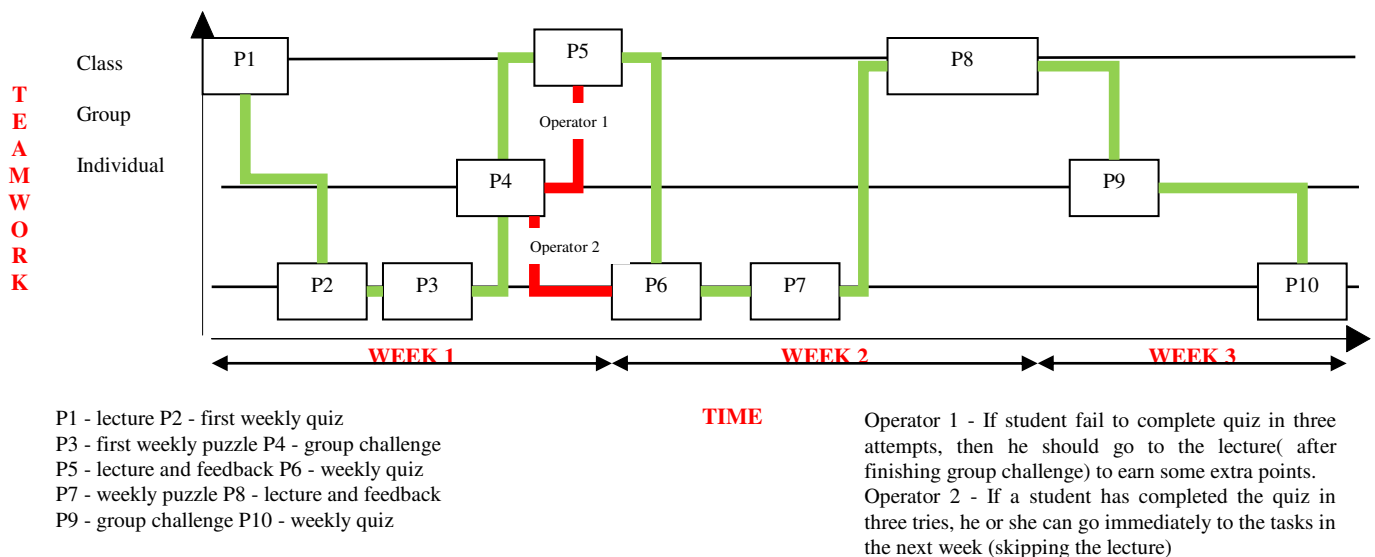

Fig.2 Orchestration graph with operators

Sporadic group challenges were organised throughout the semester to practice game development concepts learnt in class.

The above mentioned activities can be visualized using orchestration graphs (fig 2).

As you can see above operators fit into the framework of the previously described ones. Operator 1 and 2 contains operators(mentioned in chapter III) such as leveling, challenge, countdown, loss aversion(not getting a reward, but avoiding punishment).

By using graphs we can accurately plan student behavior, enhance all educational-related factors - participation in lectures (gaining extra points), group work (brainstorm to overcome difficult challenges), knowledge exchange ( to shorten task execution time).

## V. CONCLUSION

So far orchestration graphs have been used as a tool to support the functioning of MOOC [12]. We want to propose to use them in gamification, which is a one of the educational approaches and techniques that increase motivation and engagement of learners [15].

Use of orchestration graphs can open new opportunities for support of development of an effective strategy for the implementation of gamification in e-learning.

□

**Abstract**–*The research discusses the issue how to describe data quality and what should be taken into account when developing an universal data quality management solution. The proposed approach is to create quality specifications for each kind of data objects and to make them executable. The specification can be executed step-by-step according to business process descriptions, ensuring the gradual accumulation of data in the database and data quality checking according to the specific use case. The described approach can be applied to check the completeness, accuracy, timeliness and consistency of accumulated data.*

**Keywords**– *Data quality, domain-specific modelling languages, executable business processes*

### I. INTRODUCTION

The term “quality” depends highly on the context in which it is applied. The term is commonly used to indicate the superiority of a manufactured good or attest to a high degree of craftsmanship or artistry [1]. In manufacturing industries, quality is viewed as a desirable goal to be achieved through management of the production process.

Data quality is an IT-specific term, and it can be defined as the degree to which the data fulfills requirements of characteristics [2]. Examples of data quality characteristics are: completeness, validity, accuracy, consistency, availability, and timeliness.

The data quality problem is topical since over 50 years, and many different approaches are discussed in scientific publications addressing data quality issues. In the major part of sources the central attention is paid to defining of data quality characteristics informally and measuring of their values. Mechanisms for specifying of data quality characteristics in formalized languages usually are not considered. The main task of this research is to provide data quality management mechanisms being able to execute data quality specifications which are defined using formalized domain specific language (DSL).

To evaluate the data quality for the specific usage, the requirements for data must be described. The descriptions

should be executable, as the stored data will be “scanned” and its’ compliance to requirements will be checked.

In order to achieve the goal, two key requirements for specifying the data quality were formulated. Firstly, the ISO 9001:2015 standard considers data quality as a relative concept, largely dependent on specific requirements resulting from the data usage. It means the same data can be of good quality for one usage and completely unusable for another. For instance, to determine a count of students in a high school, only the status of students is of interest, not other data like students’ age or gender. The same data may be checked for it’s accordance to different quality requirements. It should also be emphasized that many conditions and requirements can’t be checked during the data input as they are dependent on values of other data objects that are not entered yet. For instance, at the time of student’s enrollment not all information about his/her financial obligations is available and/or entered in the database. This is the reason why high-quality data in practice occurs rarely.

The proposed approach intends creating of specific data quality model for each information system. The model is described by using means of a DSL, and it lets clearly define requirements for data objects attribute values and compatibility. The data quality model is executable: both the syntactic and the semantic controls are performed. The approach provides the possibility to use the data quality model for measurement of data quality.

The paper deals with following issues: overview about the related research (Section 2), and a description of the proposed solution (Section 3).

### II. RELATED WORKS

There are three main research branches present: (1) the total data quality management (TDQM) theory, (2) the data quality defining by using the Object Constraint Language (OCL), (3) the data quality management using SSIS tools. They all are described in this chapter.

#### A. Total Data Quality anagement

The issue of data quality is essential since the very beginning of the IT industry. Numerous studies have led to various definitions of data quality. For instance, data are of good quality if they satisfy the requirements imposed by the intended use [3].

□ The research leading to these results has received funding from the research project “Information and Communication Technology Competence Center” of EU Structural funds, contract nr. 1.2.1.1/16/A/007 signed between ICT Competence Centre and CFLA of Latvia, Research No. 1.8 „Data Quality Management by using Executable Business Process Models”.

Data are of high quality if they are fit for their intended uses in operations, decision making, and planning. According to Joseph Juran [4] data are fit for use if they are free of defects (accessible, accurate, timely, complete) and possess desired properties (relevant, comprehensive, proper level of detail, easy to read, easy to interpret) [5].

Data quality can also be characterized by different dimensions. In 1996 Wang and Strong [6] defined 15 data quality dimensions which are confederated in four quality groups: intrinsic, contextual, representational, accessibility.

Redman [5] provides 51 data quality dimensions, arranged in 9 data quality groups. Such a deep data quality gradation may seem an overstatement, especially for practitioners. In 2013 the Data Management Association International UK Working Group possesses only 6 dimensions: Completeness, Uniqueness, Timeliness, Validity, Accuracy, Consistency.

### *B. Object Constraint Language*

The OCL started as a complement of the UML notation with the goal to overcome the limitations of UML in terms of precisely specifying detailed aspects of a system design [7]. Since then, OCL has become a key component of any model-driven engineering (MDE) technique as the default language for expressing all kinds of (meta)model query, manipulation and specification requirements [8].

Constraints at the model level state conditions that the “data” of the system must satisfy at runtime. Therefore, the implementation of a system must guarantee that all operations that modify the system state will leave the data in a consistent state (a state that evaluates to true all model invariants). Clearly, the best way to achieve this goal is by providing code-generation techniques that take the OCL constraints and produce the appropriate checking code in the target platform where the system is going to be executed.

Typically, OCL expressions are translated into code either as database triggers or as part of the method bodies in the classes corresponding to the constraint context types. Roughly, in the database strategy each invariant is translated as a SQL SELECT expression that returns a value if the data does not satisfy that given constraint. This SELECT expression is called inside the body of a trigger so that if the SELECT returns a non-empty value then the trigger raises an exception. Triggers are fired after every change on the data to make sure that the system is always in a consistent state. The OCL has many positive qualities: (1) OCL is an extension of UML, and it has gained a wide popularity in the computer scientists’ community, (2) OCL provides a rich range of means of expression, allowing the use of widely used programming constructions. At the same time the disadvantages of OCL should also be recognized: (1) OCL is a declarative language without graphical notation, (2) constraints of OCL are closely related with the data storage in a relational database, (3) defining of data quality constraints in OCL requires good programming skills.

Furthermore, the OCL is missing a number of features that are necessary for data quality:

- no data read/write operations,
- no operations for reading and checking of discrete data objects that are not related to database (such operations are necessary for verifying of data entered via screen forms),
- constraints in OCL are described linearly (like a program code) and not graphically,
- defining and understanding of OCL constraints requires deep knowledge and skills in object-oriented programming; it makes the OCL unsuitable for industry professionals without appropriate IT background.

Usually data quality controls are hard-coded in data processing programs and can not be changed without involvement of programmers. As a result, often inconsistent data is entered and stored in databases.

OCL-based data quality solutions are hard to use practically due to the dynamic data input into database as well as to the complexity of OCL.

### *C. SQL Server Integration Services*

As every solution, Microsoft SQL Server Integration Services (SSIS) has various advantages and disadvantages [9]. SSIS offers wide range of features for data migration, and designing of ETL and transformation processes [10]. To cover a broad spectrum of requirements for data migration and ETL processes, SSIS includes both standardized operations for many widely-used database management systems, and add-ons for different import/ export formats, and opportunities for developers to use the programming environment VisualStudio.

Furthermore, SSIS is open platform allowing create and use external add-ons. Hence SSIS should be considered as a mature platform that is suitable not only for solving of ETL tasks but also for processing of emails, linear text files, XML files, and other operations. The rich range of included features enables creating of SSIS packages from predefined components or to develop them by programming.

Microsoft has designed this product to provide better approach towards data migration, manipulation and transformation. With the power to define the workflow of process and task, user can easily define how the process should flow and perform some task on different interval. It also provides color codification and real-time monitoring.

SSIS advantages:

- SSIS can handle data from heterogeneous data sources,
- SSIS provides transformation functionality,
- Tightly integrated with Microsoft Visual Studio and Microsoft SQL Server,
- suitable for complex transformations, multi-step operations and structured exception handling.

SSIS disadvantages:

- to see package execution report needs Management Studio rather than being published to reporting services,
- SSIS memory usage is high and it conflicts with SQL.

Authors of [11] assure that usage of SSIS removes need of hardcore programmers as SSIS is apparently easy to understand and manage. In contradiction to [11] the authors of this research believe that the usage of SSIS have some fundamental barriers. The complexity of the approach is high; the usage of the solution for data processing and data quality management require either programmer's level of understanding of process execution, or many years of experience with SSIS.

Although not designed specifically for data quality management, features offered by SSIS provide a number of suitable solutions. Currently there are not known SSIS uses for data quality management which were not related to data migration. However, data quality management elements offered by SSIS are practically usable and should be taken over in further data quality solutions.

### III. PROPOSED APPROACH

The data is stored in the database gradually in various steps. Hence the data quality requirements should be formulated for several levels of a data object – (1) discrete data object, (2) contextual control on interrelated data, (3) contextual control on the database, and (4) contextual control on several databases.

#### A. Data Quality Requirements for a Separate Data Object

The proposed ideas will be demonstrated with the help of a simple example. Let us consider a working time tracking (WTT) system having the ER model given in the Fig.1. There are many active projects in an enterprise (entity Projects); every project has several employees (entity Developers); each employee (developer) may be involved in several projects; the working time spent by an employee (developer) in a specific time frame is aligned to one specific project (entity Work\_time).

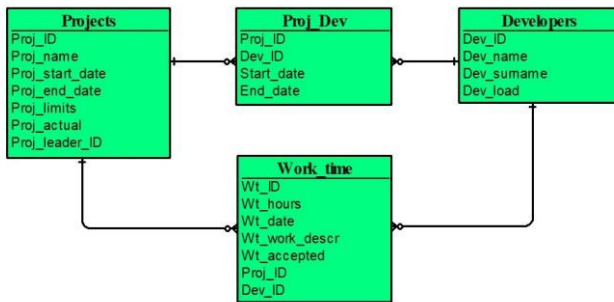

Fig. 1 WTT data model

The entity *Projects* has the following attributes: *Proj\_ID* (project identifier to specify the project to which the spent working time should be referred), *Proj\_name* (project name), *Proj\_volume* (the estimated work amount of the project in man-hours), *Proj\_start\_date*, *Proj\_end\_date*, *Proj\_limits* (the maximum allowable work amount of the project in man-

hours), *Proj\_actual* (project is active/passive), *Proj\_leader\_ID* (project manager).

The entity *Developers* has the following attributes: *Dev\_ID* (the developer to whom the spent time should be referred), *Dev\_name* (developer's name), *Dev\_surname*, *Dev\_load* (the minimum monthly developer's workload).

The entity *Work\_time* has the following attributes: *Wt\_ID* (identifier of the spent working time record), *Wt\_hours* (spent working time of the developer), *Wt\_date* (date of the spent working time), *Wt\_work\_descr* (description of the performed work), *Wt\_accept* (reported working time is accepted by the project manager, Yes/ No), *Proj\_ID* (the project to which the time should be referred), *Dev\_ID* (the developer to whom the time should be referred).

The entity *Proj\_Dev\_time* is a junction table for dealing with many-to-many relationships, and it has the following attributes: *Proj\_ID* (the project where the *Dev\_ID* works), *Dev\_ID* (the developer working in the project *Proj\_ID*), *Start\_date* (the date when the developer *Dev\_ID* started to work in the project *Proj\_ID*), *End\_date* (the date by which the *Dev\_ID* will be assigned to the *Proj\_ID*).

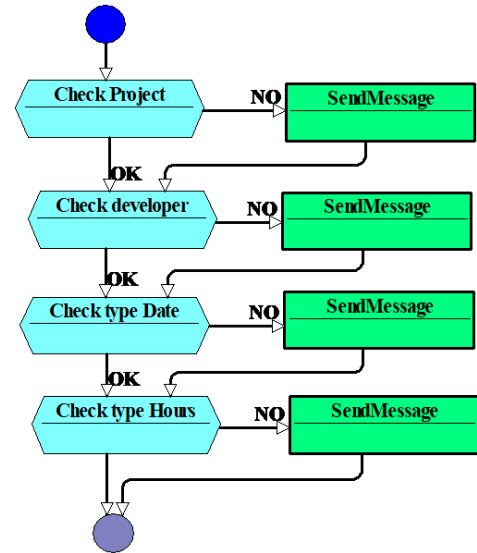

Fig. 2 Example of data object's syntactic control

Let us assume, the developers prepare reports about their working time autonomously and send the reports to data base where all enterprise data from various sources is collected. The procedure receives values of attributes:

< *Proj\_ID*, *Dev\_ID*, *Wt\_date*, *Wt\_hours*, *Wt\_work\_descr* >

The quality specification of report shown in the Fig.2 ensures quality control within one input message: (1) are all mandatory fields completed (*Proj\_ID*, *Dev\_ID*)?, (2) have input values correct data types (*Wt\_date*, *Wt\_hours*)?

In order to make the quality specification executable, informal texts should be replaced by program routines executing the desired operations.

### B. Contextual control on interrelated data

Contextual control on interrelated data (see Fig.3) ensures quality control using attribute values of mutually interconnected data objects: (1) does the message contain object instances with references to other data objects (Project exists, Developer exists)?, (2) are the attribute values of input data in compliance with related data objects?

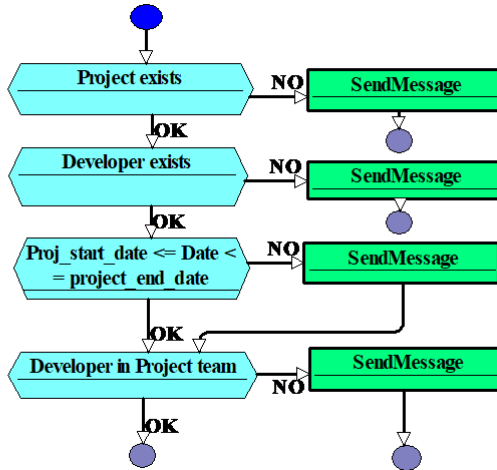

Fig. 3 Example of contextual control on interrelated data

In order to make the quality specification executable, informal texts should be replaced by SQL statements for data retrieving and control of constraints (see. Fig.4). Tools like SSIS may be used – these also offer statements for execution of SQL statements and validation of results.

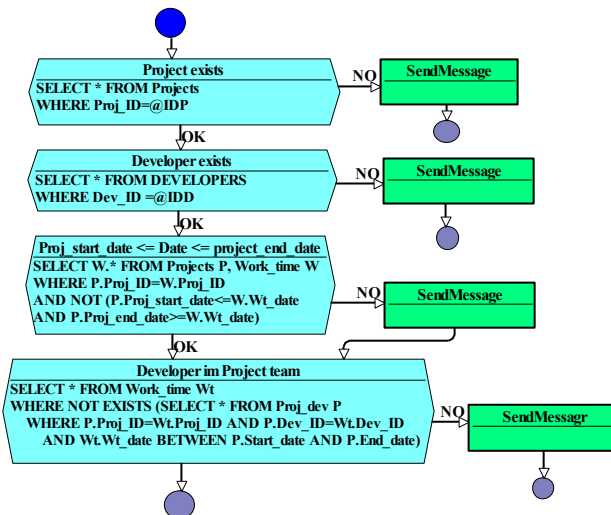

Fig. 4 Example of executable contextual control on interrelated data

### C. Contextual control on the database

Contextual control on the database (see Fig.5) checks the compliance with conditions valid for the whole data base (examples: isn't the maximum of work amount allowed for the project exceeded, do the reports of employee cover the minimal workload of the employee in the time period, etc.).

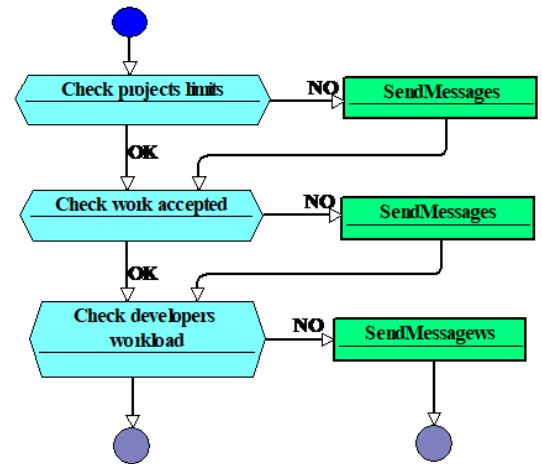

Fig. 5 Example of contextual control on the database

In order to make the quality specification executable, informal texts should be replaced by SQL statements for data retrieving and control of constraints (see. Fig. 6).

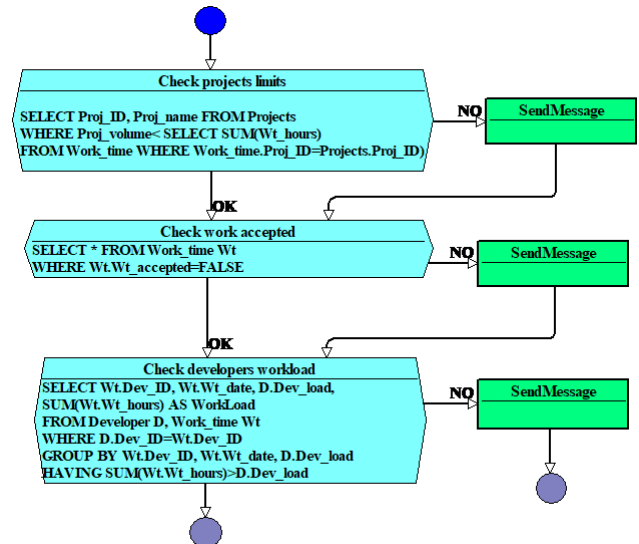

Fig. 6 Example of executable contextual control on the database

Diagrams in Fig.2, Fig.3 and Fig.5 form an informal data quality specification of working time tracking (WTT) system. It may be useful for industry experts to describe data quality requirements as a more formalized specification of executable controls is not practically applicable without IT skills. Executable data quality specifications can be used in business process steps to check data quality in certain points of processes.

Practical uses of the proposed approach have shown advantages of graphically represented data quality specification as they were more effective in discovering of information system-caused data quality errors than the traditionally used informal data quality specifications in the textual form. It reaffirmed advantages of graphic diagrams in comparison to natural language texts in standardized documents.

Additional advantages can be gained if the data quality specifications are transformed to executable specifications. Although additional programming is needed to ensure the executability, a much higher data quality can be achieved in an information system as a whole if data quality controls are incorporated in business process steps.

First two of mentioned data controls typically are applied during data input. In case data should be saved anyway it is marked as incorrect. As this one control over database could be rather resource-intensive (time, server memory, processor time, data locking) it can not be executed on every data manipulation. Contextual control on the database usually is executed out of business hours and even not every day. Still the proposed approach is universal, and it is applicable in different cases – during the initial data input in information system, migrating data from one information system to another, performing data transformation to data warehouse.

#### *D. Contextual control on several databases*

The above described approach is also applicable in cases when several information systems of different enterprises are involved. Such a case is typical for public institutions with different but interrelating state information systems.

This problem has been addressed in Latvia since 2000. The essential data of public interest are accumulated in different state information systems: Population Register, Business Register, Vehicle register, etc. Each of the registers is managed and maintained by some public body which is responsible for the quality of the accumulated data.

The registers should also mutually exchange data; usually it is organized with the help of web services serving and receiving data – concrete values of data objects' attributes. Each data exchange session may require only few attribute values. When using data quality specifications, it is possible to check and evaluate the quality of received data.

Like the Latvian Integrated State Information System project [12], the described problem is also addressed in Estonia [13], Lithuania [14] etc.

Currently development of various industry-specific state information systems is continuing, and the identified data quality problem persists in each system again and again.

## IV. CONCLUSIONS

The research shows the relative and dynamic nature of data quality. The usage of data implies requirements for data quality; the data are accumulated and verified step-by-step. Consequently a data quality management system has to fulfill the following key requirements:

- Data quality requirements are formulated for different levels – a discrete data object, interrelated data objects, data in a database, data in several databases.
- Data quality requirements should be specified in an easy-to-understand definition language to ensure that industry experts will be able to formulate data quality

requirements without involvement of IT professionals. It is advisable to use graphical DSL.

- If considering usage of the OCL – a quite popular language in computer scientists' community – , there should be taken into account that OCL is declarative language without graphical notation, it's constraints are closely related to the way how data is stored in a relational database, and formulating of data quality constraints is rather complicated and requires good skills in programming.

- The SSIS, developed by Microsoft, offers a range of useful features for data quality management including extracting data from different types of information sources and checking the validity and correctness of different data object relations. SSIS is an integrated part of Microsoft SQL Server and Visual Studio.

The proposed approach and tools for designing of executable data quality specifications in different levels let to design, develop and use the specifications as steps in executable business processes.

The paper is a continuation of authors' researches in the area of executable models and DSL [15], [16], [17].

**Abstract**—Popularization of process approach as a standard necessitates changing the ways of defining and identifying requisite competencies. They should be seen in the framework of tasks implemented within the business process. The complex nature of competencies requires expressive forms of description regarding their multidimensional character therefore codification of competencies is the area predestinated to make use of ontologies. The aim of this paper is to show how the ontology describing competencies can be linked with business process models to support process-oriented, dynamic competency management in a company. With this aim in mind a proposal of practical implementation of ontology-enhanced business process model was presented and illustrated by the example of software development.

### I. INTRODUCTION

**D**YNAMIC economic environment along with new challenges posed by globalization and latest information technology developments are reflected in a steady growth of interest in competency management. The complex nature of competencies requires expressive forms of description regarding their multidimensional character. According to Bratnicki [1 p.64], competencies are „complex bundle of resources, processes and abilities” which are important for gaining competitive advantage on a particular market. The competencies of organization allow for conducting its business by coordinating its owned resources. In the light of resource-based view, competitive advantage is based on a concept of distinctive competencies of organization. This term was introduced by Philip Selznick in 1957 referring to the activities which organization does particularly well comparing to its competitors [2]. Similar concept of core competencies was put forward in 1990 by Prahalad and Hamel [3] as the bedrock upon which to build strategies.

From this point of view, apart from identification and evaluation of distinctive competencies, it is also important to monitor changes in the environment regarding new needs, products and technologies. These changes create the need for adjustment of business processes and searching or developing new competencies. Human capital is the carrier of the organization’s knowledge and skills, therefore developing core competencies requires developing individual and team competencies.

The vision of the strategic core competencies is the driver for development of collective or individual competencies. The requirements in this area should follow from the processes and tasks performed by the working group or the whole organization. Therefore the main focus of this study is on individual and team competencies.

Popularization of both process and ontological approach as standards necessitates changing the ways of defining and identifying requisite competencies. They should be seen in the framework of tasks implemented within the process rather than by position of the employee in organization hierarchy. Therefore, in dynamic environment of contemporary organizations a Competency-oriented Business Process Analysis [4] can be the right choice. A Business Process Model is a step-by-step description of what one or more participants should do to accomplish a specific business goal. According to Gartner [5] business process analysis tools are primarily intended for use by business end users looking to document, analyze and streamline complex processes, thereby improving productivity, increasing quality, and becoming more agile and effective. Classic business process analysis is oriented on analyzing and optimizing business processes for better productivity by saving time, costs or creating a more desirable product for customers.

Due to the increased need of agility competency-based management is crucial activity of contemporary business organizations. In this situation information technology support is the core element of the processes such as recruiting the most appropriate candidates, effective planning of employee development programs and project management. In many cases the information about competencies are exchanged between collaborating organizations.

The IT tools for supporting process modelling should therefore provide possibility to view the business process from the perspective of competencies required to perform particular tasks. Provision of information describing needed competencies of individuals involved in the process can help not only in workforce planning for the particular process but also in other management tasks such as expert finding, personalization of career paths and staff trainings.

The area of enhancing business process models by competency information requires resolving two basic issues. Unfortunately none of the current business process modeling languages support the characterization of the business process in terms of competencies. Therefore the first issue is to find appropriate notation to include competency data in process models. The second challenge is to design a formal representation that would be enough expressive to provide the detailed view of the process from the competency perspective.

In recent years semantic models in form of ontology are increasingly popular way of formalizing, encoding and integrating knowledge from various sources to support business processes. In the domain of competency management semantic models can provide common definitions that can facilitate information exchange within an enterprise and throughout an industry. Another advantage of semantics is the possibility of automatic reasoning on the basis of semantic model and available information. This feature can be of great value while collecting data on competencies from many different resources such as internet portals with job offers, CVs of job applicants and databases of other organizations. Ultimately semantic models can help HR managers to compare and evaluate employees' knowledge and skills which is useful while developing project staffing plans or employees' professional trainings. The aim of this paper is to show how the ontology describing competencies can be linked with business process models to support process-oriented, dynamic competency management in a company.

There are many frameworks describing competencies or useful to define them, which can be potentially useful in different domains. This frameworks are briefly described in section 2. With this aim in mind the possibility of extending BPMN notation was presented in section 3. Ontological representation was proposed for annotating business process models and employee profiles. Further, a proposal of practical implementation of ontology-enhanced business process model was presented and illustrated by the example of software development (described in section 4).

## II. SEMANTIC MODELS FOR COMPETENCY MANAGEMENT

According to Halper [6] a semantic model is a kind of knowledge model, which consists of a network of concepts and the relationships between those concepts. Concepts are a particular ideas or topics with which the user is concerned. The concepts and relationships together are often known as an ontology - the semantic model that describes knowledge. Competence models are one of the abstract layers of information system. They describe features and behaviors of people in relations to performed professional activities. Semantic models allow for systemizing the area of competency management by unifying concepts, measures and information resources about competencies. Therefore the semantic competence models can be useful in many areas such as knowledge management, planning career

paths, personalizing vocational trainings, project management, periodic evaluation, employees' development.

From the manager's point of view an adequate approximation of employees efficiency is necessary, which can be presented as comprehend view of the knowledge, skills and personality features with regard to already performed or potential tasks. In the context of IT support, the effective competency management requires first of all well-defined meaning and unified understanding of competencies in perspective or business processes, finding balance between a level of detail in competency definition and complexity of management processes and well organized technical background consisting of different systems and services for supporting human resources management, employee training and knowledge management.

Current activities in the area of modelling and standardization of competency management include a number of initiatives oriented on different applications, namely:

- IMS-RDCEO - The Reusable Definition of Competency or Educational Objective (RDCEO) specification provides a means to create common understandings of competencies that appear as part of a learning or career plan, as learning pre-requisites, or as learning outcomes. The information model in this specification can be used to exchange these definitions between learning systems, human resource systems, learning content, competency or skills repositories, and other relevant systems. RDCEO provides unique references to descriptions of competencies or objectives for inclusion in other information models [7].
- HR-XML is a library of XML schemas developed by the HR-XML Consortium, Inc. to support a variety of business processes related to human resources management. The competencies schema which is a part of HR-XML allows for capturing of information about evidence used to substantiate a competency together with ratings and weights that can be used to rank, compare, and evaluate the sufficiency or desirability of a competency [8].
- InLOC [9] provides ways of representing intended learning outcomes, including knowledge, skills and competencies, so that the related information may be communicated between and used by ICT tools and services of all kinds, interoperably.
- O\*NET [10] – is a database of all occupations in the US economy. It provides taxonomy of competencies and their elements and such as knowledge, skills, abilities and many other. The data was collected from companies operating in United States. The O\*NET database can also serve as statistical tool to examine labor market in USA because it contains results of measurement of competency levels.
- E-CF – European e-Competence Framework - provides a reference of 40 competencies as applied at the Information and Communication Technology (ICT) workplace, using a common language for competencies, skills, knowledge and proficiency levels that can be understood across Europe [11].

Codification of competencies is the area predestinated to make use of ontologies. Competencies can be organized in a hierarchical, or a tree-like manner. Each competency can have any number of sub-competencies, which themselves can have sub-competencies. Creating a taxonomy is the first step to codification of organizational competencies. Then the semantic model can be formally defined and presented as ontology.

The ontologies of competencies can be employed in information systems supporting decision taking in domain of human resources, manufacturing and other related domains. Ontologies enhance the capabilities of applications in terms of searching for people with similar competencies regarding domain and level of knowledge and skills.

### III. EXTENDING BPMN

In the business process management area, the Business Process Modeling Notation (BPMN) is the de-facto standard approved by ISO/OSI [12] which allows for multi-view and high-level description of business processes. BPMN provides means to describe collaboration, choreography and conversation aspects of business processes. However it does not offer standard support for the characterization of the business process in terms of many other specific aspects. These aspects are often related to the area in which the process is executed, some formal regulations and standards that the process must comply with.

There are many attempts described in literature aiming at enhancing modelling notations by additional information, which would help to understand better the domain or offer the specific views of the process. For example A. Rodríguez et al. [13] propose an extension for including data quality requirements in process models. P. Bocciarelli and A. D'Ambrogio describe a BPMN extension for modeling nonfunctional properties of business processes [14]. The extension of BPMN facilitating security risk management was proposed by O. Altuhhova et al. [15]. Few works focus on the methodology of extending BPMN by user-defined elements [16], so it can be interpreted as a lack of maturity in this area.

BPMN2.0 offers extensibility mechanism for enhancing standard BPMN notation with user-defined attributes and elements. This extensibility feature allows for addition of new types of artifacts. Modeling tools may include features to hide, or show these Artifacts. However the operations of adding the artifacts, hiding or showing them do not influence the sequence flow of the BPMN model. This is to ensure that BPMN diagrams always have a consistent structure and behavior [17].

The BPMN2.0 extension element consists essentially of four different classes which are [18 p.179]:

- Extension `ExtensionDefinition` defines additional attributes,
- Extension `AttributeDefinition`, presents the list of attributes that can be attached to any BPMN element,
- Extension `AttributeValue` contains attribute value.

The extension element of BPMN imports the definition and attributes with their values do the business process model.

Adding new concepts to the model provides possibility to analyze it in different perspectives. From the point of view of competency management, BPMN models can be enhanced by artefacts representing knowledge and skills necessary to run the process. Such an extension would allow for establishing and populating competence requirements across the organization, its business partners and job candidates. BPMN models with references to the descriptions of the required competencies create yet another perspective for analyzing the process performance regarding human factor. Moreover having a unified model for description of competencies allows for addressing them on the stage of process design and further adjusting the process according to the current abilities of human resources.

In the next section a case study of integrating process model and a semantic model of competencies in form of ontology is presented on the basis of a process of software configuration management.

### IV. INTEGRATING COMPETENCIES INTO PROCESS MODELS

#### *A. Business process model with competency annotations*

This section describes a proposition of solution which integrates process models with competency ontology. The issue is presented on basis of software configuration management (SCM) process. SCM is one of the processes being integral part of software engineering projects carried out by software companies. The process of software configuration management consists of identifying and defining the configuration items, controlling the release and change of these items throughout the system lifecycle, recording and reporting the status of configuration items and change requests, and verifying the completeness and correctness of configuration items. It is a knowledge-intensive process that involves cooperation of many participants such as, managers, analysts, developers, testers and end-users.

The goal the SCM process is to successfully deliver a software product to a customer or market in accordance with customer's requirements and software company's business plan [19]. The decisions taken during this process by project managers are usually taken under the pressure of time and require skills from the areas such as: software design, construction, testing, sustainment, quality, security, safety, measurement and human-computer interaction.

The performance of SCM process is essential for software company because it directly impacts the customer satisfaction. Therefore decisions taken during the SCM process should regard both the customer's needs and the business case perspective. Therefore knowledge of related disciplines is very important as well as cognitive skills and behavioral attributes of the team members. The BPMN diagram of software configuration management process enhanced by competence artifacts is illustrated on fig. 1.

The presented business process model is annotated by the information on needed competencies. The annotations are added as an additional artefacts connected to the process tasks with dotted line. To make the diagram more readable added elements contain symbols (for example: A1, B2, C2) which reference to the Software Competence Ontology - SCO (which is described later in this section). The symbols are displayed in form of hyperlinks so it is possible at any time to look up the detailed descriptions of knowledge and skills needed on each stage of the process.

In an example scenario a project manager wants to find the right people for preparing software and hardware configuration report which is one of the tasks in software configuration management process (fig.1). The presented business process model is annotated by the information on needed competencies. The annotations are added as an additional artefacts connected to the process tasks with dotted line. To make the diagram more readable added elements contain symbols (for example: A1, B2, C2) which reference to the Software Competence Ontology - SCO (which is described later in this section). The symbols are displayed in form of hyperlinks so it is possible at any time to look up the detailed descriptions of knowledge and skills needed on each stage of the process.

In an example scenario a project manager wants to find the right people for preparing software and hardware

configuration report which is one of the tasks in software configuration management process (fig.1).

The manager formulates a query to find persons who have competency denoted in the process model as: B3(S5), which is described in SCO as follows:

- B – area “Build” – consists of competencies needed for building software.

- B3 – Competence no.3: “Constructs and executes systematic test procedures for ICT systems or customer usability requirements to establish compliance with design specifications. Ensures that new or revised components or systems perform to expectation. Ensures meeting of internal, external, national and international standards; including health and safety, usability, performance, reliability or compatibility. Produces documents and reports to evidence certification requirements.”

- S5 – Skill no.5 of reporting and documenting tests and results.

The required level of competence are declared in the ontology using scale 1 – 5, where 5 means the most advanced knowledge and skills. Meanings of particular levels are also explained in ontology. The classes and relations of the Software Competence Ontology are described in more detail in section 4.3.

### B. General framework of the proposed solution

The solution of integrating previously presented process with Software Competence Ontology is aimed first of all to facilitate finding the right person to perform a task in the process. Moreover the Software Competence Ontology can act as “common language” to describe the details of employees’ profiles, annotating the CVs of job seekers, creating job postings and building a database of existing or potential business partners.

A general scheme of the platform supporting competency management is presented on fig.2. The project manager or HR manager while analyzing business process from the perspective of the competencies can formulate a query containing all the needed competencies and receive the list of potential contractors able to perform particular tasks.

The contractor can be an employee, a job seeker or a business partner who has knowledge and skills fully or partially consistent with the defined requirements. If there is no single person among the employees having all the required knowledge and skills for the given task, a team can be formulated consisting of the suggested individuals.

There are many possible data sources to use. The internal resources contain employees’ profiles and CV of job candidates annotated with ontology concepts and references to knowledge and skills elements specified as the instances in the ontology. The external data sources may include information extracted from job hunting websites and databases shared by other organizations. If there are no people with proper competencies among the employees the

database of job candidates or external databases exposed by business partners or job hunting portals can be searched through.

### C. Ontology of competencies

As a reference for formalizing and codifying employees’ competencies the European e-Competence Framework (E e-CF) was used. The choice was governed by many features of the E e-CF, which make it suitable for applying it in software development domain. The E e-CF is not based on job profiles but rather on competencies. This approach is more flexible and suitable for project-oriented companies (which is common in software industry) characterized by dynamic nature of the work environment, where employees are often from different departments and have different job titles. E e-CF provides general and comprehensive specification of e-Competencies described in a multidimensional structure which consists of:

- 5 competence areas - the E e-CF distinguishes between five competence areas derived from the general framework of ICT business process consisting in five phases: (A) plan, (B) build, (C) run, (D) enable, (E) manage,
- 40 competencies,
- 5 proficiency levels, where 1 denotes the weakest knowledge or skills,
- knowledge and skills examples.

All the dimensions can be adapted and customized into different contexts from ICT business. One drawback of the E e-CF is the lack of level specification for detailed knowledge and skills elements. There is only desired level

Fig. 2 General scheme of competency management framework  
Source: Own elaboration

assigned to competencies. For example, the competence “A.1. IS and Business Strategy Alignment” has desired proficiency level 4 or 5 (in the 1-5 scale). Therefore to compare the evidenced skills and knowledge of a person with desired level of competency specified in the ontology it is necessary to make assumptions about the desired levels of knowledge and skills elements.

In the prototype solution described here, the assumption was made that the desired levels of skills and knowledge are inherited from competency class. Therefore if the A1 Competence has desired level 4 or 5, we assume that all the skills and knowledge elements also have the same desired levels (higher than 4).

The classes and relations in Software Competence Ontology are presented on fig. 3.

The proposed definition of classes, properties and relations allows for semantic searching and reasoning. The following example queries can be posed:

- find persons who have evidenced level of competencies at least 3 in the area B (Build),
- find a person who can substitute with manager X in the project Y.

The first example is simple and could be attained by a single query to the database. In the second case, if the requirements for project Y are defined according to the areas and levels specified in the ontology, the aim is to find a person who at least fulfills these requirements (the levels of competencies of the person are equal or higher than requirements). Another approach is to find a person who is most similar to Manager X regarding values of her

competencies. Similarity can be calculated in many ways e.g. applying selected distance measure and computing distance between levels of competence of each pair of the persons.

Because the competency values can be represented as a vector, cosine similarity measure can be used. The cosine similarity for two vectors A and B is calculated as follows:

$$\text{similarity} = \cos(\theta) = \frac{A \cdot B}{\|A\| \cdot \|B\|} = \frac{\sum_{i=1}^n A_i B_i}{\sqrt{\sum_{i=1}^n A_i^2} \sqrt{\sum_{i=1}^n B_i^2}} \quad (1)$$

Where:

A – the vector representing values of competencies of manager X

B – the vector representing values of competencies of other employee

Results of example calculation are presented in Tab.1

The cosine similarity factor in the above example shows that the most appropriate candidate to substitute Manager X is Employee 3.

The ontology of competencies also can be helpful if there is a need to analyze unstructured information such as CVs of candidates or new employees. In such a case semantic similarity measures can be used. The process of measuring semantic similarity is iterative and can be as follows:

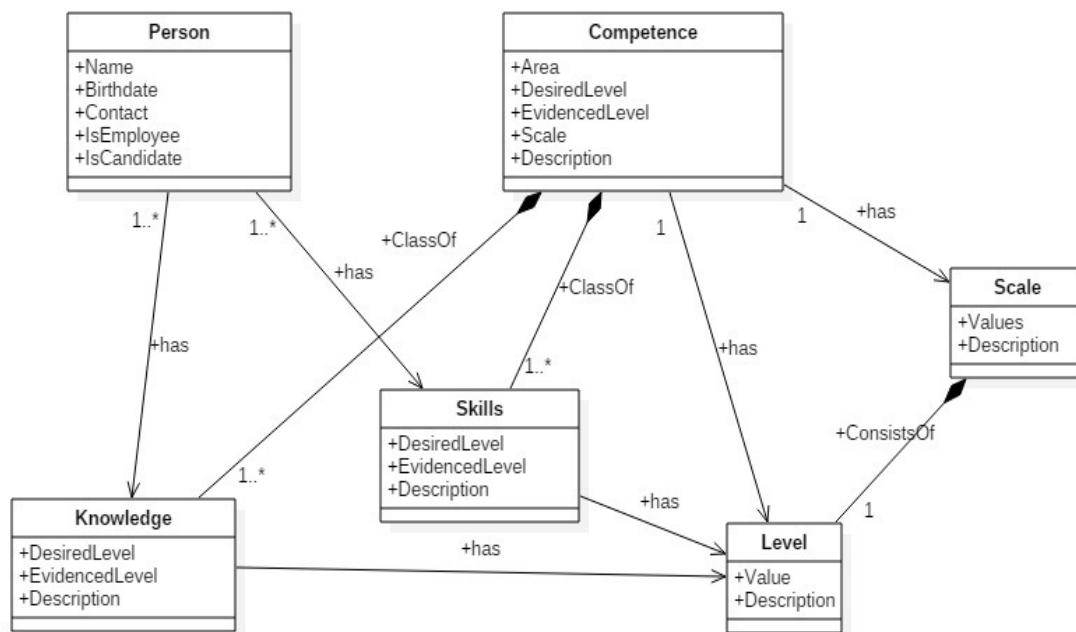

Fig. 3 Classes and relations in IT Competence Ontology  
Source: Own elaboration

TABLE I.  
FINDING SIMILARITIES BETWEEN COMPETENCIES OF MANAGER X AND OTHER EMPLOYEES

Competencies needed in project Y	C.2. Change Support	C.3. Service Delivery	D.9. Personnel Development	D.10. Information and Knowledge Management	E.8. Information Security Management	D.1. Information Security Strategy Development	Cosine similarity
Manager X	4	3	5	5	4	3	-
Employee 1	3	2	5	4	3	2	0,9895725
Employee 2	4	3	2	4	2	2	0,94778789
Employee 3	4	2	5	5	4	3	0,995199

Source: Own elaboration

1. First, the text of the CV is analyzed to find keywords that are present in the descriptions of ontology classes and properties.

2. The thesaurus is used to find similar words in CV to those that are present in ontology.

3. Each time the keyword is found it is noted as one point for the given area and property of ontology.

4. When no more keywords are found the system displays suggestions of the areas and competencies identified for the given person.

5. The user engagement is needed to evaluate the competencies of the candidate in the scale 1-5 in the areas suggested by the system.

Another method is to apply semantic analysis of the terms used in descriptions of the employees' competencies. The

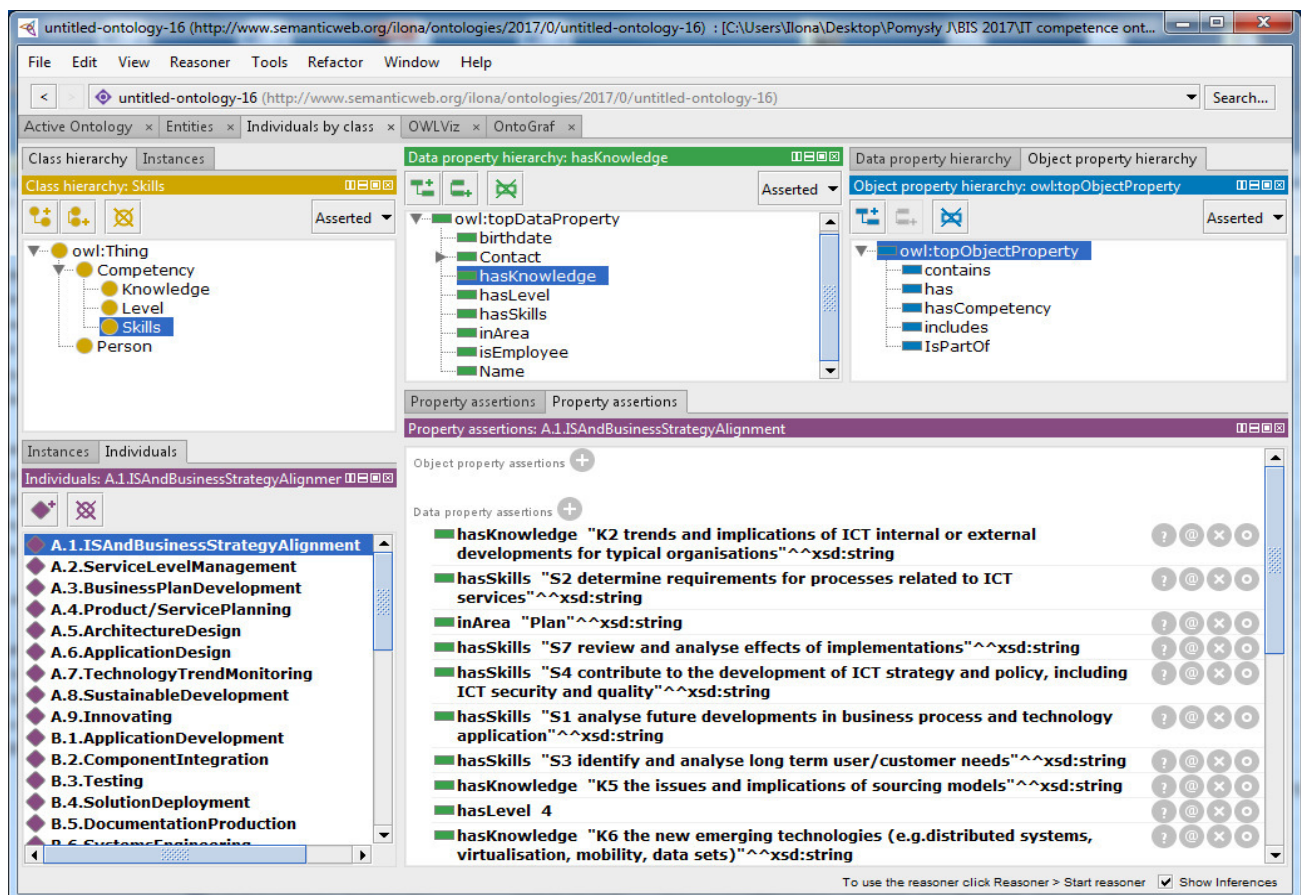

Fig. 4 Software Competence Ontology displayed in Protégé.

Source: Own elaboration

method is based on the use of a lexical database and semantic similarity algorithms. The lexical database WordNet [20] can be used as it is particularly well suited for similarity measures, since it organizes nouns and verbs into hierarchies of is-a relations [21].

The ontology of software competencies for the prototype of the system was coded using Protégé [22] platform (fig. 4). The instances of competencies on the base of E e-CF were imported from MS Excel file using Cellfie plugin of the Protégé platform.

The ontology classes are displayed in a left-top window, object and data properties in the middle and right top window. On the left bottom of the figure there are instances of competencies. The "IS and Business Strategy Alignment" competence is selected. On the right bottom window knowledge and skills elements for the selected competence are visible. Competencies are coded according to the 5 areas specified in the E e-CF framework and denoted with letters (A – Plan, B – Build, C – Run, D – Enable, E – Manage) and numbers.

#### V. CONCLUSIONS AND FUTURE RESEARCH

In this paper the concept of the platform for supporting process-oriented competency management has been proposed and illustrated by the example software configuration management process. The performance of SCM process depends upon proficiency of people involved in the process execution, therefore it is necessary to know the ideal bundle of competencies that the project team should evidence. Having a database of employees and job applicants profiles with specified skills, knowledge and employment history, allows to match the competencies specified in the process model against evidenced levels of proficiency.

The dynamic approach to manage competencies on the base of business process flow can be valuable for process based and virtual organizations where the environment is dynamic and frequent changes are needed to preserve the company's competitiveness and agility, this is often the case of software companies. IT labor market is, constantly changing due to continuous advancements in technology and innovative products. New competencies show up and competencies that are already in existence, change their contents [23].

The Software Competence Ontology was developed in Protégé on the basis of European e-Competence Framework. The proposed Ontology will be further developed, especially by additional dictionaries and domain ontologies with the aim to improve semantic search algorithms. By the use of dictionaries of synonyms it would be possible to enhance semantic search with the possibility of finding similar or the same competencies described with different terms. It is especially useful while dealing with external resources such as job hunters websites or databases of competencies that could be exposed by other business entities.

Competency management, can be seen as one of the most important drivers of business processes performance improvement, therefore there is a growing need for systematic approaches and IT support in this area.

#### ACKNOWLEDGMENT

**Abstract**—An Enterprise Architecture (EA) is used for the design and realization of the business processes, along with user roles, applications, data, and technical infrastructures. Over time, maintaining an EA update may become a complex issue, let alone an organization-wide architecture and its related artifacts. EA practices provide much of the required guidelines for the design and development of EAs. However, they cannot present a comprehensive method or solution for the re-engineering processes of EAs. In this paper, we propose an EA re-engineering model and present its potential contributions. The study is conducted according to the Design Science Research Method. The research contribution is classified as an “application of a new solution (process model) to a known problem (re-engineering EA)”. The future research efforts will focus on the implementation and evaluation of the model in case studies for gathering empirical evidences.

## I. INTRODUCTION

THE volume of Information Technologies (IT) has been growing more than expected and the dependency on IT continues to increase as well. The industry has witnessed the development of information systems, and a great majority of them has been built over the past decades. Today, it is nearly impossible to think of an enterprise without IT and also its applications which are based on various business processes and infrastructure. One instance is an Enterprise Architecture (EA); it is defined as a “coherent whole of principles, methods, and models that are used in the design and realization of an enterprise’s organizational structure, business processes, information systems, and infrastructure [1]”. Being a discipline representing an enterprise in various aspects, it is also a means to facilitate communication between different types of stakeholders in an organization.

There have been various frameworks for EAs, such as TOGAF, Zachman, DoDAF, etc. [2]. While presenting the core concepts, definitions and a basis for EAs, they also provide methods and techniques for the design and development of EAs. Thus, EA models can be used by different stakeholders in an organization to support the decision-making processes. A large organization or an enterprise can consist of different architectural elements, such as processes, applications, and technical infrastructures. For example, Figure 1 represents a small to medium size enterprise with a generic EA model:

**Fig.1.** Enterprise Architecture

Only are the business, application and technical layers, each with simple components, included, and we exclude the layer for users and roles for simplicity purpose. In recent years, changes in various aspects of business and technology have also made some changes to the design, development or maintenance of EAs inevitable. In this context, the ever-changing organizational environment necessitates the architects take required measures to reflect these changes to the EAs.

A great body of knowledge has been accumulated [3] in EA and thus, EA practices can provide much of the required guidelines, methods and techniques for the development or management of EAs. Implementing a change and assessing its impact are the two important activities when improving EAs. Over time, keeping or maintaining a single IT system and component update becomes a complex issue [4], let alone managing a large organizational architecture and its

related IT artifacts. On the other hand, developing an EA from scratch is usually cumbersome and resource-consuming process; in addition, discarding or re-developing encompasses many risks as well. Therefore, poor maintenance of EAs may require the re-engineering of EAs. Re-engineering can be defined as “the examination or alteration of a subject system to reconstitute it in a new form and subsequent implementation of that form [5]”. It improves the understanding of a system and its structure for increased maintainability, reusability, and evolvability. Although re-engineering has potential for contributing to the EA knowledge domain, the review of literature on EA cannot provide sufficient examples and indicates that it is still a less-explored research topic [3].

In this study, therefore, we propose an EA re-engineering process model and present its potential contributions. This model, along with its prescriptions for improving EA re-engineering, can be regarded as the main contributions of our work. The other parts of this paper include the method, proposed model, and conclusion sections respectively.

## II. METHOD

We followed the guidelines of Design Science Research (DSR) for this study [6]. This research method focuses on the creation of scientific knowledge when solving a real-world problem and developing IT artifacts in the Information Systems (IS) domain [7]. The research output is the “application of a new solution (process model) to a known problem (re-engineering EA) [8]”.

problem. Therefore, the acceptance criteria for the evaluation of the proposed model were defined as follows:

- The model was expected to consider and reflect the concerns of stakeholders relevant to EAs during the re-engineering process.
- It should also allow the use and integration of tools, techniques, and experiences that may belong to other knowledge bases, such as software engineering and information systems.

The model was developed during the design-build-evaluate phase, at which the critical research activities were conducted. This was also an iterative and incremental process with the generation of design alternatives [7]. However, the evaluation of the EA re-engineering model was left to the next paper because of research limitations.

## III. RE-ENGINEERING AN ENTERPRISE ARCHITECTURE

### A. Requirement Analysis and Specification

Our proposed process model is given in Figure 2. EA re-engineering starts with determining the current state of the architecture and specifying new structural, behavioral, and quality requirements which reflect the views of all stakeholders. Actually, the requirements management is a continuous process that ensures any changes to the requirements are handled and reflected in other phases. One important point here is scoping the architectural activities according to the re-engineering objectives, stakeholder concerns, availability of people and resources. Moreover,

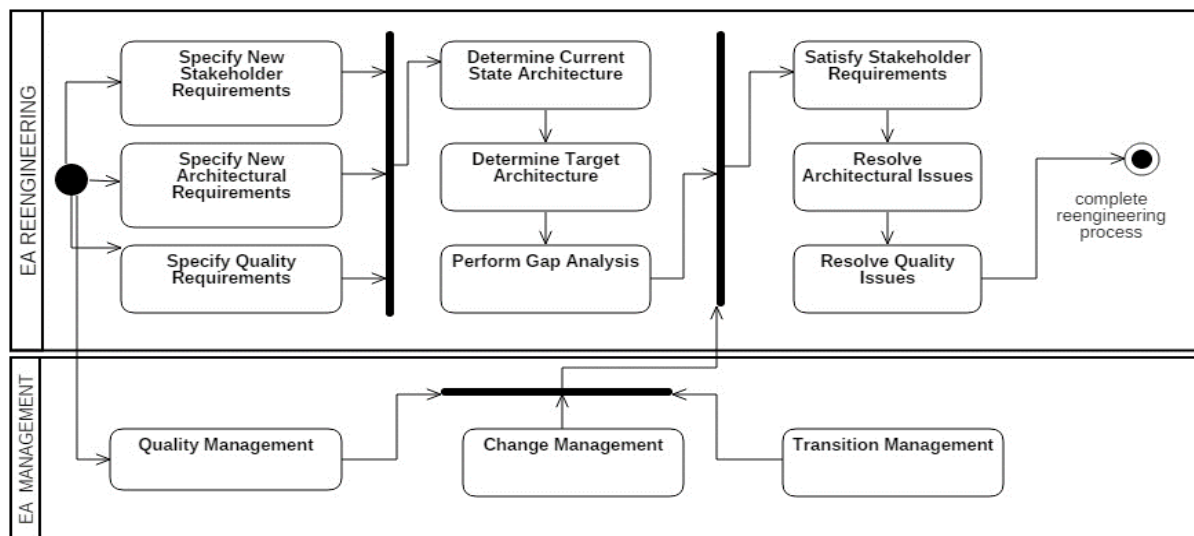

Fig. 2. EA Re-engineering Process Model

The study began with identifying a problem in the EA application environment. This was the need for a model that would guide the EA re-engineering processes. Current EA practices could provide the knowledge for the design, development and evaluation of EAs. However, how to re-engineer EAs is missing in the research. The other important issue was the solution specification for this research

these dimensions should be considered as well: (a) breadth (the part that re-engineering efforts will deal with); (b) depth (the level of detail that the re-engineering efforts will go); (c) time period; and (d) any or all of the architecture domains (business, data, application, technology) [9].

One issue is to know how an organization is capable of conducting the EA design and development processes, as well as the re-engineering. Capability Maturity Models

(CMMs) can address this problem by providing effective and proven methods and practices. It has already been indicated that a successful EA practice needs to establish its capabilities in the management areas, such as financial, performance, service, resource, risk, stakeholder, configuration [9].

Another issue during the re-engineering of an EA is to specify the requirements for the quality of both current and target EAs. Several works propose different types of quality criteria for EAs; however, the literature review cannot provide a comprehensive framework or complete solution [10]. Although it is dedicated to software product quality only, we believe that ISO Quality Requirements and Evaluation (SQuaRE) standard [11] has great potential for providing the benefits of defining, measuring, and evaluating the quality of EAs for both an artifact and a re-engineering process. Therefore, we adopt the SQuaRE framework, which is the approved series of standards for software quality. It has five divisions that cover modeling, managing, specifying, measuring, and evaluation of the quality of various software products. Its main purpose is to guide and assist people who acquire or develop software products with the quality requirements.

SQuaRE considers three areas as vital for assuring quality [12]. The (a) “internal quality” which is the degree to which static attributes of a product satisfy the stated needs. The (b) “external quality” indicates the behavior of how the system satisfies the needs in a testing environment. Finally, (c) the “quality in use” determines whether a product meets the requirements of the specified users in a realistic environment. In this framework, thus, the quality in use depends on the external quality, and the external quality depends on the internal quality respectively. This standard also provides different sets of quality measures, most of which can be used for EAs. Functional suitability, efficiency, compatibility, usability, reliability, maintainability are some of the measures. Therefore, the quality management process of an EA in Figure 2 can be accomplished by the SQuaRE standards. After the requirement analysis and specification, the following main steps are taken during the EA re-engineering process:

#### *B. Determine the Scope, Breadth and Depth of EA:*

In most cases, requirement analysis and specifications will naturally drive the whole process. However, determining the scope and breadth of the re-engineering project is still the first and important challenge. Although a complete EA is expected to address all of the business, data, application, and technology architecture domains [9], a single, all-inclusive, organization-wide architecture may be too complex and resource consuming. In this case, focusing on particular business segments, specific organizational and quality requirements may be suggested. For some cases, creating the EA as a federation of architectures may be another option, although it would bring additional issues, such as consistency, maintenance, and integration. Also, special care should be given to the depth of the EA, which

indicates the appropriate level of detail to be captured during re-engineering. This level can be relevant to the extent that the required details are included while the unnecessary ones are excluded for the sake of usefulness and simplicity.

#### *C. Determine Current State, Reference and Baseline Architectures:*

An EA re-engineering project usually results from the deficiencies of current EA(s) or new enterprise requirements. However, the re-use of appropriate architectures existed in the repository (if exist) may be suggested. Reference architectures and architectural patterns accepted within the organization, or previous architectural work relevant to the project outcomes may be used for the baseline architecture descriptions.

#### *D. Determine Target Architectures:*

The target architecture(s) represents overall and final descriptions of a future state of the EA or its part that is being re-engineered. They demonstrate a response to the project goals and the concerns for the functional and quality requirements of the current EA. To this end, architects can also make use of foundation and common systems architectures [9], as well as the organization-specific architectures or elements that may be re-usable when considering the re-engineering objectives. While a foundation architecture consists of principles and generic components, a common system architecture may be a network or operation architecture, but it is still incomplete in terms of general system functionality [9]. At a more detailed or specific level, industry architectures, which reflect the standards and requirements specific to an industry, can be utilized for the specification of target EA(s).

#### *E. Perform Gap Analysis and Determine Transition Architectures:*

After determining the target architectures, we conduct a gap analysis to identify the differences between the states of current and target EAs. Transition Architectures are evolutionary in nature and converge on the targets while describing the specifics of each increment in line with the architecture descriptions. If the project requires a large scale architectural transformation, it is advisable to address the issues of the EA layers to the extent that the re-engineering objectives are met. For example, much of the focus may be given to an Enterprise Information System Architecture, which is composed of two main domains: data and application architectures [9].

Data architecture domain includes data entities used by business processes, functions, or services, as well as showing how data are created, stored, reported and transported. It is also important to note the level of data complexity, data migration, and data integration requirements needed to support data exchanges between applications. Therefore, architecture definition documents comprise some or all of the business, logical and physical data models along with the diagrams, such as conceptual, logical, security, and migration.

The other domain is Application Architecture that enables business architecture and addresses the stakeholder concerns. While developing this type of architecture, an architect can consider the following: (a) forming a list of applications as a portfolio; (b) decomposing complicated applications into simplified applications; and (c) using different matrices to relate the application architecture to corresponding business and data architectures. How the applications will function and handle the integration, migration, and operational concerns is another issue. For this purpose, TOGAF proposes the use of diagrams, such as application, use-case, realization, and migration, for this process [9].

#### F. Quality Management:

Another important issue is defining the quality attributes of the target EAs. As mentioned before, the SQuaRE standards provide the required guidance for reflecting on the stated and implied quality needs. The focus, therefore, should be on what to measure, how to conduct measurements, and how to evaluate the EA's characteristics influencing its quality. For example, it is possible to use the ISO/IEC 2502n Quality Measurement Standards and their external and quality-in-use measures for the EA elements belonging to Application and Data Layer [13] though it may not be practically possible to include all scenarios and still conduct the quality assurance procedures. Considering the fact that different quality measures are dependent on the EA re-engineering goals, the ISO/IEC 2501n quality models [12] can be tailored. The enterprise resources required for the quality management should also be allocated according to the project objectives.

#### G. Change and Transition Management While Resolving Architectural Issues

We develop an implementation and migration plan, as well as an architecture road map to take into account the gaps between the baseline and target architectures [9]. The migration plan is a mean to move from the baseline and transition architectures to the target architectures. The changes are logically grouped into work packages in transition architectures, and the project team concentrates on how to improve the EA. The proposed solutions usually indicate the construction and specification of the architectures at the corresponding levels of the target EA. While trying to ensure conformance with the target architecture, the other re-engineering activities would be the assessment of dependencies between EA elements, costs and benefits, estimating the time and resource requirements and so on. Consequently, the target architectures are deployed and delivered as a series of EA transitions. This also enables

early realization of the expected business benefits, reflecting on the business priorities, and thus, minimizing the possible risks during the implementation of an EA re-engineering program.

#### IV. CONCLUSION

As the volume of IT and the dependency on IT increases, so does the variety of IT management methods and tools. An EA is an example of having a lot to do with enterprise IT management. It, therefore, has been gaining popularity in the IS research community. The current EA practices may provide much of the required guidelines for the design and development of EAs; however, they are still far away from presenting a comprehensive solution to the problems of EA re-engineering.

In this paper, we proposed an EA re-engineering process model and outlined its main steps and components. Additionally, we adopted a quality management framework, not only for the re-engineering purposes, but also for the whole EA design and development processes. However, the research and space limitations led us to present only the conceptual background. Therefore, our future research efforts will focus on the implementation and evaluation of the proposed model in case studies for gathering empirical evidences.

**Abstract**—Due to high availability of e-commerce websites providing similar services and products, the website usability becomes one of the most critical factors affecting online businesses' success. Therefore, website quality and user experience evaluation is an important research task. There are multiple methodologies for performing the evaluation. The proposed in our earlier studies PEQUAL methodology extends the classical eQual method by taking into account different aspects of preference modeling and aggregation derived from Multi-Criteria Decision Analysis (MCDA). This paper extends the PEQUAL methodology further by incorporating eye tracking based measurement and analysis into the criteria set. The results of the conducted empirical verification of proposed approach are presented.

## I. INTRODUCTION

**I**N JANUARY 2017 out of the total world population of 7.5 billion people, 50% were Internet users and 66% used mobile devices [1]. A growth of 482 million users, i.e. 21%, was observed among active social media users since January 2016. According to January 2016 data [2], 79% of UK population searched online for a product or service to buy at least once within a 30-days period and 77% made a purchase. In 2015, the total value of online sales in Europe was 455 billion euro [3], compared to 131.61 billion euro in 2013 and 156.28 billion euro in 2014.

The competition in e-commerce is high. In June 2016 there were 12 million stores online, however only 650 thousands of them (5.4%) sold more than \$1,000 per year [4]. With such hot competition, entrepreneurs try to increase their chances by marketing and using analytic tools [5], refactoring the usability of the website and its assessment [6], providing web content accessibility [7] or ascertaining credibility of the website [8]. The credibility is the perception of being trustworthy and believable and it can be built, among other things, by providing great user experience and high levels of usability and quality [8].

With such a tough competition, it is beneficial to evaluate the websites' quality, usability and user experience [9]. There

are multiple website and e-commerce evaluation methods, including eQual[10], SiteQual [11], E-S-QUAL [12] to name just a few. The methods differ in the range of possible applications, assessment scale used, their theoretical basis, verification of solution or minimum number of evaluators.

Since the websites quality evaluation is a multi-criteria problem, the Multi-Criteria Decision Analysis (MCDA) methods can be used to approach it, such as TOPSIS [13] or PROMETHEE [14] in their classic or fuzzy variants [15] [16]. Also a hybrid approach is possible that combines the classic methods with MCDA methods, such as PEQUAL [17].

The aforementioned methods are commonly based on survey data, which causes some problems. The number of questions needs to be limited so the survey is manageable for the respondents. Also real users from the target group should be involved in response collecting process [10]. On the other hand, a growing popularity of research tools based on eye tracking can be observed. Originally they were used mainly in medicine, however, currently we can also find studies on user experience [18], website quality [19] and usability evaluation [20] founded on the data collected with these tools [21].

While numerous studies based on eye tracking and survey website evaluation can be found, the lack of integrated eye tracking and MCDA approach is observed. Therefore, the combination of the eye tracking tools' results and the MCDA methods foundations constitute an interesting research gap, which this paper is addressing. The main objective of this paper is to extend the PEQUAL website quality evaluation model of the world most popular e-commerce websites by combining the EQUAL criteria survey data with the perceptual measurements criteria. An eye-tracking device has been used to collect selected metrics and they have been included into the PEQUAL method.

The paper is split into sections. Section II contains literature review. The methodological framework of the proposed approach is presented in section III. Section IV contains

empirical study results. The conclusions and future directions are outlined in section V.

## II. LITERATURE REVIEW

### A. Website Quality, Usability and User Experience

It has been noted in [32] and [33] that the focus time span of the average human is eight seconds. Therefore, the websites' designers must create the websites in a manner that the user will be able to find all sought data easily within this time. In other terms, the website needs to be characterized by high levels of quality, usability and user experience.

As noted in [34], the quality and usability are terms related to each other. The ISO 9241-11:1998 standard [35] defines usability as the "extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use", and the ISO 25010:2011 standard [36] defines it as "the ability of software to be in intelligible, easy to learn and use as well as attractive to the user in specified circumstances".

The authors of [9] point out that it is beneficial to evaluate the quality, usability and user experience of a website. It is especially important, considered the systems' usability changes over time, depending among other things on the user preferences or software and hardware evolution [34].

The authors of [37] grouped the usability evaluation methods into five groups: user testing, inspection methods, inquiry methods, analytical modeling and simulation methods. The website quality evaluation methods, on the other hand, can be split into three groups [38]: expert evaluation, user traces analysis, interviews and surveys.

### B. Classic Website Evaluation Methods

The methods employed in websites evaluation differ in the type, quantity and structure of criteria used. However, they often follow the same procedure, where initially the users' thoughts are obtained by surveys or questionnaires, and later the responses are put on a Likert scale. The actual degree of the scale depends on the method.

The Ahn method utilizes the Technology Acceptance Model (TAM) provided by Davis [39]. It can be used for evaluation of e-banking and e-commerce. It utilizes 54 criteria with assessment scale of 1-7. Consistency reliability of the questionnaires is performed [40]. The SiteQual method [41] is based on the set of 28 criteria, each assessed in the scale of 1-9. It utilizes the SERVQUAL service quality instrument [42] and information quality criteria to allow B2C websites quality evaluation [11]. The E-S-QUAL [12] and E-RecS-Qual methods evolved from the SERVQUAL technique and can be utilized for the evaluation of e-banking and e-commerce. They are based on two sets of 22 and 11 criteria assessed in the scale of 1-5 [43]. The Website Attribute Evaluation System (WAES) method [44] is intended for surveying office and organization sites. It is an expert evaluation method of examining the website quality. The Website Evaluation Questionnaire (WEQ) [45] is a research-tool developed for informational websites evaluation. It uses 18 criteria and additional 8 negative criteria

for verification. Web Portal Site Quality (WPSQ) method [46] provides means to evaluate information portals, and the obtained solution is then verified by a set of complex reliability tests. The Website Quality Model (WQM) method [47] uses the Kano quality model, in which there are three levels of clients' desires: essential, execution and energizing.

Last, but not least, one of the most popular websites evaluation methods is the eQual method [10]. It has been successfully used for the evaluation of e-commerce, e-government, university websites and WAP websites. It uses 22 criteria divided into Usability, Information Quality and Service Interaction quality groups. The Usability group is further divided into Usability and Design subcategories, and the Service Interaction quality group is further divided into Trust and Empathy subcategories.

### C. Eye Tracking Devices in Website Evaluation

As it was pointed out, the original area of the eye tracking (ET) usage has been significantly expanded with new research areas. The usability testing and user experience (UX) is one of the current, dynamically developing environments. UX is a concept related to usability and it is defined as "a momentary, primarily evaluative feeling (good-bad) while interacting with a product or service" [48]. Literature review provides a broad overview of the use of ET in these fields. In categorizing this area, two groups of the eye tracking applications can be identified in the usability research:

- ET based usability studies,
- ET + surveys based approaches.

The fundamental difference between these groups is that group II includes usability evaluation surveys either before or after the ET study, and in the case of group I, the usability assessment is based only on measurable factors, such as AOI [18], TFF, FBT [22], visits and revisits [19] or the time required to complete a given task [31]. The cited works describe the indicated measures in detail.

When analyzing the first group (see Table I), it can be observed that in many works, even the ET perceptual measurements alone are indicated as an effective tool of website evaluation. It is worth pointing out that the practical areas of the research cover various practical areas of commercial websites, such as e-commerce [18], social commerce [23], online booking [30] or tourism [24]. The principal limitation of these studies is, however, a relatively narrow focus of each of them on the selected measurement aspects, e.g. in [23] the impact of the price level, position and the presentation of the product by a famous person on the fixation time on the website and on the price is analyzed, while in [22] location typicality and efficiency in finding target web objects on the homepages was analyzed.

In the case of the second group, ET + surveys based approaches (see Table II), the vast majority of the analyzed works is oriented towards a wider usability or UX of the analyzed web pages. Thus, the introduction of the survey data into the final assessment extends the scope of the evaluation process.

TABLE I  
EYE TRACKING USAGE IN WEBSITES EVALUATION

Ref.	Application	Users	Aim of the research	Data analysis methods and results	Criteria
[18]	e-commerce websites	21	Study how the site interface affects the end user recommendation process.	Comparison of fixation times for selected AOIs for different structures and fixation times on products. ANOVA analysis was used. The total number of users who selected any product was compared to how many users selected the product in each interface, and from which AOI the highest number of products was selected.	3 number of users who chose a product, average number of products, percentage of products chosen in each AOI
[22]	online shops, online newspapers, company webpages	40	To examine the relation between location typicality and efficiency in finding target web objects on the homepages	Analysis of location typicality, time to first fixation (TFF) and fixations before target (FBT) using Wilcoxon signed-rank tests	2 TFF, FBT
[23]	social commerce	34	Analysis of the impact of the price level and position, and the presentation of the product by a famous person to the fixation time on the website and on the price.	Statistical tests for the time of fixations on the page and price, and gender comparison.	2 fixation time on the page, fixation time on the price
[20]	mobile phone manufacturers' websites	17	Website usability analysis.	ANOVA statistical analysis with the exception of response time that was tested with Chi2	5 fixation times, count, response time, time of task completion, spatial density of fixations
[24]	eTourism 2.0	60	Hypotheses analysis what kind of advertising is more effective.	Statistical analysis, t test. Three separate covariance analyses (ANCOVAs) were computed, with gender, expert level and type of advertisement as independent variables and age as metric covariate.	3 time to first fixation, fixation duration, fixations before time to first
[25]	e-commerce	42	Examination how the website's complexity affects the user's attention and behavior, considering different cognitive loads.	ANOVA analysis was used to measure website complexity.	3 fixation, fixation duration, total time
[26]	clinical guidelines on the Web	14	Study of the usefulness of the sites containing medical guidelines for doctors.	Comparison of the task success evaluation to the user experience. Overall performance of the websites was calculated with the geometric mean of the task execution time.	4

Additionally, it should be noted that the surveys evaluations in the second group are often based on the methodological patterns from the AHN or eQual group of methods (see subsection II-B). These works have, contrarily to the ones from the first group, a broad domain scope and include the assessment of usability in the e-commerce [27], online banking [28], e-government [29] or online booking systems [30].

When analyzing the methodological aspects of the works contained in Table I and II, one should note the dominant role of the research with strong sociological rigor (oriented on the verification of the selected statistical hypotheses), and as a consequence, their methodological side is based on the statistical analysis elements, such as statistical tests or ANOVA analyzes. However, the statistical analysis techniques (correlation [27], covariance of variables [24] or ANOVA [25]) remain the basic research tool. Also in the case of the second group, the sociological cognitive tone of research remains dominant.

#### D. MCDA Website Evaluation Methods

Apart from the evaluation methods mentioned above, during the literature review, endeavors at utilizing the MCDA tech-

niques for websites' assessment can be found. The MCDA approach is justified, since the evaluation of websites is a multi-criteria problem, in which multiple dimensions and measurements need to be considered [49]. For example, Chmielarz broadly utilizes scoring method to assess an extensive variety of business oriented websites [50], [51], [52]. Lee and Kozar applied the AHP method to evaluate e-tourist and e-commerce websites [53]. Sun and Lin used the fuzzy TOPSIS method to evaluate e-commerce websites [15]. Del Vasto-Terrientes et al. used the ELECTRE-III-H method on traveler websites [54]. Furthermore, hybrids of different MCDA techniques can be used [16], [55], [56].

The literature review demonstrates that the majority of the MCDA use surveys to collect data for the evaluations. The weights of the criteria are commonly compared pairwise and AHP technique is used. While most of the methods use a predetermined set of criteria, some papers used theoretical bases identifying the need for presenting both specific quality measures and criteria [54], [55].

The application of the MCDA methods to the websites' evaluation problems has a greater potential than just constructing a ranking. This can be illustrated by a model of a decision

TABLE II  
EYE TRACKING COMBINED WITH SURVEYS USAGE IN WEBSITES EVALUATION

Ref.	Application	Users	Aim of the research	Data analysis methods and results	Criteria
[27]	e-commerce, B2B	25	Study of the difference in perception of B2B sites by different cultural groups.	Calculation of the correlation, to what extent each of the 7 criteria affect the attractiveness of the pages and comparison of two cultural groups.	7
[28]	online banking	10	Usability study of the electronic banking login interface.	The results consisted of comparison of the numerical data (criteria) obtained during the study and heat maps and AOI trajectory maps. Data obtained during the interview was analyzed.	3 time to first fixation, fixation duration, total time
[19]	e-commerce	38	Study of the impact of the presence of a human brand element on the quality of online shopping decisions	ANOVA statistical analysis.	4 viewers, first view, watched time, revisits
[9]	websites of mobile service providers (telecoms)	44	Comparative evaluation of user experience (UX) and usability.	Basic statistics. Comparison of the obtained results of each criterion for each page (min, max mean, median). For each value: job completion time, time and count of fixations since first click, time to find the target, number of pages viewed during task execution.	3
[29]	e-government websites	9	Study of usefulness of e-government websites.	Basic statistics of the experiment and comparison of the results from the eye tracker with the results from the survey after the experiment.	3 task completion time, fixation duration, fixations count
[30]	online hotel booking websites	16 valid	The purpose of the study was to analyze the impact of images and the size of selection sets on the decision-making process of hotel reservations online.	Based on the data collected in a combined (eye tracking and surveys) experiment, hypotheses were statistically confirmed by comparing the time and number of fixations.	3 task completion time, fixation duration, fixations count
[31]	e-commerce, Amazon	30	The purpose of this study was to examine the credibility of the seller and to find the factors that influence the choice of payment methods for online purchases.	Confirmation or denial of hypotheses using statistics on the choice of payment method, with each criterion. Data analysis methods: - ANOVA for price and sales criteria in the choice of payment method. - Fixation times in AOI (price, sales) in different product types. - Logistic regression to identify factors influencing the choice of payment method.	2 task completion time, fixation duration

process defined by Guitouni [57], where exploitation and recommendation stages are important steps. On the operation stage, the analysis of the obtained solution can be performed, such as its stability examination [58], [59] or the analysis of the decision-makers' preference.

As demonstrated in [17] and [43], MCDA is an effective multi-aspect data analysis tool. However, in order to use the MCDA methodology properly, the decision support / evaluation model needs to be supplied with the complete domain data set [60], [61], [57]. The aforementioned MCDA requirements, along with the advantages of ET and ET + surveys approaches, motivate the authors' contribution to modify the approach presented in [17] and [43] and to introduce to the evaluation model the ET-based data.

### III. METHODOLOGICAL FRAMEWORK

#### A. PEQUAL Methodological Foundations

The website evaluation procedure presented in this paper is based on the PEQUAL methodology of website quality assessment [17]. The methodology depends on the eQual and PROMETHEE II methods. The eQual method has its foundations in Quality Function Deployment. The PROMETHEE II method is a popular MCDA method that employs pairwise comparison and outranking flows to produce a ranking of best decision variants [43].

Initially, pairwise comparison of the alternatives on particular criterion is considered. The preference of one alternative over another on a criterion  $j$  can be expressed with the usage of a preference function  $P_j(a, b)$ , where  $a$  and  $b$  belong to the  $A$  set of alternatives. For each  $a$  and  $b$ :

$$0 \leq P_j(a, b) \leq 1 \quad (1)$$

Promethee methods offer six preference functions: usual criterion, U-shape criterion, V-shape criterion, level criterion, v-shape with indifference criterion, Gaussian criterion [14]. Next, aggregated preference index of alternatives is calculated with formula (2).

$$\begin{cases} \pi(a, b) = \sum_{j=1}^k P_j(a, b)w_j \\ \pi(b, a) = \sum_{j=1}^k P_j(b, a)w_j \end{cases} \quad (2)$$

where  $w_j$  is the weight assigned to the  $j$ -th criterion.  $\pi(a, b) \sim 0$  implies a weak and  $\pi(a, b) \sim 1$  implies a strong global preference of  $a$  over  $b$ .

$P_j(a, b)$ ,  $P_j(b, a)$ ,  $\pi(a, b)$  and  $\pi(b, a)$  are real numbers without units, completely independent of the scales of the criteria.

Subsequently, the obtained indices are used to calculate positive and negative outranking flows with formulae (3) and (4) [14]:

$$\phi^+(a) = \frac{1}{n-1} \sum_{x \in A} \pi(a, x) \quad (3)$$

$$\phi^-(a) = \frac{1}{n-1} \sum_{x \in A} \pi(x, a) \quad (4)$$

The  $\phi^+(a)$  value represents how an alternative  $a$  is outranking other alternatives, whereas the  $\phi^-(a)$  value shows how the alternative is outranked by the others.

Eventually, the net outranking flow is calculated as a difference between the positive and negative outranking flows:

$$\phi(a) = \phi^+(a) - \phi^-(a) \quad (5)$$

In the Promethee I method, two rankings are produced, based separately on the  $\phi^+(a)$  and  $\phi^-(a)$  values. In the Promethee II method, a single ranking is created, based exclusively on the  $\phi(a)$  value.

### B. Modified PEQUAL Framework Gaze Data Analysis

To perform the empirical research, at first, the survey results from [17] were combined with the data from a perceptual evaluation study. The original PEQUAL result set contained data collected from surveys from 41 users, who were experienced in online shopping.

The experiment result set was obtained from a group of 20 students, using an eye tracking device and GazePoint software. The same set of 10 websites as in [17] was studied: Alibaba, Amazon, Apple, BestBuy, eBay, Macy's, Rakuten, Staples, Target and Walmart. Three slides were prepared for each of the websites:

- home page – the front page of each website, containing, among other things, a product search form and a list of categories;
- product page – the main page of a single product in offer, containing a description, images and price;
- payment page – one of the last steps of the purchase transaction, the page containing the payment method choice.

Each slide from the total set of 30 slides was displayed to the participants for a period of 10 seconds, with a 3 seconds pause between slides. An area of interest (AOI) was configured on each of the slides. On the ones presenting home pages, the participants were given the task to locate a piece of electronic - either smartphone or a watch. On the product page slides, the students were supposed to locate the price. Finally, on the payment page slides, they were asked to locate the "PayPal" payment method.

During the experiment, the software collected the following data:

- E1 – viewers – number of people who have visited the configured areas of interest (AOI);
- E2 – first view [s] – time elapsed in seconds before the area was noticed for the first time;
- E3 – watched time [s] – time spent on a given AOI, expressed in seconds;

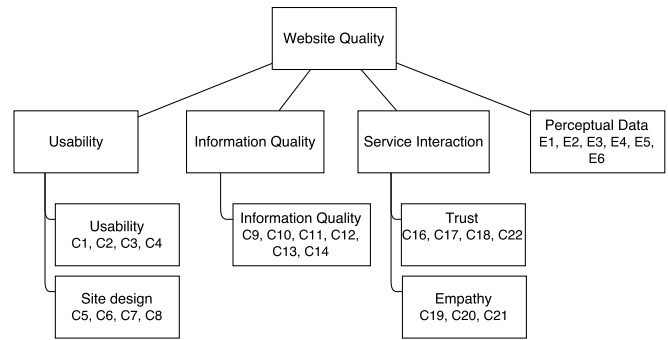

Fig. 1. Combined criteria hierarchy

- E4 – watched time [%] – time spent on a given AOI, expressed in percent;
- E5 – revisitors – the number of participants who returned to the AOI;
- E6 – revisits – number of revisits to the AOI.

Eventually, the obtained criteria E1-E6 were combined with the PEQUAL criteria C1-C22. The resulting criteria hierarchy is presented on Figure 1.

The results of the questionnaires from [17] and the empirical data from the experiment were used to build a performance table. Three scenarios were taken into consideration for the perceptual data. In the first scenario, the data regarding the home pages of the websites was used. In the second one, the data from the product pages was utilized. Finally, in the third scenario, the data from the payment pages was used.

The data in each of the scenarios was later aggregated using the Promethee II method and rankings were generated. In the next step, a broad graphical analysis of the received rankings was carried out with the usage of GAIA plane. In the third step, Promethee II and GAIA analysis was performed on the survey data combined with the averaged perceptual data. In the fourth step, sensitivity analysis was performed and stability of the obtained ranking was verified. In the next step, uncertainty analysis was performed. Finally, a comparison of the obtained ranking to a ranking based on the Gaussian preference function was performed. The results were compared to the ones received in the original PEQUAL method [17] on each step of the procedure. The presented approach is depicted in Figure 2.

## IV. RESULTS

### A. Promethee II Based Analysis

In the first step of the research, the averaged values from [17] were used along with the perceptual data to build a performance table for the Promethee II method. For the C1-C22 criteria, the V-shape preference function was used, with the indifference threshold  $q=0$  and the preference threshold  $p=7$  (maximum value in the 7-degree Likert scale used in the study), to ascertain comparability of the results received.

For the E1-E6 criteria, the V-shape preference function with indifference threshold  $q=0$  was used as well, however, since

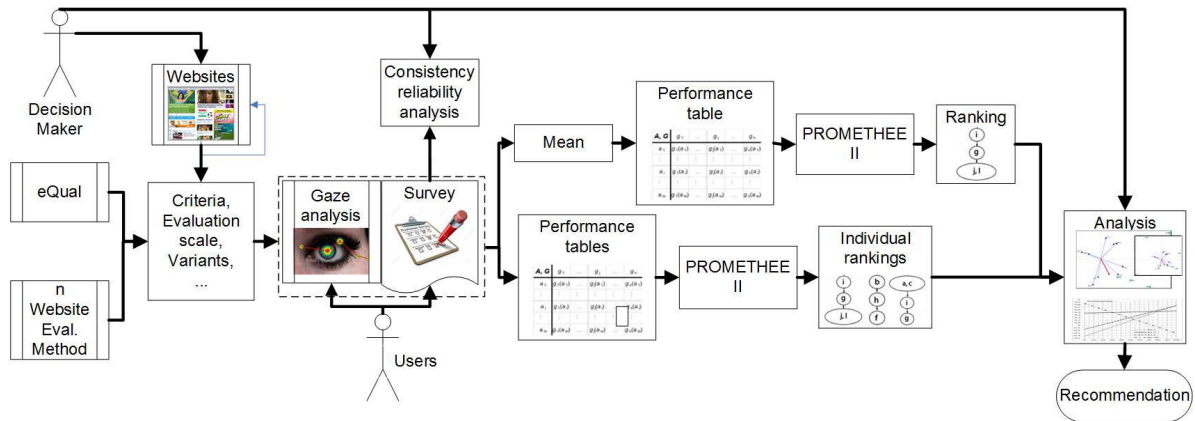

Fig. 2. Website evaluation process using PEQUAL methodology combined with perceptual evaluation criteria.

the perceptual data received is expressed in various units and scales, the preference threshold  $p$  was set for the criteria E1, E3, E4 and E5 to the maximum possible value, for the criterion E2 it was set to 5 seconds (a half of the slide display time), and for the criterion E6 it was set to 10 revisits. The preference direction for all criteria but E2 was maximized.

The weights were assigned to the criteria in a manner that the C1-C22 set of eQual survey based criteria total weight was 50% and the E1-E6 set of gaze based criteria total weight was 50%. The weights within the C1-C22 criteria set and within the E1-E6 criteria set were distributed equally, 2.27% for each C criterion and 8.34% for each E criterion. The weights distribution is presented in Table III.

For the reasons of brevity, the performance tables for scenarios 1-3 were merged into a single table. The Promethee II method was applied on each of the scenarios and the resulting rankings are presented in Table IV. The results originally obtained in [17] are presented for reference in Table V.

It can be observed that the introduction of perceptual measurements data into the analysis modified the ranking of the websites. However, the three best websites from [17] analysis, i.e. Apple, Amazon, eBay, are still in the group of the first five best websites in the combined criteria rankings. Surprisingly, the Alibaba website has dropped significantly in the new rankings, from the fourth rank to the last four ranks in the new rankings. It is visible, that the ranking varies depending on the page studied in the perceptual research. The differences might be caused by the fact that in the original study, the surveys collected opinions about the website in general. The perceptual evaluation, on the other hand, was performed on three specific pages of the website. This information can be used to find areas requiring improvement in the websites analyzed. For example, when product or payment pages are considered, Amazon receives the first rank. However, in the scenario where the users were asked to locate a piece of electronic on the home page, Amazon ranks much worse, with 5th position in the ranking. This might mean that the layout of the home page of this website does not expose electronic devices enough.

TABLE III  
WEIGHTS ASSIGNED TO CRITERIA, GROUPS AND CLUSTERS.

Cluster of criteria	Group of criteria	Criterion	Weight
Usability 18.2%	Usability 9.1%	C1	2.27%
		C2	2.27%
		C3	2.27%
		C4	2.27%
	Site design 9.1%	C5	2.27%
		C6	2.27%
		C7	2.27%
		C8	2.27%
Information quality 15.9%	Information quality 15.9%	C9	2.27%
		C10	2.27%
		C11	2.27%
		C12	2.27%
		C13	2.27%
		C14	2.27%
		C15	2.27%
Service Interaction 15.9%	Trust 9.1%	C16	2.27%
		C17	2.27%
		C18	2.27%
		C22	2.27%
	Empathy 6.8%	C19	2.27%
		C20	2.27%
Perceptual 50%	Perceptual 50%	C21	2.27%
		E1	8.34%
		E2	8.34%
		E3	8.34%
		E4	8.34%
		E5	8.34%
		E6	8.34%

### B. Graphical Analysis of Promethee II Solution

The results obtained by the Promethee II method were additionally analyzed using the GAIA planes. Figures 3a-i depict the scores of this analysis separately for individual criteria, groups and clusters for each of the three analyzed criteria.

TABLE IV  
RANKING OF WEBSITES BASED ON PROMETHEE II AND A) HOME PAGES, B) PRODUCT PAGES, C) PAYMENT PAGES, D) AVERAGE PERCEPTUAL EVALUATION DATA (V-SHAPE PREFERENCE FUNCTION)

	Website	Alibaba	Amazon	Apple	BestBuy	eBay	Macy's	Rakuten	Staples	Target	Walmart
a	$\phi$	-0.0899	0.0266	0.0547	0.0805	0.055	-0.063	-0.0324	-0.0157	0.0369	-0.0528
	Rank	10	5	3	1	2	9	7	6	4	8
b	$\phi$	-0.0369	0.0565	0.032	0.0032	0.0371	0.0123	-0.0205	0.0094	-0.0331	-0.06
	Rank	9	1	3	6	2	4	7	5	8	10
c	$\phi$	-0.0364	0.1136	0.0782	-0.016	0.0708	-0.0616	-0.095	0.0739	-0.1042	-0.0232
	Rank	7	1	2	5	4	8	9	3	10	6

	Rank	10	1	2	4	3	7	9	5	6	8

TABLE V  
RANKING OF WEBSITES BASED ON PROMETHEE II AND AVERAGE CRITERIA EVALUATIONS AS IN [17]

Website	Apple	Amazon	eBay	Alibaba	Walmart	Macy's	BestBuy	Staples	Rakuten	Target
$\phi$	0.1037	0.0822	0.0629	-0.0137	-0.0191	-0.0272	-0.0343	-0.0380	-0.0559	-0.0607
Rank	1	2	3	4	5	6	7	8	9	10

The analysis of Figure 3a shows that the criteria support the five leading variants from ranking in Table IVa, i.e. BestBuy, eBay, Apple, Target and Amazon, in varying degrees. BestBuy, eBay and Target are supported by the perceptual criteria, while Amazon and Apple are supported by the survey criteria. The criteria E1, E5 and E2 have the highest impact on the final ranking. No conflicts are observed between the perceptual criteria, however, they are in strong conflict with the criterion C11, which means that the websites which are highly evaluated with regard to this criterion receive lower evaluation in perceptual study. Because of the length of the C11 criterion vector, the E3, E4 and E6 criteria would be affected mostly. The interpretation of this fact can be that the websites providing timely information, at the same time introduce some distraction which reduces the length of watching and the number of revisits in the AOI.

The analysis of Figure 3d demonstrates that most of the criteria, survey and perceptual alike, support the three leading websites from ranking in Table IVb. It can be observed, that the vectors of the criteria E5 and E6, as well as of the criteria E3 and E4, are pointing in very similar directions. This means that receiving higher score in E5 criterion resulted in getting higher score in E6 criterion, and similarly scoring higher in E3 resulted in better result in E4. The C5 criterion (attractive appearance of the website) is pointing in similar direction as the E1 criterion, which might mean that when the website look was more appealing, the attention of more users was attracted to the AOI. However, the rest of the perceptual criteria are in conflict with the criterion C5, which could mean, that the attractive appearance of the website resulted in smaller number of revisits, shorter watch time, as well as longer time to notice the AOI.

When analyzing the Figure 3g, one can find out that almost all criteria support the four leading websites from the ranking in Table IVc. It is confirmed by the  $\phi$  net outranking flow

values. The four leading websites have positive  $\phi$  values, whereas the remaining six websites have negative  $\phi$  values, which means the latter are more outranked by all the criteria.

Subsequently, an analysis of GAIA planes with groups (Figures 3b, 3e, 3h) and clusters (Figures 3c, 3f, 3i) of criteria was performed. All the six figures demonstrate that the perceptual criteria are represented on the GAIA planes by axes more-or-less orthogonal to the Service Interaction and Usability survey criteria clusters, which means that these criteria clusters are not related to each others in terms of preferences.

Figures 3b, 3c, 3e, 3f show that the Information Quality axis is less orthogonal to the Perceptual axis than the rest of the groups and clusters on the home pages and the product pages, which means that these clusters are expressing slightly similar preferences. However, figures 3h and 3i show that on the payment pages the Information Quality axis is orthogonal to the Perceptual axis, meaning they are unrelated to each other in terms of preferences. On the payment pages it is the Service Interaction cluster, and, more precisely, the Trust group, that expresses the greatest preferences' similarity to the Perceptual cluster.

### C. Promethee II and GAIA Analysis Based on Averaged Perceptual Data

In the next step, the perceptual data from the 3 scenarios was averaged and only then was it combined with the survey data. Subsequently, Promethee II analysis was performed on the received data set. The ranking produced by this analysis is presented in Table IVd. It differs from the rankings calculated with the data from the separate home, product and payment page perceptual evaluations, however Amazon, Apple and eBay websites remain the leaders. It is worth noting, that in the ranking based on the averaged perceptual data, these three websites receive positions most similar to the ranks received in the original PEQUAL ranking (Table V).

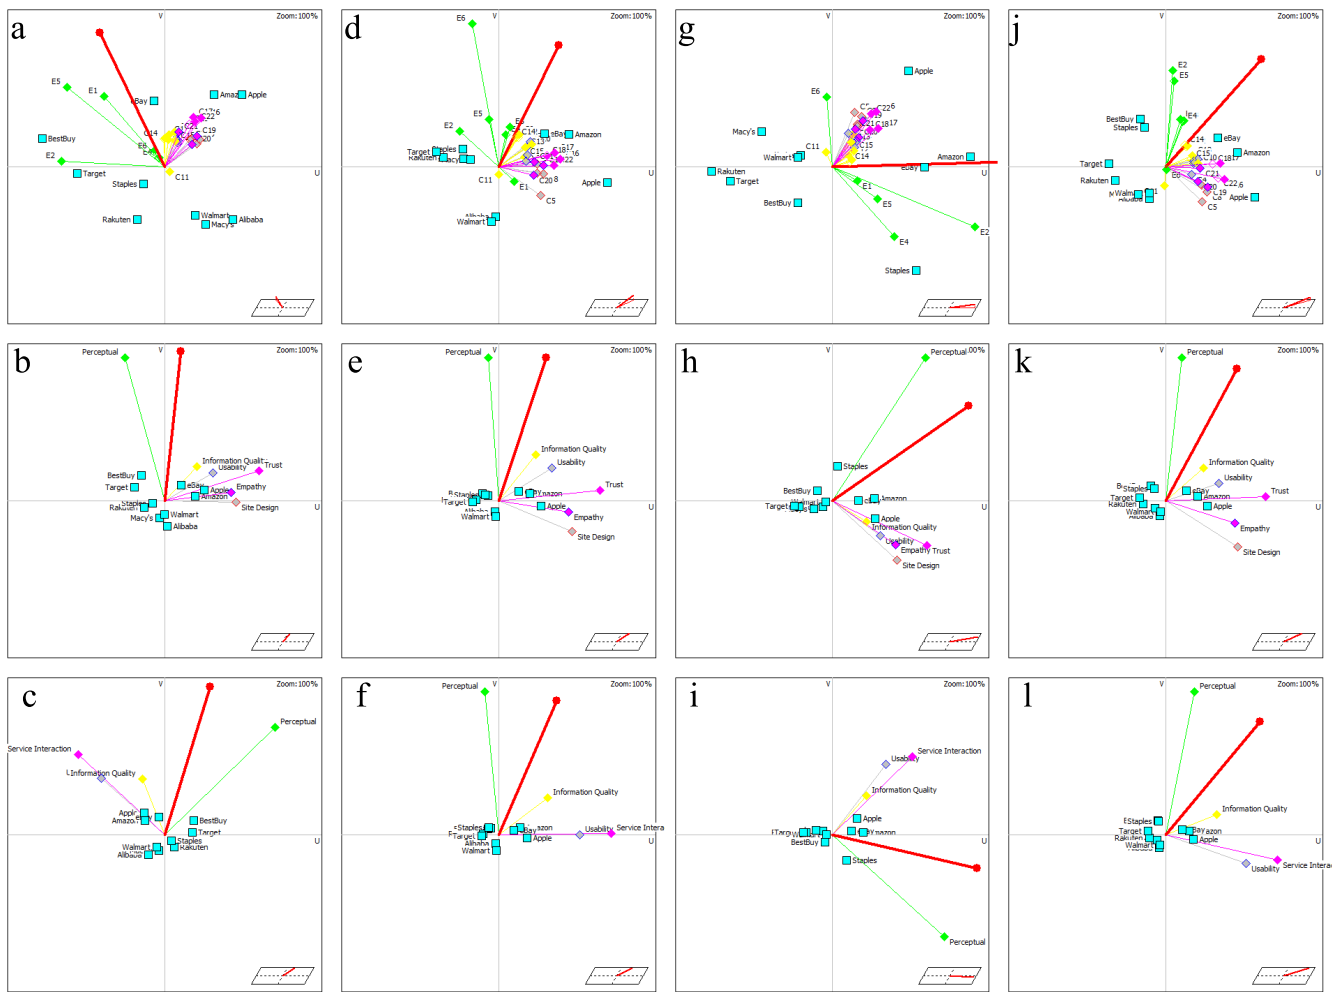

Fig. 3. GAIA analysis for home page scenario: a) criteria, b) groups, c) clusters; product page scenario d) criteria, e) groups, f) clusters; payment page scenario: g) criteria, h) groups, i) clusters; averaged data scenario: j) criteria, k) groups, l) clusters;

GAIA planes analysis was also performed for the new combined data set. Figures 3j-l depict the GAIA planes criteria, groups and criteria respectively. Figure 3j shows that the three leading websites are supported in various degrees by almost all criteria, both perceptual and survey. The websites with rank 4 and 5, i.e. BestBuy and Staples, are supported by the perceptual criteria, which explains why they advanced from ranks 7 and 8 in the ranking based on the survey data exclusively.

The analysis of the clusters in Figure 3l shows that when the averaged perceptual data from the three scenarios is used, the Service Interaction cluster is not related to the Perceptual cluster in the terms of preferences, and the Information Quality cluster expresses slightly similar preferences to the Perceptual cluster. A very small conflict can be noticed between the Usability and Perceptual clusters' preferences. The analysis of Figure 3k allows to observe that it is the Site Design group of the Usability cluster that is conflicted with the Perceptual cluster, whereas the Usability group is expressing slightly

similar preferences to the Perceptual cluster.

#### D. Sensitivity Analysis

Apart from GAIA analysis, sensitivity analysis of the rankings, taking into account changes in weights of criteria, was performed. Table VI presents the ranges of stability for the weights of the criteria clusters.

It can be observed, that the stability of the ranking depends on the perceptual data scenario chosen. The ranking based on the payment page scenario appears to be the most stable one, and the home page scenario ranking seems to be the least stable one. It is important to notice, that the weight of the Perceptual cluster criteria cannot be reduced below some determined value.

When the results of the stability analysis are compared to the PEQUAL's one, it can be observed that the rankings based on the combined criteria are more sensitive to the weights' changes. This might be caused by the fact that only 6 perceptual criteria were added, so a change in the weight of

each of them results in more significant changes than in the case of the original 22 PEQUAL criteria.

#### E. Uncertainty Analysis

In the subsequent step of the analysis, the influence of the uncertainty of the partial evaluations on the sequence of the rankings was verified. The preference function was modified to V-shape with indifference area, where the preference threshold  $p$  remained unchanged and the indifference threshold was set to  $q=1$  for the C1-C22 criteria, to remain comparable with the PEQUAL analysis in [17], and to  $q=10$  for E1,  $q=9$  for E2,  $q=1$  for E3,  $q=10$  for E4,  $q=10$  for E5 and  $q=1$  for E6. The obtained ranking is presented in Table VII.

There was a shift in the ranking between Amazon and Apple, also Staples received a higher rank of 2, whereas BestBuy dropped from position 4 to position 6. This is in contrast to the results obtained for the ranking based on survey data only, and is probably caused by the fact that while survey data is based on a subjective Likert scale, the perceptual data is collected with a very high precision by the eye tracking device.

#### F. Comparison to Gaussian Preference

In the final step of the analysis, the preference function of each of the criteria was changed to a Gaussian type, with  $s=3$  for the criteria C1-C22,  $s=10$  for E1 and E5,  $s=8$  for E2,  $s=5$  for E3 and E6 and  $s=50$  for E4. The resulting ranking is presented in Table VIII. It is very similar to the ranking obtained with the use of V-shape function with no indifference, except the shifts on positions 1-2 and 6-7. However, the ranking obtained with the Gaussian preference function is much more stable, which fact is presented in Table IX.

### V. CONCLUSIONS

E-commerce is one of the most important sectors of online business. Considering the tough rivalry in the sector and continuous evolution of software, hardware and users' preferences, it is important to perform a systematic evaluation of e-commerce websites and their comparison to the ones owned by the competitors.

The prior MCDA methods were based on data collected from surveys or interviews. Some work has been done in the area of perceptual evaluation data usage, from eye tracking or EEG devices, in websites' evaluation. The authors' contribution in this paper was to extend the preexistent MCDA methods by the application of a combined survey and perceptual evaluation criteria set. In the proposed approach, a unique multistage construction of the model was realized. A new cluster of 6 perceptual evaluation criteria was added to the set of 22 eQual survey criteria.

An experiment was conducted to investigate the top 10 most popular e-commerce sites. Survey data from PEQUAL [17] was used to allow comparative analysis between results obtained by a Promethee II analysis based on survey-only criteria and combined criteria sets. Sensitivity and uncertainty analyses of the obtained rankings was performed. A study was

performed on the influence of the preference function chosen on the ranking order and its stability. The GAIA analysis allowed to examine mutual dependencies between the survey and perceptual criteria.

The survey data allows researchers to learn about users' subjective opinions on the evaluated websites. The perceptual evaluation performed with the devices such as an eye tracker, on the other hand, provides palpable, measurable data. The extension of the survey data with the perceptual evaluation data from particular websites' parts, such as the home, product or payment page, allows to create rankings of quality of those websites with special emphasis on those parts. Nevertheless, survey data provides a more general view of the evaluated websites. Therefore, it is beneficial to combine the advantages provided by the both aforementioned kinds of data.

During the research, possible areas of improvement and future work directions were identified. It would be beneficial to increase the diversity of the perceptual criteria combined to the model. Also, more areas of the website could be evaluated with the use of eye tracking devices to provide more general metrics of the website quality. In the proposed approach, all perceptual criteria were grouped into a single cluster. Further research could be performed to introduce a more comprehensive structure of the perceptual evaluation criteria.

# The ICT adoption in enterprises in the context of the sustainable information society

Ewa Ziemba

Faculty of Finance and Insurance  
University of Economics in Katowice  
1 Maja 50, 40-287 Katowice, Poland  
ewa.ziemba@ue.katowice.pl

**Abstract**— This study, part of an ongoing global study, aims to advance information society research and practice by examining and understanding the information and communication technologies (ICT) adoption in enterprises in the context of the sustainable information society (SIS). In this study, the ICT adoption is described by four components, i.e. outlay on ICT, information culture, ICT management, and ICT quality, whereas the sustainability is composed of ecological, economic, socio-cultural, and political sustainability. This study employs a quantitative approach to identify the levels of ICT adoption and sustainability in enterprises as well as investigate the correlation between these two constructs. The survey questionnaire was used and data collected from 394 enterprises were analyzed. The research findings reveal that there were significant statistical differences between the highest level of outlay on ICT and the lowest ones, namely the levels of ICT quality and ICT management. Moreover, the economic sustainability was at the highest level, whereas the lowest and similar levels were specific to ecological and political sustainability. Finally, it is investigated that the ICT quality, ICT management, and information culture have a significant impact on the sustainability, whereas the outlay on ICT does not have such an impact. This study advances the information society research and practice by measuring the ICT adoption, sustainability and correlation between them in the Polish enterprises.

## I. INTRODUCTION

The sustainable information society (SIS) is a new phase of information society development in which information and communication technologies (ICT) are becoming key enablers of sustainability [1]-[10]. Researchers and various organizations have explored the areas where the information society, sustainable development, and ICT come together, and identified some correlations between those concepts [11-17]. Overall, the SIS is a multidimensional concept encompassing environmental, economic, cultural, social, and political aspects, all of which could be strongly influenced by adopting ICT by society stakeholders, mainly enterprises, households, and public administration [10].

In general terms, enormous ICT potential for the SIS development can be approached from two angles: ICT as an industry and ICT as a tool [10]. As an industry, ICT have become a major economic driver in the hardware, software, telecommunications, and consulting services sectors. ICT as a tool can be used to transform and improve business, everyday life of people, and public governance.

ICT used as a tool to revolutionize business is examined in this study. Some researchers have identified ICT as one of the most important tools in building sustainable business practices [17] and supporting the success of businesses [18]. It is contended that ICT enable businesses to improve productivity, support innovation, reduce costs, increase the effectiveness of processes services, enhance the efficiency of business decision-making, respond to customers at a faster rate, and acquire new customers [14], [17]. Moreover, the ICT adoption in enterprises can yield benefits in environmental preservation by increasing energy efficiency and equipment utilization [4] as well as it can influence social development by making information available to all society stakeholders [7].

All these possibilities make ICT enablers of sustainability in several respects, i.e. environmental protection (ecological sustainability), economic growth (economic sustainability), socio-cultural development (socio-cultural sustainability), and governance (political sustainability) [10].

Following an extensive review of the literature, it did not uncover any deep studies to identify levels of ICT adoption and sustainability in enterprises as well as interpret how the ICT adoption in enterprises improves the SIS. Moreover, there is a lack of research on the SIS and correlations between the ICT adoption and sustainable development in less developed European countries, which are called transition economies [19]. The European transition economies are the former Eastern Bloc countries, which, since the early 1990s, have been undergoing transition from the command economy model to the free market model. We can identify the leaders and the followers of the transition process. In the first group there are: Poland, the Czech Republic, Hungary, Slovakia, Slovenia, Lithuania, Latvia, Estonia, Croatia, Romania and Bulgaria. The second group includes Belarus, Russia, Georgia, Moldova, Ukraine, Serbia and Montenegro.

In light of the above limitations, this paper focuses on exploring the ICT adoption and sustainability in enterprises. Its aims are to identify the levels of ICT adoption and sustainability in enterprises, and investigate the correlation between the two constructs.

The paper is structured as follows. Section I is an introduction to the subject. Section II states the theoretical background of ICT adoption and sustainability, and poses research questions. Section III describes the research

methodology. Section IV presents the research findings on the levels of ICT adoption and sustainability in enterprises, and the correlations between the ICT adoption and sustainability. Section V provides the study's contributions, implications, and limitations as well as considerations for future investigative work.

## II. THEORETICAL BACKGROUND AND RESEARCH QUESTION

### A. The ICT adoption

ICT are defined as a diverse set of software and hardware, to perform together various functions of information creation, storing, processing, preservation and delivery, in a growing diversity of ways [20]. Based on works about the adoption and implementation of enterprise's information system, the adoption of ICT can be defined as ICT design, implementation, stabilization, and continuous improvement [21]. In this study, ICT adoption is understood as the whole spectrum of activities from the period when enterprises justify the need for adopting ICT until the period when enterprises experience the full potential of ICT and derive benefits from them [22].

Based on a stream of research, Ziemba [22] advanced a model, which categorized the adoption of ICT into four components: outlay on ICT (Out), information culture (Cul), ICT management (Man), and ICT quality (Qua). The component of outlay on ICT included the enterprises' financial capabilities and expenditure on the ICT adoption, as well as funding acquired by enterprises from the European

funds. The information culture component embraced digital and socio-cultural competences of enterprises' employees and managers, constant improvement of these competences, personal mastery, and incentive systems encouraging employees to adopt ICT. The ICT management component comprised of the alignment between business and ICT, top management support for ICT projects in the entire ICT adoption lifecycle, implementation of law regulations associated with the ICT adoption, regulations on ICT and information security and protection. The ICT quality component consisted of the quality and security of back- and front-office information systems, quality of hardware, maturity of e-services, and adoption of ERP and BI systems. See Table 1 for the description of each ICT adoption component. The construct asserted that the four components were interrelated and critical to the design of the ICT adoption in enterprises in the context of the SIS.

### B. The sustainability

The definition of sustainable development [23] was, in this paper, taken as a basis for the conceptualization and operationalization of sustainability. According to Schauer [7], sustainable development has four dimensions which are ecological, social, economic and cultural sustainability. In a further study, Ziemba [22] proposed an expanded sustainability which included four sustainability components, i.e. ecological, economic, socio-cultural, and political. Regarding businesses, the sustainability components are [22]:

TABLE I.  
PRIMARY VARIABLES OF ICT ADOPTION AND SUSTAINABILITY CONSTRUCTS

Primary variables of the ICT adoption construct				Primary variables of the sustainability construct	
<b>Out1</b>	Financial capabilities	<b>Man16</b>	ICT project team	<b>Ecl1</b>	Sustainability in ICT
<b>Out2</b>	Expenditure on ICT	<b>Man17</b>	Top management support	<b>Ecl2</b>	Sustainability by ICT

Source: on the basis of [22].

- Ecological sustainability (Ecl) is the ability of enterprises to maintain rates of renewable resource harvest, pollution creation, and non-renewable resource depletion by means of conservation and proper use of air, water, and land resources [24], [25];
- Economic sustainability (Eco) of enterprises means that enterprises can gain competitive edge, increase their market share, and boost shareholder value by adopting sustainable practices and models. Among the core drivers of a business case for sustainability are: cost and cost reduction, sales and profit margin, reputation and brand value, innovative capabilities [14], [15];
- Socio-cultural sustainability (Soc) is based on the socio-cultural aspects that need to be sustained, e.g. trust, common meaning, diversity as well as capacity for learning and capacity for self-organization [26]. It is seen as dependent on social networks, making community contributions, creating a sense of place and offering community stability and security [27], [28]; and
- Political sustainability (Pol) must rest on the basic values of democracy and effective appropriation of all rights. It is related to the engagement of enterprises in creating democratic society [28].

Table 1 presents the description of each sustainability component.

#### C. Correlations between ICT adoption and sustainability

Some studies show that ICT adoption affects the sustainable development. Schauer [7] stated that ICT can contribute to the sustainable development, especially to ecological, social, cultural, and economic sustainability. Hilty and others asserted that information systems can facilitate the sustainable development by creating the kind of economic activity that harmonizes nature with human and social welfare in the long term [29]. Johnston referred to the ICT impact on the SIS, pointing out to the need for “greater synergy between RTD (research and technology development), regulation and deployment actions; greater investment in more effective public services, notably for health care and education, as well as for administrations; and more active promotion of ‘eco-efficient’ technologies and their use” [30, p. 203].

Curry and Donnellan [12] proposed the Sustainable ICT Capability Maturity Framework (SICT-CMF). The framework provides a comprehensive value-based model for organizing, evaluating, planning, and managing sustainable ICT capabilities. Using the framework, organizations can assess the maturity of their SICT capability and systematically improve capabilities in a measurable way to meet the sustainability objectives including reducing environmental impacts and increasing profitability. However, the SICT-CMF goes beyond ICT to encompass other factors such as alignment with corporate sustainability

strategy, project planning, developing expertise, culture, and governance.

#### D. Research questions

According to Ziemba [22], the SIS is a multidimensional concept encompassing two constructs: the ICT adoption and sustainability, as well as correlations between them. The sustainability construct embracing the environmental, economic, socio-cultural, and political sustainability can be strongly influenced by the ICT adoption consisting of the outlay on ICT, information culture, ICT management, and ICT quality.

In the previous study Ziemba [22] assessed the quality of the two constructs by examining the construct reliability [31], convergent validity [32], [33], and discriminant validity [32], [34]. The following measures were calculated: the loadings of each item of each component, composite reliability (CR) of all components, average variance extracted (AVE) of all components, Cronbach’s Alpha of all components, correlations between the components, the square root of AVE for each component. Overall, the results successfully established the reliability, convergent validity, and discriminant validity of the proposed constructs and their components [22].

The present study examines the SIS in the context of Polish enterprises and focuses on addressing the following research question:

RQ1: What is the level of ICT adoption in Polish enterprises?

RQ2: What is the level of sustainability in Polish enterprises?

RQ3: How does the ICT adoption influence the sustainability in Polish enterprises?

### III. RESEARCH METHODOLOGY

#### A. Research instrument

The Likert-type instrument (questionnaire) was developed that consisted of two SIS constructs: the ICT adoption and sustainability. The task of respondents was to assess the primary variables describing:

- The four components of the ICT adoption construct, i.e. outlay on ICT (Out), information culture (Cul), ICT management (Man), and ICT quality (Qua) (Table 1). The respondents answered the question: *Using a scale of 1 to 5, state to what extent do you agree that the following situations and phenomena result in the efficient and effective ICT adoption in your enterprise?* The scale’s descriptions were: 5 – strongly agree, 4 – rather agree, 3 – neither agree nor disagree, 2 – rather disagree, 1 – strongly disagree; and
- The four components of the sustainability construct, i.e. ecological (Ecl), economic (Eco), socio-cultural (Soc), and political sustainability (Pol) (see Table 1).

The respondents answered the question: *Using a scale of 1 to 5, evaluate the following benefits for your enterprise resulting from the efficient and effective ICT adoption?* The scale's descriptions were: 5 – strongly large, 4 – rather large, 3 – neither large nor disagree, 2 – rather small, 1 – strongly small.

### B. Research subjects and procedures

In April 2016, the pilot study was conducted to verify the survey questionnaire. Ten experts participated in the study, i.e. five researchers in business informatics and five managers from five enterprises – leaders in the ICT application. Finishing touches were put into the questionnaire, especially of a formal and technical nature. No substantive amendments were required.

The subjects in the study were enterprises from the Silesian Province in Poland. The choice of this region was driven by the fact of its continuous and creative transformations related to restructuring and reducing the role of heavy industry in the development of research and science, supporting innovation, using *know-how* and transferring new technologies, as well as increasing importance of services. In response to the changing socio-economic and technological environment intensive work on the development of the information society has been undertaken in the region for several years. In the next development strategies of the information society it was and is assumed that the potential of the region, especially in the design, provision and use of advanced information and communication technologies will be increased [35]. All this means that the results of this research can be reflected in innovative efforts to build a sustainable information society in the region and, at the same time, constitute *a modus operandi* for other regions throughout the country and other countries.

Selecting a sample is a fundamental element of a positivistic study [36]. The stratified sampling and snowball sampling were therefore used to obtain the sample that can be taken to be true for the whole population. The following strata were identified based on enterprise's size (defined in terms of the number of employees).

The subjects were advised that their participation in completing the survey was voluntary. At the same time, they were assured anonymity and guaranteed that their responses would be kept confidential.

### C. Data collection

Having applied the Computer Assisted Web Interview and employed the SurveyMonkey platform, the survey questionnaire was uploaded to the website. The data were collected during a two-month period of intense work, between 12 May 2016 and 12 July 2016. After screening the responses and excluding outliers, there was a final sample of 394 usable, correct, and complete responses. The sample

ensured that the error margin for the 97% confidence interval was 5%.

Table 2 provides details about enterprise's size, type of the business activities, and economy sector.

TABLE II.  
ANALYSIS OF ENTERPRISES PROFILES (N=394)

Characteristics	Frequency	Percentage
<b>Number of employees</b>		
250 and above (large)	78	19.80%
50–249 (medium)	83	21.07%
10–49 (small)	122	30.96%
less than 10 (micro)	111	28.17%
<b>Economy sector</b>		
I sector – producing raw material and basic foods	27	6.85%
II sector – manufacturing, processing, and construction	83	21.07%
III sector – providing services to the general population and to businesses	238	60.40%
IV sector – including intellectual activities	46	11.68%
<b>Business activities</b>		
ICT (manufacturing, trade, services)	136	34.52%
No ICT	258	65.48%

Source: own elaboration.

### D. Data analysis

The data was stored in Microsoft Excel format. Using Statistica package and Microsoft Excel, and analyzed in two stages. The first stage assessed the levels of the ICT adoption and sustainability construct, and the second stage examined the significance of construct correlations and provided regression analysis.

In the first stage, the descriptive statistical analysis was employed to describe the levels of the ICT adoption and sustainability in enterprises. The following statistics were calculated: mean, median (MDN), first quartile (Q25), third quartile (Q75), mode, variance (VAR), standard deviation (SD), coefficient of variation (CV), skewness (SK), and coefficient of kurtosis (CK). Additionally, the analysis of variance (Anova Kruskala-Wallis) was used to determine if there were statistically significant differences between distributions of scores for the ICT adoption components and sustainability components.

In the second stage, the correlation and regression analysis [37] were used to estimate the correlations between a dependent variable and one or more independent variables. The coefficient of determination, denoted  $R^2$  and advanced  $R^2$ , determines the productiveness of the proposed theoretical model. Falk and Miller [38] recommended that

$R^2$  values should be equal to or greater than 0.10 in order to be deemed adequate for the variance explained of a particular endogenous components (sub-constructs).

#### IV. RESEARCH FINDINGS

##### A. The level of ICT adoption in enterprises

In order to answer the research question *RQ1: What is the level of ICT adoption in Polish enterprises?*, a detailed descriptive analysis was conducted. The results are presented in Table 3.

It has been found that the average levels of ICT adoption components ranged from 3.58 to 3.78 (on a 5-point scale from 1.00 to 5.00). Median values were in the range between 3.60 and 4.00. On average, the level of outlay on ICT was the highest, followed by the level of information culture. The levels of ICT management and ICT quality were the lowest. The levels of the ICT adoption components were above their average levels in most enterprises.

The values of h-Kruskala-Wallis  $H(3, N=1576)=17.980$  and  $p = 0.000$  and Chi-square statistic (Chi-square = 6.669,  $df = 3$ ,  $p = 0.083$ ), and finally *post-hoc* analysis confirmed significant differences between the distribution of scores for the ICT outlay and the distributions of scores for the ICT management ( $p = 0.001$ ) and ICT quality ( $p = 0.008$ ).

##### B. The level of sustainability in enterprises

In order to answer the research question *RQ1: What is the level of sustainability in Polish enterprises?*, a detailed descriptive analysis was conducted. The results are presented in Table 3.

It has been found that the average levels of sustainability components ranged from 3.44 to 3.68 (on a 5-point scale from 1.00 to 5.00). Median values were in the range between 3.50 and 3.75. On average, the level of economic sustainability was the highest, whereas the levels of

ecological and political sustainability were the lowest. The levels of the sustainability components were above their average levels in most enterprises.

The values of h-Kruskala-Wallis ( $H(3, N=1576)=13.731$ ,  $p=0.003$ ) and (Chi-square=9.369,  $df=3$ ,  $p=0.025$ ), and finally *post-hoc* analysis confirmed significant differences between the distributions of scores for the economic sustainability and the distributions of scores for the ecological ( $p=0.009$ ) and political ( $p=0.010$ ) sustainability.

##### C. The contribution of ICT adoption to sustainability

Table 4 shows the results of the correlations between:

- the ICT adoption components and the components of the sustainability; and
- the ICT adoption components and the total sustainability construct (Y).

TABLE IV.  
CORRELATIONS AMONG COMPONENTS OF ICT ADOPTION AND THE TOTAL SUSTAINABILITY AND ITS COMPONENTS

Components	Ecl	Eco	Soc	Pol	Y
Out	0.317	0.350	0.355	0.256 $p=0.184$	0.395
Cul	0.402	0.529	0.527	0.337	0.572
Man	0.438	0.596	0.604	0.442	0.656
Qua	0.503	0.603	0.616	0.398	0.667

Source: own elaboration.

The correlation coefficients for the components of ICT adoption and the components of sustainability were significantly different from zero ( $p = 0.000 < 0.05 = \alpha$ ), with the exception of one correlation between the outlay on ICT and the political sustainability ( $p = 0.184$ ). In all cases there was a positive linear correlation. In addition, all components of the ICT adoption construct had a significant association

TABLE III.  
THE LEVELS OF ICT ADOPTION AND SUSTAINABILITY IN ENTERPRISES

Component	Mean	Q25	MDN	Q75	VAR	SD	CV in %	SK	CK
<b>ICT adoption components</b>									
Out	3.78	3.33	4.00	4.33	0.71	0.84	22.33	-0.78	0.35
Cul	3.71	3.22	3.78	4.33	0.57	0.75	20.32	-0.46	-0.35
Man	3.58	3.10	3.60	4.20	0.62	0.79	22.07	-0.55	-0.17
Qua	3.60	3.00	3.75	4.25	0.74	0.86	23.95	-0.56	-0.22
<b>Sustainability components</b>									
Ecl	3.44	3.00	3.50	4.00	1.03	1.01	29.48	-0.40	-0.58
Eco	3.68	3.25	3.75	4.25	0.62	0.79	21.38	-0.78	0.65
Soc	3.51	3.00	3.75	4.25	0.78	0.88	25.14	-0.46	-0.35
Pol	3.44	3.00	3.50	4.00	1.02	1.01	29.41	-0.47	-0.47

Source: own elaboration.

with the total sustainability construct (Y). The ICT management and ICT quality were correlated strongly with the sustainability. The moderate correlation was between the information culture and the sustainability, whereas there was a weak correlation between the outlay on ICT and the sustainability.

The correlations analysis was sought into the linear regression. In the first step of building the regression model, the following results were established. For the component of outlay on ICT, p-value ( $p = 0.557$ ) was higher than the accepted level of significance ( $\alpha = 0.05$ ). There is not enough evidence at the 0.05 significance level to conclude that there is a linear relationship between the level of outlay on ICT and the level of sustainability in the examined population. Therefore, this component was removed from the regression model and then the correct model was received. The results of estimations are presented in Table 5.

Three components of the ICT adoption construct, i.e. the information culture, ICT management, and ICT quality explained 50% of the variance in the sustainability ( $F_{3,390}=131.98$ ;  $p<0.0000$ ). These components predicted the sustainability significantly well. The examination of coefficients indicated that the components had a positive significant impact on the sustainability. The effects of the ICT quality and ICT management were stronger than of the information culture.

Then, the relationship between the ICT adoption and sustainability in the information society may be written:

$$\hat{Y} = 1.037 + 0.161 \cdot \text{Cul} + 0.232 \cdot \text{Man} + 0.311 \cdot \text{Qua}$$

where:

$\hat{Y}_p$  – the theoretical level of sustainability in the information society in the context of enterprises, including balancing ecological, economic, socio-cultural, and political sustainability;

**Cul** – the level of information culture in enterprises;

**Man** – the level of ICT management in enterprises; and

**Qua** – the level of ICT quality in enterprises.

Generally, the estimated model is correct and there is no reason to reject it. It allows understanding of the ICT adoption contribution to the sustainability of the information society in the context of enterprises. It gives an answer to the question – whether the growth in levels of outlay on ICT, information culture, ICT management, and ICT quality in enterprises determines an increase in the level of sustainability of the information society. The above results successfully established the significant and positive contribution of information culture, ICT management, and ICT quality to the sustainability in the SIS.

## V. CONCLUSIONS

### A. Research contribution

This work contributes to existing research on the SIS, in particular the contribution of ICT adoption to the sustainability by:

- indicating and describing the level of ICT adoption in enterprises, especially the levels of the outlay on ICT, information culture, ICT management, and ICT quality;
- indicating and describing the level of sustainability in enterprises, especially the levels of ecological, economic, socio-cultural, and political sustainability; and
- investigating how the ICT adoption in enterprises, i.e. the outlay on ICT, information culture, ICT management, and ICT quality contribute to the sustainability comprising its four types, i.e. ecological, economic, socio-cultural, and political.

Firstly, this study indicated significant statistical differences in the level of outlay on ICT and the levels of ICT quality and ICT management in the Polish surveyed enterprises. On average, the outlay on ICT was at the highest level, whereas the lowest and similar levels were specific to ICT management and ICT quality. It means that enterprises should improve ICT management and ICT quality.

Secondly, the outcomes showed significant statistical differences in the level of economic sustainability and the levels of ecological and political sustainability in the Polish surveyed enterprises. On average, the economic sustainability was at the highest level, whereas the lowest and similar levels were specific to ecological and political sustainability. It means that enterprises reap more economic benefits than ecological and political benefits from adopting ICT.

Thirdly, it was indicated that the information culture, ICT management, and ICT quality significantly and positively contribute to the sustainability in the SIS. However, the effects of the ICT quality and ICT management were stronger than of the information culture.

With regard to the presented results, it is reasonable to conclude that this study expands the existing research on the SIS provided by Schauer [7], Fuchs [1], [2], Hilty et al. [4], [5], Guillemette, Paré [14], [15], and Curry and Donnellan [12], [13].

### B. Research implication for research and practice

The research findings of this study can be used by scholars to improve and expand the research on the SIS. Researchers may use the proposed methodology to do similar analyses with different sample groups in other countries, and many comparisons between different countries can be drawn. Moreover, the methodology constitutes a very comprehensive basis for identifying the levels of ICT adoption and sustainability, as well as the correlations

between the two constructs, but researchers may develop, verify and improve this methodology and its implementation.

This study offers several implications for enterprises. They may find the results appealing and useful in enhancing the adoption of ICT, experiencing the full potential of ICT and deriving various benefits from the ICT adoption. The findings suggest some framework comprising various kinds of benefits like ecological, economic, socio-cultural, and political that can be obtained thanks to the ICT adoption. In addition, they recommend some guidelines on how to effectively and efficiently adopt ICT in order to obtain those benefits. It is evident from the findings that enterprises should pay utmost attention to the improvement of information culture, ICT management, and ICT quality. In particular, this research can be largely useful for the transition economies in Central and Eastern Europe. This is because the countries are similar with regard to analogous geopolitical situation, their joint history, traditions, culture and values, the quality of ICT infrastructure, as well as building democratic state structures and a free-market economy, and participating in the European integration process.

All in all, the research results might provide a partial explanation to the issue of how enterprises can participate in the creation of sustainable development and sustainable information society.

### C. Research limitations and future works

As with many other studies, this study has its limitations. First, the ICT adoption and sustainability constructs are new constructs that have yet to be further explored and exposed to repeated empirical validation. Second, the sample included Polish enterprises only, especially from the Silesian Province. The study sample precludes statistical generalization of the results from Silesian enterprises to Polish enterprises. However, early research into the success factors for and the level of adopting ICT in Poland [39] indicated that there is no difference between Silesian enterprises and other Polish enterprises. Therefore, these research findings cannot be limited only to the Silesian enterprises and can be generalized to Polish enterprises. After all, caution should be taken when generalizing the findings to other regions and countries. Finally, the research subjects were limited to enterprises and it is therefore only the viewpoint of enterprises toward the ICT adoption for achieving the sustainability in the information society. Caution should be taken when generalizing the findings to the SIS.

Additional research must be performed to better understand the SIS, the ICT adoption and sustainability construct, and the correlations between the ICT adoption and sustainability. First, the further validation of the levels of ICT adoption and sustainability should be carried out for a larger sample comprising enterprises from different Polish provinces. Second, the methodology of the ICT adoption,

sustainability, and SIS measurement should be explored in greater depth. A composite index for the SIS with sub-indexes of ICT adoption and sustainability in enterprises should be explored.

□ **Abstract** — Building systems designed to support business processes and knowledge management requires the development of methods facilitating the integration of both these approaches. In order to use organisational knowledge during performing business processes, it is necessary to define the business process that will be supported and the scope of knowledge that will be used, as well as developing the architecture of the system that will provide codified knowledge. These issues have been addressed by the theories and application example presented in this paper. The aim of the paper is to show a developed methodology for the process of building business process oriented autopoietic knowledge management support systems.

### I. INTRODUCTION

Integration of knowledge management systems and an organisation's business processes is one of key aspects of managing an organisation's knowledge [1], [2], [3], [4]. In order to facilitate the performance of processes, it is necessary to build IT solutions which, on the one hand, support the performance of a business process, while on the other hand, provide the user with the necessary knowledge that aids them in their activity or even substitute them in decision-making. As indicated by research by Al-Mabrouk [5] and Choy Chong [6], IT technologies are one of key factors of successful use of KM in organisations. At the same time, research by Akhavan et al. [7] pointed out that the most important key factors of successful implementation of KM are the aspects of knowledge sharing and knowledge storage. Therefore, it is important to search for methods for building IT solutions which will support the process of making organisational knowledge available and storing it.

The author's earlier research [8], [9], [10], [11] has shown that the theory of software agent societies and its use in knowledge-based organisations requires a separate view of the characteristics of multi-agent systems. Especially in the area of the application of methods for knowledge representation in such systems and possibilities of using autopoietic solutions to support the different stages of the life cycle of the process of knowledge management [8], [12].

Research into the methodologies used in designing multi-agent systems [13] indicated a range of features that should be considered in the context of building agent societies designed to be used in knowledge-based organisations. Such methodologies should enable:

- Identification of agents' roles in the system and their assignment to individual entities.
- Definition of agents' objectives and tasks.
- Definition of agents' convictions and knowledge.
- Specification of the content of agents' communication.
- Definition of the architecture of agents.
- Specification of the system's architecture.
- Identification of the system's functionality.
- Conceptualisation of the project's field.
- Definition of the organisation's ontology/social relations in the organisation.
- Definition of the environment of the agent society.
- Definition of the environment's resources.
- Mechanism of an agent's interaction with its environment.

Conducted research [13], [14] found out gaps in the methodologies for supporting design of multi-agent systems considered in the context of agent societies in the area of their application for supporting knowledge-based organisations. The author's current research aims to define the possibilities of using the theory of software agent society in building a business process oriented autopoietic knowledge management support system [15], [16]. One of the aspects of creating autopoietic systems to support the integration of business processes and knowledge management is the methodological aspect of the development of such systems [27], which is addressed in the paper.

The aim of the paper is to present the developed methodology for the process of building business process oriented autopoietic knowledge management support systems designed to facilitate an auditor's activities. Chapter 2 will present theoretical elements connected with these issues.

Chapter 3 will contain the assumptions of the developed methodology. Chapter 4 will discuss an example of its application in the area of personal data protection. The summary will feature the diagnosed advantages and disadvantages of the proposed approach.

## II. PROBLEM. INTEGRATION OF BUSINESS PROCESSES AND KNOWLEDGE MANAGEMENT

Integration of business processes and knowledge management systems as part of a system being developed may refer to the process of the performance of a task undertaken in a business process or support for a decision-maker participating in the process. This paper will address the latter issue. As was pointed out by Bitkowska [17], a knowledge management system can be divided into four sub-systems:

- databases – which refer to data access and knowledge sharing.
- organizational language – which allows the terms used in an organisation to be understood.
- network links - which enable access to information and knowledge within an organisation and beyond.
- transfer - which enables transfer of knowledge between individuals.

From the perspective of integration of KM and BPM, these sub-systems have to be subject to contextual integration as part of business processes in which they will be used. For that purpose, it is necessary to develop IT solutions designed to support such processes.

In terms of the use of Business Process Management in Knowledge Management, the following postulates of this approach can be formulated [18]:

- business processes, if modelled and captured in business process repository, are a part of codified intellectual capital of the organization,
- knowledge processes in an organisation should be a part of business process repository,
- business process repository could be used for knowledge creation, sharing and distribution.

In terms of the support for participants of a business process, it is reasonable to separate the system's elements that are responsible for the implementation of a process, its flows and orchestration from analytical systems that support decision-making processes [19]. This makes it necessary to build integrating solutions which, apart from linking organisational knowledge as part of business processes, will be able to autonomously process and provide decision-makers with knowledge that is necessary for performing tasks they undertake. One of the postulated elements that integrate BPM and KM is the aspect of knowledge

codification, which should be ensured by such systems. In this case, problems that can be solved by such systems (against the background of integration of Business Intelligence and KM) include [20]:

- lack of support in defining business rules for getting proactive information and support in consulting in the process of decision making,
- lack of a semantic layer describing relations between different economic topics,
- lack of support in presenting the information of different users (employees) and their individual needs,
- difficulty in rapidly modifying existing databases and data warehouses in the case of new analytic requirements.

The above-indicated issues refer to the aspect of the integration of BPM and KM, but are not the only ones in the context discussed in this paper. The problem that appears during the design of systems discussed in this paper is specification of business processes and knowledge resources, as well as translating the defined elements of the system into the application of an IT system designed to support a decision-maker's actions. The definition of organisational knowledge resources in the form of knowledge portals forces a decision-maker to search for specific knowledge needed to perform their tasks. On top of that, part of organisational knowledge can be scattered in the organisation, and tasks will take more time to perform. It is thus reasonable to support the process of integration of organisational knowledge as part of the tasks of business processes performed by decision-makers and to facilitate the methods for building IT systems that aid adaptation of knowledge to process participants.

Notations designed to support business process modelling, such as ARIS [21], BPMN [22] or IDEF0 [23], do not provide ready solutions that specify what knowledge will be provided to a decision-maker during their tasks, its sources or specification. This problem may be solved by using e.g. the KMDL (Knowledge Modelling and Description Language) language [24], but such solution in the case of business analysts requires the use of a new notation when business processes in a company are already documented by means of business process-oriented notations. When a new design notation is used, all the elements of a process have to be mapped to new artefacts. Another problem that appears is specification of knowledge resources. Applied notations usually define their own artefacts describing organisational knowledge without clear indication of how they are codified in the IT system. This results in inconsistency between the definition of knowledge resources in the design and their actual implementation in the IT system. Often, proposed design notations do not address the issues of standards for specification of knowledge resources, defined e.g. by W3C

organisation, which indicate what the structure of the ontology describing knowledge resources should look like.

Specification of knowledge resources based on proprietary sets of artefacts does not allow for their direct translation into available standards for knowledge codification. By using standards for describing knowledge resources in the form of ontology description languages OWL, OWL 2, RDF or RDFS, it will be possible to use the developed ontology again in another project and organisation. This is possible thanks to semantic description of the meanings of the terms used in ontologies.

Another aspect is semantic identifiability of the terms used during the design of knowledge resources by a knowledge engineer, which would make it possible to use the ontology for designing purposes (interpretable by the IT system being designed and by process participants) and for the purpose of system implementation. It would allow a once prepared definition of knowledge resources to be an element of design specification, an element of the system being implemented and to be used to integrate an organisation's knowledge resources with other ontologies.

The literature offers [25], [26] a range of studies which define how knowledge is codified based on ontology description languages. The main types of ontology include core, upper-level, domain, task, and application ontologies. The example presented further in the paper represents domain ontology with elements of application ontology.

It can be concluded that in terms of integration of business processes as part of knowledge management systems, it is necessary to create solutions that ensure:

- The use of generally accepted standards for describing an organisation's business processes, which will allow already operating organisations with diagnosed business processes to easily integrate the knowledge management system as part of employees' tasks.
- The use of standardised descriptions of an organisation's knowledge resources in the form of ontologies and ontology description languages and possibilities of using already applied standards in the process of defining field ontology.
- Mechanisms that allow for translation of the defined ontologies into a format that can be recognised by IT systems, thus shortening the time it takes to implement the system (the ontology developed at the stage of specifying the system's knowledge resources will be able to be automatically used during its implementation) and ensuring interoperability of knowledge resources across various projects and organisations.
- Linkage of the process of specifying business processes and organisational knowledge resources with the process of designing not only systems that automate the performance of processes but also systems that support decision-making.

- The use of codified knowledge resources in defining business rules of a business process and rules for the operation of a decision-making support system. Such translation makes it easier to define control mechanisms that control the operation of a system's elements.
- Extension of the architecture of built systems for integration of business processes and knowledge management by autopoietic elements that support decision-makers' actions through processing the codified resources of the system's knowledge.

The first four postulates refer directly to the aspect of integration of BPM and KM. The next two are connected with integration of autopoietic solutions as part of such a solution. The use of the theory of autopoietic systems impacts additional features of the solution being developed. They include: partially open, self-reference, self-control, boundary-generation, self-organisation through self-production. In such systems, business processes are performed dynamically based on system-resident components, and are subject to constant control. By using the theory of autopoiesis in the process of supporting the performance of business processes, system elements are not only subject to self-organisation, but - through the process - performed production processes can be reproduced and then incorporated into the business process being performed. These actions are carried out in a partially open system, where system elements interact with one another, which is equipped with control mechanisms that limit undesired behaviours within the whole system.

The methodology presented further in the paper and the tool developed to support its implementation fulfils the above-mentioned postulates and constitutes a response to the problems pointed out in this chapter.

### III. ELEMENTS OF THE PROPOSED METHODOLOGY

The proposed methodology has been developed based on three main stages with a loopback, which involve the specification of business processes of an organisation, its knowledge resources and an autopoietic element that facilitates integration of knowledge resources within a business process [27]. The methodology comprises the following stages:

- First stage - identification and modelling of business processes.
- Second stage - identification and modelling of an organisation's knowledge resources.
- Third stage - designing and implementation of a process oriented autopoietic knowledge management support system.

Figure 1. Elements of the proposed methodology

Figure 1 presents elements of the proposed design methodology along with the impact of the individual stages on each other. In accordance with figure 1, the following stages have been identified in the methodology:

1. Analysis and development of a business process.
2. Identification of organisational knowledge resources.
3. Designing and implementation of a process oriented autopoietic knowledge management support system:
  - 3.1. Identification of the context of usage.
  - 3.2. Analysis of the roles and responsibilities of autopoietic system.
  - 3.3. Determining the hierarchical structure of the relationship inside the organization.
  - 3.4. Preliminary definition of the architecture of an autopoietic system.
  - 3.5. Indication of the impact of control mechanism on the autopoietic system.
  - 3.6. Essential definition of the autopoietic element internal architecture.
  - 3.7. Designing the interaction autopoietic elements.

The first stage refers to identification and specification of the business process that is supported. On this basis, the usage context of the system being built is defined. The proposed approach uses the BPMN notation for specification of the process supported by a business process oriented autopoietic knowledge management support system. This allows for the use of this approach to an organisation that already has codified processes without the need to codify them once again. Further, the task of a knowledge engineer is to indicate knowledge resources. For this stage, it is necessary to indicate the ontology defining the scope of terms used by the knowledge management system and the

objects that are defined by means of them. In the proposed approach, ontology is defined using the author-developed editor, which uses notation in compliance with OWL 2 specification. The preliminary definition of a business process and knowledge resources can precede the process of designing a business process oriented autopoietic knowledge management support system. The proposed stages of the process of designing such a solution refer to the context of its application, architecture, impact on its environment, rules applied in the system and its interactions. Such division enables the fulfilment of the expected requirements (presented in the introduction), which could facilitate the design of business process oriented autopoietic knowledge management support systems to support knowledge-based organisations. The next chapter will present elements of the proposed methodology as well as the application of the developed design tools.

#### IV. EXAMPLE OF APPLICATION

The application of elements of the proposed methodology will refer to the process of verification of personal data protection in an organisation. Pursuant to the Act on personal data protection in force on the territory of Poland (Personal Data Protection Act (Journal of Laws of 2016 item 922) and the Resolution of the European Parliament and European Council (UE) 2016/679 of 27 April 2016 on protection of individuals with regard to personal data processing and on free flow of such data, economic entities are obliged to implement a security policy for personal data protection. One of the aspects of this policy is security audits specified in the Act which should be cyclically carried out by an Information Security Administrator. Such audits have to be preceded by establishment of their schedule and approved by a company's Board of Directors.

The first problem with supporting an auditor's actions is connected with the fact that part of the information he/she processes as part of the audit is stored in IT systems of the audited enterprise. The systems where such data is stored do not support business processes connected with personal data protection. The second reason for using the solutions proposed in the paper is the necessity of examining the process of data processing in the context of physical, technical and organisational security measures. This requires that the person who undertakes such activities not only possesses knowledge about the processes taking place in the organisation, their participants and processed information resources, but also checks whether physical and IT security measures work properly, which often goes beyond the auditor's competencies. Therefore, it is reasonable to apply a system for decision-making support which will facilitate the audit process. Another reason is connected with the auditor's needs regarding knowledge resources. In the case of an audit, knowledge about the organisation often has extend beyond the boundaries of the organisation, because the IT

systems used in the organisation can be located at any place (e.g. as a result of using Cloud Computing), and information flows go beyond the organisation. As a result, audit-related activities have to refer to the aspect of IT systems and information flows that are located outside the audited entity. Consequently, we can list a range of premises that indicate the necessity of using the proposed approach to modelling business process oriented autopoietic knowledge management support systems:

- Lack of support of the audit process by IT systems of the audited organisation.
- Necessity of possessing knowledge about organisational, physical and technical aspects of the organisation's operation.
- Necessity of integrating not only IT systems but above all the knowledge about processes in the organisation.
- Necessity of providing the auditor with organisational knowledge about the audit process and knowledge about the organisation itself.
- Necessity of analysing business processes in the organisation and beyond.

Currently available IT systems dedicated to the aspect of personal data protection do not address these issues in a sufficient way and focus on the process of preparing audit documents rather than supporting their preparation. The following sections will present selected aspects of using the proposed methodology in the process of preparing elements of a system designed to support a decision-maker in this process. All the above-mentioned stages are supported by design tools developed by the author.

#### A. Specification of a business process

As was already mentioned, the first stage is indication of the context of the system's operation connected with modelling the structure of the business process that will be supported. For modelling of this stage, the notation BPMN has been used.

An audit process comprises a number of stages presented in figures 2 and 3. Stages of business process specification include:

- Specification of organizations involved in the process and the posts performing the tasks.
- Determination of relationships inside the organization. At this stage, the relationship is defined within the organizational structure that supports the system. In the case of an organization, it is a structure linking.
- Defining the rules of starting and ending the process.
- Diagnosing the business process tasks.
- Diagnosing the business process events.
- Defining the conditions governing decision gates.

The initial phase involves establishment of audit schedules which have to be approved by the Board of Directors (figure 2).

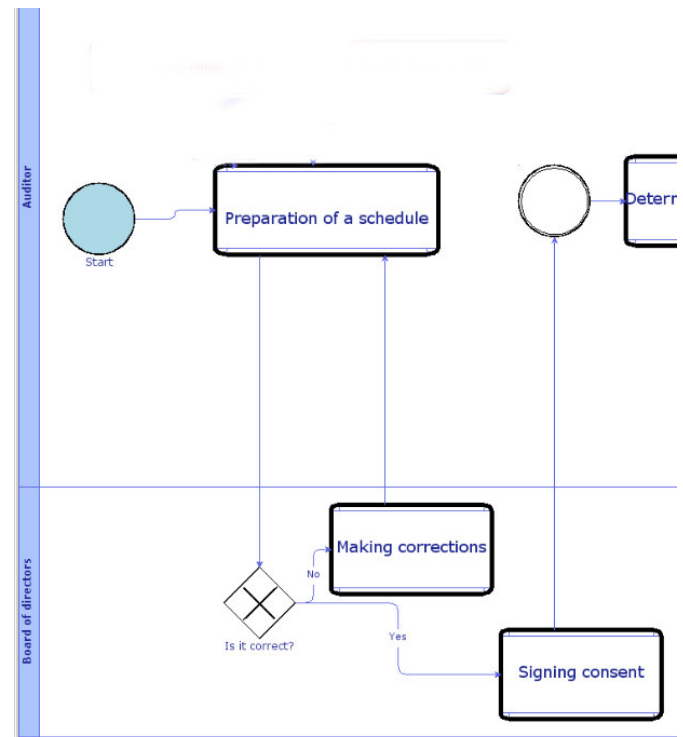

Figure 2. Initial phase of the process of information security audit.

On this basis, cyclical audits are performed during which technical and physical security measures as well as organisational procedures are checked. This aspect is presented in figure 3.

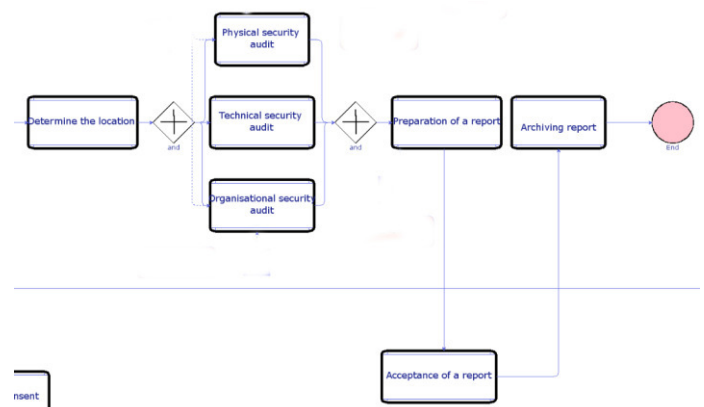

Figure 3. Phase of an information security audit.

A business process specified in this way indicates only an employee's tasks to be performed and is consistent with BPMN notation. In the next steps, it will be extended by KM elements.

### B. Specification of knowledge resources

Once elements of a business process are defined (in accordance with the developed methodology), it is necessary to define which resources of organisational knowledge can be used during its performance. The second stage consists of the following sub-stages:

1. Identification of codified knowledge sources (e.g. documents, websites, system-generated knowledge developed in earlier iterations).
2. Identification of non-codified knowledge sources (e.g. experts).
3. Development or update of the ontological model (meta-knowledge) about knowledge resources.

The third stage consists of the following sub-stages:

- 3.1. Definition of the aim of the implementation of the ontology.
- 3.2. Definition of the scope of the ontology and indication of possible design models of ready ontologies.
- 3.3. Indication of the main knowledge resources processed during a business process and consequently the terms of the defined ontology.
- 3.4. Definition of ontological classes.
- 3.5. Definition of class properties.
- 3.6. Definition of the relationships between classes and properties.
- 3.7. Definition of the restrictions controlling the correctness of ontologies.
- 3.8. Definition and specification of knowledge sources for defining instances of objects based on the ontology.
- 3.9. Definition of instances of objects defined by the ontology.

This process can be supported by preparation of a matrix that defines knowledge resources that will be processed during performance of a given process or specified tasks of the process that will be supported by the system. In the example, a matrix of knowledge resources to be used in the process has been defined. The example matrix has been presented in table 1.

Knowledge resource	Source	Type	Description
Leave planning schedule	ERP system	Electronic	Information on the leave planning schedule for audited employees
Building layout	Archive	Electronic/paper	Plan of the rooms in the audited organisation
Site plan	Archive	Electronic/Paper	Plan of the audited room
Certificate of the validity of inspections and systems	Organisational unit	Electronic/Paper	Documents confirming the validity of the inspection of fire extinguishers, alarm system, fire-extinguishing system, UPC, anti-virus system
Collection of data sets	ABI	Electronic/Paper	The enterprise's personal data sets
List of authorisations	ABI	Electronic/Paper	Authorisations to process data
...	...	...	...

Table 1. Fragment of knowledge resources necessary during an information security audit

The knowledge resources diagnosed in this way can be represented in the system as knowledge resources used by the system. For the purpose of specification of knowledge resources, the developed software allows for the development of an ontology diagram which uses terms applied in OWL 2 [28]. This enables a knowledge engineer to adapt the specification of organisational knowledge resources to the requirements and apply commonly used ontologies that allow for the description of the area of the problem being modelled. The design presented in the paper uses elements of the specification The Organization Ontology (W3C Recommendation from 2014) [29]. This ontology uses a range of concepts that enable the description of the structure of an organisation, its members and roles. Figure 4 shows elements of this ontology and elements that extend it, as defined by a knowledge engineer. The defined classes and property assertion are consistent with the specification OWL 2.

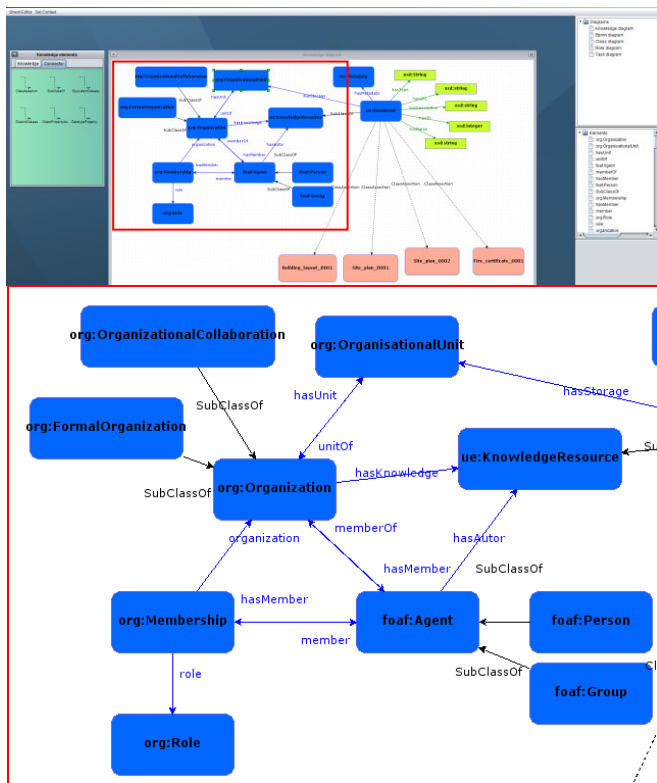

Figure 4. Elements of the domain ontology of the defined knowledge resources of an organisation

Knowledge resources defined in this way can be ascribed to a business process and used during specification of an autopoietic system. A knowledge engineer can ascribe certain knowledge resources in the form of class instances to the process defined at stage 1, define the whole ontology or its fragment. Thanks to that, the person performing the process will have access not only to one/several instances of knowledge resources, but the whole database. The proposal to extend BPMN by ontological elements of the defined knowledge resources is presented in figure 5.

Figure 5. Notation BPMN extended by elements of specified knowledge resources

As the figure shows, the stages of the verification of the physical resources have been extended by elements of the presented ontology. This makes it possible to indicate which elements of organisational knowledge will be processed as part of a business process. At the same time, elements of knowledge resources, thanks to their semantic codification, can be used in the development of an autopoietic system. A

fragment of specified knowledge resources in languages OWL 2, RDF and RDFS has been presented in figure 6.

Figure 6. Example of codified knowledge resource in the language OWL 2

The definition covering the semantics of knowledge structures and their implementation can be included into the knowledge database of knowledge management systems and processed by the other IT systems in an organisation.

### C. Specification of elements of an autopoietic system

In accordance with the proposed methodology (stage 3.1), the process of designing the system begins with definition of a set of tasks performed by the system. To show the elements of the proposed methodology, the following set of tasks, as presented in figure 7, has been defined. In accordance with the defined table 1, the elements of the tasks performed by the autopoietic system refer to selected knowledge resources. The possible defined tasks include:

- Providing knowledge resources concerning the leave planning schedule.
- Providing knowledge resources concerning the building layout.
- Providing knowledge resources concerning the site plan.
- Providing knowledge resources concerning the certificates.
- Providing knowledge concerning data sets.
- Providing knowledge concerning authorisations.

The main tasks, which have been defined in this way, can be presented based on a use case diagram and by means of a diagram of the hierarchy of a system's tasks. Each of the defined tasks is subject to a separate iteration during the development of an autopoietic system and is treated as one case of its usage. Figure 7 shows the results of one iteration of the developed system with defined tasks of an autopoietic system linked with the task of a business process. This diagram is built during the execution of stage 3.2.1.

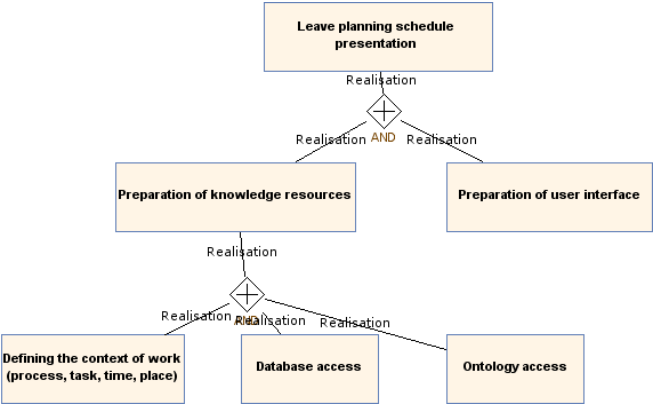

Figure 7. Diagram of the hierarchy of an autopoietic system's tasks (Providing knowledge resources concerning the leave planning schedule)

The tasks, which are defined in this way, can be combined in stage 3.2.2 in roles that are performed by an autopoietic element. These roles may refer to the process of knowledge processing or actions connected with provision of knowledge to the system from external systems. Figure 8 shows an example of defined roles of a system as part of the designed system.

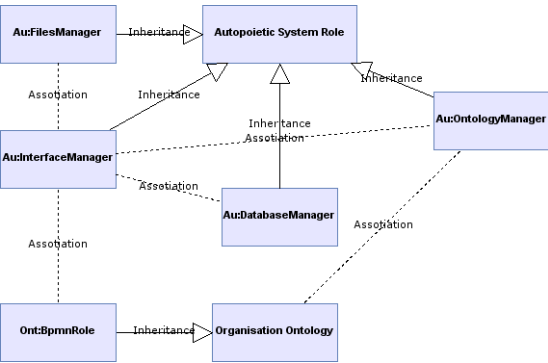

Figure 8. Diagram of roles of an autopoietic system

After defining the tasks to be performed by an autopoietic system, the scope of knowledge and roles of the system's elements, it is possible to design a diagram of programming classes which, thanks to the earlier stages, will be linked to knowledge resources, the system's tasks and roles. On this basis, it is possible to define the code of the autopoietic element. Figure 9 presents a fragment of an autopoietic system class.

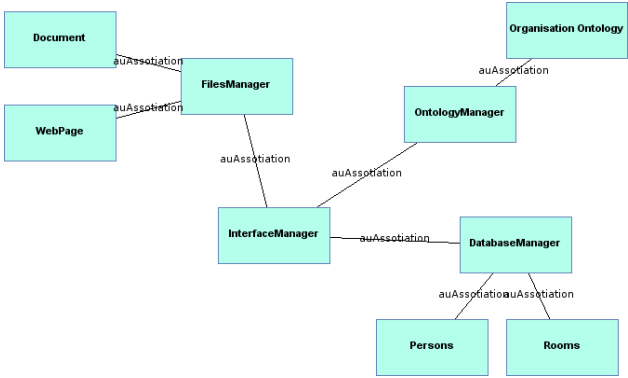

Figure 9. Diagram of classes of a designed system

As a result, the autopoietic element, which is prepared in this way, is able to provide a decision-maker with specific knowledge when a given task performed by a business process is triggered. In this example, it supports, through defined knowledge resources, the defined stages of the verification of data processing compliance.

An element of the user interface of the developed system has been presented in figure 10.

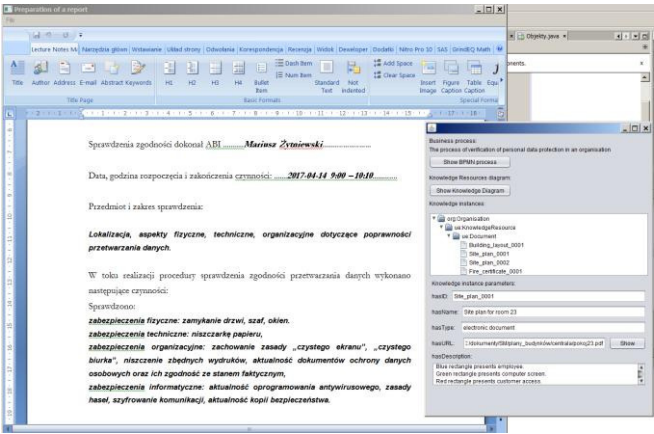

Figure 10. Example of the operation of the developed system

Figure 10 presents a fragment of a report from an audit process and instances of knowledge resources to which the auditor has access.

The design elements presented here fragmentarily address the specification of the system, which can be defined based on the proposed methodology. They do not tackle the aspect of communication between the system's elements or analysis of actions undertaken by autopoietic elements. Examples of the application of these elements of the methodology will be the subject of the author's further research.

## V.CONCLUSION

The example of the methodology for designing and building a business process oriented autopoietic knowledge management support system, which has been presented in the paper, covers a broad range of aspects of designing and building decision-making support systems that focus on supporting business processes and knowledge management. The methodology for designing such solutions proposed by the author is applied in his current projects, and its functionality is extended through the developed design tool whose application has been presented in this paper.

The example presented in the paper covers selected aspects of designing a system that integrates BPM and KM. It shows the process of specification of an organisation's business process, the process of defining organisational knowledge in the context of tasks undertaken in a process, the aspect of extending the specification of a business process by elements of knowledge resources and elements of the specification of an autopoietic system.

The main advantages of the proposed approach include:

- Supporting decision-making processes of decision-makers by providing them with contextual knowledge.
- Integration of the ontology on organisational knowledge resources, which can be used in the subsequent iterations of the process of building a system.
- Possibility of terminological integration of defined knowledge resources within the framework of the terms used in standardised ontologies (the example shows elements of integration of a domain ontology with The Organization Ontology, which is a standard of W3C).
- The use of elements of BPMN notation and extension of its artefacts by elements used by a knowledge engineer in designing a system.
- Indication of methods for integrating autopoietic systems as part of decision-making processes of a decision-maker.
- Iterational character of the approach with respect to certain tasks of a business process.
- Possibility of using this approach to build systems that automate business processes and systems designed to support business decisions.

As figure 1 shows, the developed methodology defines a range of loopbacks that impact the process of designing the system and facilitate its integration as part of KM and BPM. In particular, the methodology is contextually oriented. This aspect will be addressed by the author in next papers.

The developed solution has also contributed to gaining a better understanding of processes taking place in an organisation and improving the way they are performed. In particular, the following impact of the implementation

carried out on an organisation's operation can be highlighted:

- Definition of a range of business processes related with the process of personal data protection audit, which has contributed to audited persons' better understanding of the principles of the organisation's operation. Thanks to their codification in BPMN, the person subject to an audit process knows its rules and how it is performed. Additionally, business processes defined in this way can become an element of a map of business processes taking place in an organisation and be used by an autopoietic system.
- Development of the ontology of organisational knowledge resources, which allows knowledge resources to be linked with business processes performed in an organisation. Defined knowledge resources can be used in the process of extending the functionality of the developed software solution. Additionally, if further processes taking place in an organisation are diagnosed, they can be re-used and assigned to further tasks of a business process.
- Inclusion of defined knowledge resources into the operation of an organisation's knowledge portal. Thanks to that, knowledge on the performance of the process of verification of personal data protection and other defined business processes can be made available to employees and help them to better understand how the organisation works.

As a result, the proposed solution supports a typical life cycle of the process of knowledge management and applies to knowledge generation, knowledge evaluation, knowledge sharing, knowledge leveraging and knowledge discovery.

From the perspective of an auditor, the solution has contributed to acceleration of the process of preparing post audit documentation through its partial automation due to the development of an editor for post audit documents.

# 5<sup>th</sup> Workshop on Information Technologies for Logistics

**T**HE main purpose of the workshop is to provide a forum for researchers and practitioners to present and discuss current issues concerning use of ICT in logistic applications (hardware and software). There will be also an opportunity for hardware integrators, software developers and logistics companies to demonstrate their solutions, as well as achievements, in different logistic systems.

## TOPICS:

The topics of interest include but are not limited to:

- Innovations in information systems supporting logistics and its management (WMS, SCM, TMS, LIS, VMI, CRP, PLM, and others)
- Innovative technologies in warehouse management: RFID, Voice Picking, Image Recognition, Pick Radar, etc.
- Logistics process modeling, including influence of warehouse automatic
- Optimization of logistics processes:
  - optimal vehicle routing and management, boundary conditions
  - optimal picking routing (global optimization, fast search, collision prediction and prevention)
  - shared mobility systems
  - day-to-day dynamic traffic assignment models
  - effective methods of picking (multi picking, batch picking ect.)
  - relationships between picking efficiency and products decomposition in warehouse area
- Environmental protection (for example carbon-aware transportation)
- Artificial intelligence systems and decision support systems in logistics
- BI, data mining and process mining in logistics
- Quality management algorithms and methods
- Material Flow Theory and applications

**Abstract**—Future warehouses will be made of modular embedded entities with communication ability and energy aware operation attached to the traditional materials handling and warehousing objects. This advancement is mainly to fulfill the flexibility and scalability needs of the emerging warehouses. However, it leads to a new layer of complexity during development and evaluation of such systems due to the multidisciplinary in logistics, embedded systems, and wireless communications. Although each discipline provides theoretical approaches and simulations for these tasks, many issues are often discovered in a real deployment of the full system. In this paper we introduce *PhyNetLab* as a real scale warehouse testbed made of cyber physical objects (*PhyNodes*) developed for this type of application. The presented platform provides a possibility to check the industrial requirement of an IoT-based warehouse in addition to the typical wireless sensor networks tests. We describe the hardware and software components of the nodes in addition to the overall structure of the testbed. Finally, we will demonstrate the advantages of the testbed by evaluating the performance of the ETSI compliant radio channel access procedure for an IoT warehouse.

## I. INTRODUCTION

**F**LEXIBILITY of system, modularity and reliable throughput, in addition to the scalability play major roles in the quality of materials handling and warehousing systems [1]. The Integration of embedded devices in current systems is the first step into this direction that will evolve classic warehouses into decentralized modular systems with improved performance. Multiple research instances of logistics turned into implementing distributed Cyber Physical Systems (CPS) for modern production, transportation and distribution strategies [2]. But the full potential will be reached when these entities communicate with each other and fulfill their tasks autonomously without any central management units.

Smart connectivity to communicate with the available networks and using them for context-aware computation is an indispensable part of Internet of Things (IoT) [3]. Therefore, realization of these CPS in the field of materials handling is also a move in the overall direction of the Industry 4.0 revolution with the emerging concept of IoT [1], [2].

Although the term IoT was first made in 1999 by Kevin Ashton in the context of supply chain management, the definition has been expanded into a wide range of applications during the past decade due to its interdisciplinary nature [3]–[5]. In [6] the three main paradigms for the realization of IoT are defined as *Internet oriented*, *Things oriented*, and *Semantic oriented*.

Warehousing application in a materials handling facility is exactly such a field which intersects all of these IoT aspects.

For such systems, hardware and software development becomes a challenging process, since the code base for controlling a large swarm of devices needs to be maintainable, and the implementation of new features requires a well organized software milieu with a testbed to avoid disastrous mistakes.

Another challenge is imposed by radio communications. As bandwidth and range of radio connections are limited, a great mass of intelligent containers need to reduce and adapt their communication behavior accordingly. Furthermore, the channel access must be organized very efficiently to avoid collisions and the waste of scarce energy. As we will show in this paper, commonly used approaches lead to a catastrophic increase in energy consumption in large-scale scenarios.

To tackle these challenges and enable the development, evaluation and validation of a real-life deployments, we present *PhyNetLab* (cf. Fig. 1), a large scale IoT testbed for future logistic systems, and perform an exemplary evaluation of an established channel access scheme.

## II. RELATED WORKS

Wireless Sensor Networks (WSN) have been a major research topic during the last few years [7] which spans a diverse research area, e.g. routing algorithms, energy harvesting, management, security and privacy. According to this versatile range of work, wide variation of WSN testbeds are developed. In addition, there are federations of WSNs combining multiple

Fig. 1. Photograph of the *PhyNetLab*, a large logistics hall containing numerous smart containers, each attached with a communicating *PhyNode*. *PhyNetLab* serves as a large-scale testbed for the development of future, IoT-based warehouses.

installations into a single wide spread platform. Some of the most famous platforms are:

a) *MoteLab*: A wireless network developed by Harvard and published in 2005 [8]. It was one of the first fully developed WSNs. MoteLab is an open source tool that is accessible on the Internet. Its web access facilitates remote programming and user scheduling.

b) *Future Internet of Things*: FIT/IoT-Lab [9] is a heterogeneous large-scale research facility with a federation of more than 6 locations and more than 2000 nodes altogether [10]. To interact with nodes it has command line interfaces through user virtual machines.

c) *Indriya*: is a low-cost 3D WSN testbed implemented at the National University of Singapore [11]. The 127 wireless nodes are connected with active USB cables. This USB infrastructure provides a back channel for remote programming and powering the sensor nodes.

d) *WISEBED*: is an IoT research facility with a heterogeneous implementation where each partner maintains its own testbed [12]. There is also an overlay network giving access to all testbeds as one, large IoT implementation for analysis. Anyhow, each testbed can also be handled separately [10].

Beyond that, numerous other WSNs are shown in surveys, such as [4], [7], which categorize them into general testbeds, server-based testbeds, single PC-based testbeds, multiple site testbeds, in-band management traffic testbeds, and specialized testbeds.

According to this categorization, PhyNetLab is considered to be a specialized testbed because it is designed to be a wireless sensor network testbed, which is built very close to a real world scenario. The major research challenges are to develop communication protocols and energy-aware syntactics, which are required for a deep integration in industrial systems such as a materials handling facility.

### III. SYSTEM STRUCTURE AND HARDWARE COMPONENTS

Here, we give an overview of PhyNetLab, which is shown in Fig. 1. It is located in a large logistics hall providing space for a continuously extending amount of containers. Each container carries a PhyNode at its front which enables communication capabilities with the infrastructure. They are attached to equally distributed Access Points (APs), which serve as gateways to the internet via an optimized Long Term Evolution (LTE) link [13]. This cellular structure reduces the necessary transmission power and increases the network capacity by reusing radio channels. A detailed description of the PhyNetLab and of its components is presented in [10]. Due to limited space, this paper only briefly introduces the PhyNode platform, which is most important for the presented experiment.

The PhyNode (cf. Fig. 2) consists of two parts, a master network board for management and the actual experiment platform, which is a Swappable Slave Board (SSB). The management platform spans a ZigBee backbone network over the testbed and can be used, e.g., for updating the slave board firmware. The heart of the SSB is a ferroelectric random access memory (FRAM)-based MCU MSP430FR5969. Comparing to

Fig. 2. Photography of the PhyNode, which is attached to every container in the PhyNetLab. It is equipped with a solar cell, display, radio interface, numerous sensors and a rechargeable battery.

conventional flash RAM, the 64 kB FRAM in the MCU is very durable concerning memory access and highly energy efficient. The radio communication is performed by a low-power Sub-1 GHz transceiver TI CC1200 in the 868 MHz Band for Short Range Devices (SRD). In addition, the board includes sensors, which capture accelerations, temperature, color, infrared and ambient light, intended for energy harvesting research. Interaction with humans is possible using buttons and a small LCD.

The SSB can be programmed to work as an energy neutral device using energy harvesting. For this purpose, and also for generic battery management, we integrated an ultra low power harvester IC with boost charger and autonomous power multiplexer. It is designed to allow switching to an alternative energy source if the solar charged energy storage is depleted.

### IV. SOFTWARE COMPONENTS

To enable a rapid development of IoT applications in ultra low-power systems, we developed an IoT end device operating system *Kratos*. It supports developers with a comprehensive set of C++ library functions that can be “tailored” to suit the needs of a distinct application and thus can save resources by only deploying the required system components.

To support the modularization that is necessary for keeping an operating system highly configurable, we used AspectC++, a set of language extensions to facilitate aspect-oriented programming concepts into C and C++ [14], [15].

*Kratos* delivers interfaces to different system architectures and features a set of useful system properties like interrupt synchronization, preemptive thread scheduling, peripheral driver interfaces and power management mechanisms.

*Kratos* was mainly developed with PhyNetLab in mind, and hence fully supports the PhyNode platform. Furthermore, PhyNetLab and *Kratos* allow mutual research on hardware and software design for large-scale and energy-aware IoT deployments. By that, PhyNetLab gives us insights on how to design energy and network-aware software components for an operating system under heavy resource constraints. In the other direction, software requirements for enabling maintainability and the deployment of applications for PhyNetLab influenced the choice of hardware components used in the PhyNode.

The main focus of *Kratos* is on power management. Here, we developed methods to incorporate detailed energy models of all components of a system into the system drivers [16].

AP. The nodes were distributed in the PhyNetLab in such a manner, that each node can perceive the activity of any other PhyNode in the network. Therefore, the free channel assessment algorithm is not negatively influenced by hidden stations. Each measurement run consists of assigning the same product to a subset of the attached PhyNodes and ten polls for that product by the AP. As soon as a PhyNode receives a matching poll message for the assigned product, it replies the call with its address and the contained amount with respect to the clear channel assessment procedure described in Sec. V. The remaining PhyNodes perform no transmissions during the run. All participants in the network count the number of successfully received and sent messages on their side and transmit those statistics to the AP after each run. The statistics also include the accounted energy of the radio transceiver, as explained in Sec. IV. For comparability, each run comprises an interval of 11.75 s, hence does not depend on the number of exchanged messages. The interval is encapsulated by broadcast messages for starting and stopping a run. These messages are required, because statistics and setup messages of the PhyNodes are exchanged over the same link as the performance runs but must be excluded from statistics in this series of measurements. Therefore, each PhyNode resets its statistics and accounted energy when receiving a start message and freezes the values after receiving a stop message.

## VII. EVALUATION AND RESULTS

In this section we evaluate the measurements from the application example in Sec. VI, which challenged the ETSI collision avoidance algorithm of the radio interface during product polls to the warehouse. These product polls, which are transmitted as broadcasts by the AP into the network, trigger instantly numerous PhyNodes to transmit a reply message. Fig. 4 shows the achieved packet throughput  $T$  during the measurements. It is defined as the ratio

$$T = \frac{N_{RX}}{\sum_A N_{TX}}, \quad (1)$$

where  $N_{RX}$  is the number of successfully received messages by the AP and  $N_{TX}$  is the number of transmitted packets by each PhyNode from the active set  $A$ .

The algorithm performs very efficient for low numbers of concurring devices and enables a throughput above 80 % in case of 8 or less devices. In the range of 1 to 17 devices the throughput behaves nearly linearly and undercuts 50 % in case of 17 devices. Higher numbers of simultaneous attempts have only a negligible effect on the throughput, which stays nearly constant at a level of 50 %.

While this degree of throughput is typically not acceptable in a common communication system, it is still reasonable in the addressed logistics scenario. Considering, i.e., an incoming order for a particular product stored in the warehouse, where numerous containers comprise many entities of the demanded product, it is not necessarily required to receive all replies. Instead, it might be sufficient that *enough* containers reply to satisfy the demanded amount. Otherwise the poll could be

Fig. 4. Performance of the ETSI SRD collision avoidance algorithm in case of massive simultaneous replies to a broadcast message (poll for a particular product in the warehouse). With an increasing number of concurring transmission attempts, the packet throughput decreases due to more collisions.

Fig. 5. Energy consumption of the radio interfaces of active PhyNodes in the presented scenario. Each sample reflects the energy consumption of one radio for receiving 11 packets and transmitting 10 replies within 11.75 s.

repeated and uncover further containers, which suffered of a collision in the first place.

More critical is the impact of congestions on the energy consumption of the PhyNodes, which is shown in Fig. 5. In case of a single replying device, which reflects the minimum required energy for a test run, the radio interface consumes in average 57 mJ. By adding one additional device, the average energy consumption of each device more than doubles to 123 mJ. This is caused by a significantly higher amount of time spent in active receive mode: A device needs to wait in receive mode until a preceding transmission finishes plus the required back-off interval. The other way round, a device that already transmitted its packet and falls back into low-power listening mode will be waked up by the replies of the remaining devices. Although the transceiver's logic discards those packets very quickly due to a mismatching address, the transceiver still spends much more time in active receive mode.

With an increasing number of concurring replies, the energy consumption of all devices raises to 1030 mJ in average for 38 active devices, which is an increase by factor 18. In addition, the deviation of the energy consumption increases as well. This is caused by the varying time instant, where the device

finally transmits its packet. If a device sends its packet very late by repeatedly hitting a large back-off interval during the contention phase, its transceiver continuously stays in an active receive mode to keep track of the ongoing transmissions. Conversely, if the transmission succeeds quickly, the devices can fall back into low power listening mode and save energy.

The results show, that the standardized ETSI collision avoidance algorithm may conform to the requirements of a logistics scenario in terms of sufficient throughput, but the large impact on the energy consumption of all devices in the network cannot be neglected for this use case. Hence, the distributed channel access brings great potential for optimizations. For example, devices could send their replies on a different channel and use a blind back-off mechanism, which shuts down the receiver during the back-off period. We will elaborate and evaluate those approaches in future works with the help of PhyNetLab.

### VIII. CONCLUSION

In this paper we presented PhyNetLab, an IoT testbed which enables a real-life evaluation of future smart logistic approaches with wireless connected containers (PhyNodes). The scope of this paper focused on the evaluation of common channel access approaches for radio communications in such an industrial IoT deployment. For this purpose, we implemented a radio-interface driver, which conforms to the ETSI specification for clear channel assessment of Short Range Devices (SRD). The driver is integrated in a novel embedded operating system *Kratos*, which highly customisable and includes efficient mechanisms for energy management and energy accounting of distinct peripheral components.

On this basis we performed a throughput and energy analysis of a realistic logistics application in the presented testbed, which is polling for a particular product in a warehouse. We showed, that synchronous replies of many PhyNodes to a single poll challenge the channel access algorithm and the energy demand of the entire network. Although the packet loss rate reaches 50 % at high numbers of replying PhyNodes, it is still acceptable for this use case, as long as the number of replies satisfies the demanded amount of goods. But the resulting *storm* of numerous reply packages leads to a significant increase of energy consumption of every single PhyNode in the network. This is caused by frequent wake ups of the radio chip due to radio channel activity and a larger listening period while waiting for a clear channel assessment. Therefore, such deployments as smart warehouses cannot rely on commonly established approaches for radio communication, but rather need specialised solutions for this application.

In future work we will incorporate the PhyNetLab to develop and validate more energy-efficient communication protocols, which satisfy the demands for scalability, extreme energy-efficiency, and a reasonable latency.

### ACKNOWLEDGMENT

Part of the work on this paper has been supported by Deutsche Forschungsgemeinschaft (DFG) within the Collaborative Research Center SFB 876 "Providing Information by Resource-Constrained Analysis", project A4.

**Abstract**—The efficient and timely distribution of freight goods is critical for supporting the demands of modern urban areas. Optimum freight ensures the survival and development of urban areas. In the contemporary logistic there are two main distribution strategies: direct distribution and multi-echelon distribution. In the direct distribution, means of transport, starting from the main distribution center, bring their freight directly to the delivery points, while in the multi-echelon systems, freight is delivered from the main distribution center to the delivery points through intermediate points (local warehouses, satellites).

This study presents a concept and implementation of a integrated approach to modeling and optimization the Multi-Echelon Systems. In the proposed approach, two methods of constraint logic programming (CLP) and mathematical programming (MP) were integrated and hybridized. The proposed hybrid approach will be compared with classical mathematical programming on the same data sets (known benchmarks) for illustrative multi-echelon model - Two-Echelon Capacitated Vehicle Routing Problem (2E-CVRP).

## I. INTRODUCTION

THE transportation of goods and services expresses one of the main activities that influences trade, market, economy, and society as it assures a vital link between suppliers and customers. Today, one of the most important aspects which takes place in freight transportation is the definition of different shipping strategies. In the current freight transportation there are two main distribution strategies: direct distribution and multi-echelon distribution. In the direct distribution, means of transport, starting from a source (the main distribution center, depot), bring their freight directly to the delivery points while in the multi-echelon systems, freight is delivered from the source to the delivery points through intermediate points (warehouses, satellites etc.).

Nowadays, multi-echelon systems have been introduced in different areas and issues:

- Urban and city logistics.
- Multimodal freight distribution.
- Different types of supply chains.
- E-commerce and home delivery distribution.
- Postal and courier services.

The overwhelming majority of formal models of optimization in distribution goods and city logistics have

been formulated as the integer programming (IP), integer linear programming (ILP), or mixed integer linear programming (MILP) problems and solved using the OR-based methods. Most often used mathematical programming (MP) [1].

MP-based approach has some weaknesses. First of all, for the real size discrete optimization problems, it is time consuming and requires a lot of system resources (memory, processors, etc.). Secondly, it only allows modeling integer, binary and linear constraints [2].

This paper proposes the concept of a hybrid approach (where two approaches of constraint logic programming (CLP) and mathematical programming (MP) were integrated) to modeling and optimization of multi-echelon systems. The illustrative example shows the potential, efficiency and flexibility of this approach.

## II. MULTI-ECHELONS TRANSPORTATION SYSTEMS

The hierarchical level in terms of distribution strategies is the way the freight goes to the delivery point. When the freight arrives to delivery point without changing means of transport unit, a direct shipping or single-echelon strategy is applied, whereas when freight is derived from its source (depot) to its final destination passing through intermediate points (satellites, warehouses), where the freight is unloaded, then loaded into the same or into a different means of transport unit, we can speak of a multi-echelon system. Especially in transportation, it is not always possible or comfortable to deliver the goods directly to the delivery point. In fact, some transportation systems use intermediary points (warehouses, distribution centers) where some operations (packing, palletizing, etc.) take place. The different means of transport unit that belong to these systems stop at some of these intermediate points, and in some cases the freight changes means of transport unit or even mode of transport. Moreover, some additional services, like palletizing, packaging, labeling, re-packing etc., can be realized at these intermediary points. One of the basic problems in such systems (multi-echelon) is Vehicle Routing Problem (VRP). The VRP is used to design an optimal route for a fleet of vehicles/means of transport units to service a set of customers' orders (known in advance), given a set of

different type of constraints. The VRP is the NP-hard type. There are several variants of VRP like VRP with Time Windows (VRPTW), the capacitated VRP (CVRP), and Dynamic Vehicle Routing Problems (DVRP), Two-Echelon Capacitated Vehicle Routing Problem (2E-CVRP) is a multi-echelon variant of CVRP etc. [2,3,4].

### III. HYBRID APPROACH

Based on literature [5,6,7] and previous studies [8,9,10] was observed some advantages and disadvantages of both CLP-based and MP-based approaches. An integrated approach of constraint logic programming (CLP) and mixed linear integer programming/integer linear programming (MILP/ILP) can help to solve optimization problems which was impossible to solve with either of the two methods alone [11,12]. Although Constraint Logic Programming (CLP) and Operations Research (OR) methods like MP have different roots, the links between the two environments have grown stronger in recent years [11]. CLP and MP environments involve decision variables and constraints imposed on them. However, the types of the decision variables and different types of constraints that are used, and the way the constraints are represented, modeled and solved, are quite different in the two environments [10]. MP-based environments are based entirely on linear equations and inequalities, i.e., there are only two types of constraints: linear (linear inequalities or equations) and integrity (stating that the decision variables have to take their values in the binary and integer numbers). In CLP-based environments in addition to linear inequalities and equations, there are various other constraints: disequalities, nonlinear, logic and symbolic such as *cumulative()*, *ordered()*, *alldifferent()*, *sequence()*, *disjunctive()*, etc. In both MP-based and CLP-based environments, there is a group of constraints that can be solved with ease and a group of constraints that are difficult to solve. The easily solved constraints by MP methods are linear inequalities and equations over rational numbers. Integrity constraints are difficult to solve using MP algorithms such as branch-and-bound, branch-and-cost and cutting plane if the size of the problem is large. In CLP, domain constraints with integers and equations between two variables are easy to solve. The inequalities and general linear constraints (more than two variables), and symbolic constraints are difficult to solve. Taking all the above features of both approaches (MP and CLP), which in many areas complement each other, conducted research on how to integrate them. Several scenarios of their integration have been studied and reported in the literature [11].

Taking into account these studies and experiences with both environments, a hybrid approach has been proposed for modeling and solving multi-echelons problems.

- Main assumptions of the proposed hybrid approach were as follows:
- Integration of CLP and MP environments following the schedule proposed by the author;

- Use of strong points and compensation of weak points in terms of problem modeling and optimization revealed in both environments;
- Problem data representation in the form of sets of facts with a suitable structure based on the relational model [13];
- Introduction of model transformation as a presolving method;
- Substantial reduction of the feasible solution space for the post-transformation models;
- Automatic generation of implementing models and their translation into the MILP/ILP form.

Figure 1 presents the general concept of the hybrid approach implementation as an implementation platform. The hybrid approach comprises several phases: modeling, presolving, generating and solving. It has two inputs and uses the set of facts. Inputs are the set of constraints and the objectives to the reference model of a given problem. Based on them, the primary model of the problem is generated as a CLP model, which is then presolved. The built-in CLP method (constraint propagation [5,7]) and the method of problem transformation designed by the authors [8,9] (Section III.A) are used for this purpose. Presolving procedure results on the transformed model  $CLP^T$ . This model is the basis for the automatic generation of the MILP (Mixed Integer Linear Programming) model, which is solved in MP (with the use of an external solver or as a library of CLP).

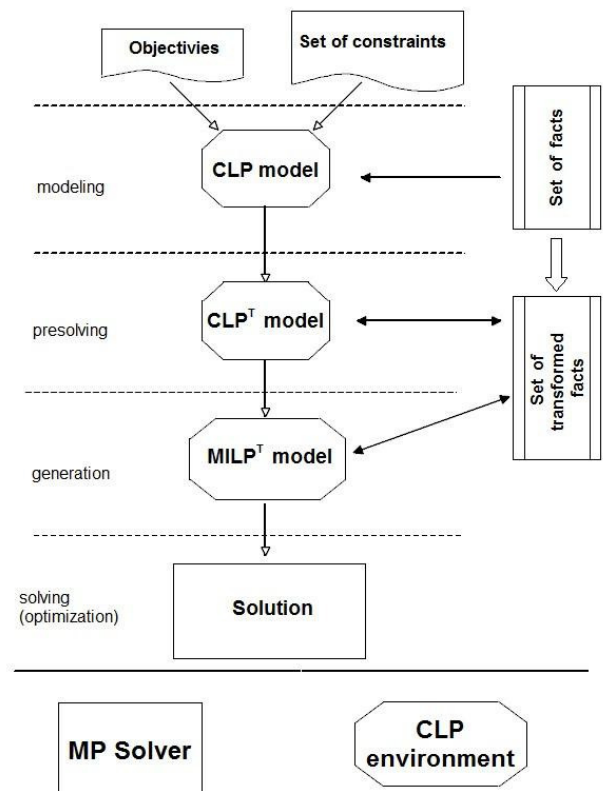

Fig. 1 A concept of a hybrid approach as an implementation platform

The general concept of hybrid approach as an implementation platform consists in modeling and presolving of a problem in the CLP environment with the final solution (optimization) found in the MP environment. In all its phases, the platform uses the set of facts having the

structure appropriate for the problem being modeled and solved (see Figure 2 for illustrative problem). The set of facts is the informational layer of the implementation platform, which can be implemented as database, XML files, etc. Description of the facts has been shown in Appendix A

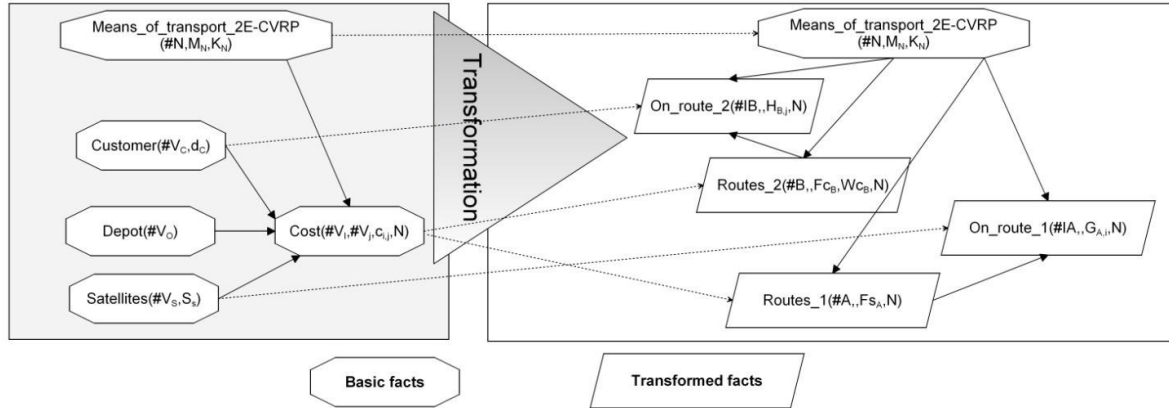

Fig. 2 A structure of facts for illustrative problem (2E-CVRP)

#### A. Transformation of the problem-presolving phase

The presolving phase is an important element of this approach as it makes it possible to simplify the model for the problem being solved and to reduce the problem search space. For the presolving phase to be effective, unfeasible combinations of model dimensions (indices) have to occur. In practice, unfeasible combinations of the index of decision variables and/or facts occur. The proposed platform uses constraint propagation and transformation for the presolving procedure. Constraint propagation is a concept and method that appears in constrained-based environments. Constraint propagation embeds any reasoning which consists in explicitly forbidding values from some variable domain of a problem, because all constraints can not be satisfied otherwise [5,7].

In the case of the illustrated problem presented, the transformation consisted in changing the problem representation from graph to routing. Instead of analyzing all possible transport connections from the source to the intermediate points and then from the intermediate points to the delivery points, only the feasible connections (source-intermediate point-delivery point) were generated and named routes. This resulted in the removal of certain indices and in the aggregation of other indices for decision variables, parameters, etc., which eventually led to the reduction in the number of decision variables and constraints [8,9,14]. The new set of decision variables, constraints and facts was the basis for creating the  $\text{CLP}^T$  model.

#### IV. ILLUSTRATIVE EXAMPLE – TWO-ECHELON VEHICLE ROUTING PROBLEM (2E-CVRP)

Possibility of using hybrid approach to modeling and optimization of multi-echelon systems is shown for the illustrative example. A good illustrative example of a multi-echelon system is 2E-CVRP. The Two-Echelon Capacitated Vehicle Routing Problem (2E-CVRP) is an extension of the

classical Capacitated Vehicle Routing Problem (CVRP) where the delivery source-delivery points pass through intermediate points (called satellites). As in CVRP, the goal is to deliver goods to delivery points (retailers, customers, etc.) with known ordered demands, minimizing the total delivery cost in the fulfillment of vehicle capacity constraints. Multi-echelon systems presented in the literature such as 2E-CVRP usually explicitly consider the routing problem at the last level of the transportation system, while a simplified routing problem is considered at higher levels [4,15].

In 2E-CVRP, the freight delivery from the source (depot) to the delivery points is managed by shipping the freight through intermediate points (satellites). Thus, the transportation network (Figure 3) is decomposed into two levels: the 1st level connecting the source point/depot (d) to intermediate points/satellites (s) and the 2nd one connecting the intermediate points/satellites (s) to the delivery points/customers (c). The objective is to minimize the total transportation cost of the vehicles involved in both levels. Constraints on the maximum capacity of the vehicles and the intermediate points are considered, while the timing of the deliveries is ignored.

Fig. 3 Sample transportation network for 2E-CVRP

### A. Mathematical model for 2E-CVRP

The formal mathematical model for 2E-CVRP in the form of MILP was taken from [4]. Table I shows the parameters and decision variables of the model. Figure 3 shows sample transportation network for 2E-CVRP.

TABLE I  
SUMMARY INDICES, PARAMETERS AND DECISION VARIABLES

Symbol	Description
<b>Indices</b>	
$n_s$	Number of intermediate points (warehouses, distribution centers, etc.)
$n_c$	Number of delivery points (retailers, shops, etc.)
$V_0=[v_0]$	Source (main distribution center)t
$V_s=\{v_{s1}, v_{s2}, \dots, v_{sn}\}$	Set of intermediate points
$V_c=\{v_{c1}, v_{c2}, \dots, v_{cn}\}$	Set of delivery points
<b>Parameters</b>	
$M_1$	Number of the means of transport unit (i.e. vehicles, trucks, etc.) (1st-level )
$M_2$	Number of the means of transport unit (i.e. vehicles, pick-ups) (2nd-level )
$K_1$	Capacity of the means of transport unit for the 1st level
$K_2$	Capacity of the means of transport unit for the 2nd level
$d_i$	Order quantity by customer $i$
$c_{i,j}$	Time /Cost of the arc $(i,j)$
$s_k$	Cost of unloading/loading procedure of the means of transport unit in intermediate point $k$
<b>Decision variables</b>	
$X_{i,j}$	An integer decision variable (the 1st-level) routing is equal to the number of means of transport units (1st-level) using arc $(i,j)$
$Y_{k,i,j}$	A binary decision variable (the 2nd-level) routing is equal to 1 if a (2nd-level) means of transport unit makes a route starting from intermediate point $k$ and goes from node $i$ to node $j$ and 0 otherwise
$Q^1_{i,j}$	The freight flow arc $(i,j)$ for the 1st-level
$Q^2_{k,i,j}$	The freight arc $(i,j)$ where $k$ represents the intermediate point where the freight is passing through.
$Z_{k,j}$	A binary decision variable that is equal to 1 if the freight to be delivered to delivery point $j$ is consolidated in intermediate point $k$ and 0 otherwise

$$\min \sum_{i,j \in V_0 \cup V_s} (c_{i,j} \cdot X_{i,j}) + \sum_{k \in V_s} \sum_{i,j \in V_s \cup V_c} (c_{i,j} \cdot Y_{k,i,j}) + \sum_{k \in V_s} (s_k \cdot Ds_k) \quad (1)$$

$$\sum_{i \in V_s} X_{0,i} \leq M_1 \quad (2)$$

$$\sum_{j \in V_s \cup V_0, j \neq k} X_{j,k} = \sum_{i \in V_s \cup V_0, i \neq k} X_{k,i} \text{ for } k \in V_s \cup V_0 \quad (3)$$

$$\sum_{k \in V_s} \sum_{j \in V_c} Y_{k,k,j} \leq M_2 \quad (4)$$

$$\sum_{i \in V_c, j \in V_c} Y_{k,i,j} = \sum_{i \in V_c, j \in V_c} Y_{k,j,i} \text{ for } k \in V_s \quad (5)$$

$$\sum_{i \in V_0 \cup V_s, i \neq j} Q^1_{i,j} - \sum_{i \in V_s, i \neq j} Q^1_{j,i} = \begin{cases} Ds_j & j \text{ is not the depot} \\ \sum_{i \in V_c} -d_i & \text{otherwise} \end{cases} \text{ for } j \in V_s \cup V_0 \quad (6)$$

$$Q^1_{i,j} \leq k_1 \cdot X_{i,j} \text{ for } i, j \in V_s \cup V_0, i \neq j \quad (7)$$

$$\sum_{i \in V_s \cup V_c, i \neq j} Q^2_{k,i,j} - \sum_{i \in V_c, i \neq j} Q^2_{k,j,i} = \begin{cases} Z_{k,j} d_j & j \text{ is not a satellite} \\ -D_j & \text{otherwise} \end{cases} \text{ for } j \in V_c \cup V_s, k \in V_s \quad (8)$$

$$Q^2_{k,i,j} \leq k_2 \cdot Y_{k,i,j} \text{ for } i, j \in V_s \cup V_c, i \neq j, k \in V_s \quad (9)$$

$$\sum_{i \in V_s} Q^1_{i,V_0} = 0 \quad (10)$$

$$\sum_{j \in V_c} Q^2_{k,j,k} = 0 \text{ for } k \in V_s \quad (11)$$

$$Y_{k,i,j} \leq Z_{k,j} \text{ for } i \in V_s \cup V_c, j \in V_c, k \in V_s \quad (12)$$

$$Y_{k,j,i} \leq Z_{k,j} \text{ for } i \in V_s, j \in V_c, k \in V_s \quad (13)$$

$$\sum_{i \in V_s \cup V_c} Y_{k,i,j} = Z_{k,j} \text{ for } k \in V_s, j \in V_c, i \neq k \quad (14)$$

$$\sum_{i \in V_s} Y_{k,i,k} = Z_{k,j} \text{ for } k \in V_s, j \in V_c, i \neq k \quad (15)$$

$$\sum_{i \in V_s} Z_{i,j} = 1 \text{ for } j \in V_c \quad (16)$$

$$Y_{k,i,j} \leq \sum_{l \in V_s \cup V_0} X_{k,l} \text{ for } k \in V_s, i, j \in V_c \quad (17)$$

$$Y_{k,i,j} \in \{0,1\}, Z_{k,l} \in \{0,1\} \text{ for } k \in V_s, i, j \in V_s \cup V_c, l \in V_c \quad (18)$$

$$X_{k,j} \in Z^+ \text{ for } k, j \in V_s \cup V_0 \quad (19)$$

$$Q^1_{i,j} \geq 0 \text{ for } i, j \in V_s \cup V_0; Q^2_{k,i,j} \geq 0 \text{ for } i, j \in V_s \cup V_c, k \in V_s \quad (20)$$

$$Ds_k = \sum_{l \in V_c} (d_j \cdot Z_{k,j}) \text{ for } k \in V_s \quad (21)$$

The objective function (1) minimizes the sum of the handling operations and transport costs (according to the individual arcs of the route). Constraint (3) ensures, for  $k=V_0$ , that each 1st-level route begins and ends at the source point, while when  $k$  is a intermediate point, impose the balance of means of transport units entering and leaving that point. Constraint (5) specifies that each 2nd-level route to begin and end to one intermediate point and the balance of means of transport units entering and leaving each delivery point. The number of the routes in the 1-st and 2-nd levels must not exceed the number of mode of transport units for that level, as forced by constraints (2) and (4). The flows balance on each network node is equal to order quantity of this node, except for the source point, where the exit flow is equal to the total order quantity of the delivery points, and for the intermediate points at the 2nd-level, where the flow is equal to the order quantity (unknown) assigned to the

intermediate points which ensure constraints (6) and (8). Moreover, constraints (6) and (8) forbid the presence of sub-routes not containing the source or a intermediate point, respectively. In fact, each node receives an amount of flow equal to its order quantity, preventing the presence of sub-routes. The capacity constraints are formulated in (7) and (9), for both levels. Constraints (10) and (11) do not allow residual flows in the routes, making the returning flow of each route to the source (1st-level) and to each intermediate point (2nd-level) equal to 0. Constraints (12) and (13) indicate that delivery point  $j$  is served by a intermediate point  $k$  ( $Z_{kj}=1$ ) only if it receives freight from that intermediate point ( $Y_{ki,j}=1$ ). Constraint (16) assigns each delivery point to one and only one intermediate point, while constraints (14) and (15) indicate that there is only one 2nd-level route passing through each delivery point and connect the both levels. Constraints (17) allow to start a 2nd-level route from a intermediate point  $k$  only if a 1st-level route has served it. Constraints from (18) to (20) result from the character of the MP-formulated problem. Constraint (21) determines transshipment volume for satellite Vs.

### B. Mathematical model for 2E-CVRP after transformation

The most important feature that characterize the hybrid approach is the presolving phase. The presolving is usually used to reduce the size of the problem (the number of decision variables and constraints), what results in an increase in the effectiveness of the search for a solution.

In hybrid approach, the main method of presolving is model transformation. In this case the transformation is based on the transition from arc to the route notation (Section III.A). During the transformation the TSP - traveling salesman problem is repeatedly solved and only the best routes in terms of costs are generated. In the process of transformation, the capacity vehicles constraints and those resulting from the set of orders are taken into account at both first and second level. Transformation is also subject to a set of facts describing the problem. The obtained model after the transformation (TC1)..(TC9) has different decision variables (Table II) and different constraints than those in the (1)..(24). Some of the decision variables are redundant; other variables are subject to aggregation. This results in a very large reduction in their number. The transformation also reduces or eliminates some of the constraints of the model.

$$\min \sum_{a=1}^W (Z_a \cdot F_{S_a}) + \sum_{b=1}^F U_b \cdot F_{C_b} \quad (TC1)$$

$$\sum_{b=1}^F U_b \leq M_2 \quad (TC2)$$

$$\sum_{b=1}^F U_b \cdot H_{b,j} = 1 \quad \forall j = 1..n_c \quad (TC3)$$

$$\sum_{b=1}^F U_b \cdot H_{b,i} \cdot W_{C_b} = \sum_a^W X_a \cdot G_{a,i} \quad \forall i = 1..n_s \quad (TC4)$$

$$\sum_{i=1}^{n_s} \sum_{b=1}^F U_b \cdot H_{b,i} \cdot W_{C_b} = \sum_a^W X_a \quad (TC5)$$

$$Z_a \cdot K_1 \geq P_{S_a} \quad \forall a = 1..W \quad (TC6)$$

$$\sum_{a=1}^W Z_a \leq M_1 \quad (TC7)$$

$$U_b \in \{0,1\} \quad \forall b = 1..F \quad (TC8)$$

$$Z_a \in C \quad \text{for } a = 1..W \quad (TC9)$$

TABLE II  
SUMMARY INDICES, PARAMETERS AND DECISION VARIABLES FOR  
TRANSFORMED MODEL

Symbol	Description
<i>Indices</i>	
$n_s$	Number of intermediate points (warehouses, distribution centers, etc.)
$n_c$	Number of delivery points (retailers, shops, etc.)
$W$	Number of possible routes from source point to intermediate points (determined by CLP during transformation)
$F$	Number of possible routes from intermediate points to delivery points (determined by CLP during transformation)
$i$	Intermediate point index
$a$	Source point-intermediate point route index
$j$	Delivery point index
$b$	Intermediate point –delivery point route index
$M_1$	Number of the 1st-level means of transport units
$M_2$	Number of the 2nd-level means of transport units
<i>Input parameters</i>	
$W_{C_b}$	Total demand for route $b$ (determined by CLP during transformation)
$F_{S_a}$	Route $a$ cost (determined by CLP during transformation)
$F_{C_b}$	Route $b$ cost (determined by CLP during transformation)
$G_{a,i}$	If $i$ is located on route $a$ $G_{a,i}=1$ , otherwise $G_{a,i}=0$
$H_{b,j}$	If intermediate or delivery point $j$ is located on route $b$ $H_{b,j}=1$ , otherwise $H_{b,j}=0$
$K_1$	Capacity of the means of transport unit for the 1st level
<i>Decision variables</i>	
$Z_a$	If the tour takes place along the route $a$ from the route set generated for level 1, then $Z_a=1$ , otherwise $Z_a=0$
$U_b$	If the tour takes place along the route $b$ from the route set generated for level 2, then $U_b=1$ , otherwise $U_b=0$
<i>Computed quantities</i>	
$X_a$	Total demand for route $a$

## V. NUMERICAL EXPERIMENTS

For the validation of the proposed hybrid approach and the implementation platform, benchmark data for 2E-CVRP

was selected. The instances for numerical experiments were built from the existing instances for CVRP [16] denoted as E-n13-k4. All the instance sets can be downloaded from the website [17]. The instance set was composed with 1 depot, 12 customers and 2 satellites. The full set of instances consisted of 66 instances because the two satellites were placed over twelve customers in all 66 possible ways (number of combinations: 2 out of 12). Twenty instances were selected for the numerical experiments.

Numerical experiments were conducted for the same data in two runs. The first run was a classical implementation of model (1)..(21) and its solution in the MP-based environment (MP). In the next run the model (1)..(21) was transformed to (TC1)..(TC9) and solved in the proposed hybrid implementation platform (HYBRID). The calculations were performed using a computer with the following specifications: Intel(R) Core(TM) I3-2100, 2x 3,106GHZ RAM 8 GB.

The results are presented in Table III. As seen above, application of the hybrid approach reduced the calculation time needed to find the optimal solution from 3 to more than 50 times, depending on data instance, in relation to mathematical programming. For some examples, mathematical programming did not find the optimal solution in acceptable time.

The final stage of the research was to optimize Two-Echelon Capacitated VRP with Time Windows (2E-CVRP-TW). In literature, this problem is the extension of 2E-CVRP where time windows on the arrival or departure time at the satellites and/or at the customers are considered.

In our case, the time window is interpreted as a non-transient time of transport at the first and second levels (independently). This interpretation of the time window is of great practical significance, i.e. it defines, for example, the maximum working time of the driver (legal regulations), the transport time of the product (freshness), etc. In this case, the hybrid approach not only accelerated the calculations but enabled time windows to be introduced without the need to change the model. During the transformation, only those routes that fulfilled the condition imposed by the time window were accepted. The results obtained for different time window values for the selected data instances are shown in Table IV. In addition, the obtained results are illustrated by diagrams showing selected routes for E-n13-k4-20 instances without time windows and TW = 50 and TW = 60 (Fig. 4, Fig. 5 and Fig.6).

## VI. CONCLUSION

The effectiveness of the proposed hybrid approach results from the reduction of the problem space and using the best properties of both components – MP and CLP. The hybrid method (Table III) makes it possible to find optimal solutions in the shorter time. In addition to solving larger problems faster, the proposed approach provides virtually unlimited modeling options with many types of constraints.

Applying a hybrid approach to this type of problems also allows you to introduce a group of constraints such as different time windows, logic exclusion etc. without having to change the model itself.

Therefore, the proposed hybrid method is recommended for optimization multi-echelon distribution problems that have a structure similar to the illustrative model (Section IV). This structure is characterized by the constraints and objective function in which the decision variables are summed up.

Further work will focus on running the optimization models with non-linear and logical constraints, multi-objective, uncertainty etc. in the hybrid optimization platform. The planned experiments will employ proposed hybrid method for Two-Echelon Capacitated VRP with Satellites Synchronization, 2E-CVRP with Pickup and Deliveries and others VRP issues in logistic issues [18].

In addition, it is envisaged to include in future models the lead times [19,20]. In the course of further work on the hybrid approach, it is planned to use it for modeling and optimization of IoT processes [21].

## APPENDIX A

TABLE A1  
DESCRIPTION OF FACTS FOR 2E-CVRP

Name	Description
Means_of_transport_2 (#N, M <sub>N</sub> , K <sub>N</sub> )	A fact that describes a particular type of transport with ID #N, including: Information on the number of means of transport on 1-level and 2-level and their capacities.
Customer(#V <sub>C</sub> , d <sub>C</sub> )	A fact that describes the recipients, including information about their orders.
Depot(#V <sub>o</sub> )	A fact that describes the depot.
Satellites(#V <sub>s</sub> , S <sub>s</sub> )	A fact that describes the satellites.
Cost(#V <sub>i</sub> , #V <sub>j</sub> , C <sub>i,j</sub> , N)	A fact describing the distance between points (costs).
Routes_1(#A, F <sub>sA</sub> , N)	A fact describing routes from depot to satellites.
On_route_1(#A, G <sub>A</sub> , N)	The fact states which points are on the route_1
Routes_2(#B, F <sub>cB</sub> , F <sub>cB</sub> , N)	A fact describing routes from satellites to customers.
On_route_2(#B, H <sub>b</sub> , N)	The fact states which points are on the route_2

**Abstract**—The purpose of the article is to outline the futuristic vision of Industry 4.0 in intra-logistics by creating a hybrid network for research and technologies thereby providing a detailed account on the research centre, available technologies and their possibilities for collaboration. Scientific challenges in the field of Industry 4.0 and intra-logistics are identified due to the new form of interaction between humans and machines. This kind of collaboration provides new possibilities of materials handling that can be developed with the support of real-time motion data tracking and virtual reality systems. These services will be provided by a new research centre for flexible human-machine cooperation networks in Dortmund. By the use of various reference and experiment systems various real-time scenarios can be emulated including digital twin simulation concepts. Big data emerges as an important paradigm in this research project where all systems are made flexible in terms of networking for all the systems to consume the data produced and also to combine all the data to arrive at new insights using concepts from machine learning and deep learning networks. This leads to the challenge of finding a common syntax for inter-operating systems. This paper describes the design and deployment strategies of research centre with the possibilities and the design insights for a futuristic Industry 4.0 material handling facility.

## I. INTRODUCTION

FOR MANY YEARS, scientists focus on the new change of paradigm in the organisation and management of the whole value-added chain and the impact on the economy and society which are caused by Industry 4.0. With Industry 4.0, the technologies, services and methods used in industrial production and logistics are changing. Dynamic, real-time and self-organising value-added networks emerge, based on the availability of the relevant information in real-time through the networking of all parties involved in the entire value-added process and the interconnection of objects, humans and systems [1]

The technological base for the Industry 4.0 is formed by data networked production facilities, products and materials as well as transport technologies, which are equipped with sensors and decentralised IT intelligence. These intelligent cyber-physical systems (CPS), which are connected over the Internet, are able to autonomously organise, control and adapt the sequence of value-added processes and the corresponding logistical functions to external requirements. The current "tech-

nology push" in the design and introduction of autonomous CPS-based production systems, advancing digitisation, and automation lead to the development of new forms of services and work organisation [2]. This new forms of services with collaborative machines can be simulated to an extent but can only be understood deeply with a level of trust for adoption into industry when demonstrators are developed.

Thus, the change driven by Industry 4.0 is not predetermined, but can be shaped [2][3]. In addition to the question about the organisation of responsible and goal-oriented action in the human-machine interaction (HMI), there should be a need-oriented debate on the topic of hybrid services. A key factor for the successful transition to Industry 4.0 is the physical implementation of demonstrators and the execution of experiments in a realistic intra-logistics environment. This article describes one such demonstrator where experiments for scenarios of Industry 4.0 can be conducted. The requirements for such a research centre is discussed in section 2 giving a detailed account on conceptual description and the scientific objectives followed by surveying existing research centres in section 3. Section 4 describes all the systems that are deployed in the research centre with information about their flexibility and interoperability. Section 5 concludes the article with the summary of the systems deployed with the direct research goals arising because of the interoperability and collaboration of the systems.

## II. CONCEPTUAL DESCRIPTION AND SCIENTIFIC OBJECTIVE

In order to cope up with the dynamics and complexity increase and thus not to lose the competitive connection, companies have to increase the adaptability of their processes and business models [4]. It is necessary to generate adaptation measures that combine the advantages of technological innovations as well as human skills. In order to analyse and evaluate the efficiency potential of the emerging socio-technical systems, in Dortmund an interdisciplinary research project is initiated that is funded by the German Federal Ministry of Education and Research (BMBF) and entitled as "Innovationslabor - Hybride Dienstleistungen in der Logistik"

Fig. 1. Structural insight into the research centre

[5]. Decentralisation, networking and localisation form the three basic pillars of an efficient hybrid work environment. With these three pillars a lot of other virtual elements can be included in the research focus such as creating a digital twin [6].

This novel form of an interdisciplinary and cross-process research environment is intended to contribute, amongst others, to answer the following central scientific questions:

- Through the emergence of hybrid cooperation networks (HCN), in which humans and machines support and complement each other in a common work space, the question arises of how responsible, secure and purposive action can be designed and organised in the future HMI.
- On the one hand, the continuously increasing amount and complexity of data in the field of intra-logistics can lead to an additional burden on employees; e.g. in the form of demotivation or excessive demand. On the other hand, the available data can improve, among other things, the quality of employee decisions. Therefore it is essential to answer the question how the innate abilities of employees (such as creativity, motor skills, experience, intuition) can optimally be combined with the abilities of technical (assistance-) systems (e.g. for data evaluation or information visualisation).
- In answer to the research question how technical systems can perceive, analyse and evaluate their environment more intelligently, e.g. by means of big-data analysis or machine intelligence techniques, a contribution is to be made to increase their adaptability and their ability to interact with humans.
- The increasing networking and decentralised control of the entities in a HCN lead to the fact that the amount of data to be processed increases by a factor of 1000 per decade [7]. From this, the question of how the emerging data volume can be transmitted securely, wirelessly and in a system guaranteed time.

For research, to develop scenarios, use cases and experimental situations the research centre is furnished with flexible reference and experiment systems and their interoperability which is described in the following chapters with a survey of research centres that are used for deriving system requirements. A 3D

render of the research is shown in fig 1.

### III. SURVEY OF RESEARCH CENTRES

This section surveys existing systems in various research domains and to arrive at the system requirements for the research centre. As stated in conceptual description of the research centre, it is important to focus on localisation and navigation systems for the future logistics facilities. From the systems [8], [9], [10], [11], [12], [13], [14], [15], [16] and the publications using these systems, it is clear to use an optical localisation system that is capable to provide location data of objects in real time in 3D. From [12] and [13], it is clear to understand the communication characteristics of various wireless communicating entities is important. Due to the amount of usable data that can be gathered from radio communication and to acquire the data and process this data on the radio system, a radio reference system is proposed in the requirements of the research centre which is capable of multi-standard baseband processing [14]. These reference systems should run synchronised with the ability to acquire data from all the available systems. The requirements from the reference are gathered from these existing research centres and with the experiment systems being generated from a futuristic Industry 4.0 warehouse where a strong HMI takes place with IoT systems playing an important role in coordinating the logistics processes.

### IV. REFERENCE AND EXPERIMENT SYSTEMS IN THE RESEARCH CENTRE

#### A. Reference systems

1) *Optical reference system:* The motion tracking system is the north star for the research centre which is a real-time localisation system (RTLS). The RTLS system requires small markers to be attached to the objects that are being tracked and with a very minimum calibration effort, the objects can be tracked using the Tracker software provided by the camera manufacturer. This system is a reference system for providing location of the objects in a precision of less than half a meter guaranteed by the software with a limitation of 1 camera having direct line of sight of at least three markers attached to the object after calibration. There are 38 cameras over an area of 570 sq. m to track and localise all the objects i.e. markers within the area. The software also guarantees a maximum computation time for estimating the location in the 3D space which is less than a second. The software exposes application programming interface (API) that can be used as both query on demand or to have a stream of all the objects that are being tracked. Each tracker can be labelled in the software to get the data labelled accordingly when consumed by another application, this provides context to other inter-operating systems.

2) *Radio reference system:* A network of Software defined radios (SDR) equipped with an array of antennas is used for sensing, tracking and to analyse the wireless communication within the hall. All communicating devices within the range of DC to 6 GHz can be covered with each SDR. The bandwidth is

up to 120 MHz. Each SDR has a clock synchronisation signal which enables all the SDR to have the same clock frequency that algorithms like time-of-flight or time-difference-of-arrival can be performed in this network of SDRs and also with the experimental systems which have low cost transceivers that are not capable of doing such baseband computation. Since ultra-low power, low data rate wireless transceivers do not allow such flexibility, these devices help in analysing, developing and to benchmark various wireless protocols, localisation or proximity algorithms.

3) *Laser projection system*: A visual system to create virtual objects and to represent temporary markings within the research area is created using a laser projection system. This system is formulated as a augmented reality system with a laser projection system software that can be controlled using a user program to create visual representations by focusing fast moving laser with a distance of 1 to 8 meters. The laser projection system can be used as a guidance system for robots or to simulate augmented reality systems, for example, a traffic visualisation with virtual elements taking part in the simulation with physically moving robots.

4) *Virtual reality system*: To facilitate concepts such as digital twin, to extend a logistics facility in a physical dimension inside the virtual world and to simulate virtual components in a simulation and to quickly understand the implications of a scenario a virtual reality wall with millimetre precise markings are printed in a roll shutter of dimensions 200 sq. m which can be folded when not required for the experiment. The markings are used as reference markers for the virtual reality device camera to estimate the position, orientation and geometrically represent objects in the virtual world in correspondence to the physical world.

## B. Experiment systems

1) *Robot systems*: Mobile robot swarms and drone swarms complement to the complexity of diverse machines that will be put to use in an Industry 4.0 materials handling facility. These systems will be used for performing distinct experiments at scale that intrinsically provides a faster way to adapt in the industry. Therefore, industrial systems and research platforms that can mimic a materials handling facility is deployed using mobile racks with robots fitted with lifts that can carry the racks from point A to point B. These robots also have automatic charging stations which provide another dimension of resource planning into the process with limited number of available stations to charge. Drones are currently used in industry for inventory management and transport of valuable items in terms of money or for the process. Therefore, drones that are programmable used as research platforms are deployed which can perform tasks in coordination with humans and other machines within the facility.

2) *LR-WPAN and other wireless networks*: Wireless sensor networks (WSN) are a derived terminology of Internet of Things (IoT) which targets a specific kind of IoT devices that are low power, low data rate devices that are used for sensing physical parameters. This has been standardised as low

rate wireless personal area network (LR-WPAN) in the IEEE Standard. In a materials handling facility, there has been a lot of penetration of such devices that ease out the complexity of processes by providing functionality. Moreover, the data recorded during these operations are accurate without human error and are available real-time that they could be reliably used for predicting and forecasting the processes they are used in. A wireless sensor network with 550 nodes is deployed under the floor, 1 meter apart, across the research centre. Each sensor node is capable of communicating wirelessly in 868 MHz and 2.4 GHz frequency bandwidth in compliance with IEEE 802.15.4 PHY and MAC [14], [17]. Devices are connected to a bus that is used for programming, providing energy for their operation and to reset them individually. Each of the lines with 15 sensor nodes are connected to a computer that can be reprogrammed.

3) *Networked computational system*: The future of an Industry 4.0 material handling facility will highly rely on the data because of the autonomy of the elements. It does not only depend on the large amount of data that is produced, but also on the metadata that is being generated which gives context to the data and also the availability of the data within the system. To provide context and to provide the data to other systems as it is available, a networked computer with high bandwidth network controller is used for concurrent network connections.

## C. Systems Interoperability

The networked computational system is connected to the synchronisation clock signal from the radio reference system. The motion capturing system is also connected to the same clock signal. Since it is not possible for each cameras to synchronise its frames before post-processed in the tracker software, the data streamed from the SDK is timestamped with the system time in ticks of the synchronisation clock. The networked computer will consume all the data using various network communication standards. This data is then available as the latest data set of all existing systems in TCP/IP to be consumed by all other systems within the field. For example, the RTLS system data as latest received by the computer from the tracker will be made available for sensors and robots to be used in their individual planning algorithms.

Since, each system communicates with its own standards, the challenges for such a system lies in finding a common syntax for inter-operating systems which also provides guarantees for the time at which the data is available. Fig 2. shows all the reference systems and experiment systems that are connected in a network. This challenge also addresses the scenario of autonomous industrial systems collaborating within each other to complete a task or a job in a materials handling facility. A system bus with systems communication paradigms or a middleware software that converts different data sources and communication standards in a harmonised way will be a challenge while implementing the research centre and also in a real-time industrial use case.

### Research centre of the Chair of Materials Handling and Warehousing

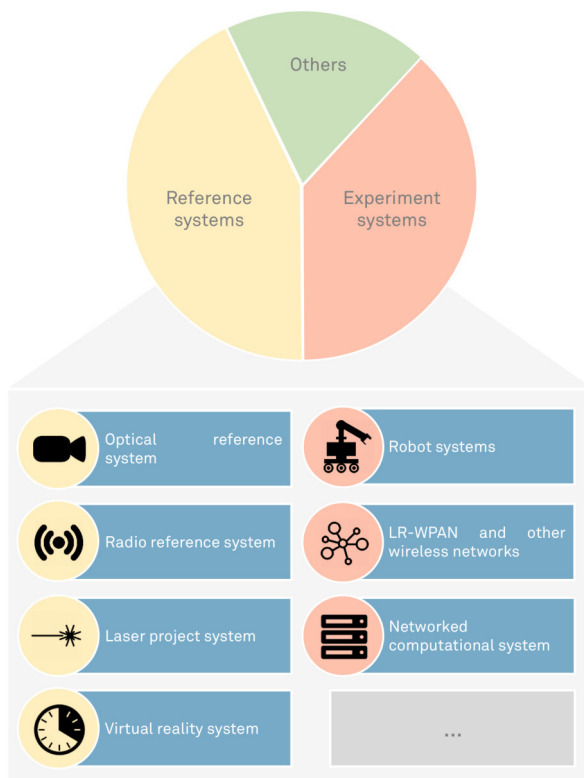

Fig. 2. Inter-operable systems at the Research Centre

### D. Conclusion

Industry 4.0 and IoT creates new forms of interaction of humans and machines. Based on CPS, a socio-technical work environment is created, in which humans and machines are in dialogue with each other and complete tasks together. The research project “Innovationslabor - Hybride Dienstleistungen in der Logistik” focuses on that new form of HMI. The novel success factor of the research centre is the interdisciplinary collaboration of logistics, IT, engineering, business as well as sociology experts.

The research centre will focus on creating decentralised logistics systems with emphasis on real-time localisation and navigation algorithms. It will also create new areas of development in HMI with emphasis on safety of the workers in the field when collaborating with the machines in the facility.

Through the emergence of HCN in materials handling where humans are supported by machines and machines complement each other in a common work space, this renders a very complex control system for logistics process control. To support in developing such a control system, the research centre is furnished with flexible reference systems and experiment systems.

### ACKNOWLEDGMENT

This article was made in cooperation with the following three projects:

“Innovationslabor - Hybride Dienstleistungen in der Logistik”, funded by the German Federal Ministry of Education and Research (BMBF)

“SFB 876, project A4 - Providing Information by Resource-Constrained Analysis”, funded by the German Research Foundation (DFG)

“Research Training Group 2193 “Adaption Intelligence of Factories in a Dynamic and Complex Environment”, funded by the German Research Foundation (DFG)

# Decision Support System for Robust Urban Transport Management

Piotr Wiśniewski, Krzysztof Kluza and Antoni Ligeza  
AGH University of Science and Technology  
al. A. Mickiewicza 30, 30-059 Krakow, Poland  
E-mail: {wpiotr, kluza, ligeza}@agh.edu.pl

**Abstract**—We present a decision support application which can be used for alternative route generation in case of tramway traffic disruptions. Our solution is based on a mixed graph network model, where vertices represent major points and edges are used to model track sections. The proposed application uses model data stored in a set of source files and enables the user to execute one of four algorithms which are useful for tramway traffic management in case of a crisis situation.

**Index Terms**—decision support, graph theory, robust traffic management, route planing, public transport, crisis management

## I. INTRODUCTION

**T**RAFFIC congestion, especially in the major cities, is constantly growing. Simultaneously, the environmental awareness level is becoming higher and higher. Thus, these two factors cause the increasing role of the public transport in our everyday. Optimized transportation services are considered as a significant factor that makes the city more effective for its inhabitants as well as business entities [1], [2]. Such situation can be observed primarily in urban agglomerations with the advanced traffic systems and the variety of public transportation.

However, even in such developed areas, the urban transport management entities have to deal with some crisis situations. There are many random factors or infrastructure conditions which cause specific crisis issues.

From the traffic management perspective, the extreme cases require an intervention of a traffic controller like emergency rerouting of vehicles. Incorrect or lack of the decision can cause instability in the whole traffic system with the consequence of financial losses.

European Commission in [3] also takes into account the problem of public transport continuity assurance. One of their thought-provoking example concerning the disruption of transportation system was the example the eruption of Eyjafjallajökull volcano in Iceland in April 2010.

This work constitutes a continuation of our previous work [4], which introduced a mixed graph-based mathematical model for public transport networks. Here, we extend our previous contribution by describing additional route generation algorithms and presenting a sample application that enables their use in practice. We focus on using our solution in the area of tramway transit, as this means of transport is more exposed to crisis situations compared to road traffic.

The paper is organized as follows. Section II presents the existing works referring to public transport management. In Section III, a graph-based network model used in the proposed solution is presented. In Section IV, the algorithms for route generation are described. Application details are presented in Section V, and its usage examples are shown in Section VI.

## II. RELATED WORKS

There are several areas related to the subject our research, such as road traffic analysis, graph theory or vehicle route planning. As ad-hoc re-planning in case of crisis situation often leads to deterioration of plan quality, a robust route planning for passenger vehicles in city traffic was proposed by Ernst [5]. His approach, similar to our solution, allows for real-time robust route planning [6]. Mandziuk and Nejman [7] proposed a method for generating optimal routes for vehicle drivers who need to reach their customers using tree search algorithm. Another work presents a solution of a Capacitated Vehicle Routing Problem using a Mixed Integer Linear Programming model [8]. Adamski [9], in turn, used stochastic processes for bus dispatching system. In [10], various types of decision support systems for vehicle fleet management were reported. In the context of a complex on-line control problem, one of such decision support system used in case of temporary railway track closures was presented in [11]. This approach combines the graphical power of Petri nets with the fuzzy sets which model rule-based expert system. Among the research concerned with optimal control of tramway networks, Blasum et al. [12] proposed three variants of solution for a problem of optimal tram scheduling in the morning – i.e. ordering tram assignments to departure. Winter and Zimmermann [13] extend this discussion on daily tram dispatching in localized depots.

## III. NETWORK MODEL

The model used as a basis for the proposed application combines the approaches where directed [14] and undirected [15] graphs are used to represent public transport systems. In this paper, a mixed graph-based model was used, where directed edges correspond to tracks on double track sections and undirected edges are used to represent bi-directional single tracks. Its simplified form is presented by formula 1.

$$G = (V, E), \quad (1)$$

where:

- $V$  is a finite set of vertices,
- $E = E_1 \cup E_2$  is a set of both directed and undirected edges.

All the edges are assigned a vector weight function  $\gamma$  which has non-negative values of the planed time of ride and section length, expressed in minutes and kilometers, respectively. It is specified by formula 2.

$$\forall e \in E, \quad \gamma(e) = \{t, l\} \quad (2)$$

Vertices of the graph correspond to selected decision points in the network, such as: track junctions, waiting points before single tracks, terminuses, parking tracks, initial stops, entrances or exits of a depot. As most of those points have a limited space for cars, a non-negative vertex capacity function  $C$ . Its values are integers expressed in units of measure or number of cars. The capacity function is given by formula 3. In order to identify terminuses a logical function  $\tau : V \rightarrow \{0, 1\}$  was defined. Its value is equal to 1 if the selected vertex is a terminus and 0 otherwise.

$$C : V \rightarrow \mathbb{Z}_{\geq 0} \quad (3)$$

In the first step of the model creation bi-directional track endpoints are connected with undirected edges while the other vertices are linked with directed edges regarding left-hand driving. An assumption is made that edges connecting two vertices within the area of one stop are given a zero-weight. The same rule applies to edges leading to single track sections.

In order to eliminate the error of changing car direction at an endpoint of a single track, the model definition contains a set of forbidden paths. A forbidden path is a path, whose any subsequence fulfills at least one of the following conditions:

- passing from one double-track section to another if there is an endpoint of a bi-directional track in between,
- entry to a single track section directly from an edge with a non-zero weight vector,
- if a vertex is an endpoint of an undirected edge and any other edge is chosen when generating path running through this vertex.

An example of a forbidden path is shown in Figure 1 which represents the "Ruda Południowa" passing loop, connecting two single track sections. According to this part of the network model there is a path designated by a sequence of vertices (2, 3, 4). In real tramway networks following this route with a car having only one driver cabin is not possible, as it would need a change of direction, which in this case is allowed only on a loop or a turning triangle.

Figure 1. Model of the passing loop "Ruda Południowa".

A tramway line is a set of paths between two vertices marked as terminuses. As the route may differ depending on the direction and time of the day, the notion of variant is used to describe a specific run. Let  $p(v_s, v_t)$  be a path from  $v_s$  to  $v_t$ , then a variant can be defined by formula 4.

$$w(v_s, v_t) = p(v_s, v_t) : \tau(v_s) = 1 \wedge \tau(v_t) = 1 \quad (4)$$

Therefore, a line is described as a set of variants marked by a specific number:

$$L(n) = \{w(v_s, v_t)\}, \quad n \in \mathbb{N}. \quad (5)$$

A train is a car or a set of cars in operation with respect to defined schedule or the orders of a traffic controller, running on a specific line or off-schedule. The solution proposed in this paper is applicable for planed trains which can be characterized by the following elements:

- 1) Train number (a line number concatenated with a running number in range 0-99).
- 2) Schedule, containing departure times from initial stops.

#### IV. SOLVING METHOD

When there is a need to temporarily close a section of the track, which corresponds to a removal of an edge in the graph model, a train approaching the blocked section has to be redirected to an alternative route. Therefore it is needed to solve a path generation problem, by finding the best destination point and the shortest route connecting with that vertex the current position  $v_p$  which can be estimated based on the timetable or using a vehicle positioning system [16]. This route is calculated using the modified Dijkstra algorithm that excludes forbidden paths during the search by assigning infinite distances to vertices reachable by such a path.

##### A. Route generation algorithm

The algorithm used in the application presented in this paper consists in generating a shortest path to each reachable terminus. Routes leading to terminuses whose capacity is exceeded are excluded from the search. The alternative route is selected by maximizing a profit function. If  $p_0$  is the subpath of the current variant, starting from vertex  $v_p$  then profit function  $Q$  is described by formula 6.

$$Q(p_0, p_a, p_c, v_a) = \frac{d(p_c) + \phi(v_a)}{|d(p_0) - d(p_a)|}, \quad (6)$$

where:

- $p_a$  is the calculated alternative path,
- $p_c$  is the common part of paths  $p_0$  i  $p_a$ ,
- $v_a$  is the terminus of  $p_a$ ,
- $d(p)$  is the length of path  $p$ ,
- $\phi(v) = 1$  if  $v$  is the terminus of  $p_0$  and 0 otherwise.

If two or more routes are assigned the same value of function  $Q$  the shortest one is chosen and if they have the same length, the one with a less occupied terminus is selected.

### B. Time of ride calculation

In real transport systems the actual time of ride may differ from the scheduled one. Minor delays happen usually in case of high traffic congestion, passenger exchange as well as weather conditions. However, more significant disruptions may occur if a train runs off-schedule on a route containing single track sections. In such a case, when calculating the time of ride between two decision points, it is needed to take into account the time spent for waiting at the entrance of each single track. The algorithm used to calculate time of ride  $t_p$  through route  $p$  which contains single tracks is as follows:

- 1) Set  $t_p = 0$  and  $t_0$  as current time.
- 2) Calculate scheduled time  $t_1$  to the nearest single track section. Set  $t_p = t + t_1$ .
- 3) Set  $t_2$  as the scheduled time of ride through the single track section. If there is a train on this section in time interval  $(t_0 + t_p, t_0 + t_p + t_2)$  then set  $t_p = t_p + 1$  and re-execute this step. Otherwise set  $t_p = t_p + t_2$ .
- 4) If there are no more single track sections on the route then calculate scheduled time of ride  $t_3$  until the end of the route and finish calculations setting  $t_p = t_p + t_3$ . Otherwise go back to step 2.

Using this method enables to estimate the real time of ride through a path, assuming that the train in the opposite direction runs without disruptions.

### C. Return algorithm

After removing the effects of a crisis situation and re-opening the blocked section it is necessary to put the re-routed trains on their original paths and return to scheduled operation as soon as possible. A method that calculates the return scenario for train  $n_p$  and point  $v_s$  at time  $t_0$ :

- 1) Find the nearest scheduled departure of train  $n_p$  from initial stop  $v_p$ .
- 2) Generate the shortest path from point  $v_s$  to  $v_p$  and calculate time of ride  $t_p$  to this vertex.
- 3) If the arrival at point  $v_p$  occurs after the scheduled departure of the next train departing from this point, then set  $v_p$  equal to the initial stop of the next departure after time  $t_0 + t_p$  and go back to point 2.
- 4) If the arrival at point  $v_p$  occurs after the scheduled departure of train  $n_p$  from this point or parking at point  $v_p$  is not possible (vertex capacity exceeded), then set  $t_0 = t_0 + t_p$  and go back to point 2.
- 5) Finish calculations. Train  $n_p$  is back to schedule at time  $t_0 + t_p$  at point  $v_p$ .

## V. APPLICATION

The aim of the created application is to support dispatchers in the process of tramway traffic management in case of operation disruptions caused by crisis situations. Usually the decisions being taken in such cases are based on the network knowledge and work experience of the dispatcher. Unified criteria of alternative route generations were not formulated, which can lead to long lasting disturbances in urban transport

circulation. The proposed system can be operated by one user, who works as a dispatcher and manages the tramway traffic within a designated area. People employed on this post are characterised by very good level of network knowledge, but in general they are not accustomed to use advanced computer tools. Moreover, there are often cases when disturbances occur in two or more places at the same time and that requires constant attention as well as contact with drivers and traffic control services. Therefore the decision support system for dispatchers needs to be simple and efficient, and provide a clear interface that demands from its user only data necessary for problem solving. The main requirement that was formulated for the application was the possibility to run it in various environments, without the necessity to use any specific equipment or dedicated software. Therefore source files should be saved in an open format which enables easy editing.

### A. Usage scenarios

According to previous assumptions made in this section only one user is needed in the application and this person uses it on their workstation only. Therefore user authentication was excluded from the scope making the assumption that the user logs into their account in the operating system. The following usage scenarios were proposed for the application:

- display network information: decision points and section parameters,
- localize train on the route,
- generate alternative route for a train when a certain section is blocked,
- return to the schedule.

### B. Data flow analysis

The input of the application is data inserted by the user and network model files. During the design phase a decision was made not to use an external database with complete network information. The reason for that decision was the simplification of the system. The assumption was made that the network model is uploaded to the system in form of source files during start-up. This solution is not optimal regarding operating memory usage, but enables the program to run without the necessity to maintain connection with a database server. A simplified data flow diagram [17], representing the proposed system's inputs and outputs was shown in Figure 2. Inbound data were marked with blue color while outbound data (information shown on the screen and logs saved to file) was marked with green color.

According to the diagram presented in Figure 2 inbound and outbound data are:

- 1) Selected function and, according to the scenario:
  - a) section or decision point ID,
  - b) train number and current time,
  - c) train number, blocked section ID, current time,
  - d) train number, train location, current time.
- 2) Model files: graph details, route list and schedules.
- 3) User information, according to the scenario:

- a) section or decision point parameters,
  - b) train location and direction,
  - c) recommended alternative route and return path,
  - d) recommended direction and estimated time of the return to schedule
- 4) Logs generated by the application and saved to a text file.

### C. Proposed solution

A sample application was created in the widely used Java language, using the IntelliJ IDEA 14.1.1 and Java SDK 1.8 package. Graphical user interface was made using Java Swing library. The network was modelled using JUNG library (*Java Universal Network/Graph Framework*) [18], dedicated to represent both directed and undirected graph. The created model described in section III was implemented using *SparseGraph* which allows to perform operations on mixed graphs. This class enables the programmer to define vertices and edges as objects and contains methods that enable to:

- specify edge type (directed or undirected),
- determine vertices incident to the selected edge,
- determine the edge connecting two vertices,
- determine successors of a vertex.

Regarding the large number of parameters, presented in section III, vertices and edges of the network graph were defined as classes. Distances in kilometers are represented as decimals and time of ride is represented as integer and expressed in minutes, which is a dominant unit in public transport scheduling [19]. Additional classes were created also to represent trains and tramway lines. Variants of the latter, as well as other paths corresponding to tramway routes used in the system, are represented as lists of vertices IDs.

The length of tramcars used in Europe can be estimated between 10 and 55 meters [20], [21]. Therefore the capacity of vertices was expressed as integer in range 0-3, where one unit corresponds to 17 meters. A zero capacity was set in case when stoppage is not allowed at the selected point.

### D. Model files

Information about the tramway network mathematical model are stored in four CSV files, each of which is used to create objects of the corresponding class. In order to use the application without errors it is necessary to define the following files:

Figure 2. Simplified data flow diagram.

- 1) File *vertices.csv* which holds information about graph vertices. Columns: vertex ID, vertex name (8 characters), description, capacity, information, if the vertex is a terminus.
- 2) *edges.csv* stores information about graph edges. Columns: start vertex ID, end vertex ID, description, capacity, scheduled time of ride, length, information if the edge is undirected. During the upload of model files each edge is assigned a unique number, which is a concatenation of its endpoints IDs, and a 17-character name in form of its endpoints names connected by a dash. In case of an undirected edge the vertex with a lower ID is used at first.
- 3) *lines.csv* stores information about tram lines. Columns: line number, variant number, description, vertices on the route (one ID per column).
- 4) *tramcars.csv* stores information about trains and timetables. Adding a new train is executed by inserting the keyword *new* in a new row, along with the train number and vehicle type. The following vertices determine the timetable. Columns: departure time, variant number.

First row of every source file is a legend for used columns and is omitted during data upload. Part of the file *lines.csv* containing the definition of line "0" and its four variants is presented in Figure 3.

	A	B	C	D	E	F	G	H	I	J	K	L
1	ID	Variant	Description	Vertices...								
2	0	0	RKT - Pl. Wolności	702	704	709	6001	6003	6012	6005		
3	0	1	Pl. Wolności - Stadion	6005	6013	6004	6019	6021	6023	6025	6027	6029
4	0	2	Stadion - Pl. Wolności	6029	6030	6028	6024	6022	6020	6003	6012	6005
5	0	9	Pl. Wolności - RKT	6005	6013	6004	6002	710	703	701		

Figure 3. Source file with line definitions, opened in a spreadsheet editor.

## VI. USAGE EXAMPLES

The application has a form of an executable JAR file which can be successfully run in Windows (7 or higher) as well as Linux (Ubuntu 14 or equal) environment. Application window is presented in Figure 4. Each of the usage scenarios is represented by a separate button.

Functionalities of the proposed application were tested using a model representing the central part of Upper-Silesian tramway network, which is the largest tramway system in Poland [22]. The test model is a mixed graph containing 135 vertices and 187 edges, 19 of which are undirected.

### A. Network Information

Pressing the button *Network Information* executes the function which returns current information about the selected point or section. A pop-up window with input fields for current time and section/point ID appears on the screen. A sample result presenting section parameters and its occupancy was presented in Figure 6.

In *TramLogs.txt* file simplified logs, which contain information about the results of a query, are saved. Full point and section descriptions were replaced with their short names having 8 and 17 characters respectively (see section V-D for details).

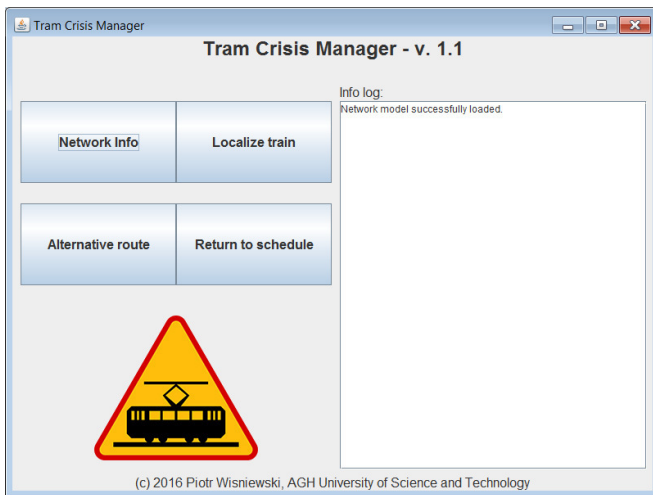

Figure 4. Initial window of the application run in Windows environment.

Figure 5. Network information data input.

### B. Train location

Train location is verified after pressing the appropriate button. The result is a point or section where the selected train is situated in the inserted time. In addition the user is informed about the line number and direction. In case of trains which are included in the list but are out of service, their depot is displayed as the current location.

### C. Alternative route generation

The most important functionality of the application which is alternative route generation is executed by pressing the *Alternative Route* button. The user is asked for traffic disruption time and the train number, for which the route will be generated, as well as for ID of the blocked section. As a response the user is given a list of decision points for the generated route, its length and the estimated time of ride calculated regarding other vehicles moving on this route. In the next step a return path to the original route is recommended. Its departure time is equal to the arrival time on the selected terminus, if it is empty or to the departure of the last train that was stationing on this terminus.

A practical example of the application utility is as follows: it was admitted that on Saturday at 12:10 PM there was a collision of a tramway with a passenger car on a rail crossing in the city center of Katowice. The car is severely damaged and its immediate removal is not possible. In such case the dispatcher takes a decision to temporarily close the section

Figure 6. System response with network information.

shown in Figure 7. This section is included in the original route of line 0. Train 01, which is approaching the closed track, needs to be directed to an alternative route. After inserting data to the application the user gets the response shown in Figure 8.

Figure 7. Closed section as a result of a collision [own work based on openstreetmap.org].

### D. Return to schedule

After re-opening the blocked section it is necessary to put the trains back on their original routes. The user executes the appropriate procedure by pressing the button *Return to schedule*. In the next step the number of the train, which is off-schedule, as well as its location (nearest decision point) and the starting time are inserted. This functionality can be illustrated by the following example: as a result of the overhead line failure the power was turned off at 3 PM on the section "Rynek - Rondo" in the city center of Katowice. Train 161 was directed to an alternative route towards Zawodzie depot. Half an hour later, at 3:30 PM, the line was repaired and the dispatcher re-opened the section. In such a case all the trains operating off-schedule have to come back to their original routes as soon as possible. Therefore the dispatcher runs the procedure whose results are presented in Figure 9.

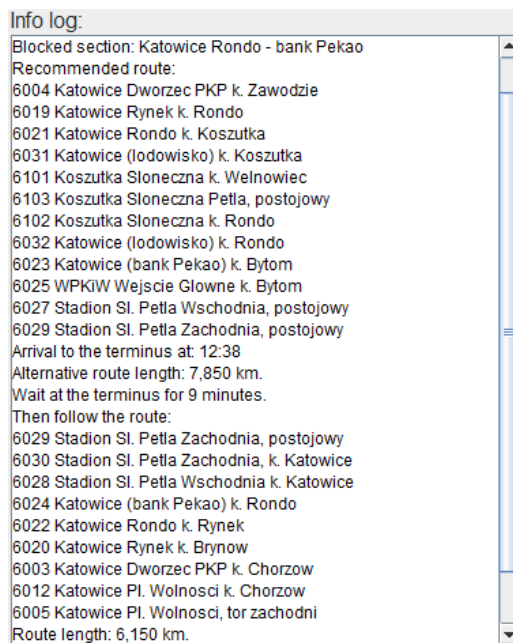

Figure 8. Alternative route generated for train 01

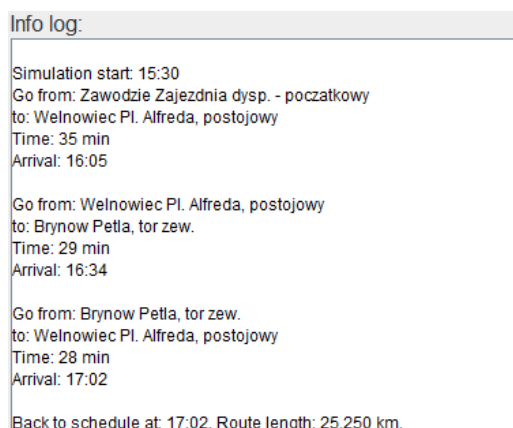

Figure 9. Recommended return plan for train 161.

## VII. CONCLUSION

In this paper, we presented a decision support system for robust traffic management. Using the proposed application is possible in different software environments, without the necessity of using additional equipment. Its practical use may lead to more efficient reactions for crisis situations occurring in public transport. A significant feature of our approach is the mixed graph-based network model which can be used to represent various types of tramway networks, including bi-directional single track routes. In our future research we plan to extend the algorithm by allowing it to generate alternative routes for more trains at one time and provide complex information for the user as well as improving a data structure containing information about the model and linking it to the existing tramway databases.

# 23<sup>rd</sup> Conference on Knowledge Acquisition and Management

**K**NOWLEDGE management is a large multidisciplinary field having its roots in Management and Artificial Intelligence. Activity of an extended organization should be supported by an organized and optimized flow of knowledge to effectively help all participants in their work.

We have the pleasure to invite you to contribute to and to participate in the conference “Knowledge Acquisition and Management”. The predecessor of the KAM conference has been organized for the first time in 1992, as a venue for scientists and practitioners to address different aspects of usage of advanced information technologies in management, with focus on intelligent techniques and knowledge management. In 2003 the conference changed somewhat its focus and was organized for the first under its current name. Furthermore, the KAM conference became an international event, with participants from around the world. In 2012 we’ve joined to Federated Conference on Computer Science and Systems becoming one of the oldest event.

The aim of this event is to create possibility of presenting and discussing approaches, techniques and tools in the knowledge acquisition and other knowledge management areas with focus on contribution of artificial intelligence for improvement of human-machine intelligence and face the challenges of this century. We expect that the conference&workshop will enable exchange of information and experiences, and delve into current trends of methodological, technological and implementation aspects of knowledge management processes.

## TOPICS

- Knowledge discovery from databases and data warehouses
- Methods and tools for knowledge acquisition
- New emerging technologies for management
- Organizing the knowledge centers and knowledge distribution
- Knowledge creation and validation
- Knowledge dynamics and machine learning
- Distance learning and knowledge sharing
- Knowledge representation models
- Management of enterprise knowledge versus personal knowledge
- Knowledge managers and workers
- Knowledge coaching and diffusion
- Knowledge engineering and software engineering
- Managerial knowledge evolution with focus on managing of best practice and cooperative activities
- Knowledge grid and social networks

- Knowledge management for design, innovation and eco-innovation process
- Business Intelligence environment for supporting knowledge management
- Knowledge management in virtual advisors and training
- Management of the innovation and eco-innovation process
- Human-machine interfaces and knowledge visualization

# Context-aware and pro-active queue management systems in intelligent environments

Radosław Klimek

AGH University of Science and Technology

Al. Mickiewicza 30, 30-059 Krakow, Poland

Email: rklimex@agh.edu.pl

**Abstract**—The Ambient intelligence (AmI) paradigm refers to electronic environments which are sensitive and responsive to the presence of people. Queue systems are practically used in various institutions and commercial enterprises constituting a challenge for the intelligent environments in smart cities. The management of the customer flows guarantees elimination or reduction of the queues as well as the economic benefits which follow the clients' satisfaction of the better service quality. There has been proposed the intelligent queue management system designed as the pro-active and context-aware system basing on multiple low-level sensors and devices constituting the IoT (Internet of Things) network. The designed context-driven system is characterized by user friendliness, as well as the client behavior understanding to generate actions that support clients. There has been proposed the conceptual version of the system. The selected aspects of the prototype version has been simulated. This prototype can be used as the necessary experience for building the target system meeting the precise needs and assumptions typical for context-aware and pro-active system basing on IoT networks.

**Index Terms**—intelligent environment; context-awareness; queue; queue management system; IoT.

## I. INTRODUCTION

SMART cities, which become more and more common and inevitable, are understood as the places where the modern ICT technologies are used in order to improve the quality of life for citizens. They enable the sustainable usage of resources available. There is no one scenario which helps to reach this goal. Developing context-driven applications is always hard and complex. We can see queues in many places of smart cities, enterprises, as well as many different types of clients who behave differently in numerous situations and have distinctive needs or preferences. The main aim of the intelligent queue management system is to adjust to those needs which enable to minimize the length of queues, shorten the time of customer service and increase the level of satisfaction of services. Indirectly, it can also influence the increase of sales volume.

The aim of this work is to propose the intelligent queue management system for a large store. Although, the idea of the queue management system is not a new one, many of the already existing systems, in spite of being described as “intelligent” which is a slight exaggeration, use mainly the simplest methods of people flow management. These are putting the physical barriers or informing users about the overall situation and statistics related to the already existing queues, by displaying messages on the screen. Such statistics

present only the simple information: how many people visited a shop at a particular hour and how much time they spent waiting in queues. There does not exist the attempt to identify the user in existing systems, considering the present behavior or historical data, assigning him/her to the particular group to be serviced in a special way. Moreover, the traditional systems are not transparent for the user, that is clients are usually in a certain interaction with the system.

The dynamic nature of a typical context-aware system is shown in Figure 1, see also [1], where different phases are repeated periodically sensing activities and to generating proper reactions enabling to operate in a smart environment. The physical world and the context-awareness software con-

Fig. 1. Context-aware and pro-activity systems

stitute the smart environment. It contains different sensors, or other IoT (Internet of Things) equipment, distributed in the whole physical area. Smart applications enable understanding context [2], and provide pro-activity, that is act in advance to deal with future situations or actions, see [3], [4], [5], [6], [7].

There is a need, that also follows the development of the ICT technologies, of creating a really intelligent system which, in a non-intrusive way, would understand people behavior, categorize them, and manage the queues in a pro-active way. It would recognize the needs and expectations as well as supports the people who found themselves in this environment. It needs to be emphasized, that the queue management system can be implemented not only for needs of shopping mall but also for the objects such as enterprises, airports, different offices and many other places.

The system, proposed in this work, has a conceptual character, however, the analysis of the available technological solutions from the ICT range proves its technical feasibility.

There has been developed the prototype and the simulation studies have been carried out. The prototype of the system can be furtherly developed and improved by implementing the new details for example related to reasoning, ontological reasoning, especially helpful in case of different methods of the clients identification, as well as developing different identifying components (biometric data, mobile phone identifier, etc.), designing the software architecture and making all other improvements. The prototype can be used as the reference point for creating the system which would be correctly located within a particular instance and needs.

There are many works considering and discussing queue management systems. Moreover, there are also commercial systems for the line management. However, there is lack of works for smart systems that works in intelligent environments, that is systems that understand human behavior providing context-aware and pro-active actions supporting customers and inhabitants. Such systems are mandatory ingredient for smart cities. Work [8] discusses queues in the context of a smart parking system. The aim of the proposed algorithm is to control traffic. Work [9] provides methods for queuing delays when using RFID systems but they don't recognize human behavior. Work [10] also don't discuss behavior aspects while new message systems are introduced. In work [11], a ticket dispenser is used. This paper follows works [12], [1] which concern observing behaviors of users/inhabitants and modelling logical specifications understood as user preferences.

## II. BASIC ASSUMPTIONS AND REQUIREMENTS

By a queue we understand an impermanent community of people which is created when waiting for the particular event such as serving. The formation of a queue is usually related to the small number of resources/people offering the service of serving. The members of the queue are usually handled in the set order, most often it is the FIFO rule, and later they leave the queue.

It is presumed that there exist the entrance devices which enable to identify people and events. Among them are:

- camera: equipped with the necessary software which enables to record and identify the biometric data of clients who enter the object and stay inside it, the new and old clients which means having the history of their presence in a particular object;
- GPS sensors: installed in the shopping trolleys and helping to monitor their location together with the client;
- scanners of the bar code embedded into the client's trolley;
- cameras, together with the software, built-in the object and helping to observe the characteristic way of moving of a client (elderly person, disabled person, person with children);
- thermal cameras detecting the increased body temperature (which suggests for example stress, haste but also the illness);
- cameras located near the cash registers which estimate the number of people waiting in a queue;

- sensors detecting the Bluetooth and GSM devices and estimating the number of people waiting in a queue as well as performing the supporting tasks. Such devices are the part of most of the private mobile phones.

The information and messages from system are introduced to different output devices such as:

- mobile applications which suggest the client a particular behavior, giving the number of the cash desks where he/she should go;
- displayer on the shopping trolley informing about the number of free cash registers;
- "help" button on trolley calling the shop assistant and helping in case of problems with the finalization of transaction (elderly people);
- publicly available displayer at the beginning of each cash register, as well as all other displayers in this part of store.

The type of data used for analysis can be: age, pregnancy, body posture, weight, clothing, height, body temperature, blood pressure, heart rhythm, amount of shopping. All those types of data are stored in a way which is transparent for a client.

The system monitoring the queue management system has a lot of information about the current situation in a monitored object, performs the basic measurements, analyzes the historical data which help to describe the preferences of regular clients. The basic parameters of the current situation in monitored object are:

- the number of people entering the store;
- the number of people who stay inside;
- the number of people classified into a certain category for example: elderly people, disabled people, mothers and families with small children, pregnant women, customers who usually do big shopping (those who have a substantial financial input), sick people and those whose body temperature is higher than the average one;
- the length of the particular queues;
- the average time of waiting in the particular queues, divided into the queues of the special meaning;
- the total time of waiting etc.

In order to estimate the length of a queue there are used different sources and methods from the video cameras to detecting the Bluetooth devices. However, the last method has its own limits related to the fact that in many mobile phones this function is switched off. On the other hand, it can be useful in describing the time of waiting in every queue, when we assume that at least some people have this function in an active mode, and observing the movement of the queue. Similar remarks concern the GSM system emitting the signal to the nearest BTS station (Base Transceiver Station).

The aim of the whole system, apart from the typical tracing of the clients' activity and their distance from the cash registers, is also detecting the distinctive types of behaviors which enable to redirect some people to the cash registers specially designated for their needs. It can be performed on the basis of the historical behaviors analysis, if they are

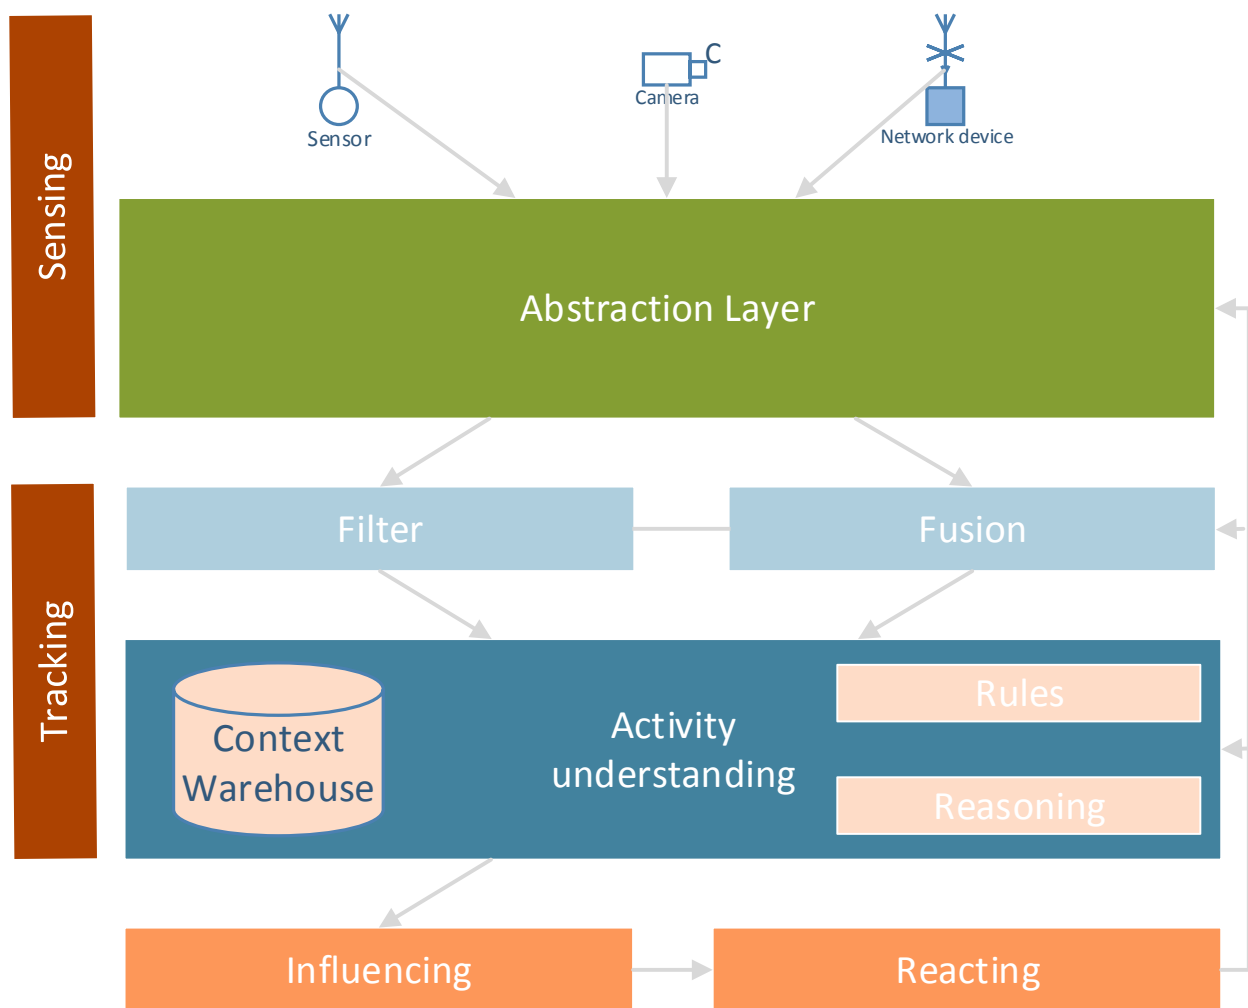

Fig. 2. Basic system architecture for activity understanding and context reasoning

available for the particular clients. This type of system, which is sensitive and context-aware and is characterized by the pro-active functioning, aims to increase the level of satisfaction among clients, adjust the selling offer and consequentially increase the trading volume.

The direct objective of the system is to

- shorten the queues, or to reduce queue time, balancing the distribution of customers;
- allocate customers to specialized queues/desks in which they will be better served;
- increase customer satisfaction.

After identification and recognition of the client there are analyzed the examples presented below:

- 1) the person is a regular client (possibility to offer discounts and better standard of service, shorter queues, personal assistants);
- 2) the size of the previous shopping (discounts, redirecting to the cash register for special customers, personal assistants, possibility of shopping delivery);

- 3) the most frequently chosen categories (household chemistry, groceries, alcohol and others – information about sales, discounts), buying the luxury products (better quality of service);
- 4) elderly people, pregnant women, people with children, disabled people (special cash desks);
- 5) when client moves quickly or walks slowly, seemingly without a special purpose (people in hurry are redirected to the shorter queues or the special queues).

There are a few types of cash registers:

- 1) special cash desk adjusted to the needs of disabled or elderly people (bigger and wider driveway, bigger displayers);
- 2) cash desks for people with small children;
- 3) cash desks for people with luxury products who are the regular customers;
- 4) cash desks for fast service of people with a few products;
- 5) special cash desks for a particular type of products (for example electronics);

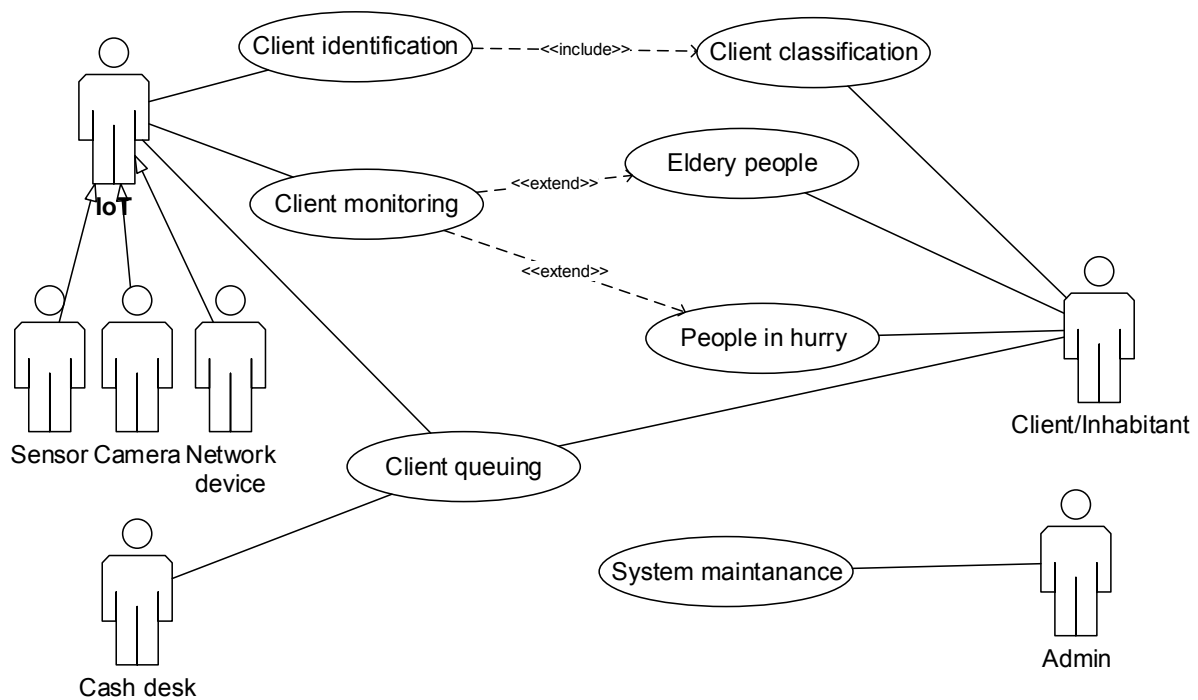

Fig. 3. Intelligent queue management system

6) normal cash registers.

### III. ARCHITECTURE

The idea of context is well established and understood in pervasive computing. Context is "...any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves" [13]. Thus, context-awareness is an ability of sensing and reacting on the environment. Sensing and context understanding are necessary and of critical importance for pro-active decisions.

The overall architecture for context-aware system that understood inhabitants activities, performing context reasoning processes is shown in Fig. 2, as an adaptation of similar ones in works [14], [1]. The Context Warehouse captures information engineering, that is it allows:

- to show all the clients attached to the monitored area,
- to provide a consolidated picture of data,
- to capture and provide access to meta data,
- to provide capability for data sharing,
- to merge historical data with current data,
- a deeper understanding of what each customers is,
- how to reconcile different views of the same objects,
- to see if a customer begins behaving uncharacteristically,
- improve quality of data, etc.

Signals are obtained from the environments. Industrial cameras also produce environmental information. Network devices, that is signals emitted by Bluetooth, GSM, and Wi-Fi

networks, allows to identify clients. Abstraction layer hides some implementation and hardware details. In other words, it translates information between different levels. Filter allows block or remove some information. Fusion enables merging of separate elements into a unified whole. Activity recognition and understanding allows to provide smart decision, that is to influence the inhabitants, or clients, in the environments. Context warehouse is a repository for all information, both historical and present, concerning objects in the monitored environments. Rules are how to process and conduct some recognized information. Reasoning enables drawing of inferences or conclusions automatically. Sensing means gathering and abstracting raw information concerning monitored environments. Tracking is a process of mining information on observed activities. Influencing provides smart decision. Reacting implements these decisions in the monitored environment.

### IV. USE CASES AND SYSTEM SCENARIOS

The basic use diagram for the queue management system is presented in Fig. 3. The case "Client identification" is responsible for identification of every new client. The identification is based on the available biometric data but also, in an alternative case, all other available data emitted by Bluetooth, GSM, or Wi-Fi network. The use case "Client classification" is obligatorily included in "Client identification" and results in precise analysis of the history of the system and on the basis of the historical data enables the current classification of the client. The use case "Client queuing" provides the final customer service at the cash register such as counting the final amount, updating the information about client in the

Fig. 4. Queue management system: the queue structure (left) and the desk area (right)

TABLE I  
USE CASE FOR ELDERLY PEOPLE

UC name: "Elderly people"
Precondition: identification of the elderly person
Scenario: The basic course of events: <ol style="list-style-type: none"> <li>1) Identification of the new client;</li> <li>2) Recognizing the client as an elderly person;</li> <li>3) Sending the message to the shop workers;</li> <li>4) System monitors the client's behavior;</li> <li>5) Cameras inform about his/her moving in direction of cash registers;</li> <li>6) System checks the length of queues;</li> <li>7) System, on the basis of the predicted waiting time and the type of client, chooses the cash register;</li> <li>8) Trolley displayer informs the client about the cash register number and additionally the voice message is displayed;</li> <li>9) Client moves in direction of a particular dedicated cash register.</li> </ol> The alternative course of events: <ol style="list-style-type: none"> <li>1) Client presses "Help" button;</li> <li>2) Shop assistant comes to him/her.</li> </ol>
Postcondition: the elderly person is serviced at the cash register and leaves the monitored area.

TABLE II  
USE CASE FOR PEOPLE IN HURRY

UC name: "People in hurry"
Precondition: identification of the person in hurry
Scenario: <ol style="list-style-type: none"> <li>1) Identification of the new client</li> <li>2) System monitors the client's behavior and informs about his/her quick pace of movement and the higher body temperature registered by the camera;</li> <li>3) Cameras inside the store inform about his/her moving in direction of cash registers;</li> <li>4) System checks the length of the queues and client is directed to a particular dedicated cash register.</li> </ol>
Postcondition: the person in hurry is serviced at the cash register and leaves the monitored area.

system, changing the client's category and all other pieces of information which build the historic data and which, in the future, will play a crucial role during the next visit and identification of the client in the object. The use case "System

maintenance" enables the current system management, typical administrative tasks, switching on and off the new devices and deleting the outdated data, keeping them in an order etc.

Among the actors of the system are:

- Cash desk – subject (a person or a device) providing the customer service for the clients waiting in a queue. His/her work should enable the smooth flow of people in a queue and its fast reduction;
- Client – the single being who stays inside the monitored object and is a part of the queue or in a short defined time is going to join it;
- Administrator – the physical person who oversees and controls working of the queue management system, configures its parameters, sensors and answers the suggestions proposed by the system itself;
- Sensor – an example of a physical element (IoT) in the system which task is to record, recognize and register the signals from the environment. It provides the information which are sent to the system in order to perform the correct interpretation.

The use case "Client monitoring" is an important and basic part of system which ensures the current observation of the identified client and recognition of the moment when he/she moves in the direction of cash registers as well as directing him/her to the appropriate cash desk as the place of trade finalization. Below, there are presented the possible scenarios for the use cases, recognizing and dealing with the special cases, divided into categories. Among them are: "Elderly people" or "People in hurry". Those cases are prompted as optional from the main case. Elderly people, who have limited movement capacities, move in a different and slower way which can easily be detected by the system, see Table I.

The next example of scenario is related to people whose behavior is atypical (for example they are in hurry). Moreover, there is a possibility of using the thermal cameras, registering the changing parameters of the client such as higher temperature, haste, see Table II.

It is possible to prepare another scenarios, for example for people with children, people with small shopping, VIP clients etc.

## V. SYSTEM PRESENTATION

There will be presented the general system scheme. Fig 4 shows organization of the queue system. Within the monitored space there is located the cash desk area *DeskArea* where are the physical cash registers (both serviced and those which require the self-service). It is supposed that every client who enters this area wants to finish his/her shopping and plans to move closer to the physical cash registers. This fact is immediately detected by the system and such client (after identification) is put to the virtual queue *VirtualQueue*. It is not the physical queue but a certain data structure in the system where are stored all clients cash registers the time when they join any physical queue or leave the area. One of the processes is constantly checking *VirtualQueue* and after the classification and assumption process, also using the historical data; chooses the target queue for a client, for example: the queue for elderly people or people in hurry. The client, after choosing the queue for him/her, is monitored by the system (mobile phone, trolley displayer or the widely available displayers within the range of the system) which informs him/her about the target queue. If the client joins the physical queue, he/she is removed from *VirtualQueue*. If suddenly the client leaves *DeskArea*, for example resigns from finalization of transaction, he/she is also removed from the system. The general algorithms for the queuing system for the use case “Client Queuing” is presented in Fig. 5.

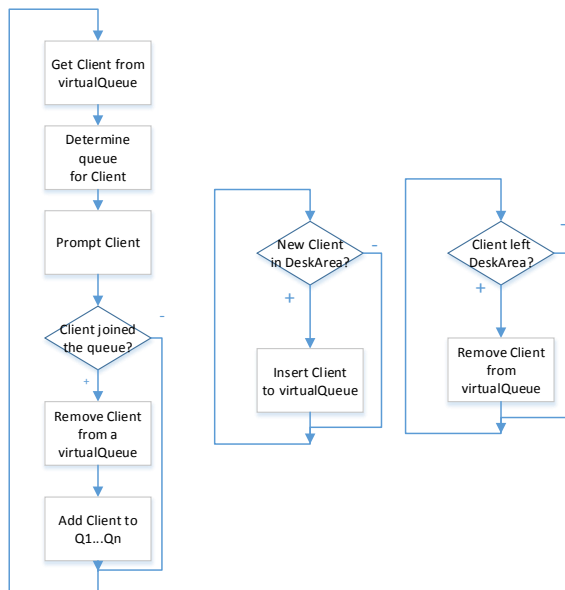

Fig. 5. Queuing, means assigning the queue to the client (left), new clients and those who leave (middle, right).

There has been created the simulation environment, or more precisely, the prototype of an application, which simulates work of the intelligent queue management system. However, this is only the beginning of work to obtain the complete system. Even if the prototype has been simplified, it still precisely portraits of how the system works. Fig. 6 presents the

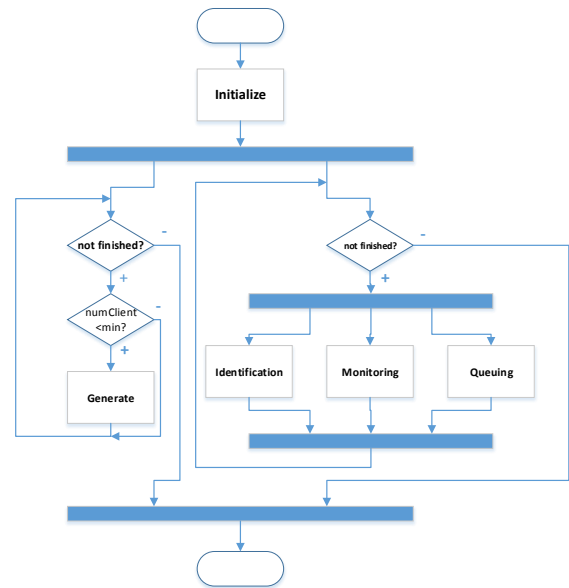

Fig. 6. Environment simulating the queue management system

general working schemata of such environment. The system is initiated, there are measured its basic parameters such as: influencing the generator of clients, random distribution, probability density and others. There is also initiated the “finished” variable which controls the end of simulation process and is set by the system administrator. The whole process of generating new clients entering the object is initiated when a current number of clients falls below a certain minimal value. The identification, monitoring and queuing are performed simultaneously.

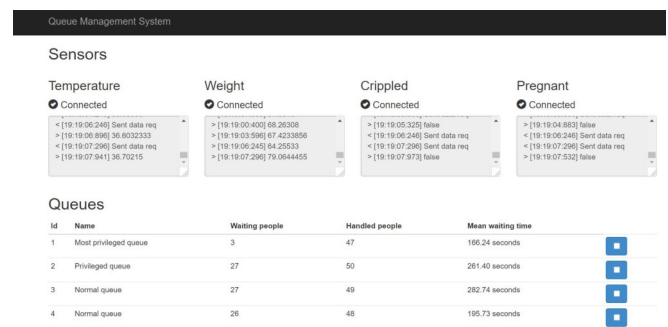

Fig. 7. Screen shot: Preview of the message exchange between sensors (IoT) and the main server.

In the simulation process, the clients are generated in a pseudo-random way, with parameters (elderly, young, physically disabled, children, men, women, pregnant women, people in hurry, regular clients, people without shopping history etc.) which enable the best possible and precise mapping of the real system. It is possible to describe the density of generating in order to map the time periods characterized by different turnout of clients (morning hours, afternoon hours).

There has been adopted the following time periods

TABLE III  
SIMULATION RESULTS

Parameter	Queue number	Simulation time			
		30s	60s	120s	240s
Number of waiting clients	1	2	3	2	2
	2	2	4	8	14
	3	2	4	7	14
	4	2	3	7	13
Number of clients serviced	1	1	3	6	12
	2	1	2	6	12
	3	1	3	5	12
	4	1	2	5	11
Average waiting time	1	15.4	22	33.3	42
	2	16.2	22.9	37.5	66.3
	3	17.3	26.4	35.5	68.5
	4	22.42	29.2	35	66.3

and time intervals between the visits: for 06.00–09.00 is  $RandomInRange(10, 60)$ ; for 09.00–14.00 is  $RandomInRange(30, 180)$ ; for 14.00–18.00 is  $RandomInRange(50, 800)$ ; for 18.00–21.00 is  $RandomInRange(30, 600)$ ; for 21.00–06.00 is  $RandomInRange(10, 100)$ , where the function  $RandomInRange(a, b)$  means the random number  $x$  in a range  $x > a$  and  $x \leq b$ . The prototype simplifies the client model to the features such as age, weight, body temperature, disability or pregnancy. When generating the people, there has been used the following statistical data: age – for 40% of population  $Gaussian(25, 3)$ , for 60% of population  $Gaussian(50, 10)$ ; weight –  $Gaussian(70, 10)$ ; temperature –  $Gaussian(36.6, 0.3)$ ; and 0.16% of population for disability, 0.09770294% for pregnancy, where Gaussian function ( $mean, stdDev$ ) gives back the number  $x$  drawn according to the normal Gaussian distribution which has the mean value  $mean$  and standard deviation  $stdDev$ . Additionally, there has been implemented

Queues

Id	Name	Waiting people	Handled people	Mean waiting time	
1	Most privileged queue	3	20	57.32 seconds	
2	Privileged queue	8	22	142.11 seconds	
3	Normal queue	4	23	120.65 seconds	
4	Normal queue	3	22	86.43 seconds	

Fig. 8. Screen shot: Preview of the queue situation: name, number of people waiting, number of people serviced by a particular queue, the average waiting time and the average waiting time of an one supplicant in a queue. In the last column there is a button which stops and starts the queue.

non-deterministic time of customer service which is equal to  $Gaussian(90000, 15000)$ . Another implemented value is a sensor error equal to 5%. Summing up the briefly presented simulation environment, it seems that the obtained environment is an appropriate framework for future works implementing the context-aware queue management system.

The exemplary screen shots presenting the system are shown in Figs. 7 and 8. Table III shows the sample results of prepared stimulation.

The further works over the system development should be carried with a special diligence according to the following non-functional requirements:

- Expansion: system needs to be designed in a way which enables its development and adding modules dealing with different spheres of controlling numerous institutions.
- Scalability: system should work smoothly in case of a sudden increase in the number of clients. The proper functioning in the period of a high burden is expected.
- Manageability: system should deploy the interfaces which help to control the queue management in a fast and effective way.
- Configurability: the system should allow the wide spectrum of configuration options – one of them is possibility of registration of the new sensors and managing the already existing ones.
- Safety: the system should be provisioned against the external attacks – it needs to use only safe and encrypted protocols.
- Stability: system should work in a stable way regardless of the environmental conditions.

The further works over the system development should also concern requirements engineering aspects [15], [16], as well as temporal issues of the system [17], [18].

## VI. CONCLUSIONS

There has been designed the queue management system in an intelligent environment. It works according to the paradigm of pervasive and ubiquitous computing. Its main task is to recognize clients who appear in the object, understand their behavior, take into account the historical data related to objects and propose the particular actions. They can cover both client support as well as simplification of the transaction finalization

and the choice of the best store cash register. There are many different cash registers and also the customers have distinctive preferences but the main goal is the client's satisfaction and his/her safety.

The newly created simulation environment enables the initial testing of the basic principles. Both the environment as well as the system itself can be furtherly developed reaching the goal which is creation of the target system. There exist many places for the system installation and one of them could be the dean's office where the system recognizes a student, analyzes his/her current situation both in case of the whole educational process and the scholarship system, and can suggest the proper solutions and an appropriate desk.

#### ACKNOWLEDGMENT

I would like to thank my students Piotr Gryt, Anna Sotwin, Jakub Pelc, and Tomasz Korecki for their help and appreciate their technical skills.

**Abstract**—The concept of persistent identification is increasingly important for research data management. At the beginnings it was only considered as a persistent naming mechanism for research datasets, which is achieved by providing an abstraction for addresses of research datasets. However, recent developments in research data management have led persistent identification to move towards a concept which realizes a virtual global research data network. The base for this is the ability of persistent identifiers of holding semantic information about the identified dataset itself. Hence, community-specific representations of research datasets are mapped into globally common data structures provided by persistent identifiers. This ultimately enables a standardized data exchange between diverse scientific fields.

Therefore, for the immense amount of research datasets, a robust and performant global resolution system is essential. However, for persistent identifiers the number of resolution systems is in comparison to the count of DNS resolvers extremely small. For the Handle System for instance, which is the most established persistent identifier system, there are currently only five globally distributed resolvers available.

The fundamental idea of this work is therefore to enable persistent identifier resolution over DNS traffic. On the one side, this leads to a faster resolution of persistent identifiers. On the other side, this approach transforms the DNS system to a data dissemination system.

## I. INTRODUCTION

THE massive growth of digital data in many different areas including the scientific area, has driven a series of profound changes in the world. For commerce, this data deluge for example provides a door for new markets. By analyzing the purchase patterns of specific buyer groups, it is possible to subject them with pinpointed advertisements which ultimately could lead to a strong increase of the profits.

In the scientific area for instance, the increasing volume of research datasets has led to an increase of their importance. The overall goal in research data management is to provide a sustainable cross-disciplinary exchange between different scientific branches. This could ultimately help to enable the discovery of new insights in various scientific fields.

The concept of persistent identification is becoming a fundamental component for research data management. Its basic function is to provide a sustainable access to research datasets, which are currently retrievable by their locators. Even small technological changes in a research data repository could lead to many invalid locators. Hence for a long-term sustainable access, locators are highly inappropriate. Since research datasets are currently mapped into web resources,

the locators are URLs. Thus, persistent identifiers currently provide an abstraction for URLs corresponding to individual research datasets.

However, with the explosive research dataset growth, the count of registered persistent identifiers is increasing enormously as well. Therefore, persistent identifier systems are increasingly subjected to high loads. Since persistent identifiers are an essential component for research data management, the performance of persistent identifier systems is highly critical for research datasets exchange. The focus of this work is therefore on the performance of the resolution procedure for persistent identifiers.

The importance of persistent identifiers for global research dataset exchange is comparable to the importance of the well-known DNS system for the current general Internet communication. The resolution procedure for both, persistent identifiers and domain names, is in principle a node traversal procedure, whereas the traversal starts at a specific root node and terminates at a responsible child node. Hence, the resolution time for domain names and persistent identifiers are generally composed of the network latencies between the traversed nodes. Moreover, the resolution procedure involves a specific proxy resolver which is tasked with the node traversal. A requesting application only submits a single resolution request to the proxy resolver, which then responds with the answer obtained from the traversal procedure. To reduce the traversal procedure, the answer of frequent resolution requests is usually cached at the proxy resolvers. In such a case, the resolution time only consists of the network latency between requesting application and proxy resolver.

For DNS, there are a myriad of publicly available proxy resolvers, such that an application can always choose a proxy resolver in its proximity. In contrast to that, the count of persistent identifier proxy resolvers is in comparison to the count of DNS proxy resolvers infinitesimally small. For the Handle System, which can be considered as the most important and established persistent identifier system, there are currently only five globally distributed proxy resolvers. Therefore, the fundamental idea of this paper is to enable the resolution of persistent identifiers over DNS proxy resolvers. Due to the global widespread of DNS proxy resolvers, with this approach, the resolution time for persistent identifiers can be significantly reduced.

The remainder of this paper is structured as follows. Section II gives an overview of the related work. In Section III we will analyze the core idea behind the concept of persistent identification. In addition, we will discuss the different possibilities to use DNS as resolution system for persistent identifiers. In Section IV, we will provide a realization of our proposed idea for the resolvability of Handle persistent identifiers over DNS traffic. Finally, in Section V we will do an evaluation of the proposed idea by means of an experimental setup. Ultimately, in Section VI will present our conclusions and give hints for future work.

## II. RELATED WORK

Persistent identifiers are in principle widely acknowledged for research data management. However, their importance is significantly increasing due to the ability of imposing semantic information into the persistent identifier record itself. Therefore, the perception for persistent identifiers increasingly moves from a simple redirection mechanism towards a global data structure for research datasets, which ultimately enables information exchange between diverse research data repositories.

A prime example for an early perception for persistent identifiers is the work [1]. The authors consider the concept of persistent identification only as a redirection mechanism. Therefore, their focus is to devise a bridge from persistent identifiers to HTTP URIs, which are associated with semantic information about research datasets. But they do not take into account the possibility of persistent identifier records for holding semantic information.

The work [2] proposes *trusty URIs* for providing trust and reliability for scientific datasets. The focus is on using cryptographic hash values in URIs corresponding to identified scientific datasets, so called *trusty URIs*. A *trusty URIs* can then be used to determine whether the identified datasets has been subjected to manipulations. However, it becomes critical for this approach when the identified research datasets moves to another location.

One of the first works which considers persistent identifiers as a more complex concept than just a redirection mechanism is given by [3]. The basic approach is an ontological refinement of metadata sets contained in persistent identifier data records, which enables a common information set for the various persistent identifier systems.

The first work which considers persistent identifiers as a data structure for semantic information is provided by [4]. The focus is the integration of common abstract datatypes into persistent identifier data records, which can be consumed by machine actors. In contrast to [3], their core emphasize is to provide a standardized set of information entities about the identified dataset itself.

Due to the versatility of persistent identifiers, they are also considered in various other fields. An example for that is the work [5]. The authors are discussing the usage of persistent identifiers in the field of Named Data Network (NDN). Their

focus is to use existing persistent identifier concepts within NDN environment for delivering big datasets.

Another example is from the field of scientist identification, the authors in [6] introduce the concept of persistent identification for scientists. In their concept, an individual persistent identifier data record corresponds to a single scientist, which also contains the respective bibliography.

However, the versatility of the concept of persistent identification can also be important for the Internet-Of-Things paradigm. For IoT, persistent identifiers can be more than just a naming component, in fact, they are perfectly suitable as the global platform for device communication. The work [7] is an example for the need of a naming component in IoT. The main idea is in principle to provide a DNS-like system specifically targeted for IoT devices. However, this is de facto already existing: The Handle System, which can be considered as the most sophisticated persistent identifier system, is already productively in use. In addition, the data structure of the Handle System is generic enough to hold any kind of data including device information. Another major advantage of the Handle System is that there are guarantees for a long-term operation.

Ultimately, all the aforementioned research efforts do not specifically address the performance of the concept of persistent identification.

In a previous work [8], we have proposed a high-performance identification concept for huge research data repositories, which already provide a sophisticated data structure and immutable identifier scheme for its research datasets. However, in that work we did not emphasize on the performance of the resolution of persistent identifiers, which is the focus of this current work.

Persistent identifiers are very well comparable with domain names of the DNS system. In both systems, basically a name is registered once and resolved many times. Therefore, the concepts which are applied for accelerating domain name resolution are also suitable for persistent identifier resolution.

The resolution of domain names can be considered as a latency problem, which is caused by the traversal of the hierarchical architecture. Therefore, in order to shorten the traversal path, usually aggressive caching is applied. The authors [9] focus on analyzing the resolution performance from the client point of view. In addition, they analyze the effectiveness of caching.

A special caching strategy of DNS records is proposed by [10]. The authors introduce a concept for proactive caching of expired DNS records, whereas particular DNS records are unsolicited refreshed before clients queries them.

Usually, individual DNS zones are composed of multiple servers for ensuring high-availability and load-balancing. Since, the domain name resolution procedure can be considered as a node traversal problem, an optimal choice of the appropriate nodes can significantly improve the performance. Thus, the impact of the DNS server selection algorithms of popular DNS proxy server implementations is provided by the work [11].

Often, nameservers of top-level domain zones are also geographically distributed. Thus, in order to redirect a domain name resolution request to the nearest nameserver, usually the technique of anycast is applied. Hence, the work [12] analyses the effectiveness of anycast for DNS server selection, whereas it reveals the general usefulness of anycast.

However, in content distribution networks (CDNs) anycast alone usually does not suffice for efficiently redirecting user requests to appropriate CDN servers. Since in anycast the routing decision is done by the network, which is based on the static hop count between different autonomous systems, dynamic parameters such as the current load at individual servers are not covered by anycasting. Therefore, in CDNs the request routing is based on special DNS servers which are basically tasked with the collection of routing relevant parameters. The collected parameters are then used to determine the most appropriate CDN server. Thus the work [13] analyzes different server selection algorithms in CDNs which are based on DNS. A similar work is provided by [14]. It analyses the functioning the Akamai infrastructure, which is one of the largest CDNs. In addition, by conducting a comprehensive measurement study it reveals the complexity in CDNs.

However, currently the fundamental problem of persistent identifier resolution is caused by the very few distribution of resolution systems. For DNS, in contrast, there are countless resolvers globally distributed. Hence, the fundamental idea of this paper is to make use of these DNS resolvers for persistent identifier resolution.

### III. THE CONCEPT OF PERSISTENT IDENTIFICATION

Since in the current Internet all resources are retrieved by their locators instead of their names, for a sustainable access temporary locators are highly inappropriate. This is especially true for research datasets. In order to prevent research datasets from being lost in the huge data deluge, research datasets are more and more interlinked with each other. In addition, data is increasingly consumed by machine actors instead of humans. For machine consumption it is necessary to employ a common data structure together with a common understanding for the elements in that data structure. Persistent identifiers initially have been conceived for providing an abstraction for locators of resources in the current Internet. The working principle of persistent identifiers is simply to map an opaque name, which is assigned to an individual research dataset, to its current locator. Another aspect of persistent identifiers is that they also enable the imposition of semantic information about research datasets. This aspect significantly increases the importance of persistent identifiers for research data management. Therefore, the registration procedure of research datasets at persistent identifier systems can be considered as a mapping from a community-specific into a standardized global representation. Whereas the global representation is used by various different machine consumers, which can access research datasets just by their globally unique names without further knowledge about their current Internet locations. In addition, these machine

consumers can autonomously operate with research datasets based on the imposed semantic information.

In its fundamental working principle, the well-known DNS system is very much comparable to a persistent identifier system. In both systems, an information entity is first registered and secondly resolved. In the DNS system, the information entity is basically an IP-address of a computer host which then is assigned a human-friendly representation for its IP-address, namely a domain name. In the case of persistent identifiers, the information entity first of all consists of a locator for a research dataset. As mentioned earlier, the information entity also increasingly includes much more complex information about the identified research dataset. Therefore, the concept of persistent identification can also be considered as a technology, which enables the realization of a virtual global research data network, wherein the communication between the actors is realized by persistent identifiers and whereby the actions are derived from the corresponding information entities.

However, the increased importance of persistent identifiers has also led to a steadily increasing load at persistent identifier systems. To provide a reliable communication between various the actors, a performant resolution of persistent identifiers is therefore highly important. Due to the global distribution and the hierarchical architecture, the resolution of persistent identifiers is usually a latency problem. As it is the case for DNS, the resolution is accomplished by a node traversing, starting from the root node and ending at the responsible node for an individual persistent identifier. The mature DNS system is a fundamental component of the current Internet, therefore its performance is highly critical for the whole Internet communication. In order to ensure a reliable and performant functioning, for the DNS system several techniques are in use. A rough categorization of these techniques is given by the following:

- a) Caching is primarily applied to hold the data in a faster storage, but in the particular case of DNS, it is applied to shorten the traversal path. Whereby the answer for frequent resolution requests is tried to be cached in a proximity node of a requestor.
- b) In order to ensure high-availability and robustness an individual DNS zone usually consists of multiple nameservers, where upon the incoming resolution requests are distributed on. This is actually better known as load-balancing.
- c) In addition to load-balancing, the technique of anycast is often used to redirect the requests to the nearest possible DNS server. Anycast is especially targeted for zones which consists of multiple geographically distributed nameservers. The top-level domain (TLD) zones are a typical example for that. The ".de" TLD zone for instance, consists of many nameservers which have been globally positioned. A request submitted by an application, which is hosted in Europe will be redirected to the European cluster of nameservers responsible for the ".de" zone. In contrast to that, a request originating

from the USA, will be answered by the nameservers located in the USA.

In anycast, multiple nodes are reachable by exactly the same IP-address. As an example, the public Google DNS resolver is reachable by the IP-address 8.8.8.8. However, since the public Google DNS resolver is globally distributed among the Google data centers, a request of an individual client will be redirected to the nearest Google DNS resolver. For anycast the request routing decision is made at the network switch level, which choose the path corresponding to the shortest hop count among a set of possible other paths.

However, for content distribution networks (CDNs), request routing based on anycast is not efficient enough. This is due to the fact that static routing decisions based on the hop count do not cover the dynamic load behavior in CDNs. Therefore, in CDNs special DNS servers have proven to provide a reliable request routing for redirecting an individual requestor to the current most efficient content server. These special DNS servers are equipped with probing information collected from previous requests which are used for the request routing.

To resolve a specific domain name into its IP-address, an application usually queries its operating system's stub resolver. The stub resolver in turn, redirects the resolution request to a pre-configured DNS proxy resolver. Such a proxy resolver then traverses the hierarchical global DNS system until it reaches a DNS server, which has the corresponding answer for the resolution request. This is depicted in Figure 1.

For the Handle System, which can be considered as the most important and elaborated persistent identifier system, the resolution of individual persistent identifiers, called Handles, is in principle very similar to the resolution procedure of domain names. In contrast to domain names, an individual Handle is composed of two parts: a prefix and a suffix part. Both parts are separated by the ASCII character '/'. The prefix part is comparable with a domain name as it consists of hierarchical labels separated by dots. The suffix part in turn, is a locally unique name assigned to an individual research dataset.

To resolve a Handle, an application has to submit the resolution request to the Global Proxy Resolver (hdl.handle.net). The Global Proxy Resolver in turn, starts at the Global Handle Registry (GHR) to find the responsible Local Handle Service (LHS). This information is stored in the so called Prefix Handle at the GHR. In the next step, the resolution request is sent to that LHS. Finally, the Global Proxy Resolver responds with the corresponding Handle Record received from the LHS. The Handle resolution procedure is depicted in Figure 2.

In summary, for DNS and Handle resolution, an application has to involve a particular proxy system. The fundamental difference between DNS and Handle resolution is the fact that for DNS resolution there is a myriad of public DNS proxy resolvers available. In contrast to that, for Handle resolution, the Global Proxy Resolver currently consists of only five globally distributed servers.

Hence, due to caching at the Global Proxy Resolver, as it is applied at any DNS proxy resolver, the resolution time of

Handles often consists to a great extent of the latency between the requesting application and the Global Proxy Resolver.

Therefore, to speedup the resolution time for Handles, it is essential to reduce the latency to the Global Proxy Resolver. The focus of this work will therefore be on the improvement of the resolution time for Handles. Since the Handle System is also a fundamental part of other important persistent identifier systems, such as the DOI System [15], an improvement of the Handle System will also affect these other persistent identifier systems. Before we will discuss the possibilities of reducing the latency between requestor and proxy system, we will first proceed with a brief comparison between DNS and Handle System.

Fig. 1: DNS Resolution Procedure

Fig. 2: Handle Resolution Procedure

#### A. DNS and Handle System Comparison

The DNS, as well as the Handle System, can be considered as a hierarchical, distributed database. Both systems define a specific protocol to ensure the global functioning. However, in contrast to DNS, the Handle protocol offers a much richer set of operations for the management of individual Handles. In addition, the Handle protocol is equipped with its own authentication and authorization mechanism, which enables the management (provided that an individual user is authorized) of any Handle Record stored at any Local Handle Service in the world. Whereas management of DNS records is still a manual process involving an administrator's action. Another strength of the Handle System is its data structure. In DNS, the data is structured as Resource Records (see

Figure 4), whereas the *type* field and the *rdata* field are the most important fields. Obviously the *type* field denotes the type of the data in the *rdata* field. In the Handle System, an individual Handle consists of multiple Handle Values which form a Handle Record (see Figure 3). Similar to a Resource Record, a Handle Value is most importantly composed of a type and a data field. However, the essential aspect of Handle Values is that there is no restriction on a set of permissible data types as it is the case for Resource Records [16]. Thus, a Handle Value can hold any type of data, which makes the Handle System also attractive for the area of the Internet-Of-Things. The Handle System can act as a global registry for any device for storing device specific information. This in turn could enable various different devices to interact with each other by means of exchanging their corresponding Handle Records.

In summary, these characteristics underline the potential of the Handle System.

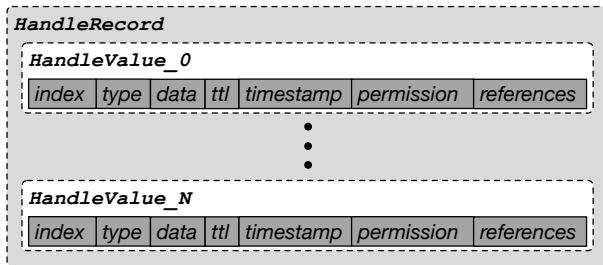

Fig. 3: Handle Record made of a set of Handle Values

Fig. 4: Resource Record

### B. Proxy System Latency Reduction

To reduce the latency between an application and the Global Proxy Resolver for resolving Handles, first of all it is necessary to increase the count of globally distributed proxy servers. This could be done by a manual setup, which is theoretically possible but associated with high costs and administration efforts. Another option would be to make use of a content distribution provider such as Akamai, where the Handle proxy system could be spread on the provider's global infrastructure. However, since in CDNs special DNS servers are tasked with the request routing, for the relative simple Handle resolution operation the request routing based on DNS would again cause a considerable overhead into the overall Handle resolution time. In addition, the usage of CDNs is also associated with additional costs. The next option is to make use of an already publicly available and globally widespread infrastructure for Handle resolution, whereby the DNS infrastructure constitutes a perfect candidate for such an endeavor. The great benefit

of this option is that one can make use of the myriad of globally available public DNS resolvers without additional costs and administrative overheads. However, the downside of this option is that it requires a translation process between the Handle and DNS protocol. For the translation process, there are in principle the two following options:

**(A) Translation at the DNS system:** In this case, the public DNS resolvers have to be extended by the Handle protocol in order to be able to communicate with the Handle System.

**(B) Translation at the Handle System:** Whereas in this case, both the Global Handle Registry as well as the Local Handle Service have to be extended by the DNS protocol in order to be able to communicate with the requesting DNS resolver.

The main obstacle for option (A) is based on the fact that there are various different implementations of DNS resolvers. For the realization of our proposed idea, it is necessary that all publicly available DNS resolvers have to be upgraded by a Handle protocol module, which can hardly be realized.

In contrast to that, all components of the Handle System are based on a common library set, called the Handle libraries [17], which are publicly available. The Handle libraries are in principle a reference implementation of the Handle protocol. Since our fundamental idea is to make use of publicly available DNS resolvers for Handle resolution, with option (B) there are no modifications in these DNS resolvers required, which is a major benefit of option (B). Therefore, in the remaining we will focus on the realization of option (B).

### C. Summary

Since the resolution procedure of Handles is very much comparable to the one of domain names, the resolution time mainly consists of the network latency between the different nodes which have to be traversed until the responsible node is found. For both domain names and Handles it is necessary to instruct a specific proxy resolver, which is tasked with the traversal of all the necessary nodes. However, for Handle resolution, currently there are only five proxy resolvers globally distributed. In contrast to that, for the domain names there are a myriad of publicly available DNS resolvers. This means that the resolution time of Handles suffers from the relative low density of the global distribution of the Handle proxy resolvers. Therefore, the network latency between the requesting client and the Handle proxy resolver has generally a high contribution to the overall Handle resolution time. To reduce this latency between client and Handle proxy resolver, the fundamental idea of this work is to make use of publicly available DNS resolvers for resolving Handles. This is based on the fact that the global distribution of DNS resolvers has a much higher density than the global distribution of Handle resolvers.

## IV. IMPLEMENTATION

In this section, we will consider the implementation of option (B) for enabling Handle resolution over DNS traffic.

The realization of this approach covers the following four parts:

- (1) Handle server with DNS interface
- (2) Mapping of Handle Values into DNS Resource Records
- (3) Representation of Handles as domain names
- (4) Appropriate Resolution Procedure

Therefore, in this section we will provide insight into all these parts.

#### A. Handle server with DNS interface

Since our fundamental idea is basically to embed the Handle System into the DNS system, for the proposed solution it is necessary to extend the individual Handle servers with a DNS interface. A DNS interface enables the communication with Handle servers by means of the DNS protocol. It should be noted that the Handle libraries already include a DNS interface, which can be enabled in Handle servers for listening on DNS traffic. However, this DNS interface is intended for Handle servers to act as ordinary DNS servers. It does not enable the resolution of ordinary Handle Records over DNS traffic, which is our objective. This stems from the fact that DNS Resource Records are limited on a permitted set of data types, whereas Handle Records can contain Handle Values with any type of data. In this built-in DNS interface, the mapping direction is from DNS Resource Records into Handle Values. In addition, only Handle Values containing real DNS Resource Records can be resolved. In contrast to that, our approach is to enable the resolution of any type of Handle Values over DNS traffic. The key challenge for this endeavor is to transform Handle Values containing any type of data into Resource Records, which are actually limited on a specific set of data types. Hence, in contrast to the built-in mechanism, for our approach the mapping direction is from Handle Values into Resource Records. However, we make use of the already built-in DNS interface for the request and response encoding and decoding. The algorithm in the Handle server, however, for requests received at the DNS interface has been modified in order to realize the resolution of Handle Records over DNS traffic, which will be discussed in the following subsections.

#### B. DNS Resource Records Types

The mapping of Handle Values into DNS Resource Records constitutes the core part of our approach. Initially, DNS has been conceived for providing human-friendly addressing for computer hosts, which are actually addressed by their IP-addresses. Therefore, most DNS Resource Records contain data which is specifically related to computer hosts. Among them, the Resource Record with the type "A" can be considered as the most used type since the corresponding data field contains an IP-address of an individual computer host. As already mentioned, Resource Records are limited on a particular set of permitted data types [16], however, none of them is targeted for holding descriptive information about digital datasets (such as research datasets) or IoT devices. The ability of providing meta information would transform DNS from a simple resolution system into a data dissemination

system. To realize this approach, either the permitted set of Resource Records has to be extended by additional types for the dissemination of datasets or one has to exploit specific types of the permitted set. The core problem of extending the set of permitted Resource Record types is based on the requirement that public DNS resolvers also have to support these new types. This is quite challenging since many public DNS resolvers even do not support all of the currently permitted types. Therefore, we concentrate on the exploitation of already permitted data types. For that, we have identified specific types of Resource Records, which we will analyze in the following:

**NAPTR Resource Records:** NAPTR typed Resource Records have been introduced to enable DNS to act as a rule database for the Dynamic Delegation Discovery System (DDDS) [18]. DDDS is basically an abstract concept for applications to enable resource access through applying rules on input strings. The rules are provided by the NAPTR Resource Records, which are then applied by the requesting DDDS applications to compose the locators of resources. Hence, DDDS applications are compelled to implement a specific algorithm in order to apply the rules contained in NAPTR Resource Records. In contrast to that, in ordinary persistent identifier systems the locator of a resource is retrieved directly through a resolution process.

**SRV Resource Records:** SRV Resource Records are used to describe available services on hosts. It allows to specify the service, its protocols and the corresponding ports on which the service is listening on the host.

**URI Resource Records:** The URI Resource Record is an alternative to the SRV Resource Record. It does only hold the URI for a resource. However, in order to access a digital datasets, it is often also necessary to specify the port number of the repository system.

**TXT Resource Records:** The TXT Resource Record is intended to transfer arbitrary textual information with DNS traffic. However, in principle it is possible to transfer any kind of data encoded as a character string. As such, it is pretty well suitable for transferring Handle Values.

Among the listed Resource Records, the TXT Resource Record is the most flexible one. Another aspect which is quite beneficial for our approach is given by the fact that this Resource Record is also widely supported by public DNS resolvers. The problem with the remaining Resource Records is that for them there are already defined standard procedures for their consumption, which is not the case for TXT. The general idea of using the TXT Resource Record to store key-value pairs is not new, as can be seen in [19], however, it was never considered in conjunction with persistent identifiers. Ultimately, for the realization of our approach, the TXT Resource Record is the most reasonable choice. Thus, in the next subsection we will provide the actual mapping from a Handle Value into a TXT typed Resource Record.

### C. Mapping of Handle Values into DNS Resource Records

Each Handle Value is mapped into a Resource Record with a TXT typed field. The *data* field of the Resource Record is composed of the Handle Value *type* field together with its corresponding *data* field, whereas the equal character ('=') is used as delimiter. In addition, the Handle Value *ttl* field, which is used for caching, is mapped into the *ttl* field of the Resource Record. An important aspect at this mapping procedure is that Handle Records may also contain Handle Values, which are not allowed to be consumed by the public. Hence, all Handle Values with restricted reading rights, which is recognized by the *permission* field, are discarded at the mapping procedure. Since a Handle Record can contain multiple Handle Values, the *index* field is used as an unique internal identifier within the Handle Record. This is not necessary for Resource Records and therefore the index is not considered at the mapping. The *name* field of the Resource Record is replaced by the domain name representation of the corresponding Handle identifier string. Finally, the overall mapping procedure is depicted in Figure 5.

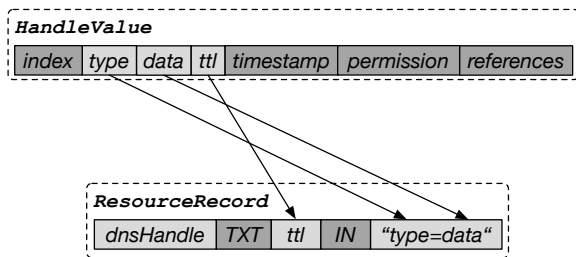

Fig. 5: Mapping of Handle Value into TXT typed Resource Record

### D. Representation of Handles as Domain Names

Another fundamental aspect for the resolution of Handles through DNS traffic is their representation as domain names. This is discussed in the following three points:

#### (1) Character Set:

In principal, a Handle may consist of any character from the Unicode character set. In contrast to that, a domain name can only contain letters from A to Z, the digits from 0 to 9, a hyphen (-) and a dot (.) as separator. Hence, in order to represent each possible Handle as a domain name there is an additional encoding algorithm necessary. However, for internationalized domain names (IDNs), which also consist of Unicode characters, there is already an algorithm available for converting them into regular domain names. This conversion algorithm could be extended to encode a general Handle as a regular domain name. Since, Handle strings are usually composed of known identifiers, such as UUIDs, which are representable as regular domain names without additional encoding efforts, in this work we will only focus on such Handles identifiers. For general Handles there is future

research necessary in order to deduce an appropriate conversion algorithm.

#### (2) Namespace Hierarchy:

Domain names are composed as hierarchically dot separated labels. From an individual label point of view the label next to the right denotes its parent label. Handles in turn are composed of a prefix and a suffix. As for domain names, the prefix consists of hierarchically dot separated labels. However, in contrast to domain names, in a Handle prefix the rightmost label denotes the lowest level of the hierarchy. The prefix is followed by the slash (/) character, which separates the suffix from the prefix. The suffix in turn is basically a locally unique identifier. In summary, this means that a Handle identifier incorporates two different separators: dots for the prefix and a slash to distinguish the suffix. In order to represent the a Handle as a domain name, it is first of all necessary to replace the slash by a character which is allowed for domain names. Hence, a slash is replaced by a dot. In addition, the resulting Handle identifier has to be reversed to ensure the right traversing order at the resolution process by a DNS resolver.

#### (3) Handle DNS Zone:

For the resolution of both, domain names and Handles, it is necessary to traverse to the responsible node. For domain names, the traversal path is given by its composing labels, whereas for Handles it is given by the prefix. The Handle prefix is controlled by the Global Handle Registry, which holds the addresses of the responsible Handle servers for each individual prefix. Hence, the resolution procedure of Handles over DNS traffic has to involve the Global Handle Registry in order to find the addresses for the responsible Handle servers. For the representation of Handles as domain names, this means that they have to include a common DNS zone name, which is composed of the servers forming the Global Handle Registry: The Handle Zone. However, currently there is only the "hdl.handle.net." zone, which is composed of the Global Proxy Resolvers. For the realization of our approach it is instead necessary to register an additional zone for the Global Handle Registry, e.g. "handle.pid."

To summarize this discussion, Figure 6 provides an example for the transformation of an individual Handle into the corresponding domain name. The corresponding *name* field of the Resource Record is denoted as *dnsHandle* (see Figure 5).

Fig. 6: Domain Name Representation of a Handle

### E. Resolution Procedure

The appropriate resolution procedure is depicted in Figure 7. To resolve a Handle over DNS, the Handle has to be transformed into its domain name representation, which is done at step 0. For a Java-based application we have implemented a transformation module (*HandleDNSResolver*) on top of an already existing DNS module for Java (*dnsjava*) [20]. The method `getTypesByName(handle)` returns all type-data pairs as a JSON string. In addition, the method `getTypeValueByName(handle, type)` returns only the type-value pairs for a specified type.

The steps 1 to 5 are required to be traversed until the actual Handle DNS zone is reached. In these steps, the DNS resolver communicates with ordinary DNS servers in order to reach the Handle DNS zone. At step 6, the DNS resolver communicates with the DNS interface of the Global Handle Registry to find the authoritative Handle server for a specific prefix. The Global Handle Registry in turn, responds with a referral to the responsible Handle server. At step 8, the DNS resolver queries the responsible Handle server through DNS traffic about a specific domain name. At the responsible Handle server the queried domain name is transformed into a Handle identifier for which the Handle Record is retrieved from the database. After applying the mapping procedure (Figure 5) on the retrieved Handle Record, the Handle server responds with multiple TXT Resource Records (step 9). Finally, the response is forwarded to the requesting application.

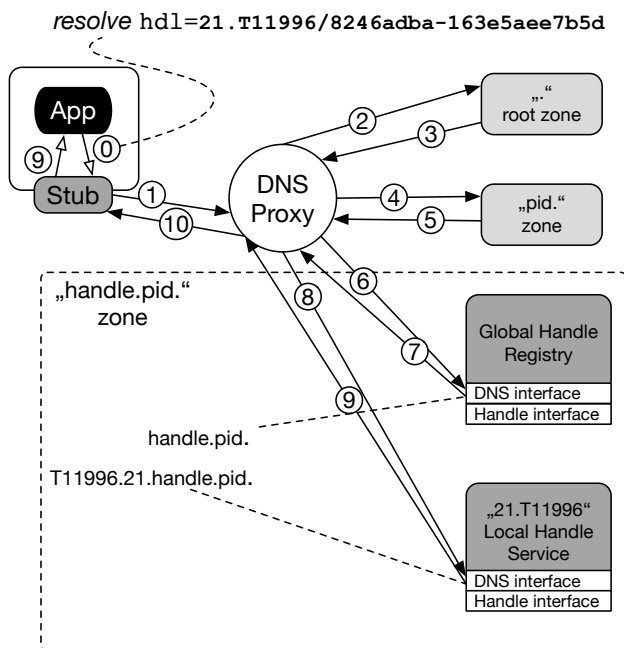

Fig. 7: Resolution Procedure for Handles for DNS

## V. EVALUATION

In this section, we will evaluate our approach of resolving Handles over DNS traffic. Important parts of our experimental

setup, which we will describe in the next subsection, are based on the GWDG infrastructure. GWDG is the service provider for Max-Planck Society of Germany and the University of Göttingen. Moreover, the persistent identifier systems offered by GWDG are based on the Handle System. In addition, GWDG is also member of the DONA Foundation [21], which is controlling the global Handle System infrastructure.

### A. Experimental Setup

Our experimental setup consists of the following components:

- **Imitation of Global Handle Registry:**

For the evaluation we have setup an imitation of the GHR equipped with a DNS interface. This imitated GHR consists of two servers, whereas the primary is hosted at GWDG and the mirror on an Amazon EC2 instance. In addition, these two servers are the nameservers for our experimental Handle DNS zone "hx.gwdg.de.", which is a sub zone under the GWDG zone "gwdg.de."

- **Local Handle Service:**

Also the LHS consists of a primary and a mirror Handle server, whereas both are hosted at GWDG and equipped with our DNS extension. This LHS is responsible for Handles under the prefix "21.T11996". In addition, the Handle servers of this LHS are at the same time the nameservers for the "T11996.21.hx.gwdg.de." zone.

- **Load Generator Application:**

The load generator is a Java-based application hosted on an Amazon EC2 instance located in Frankfurt. This application is equipped with three different modules: The first module is used to resolve Handles directly by means of the Handle libraries, without involving a specific proxy system. The second module is used to resolve Handles through the Global Proxy Resolver (hdl.handle.net), which is the current standard way for resolving Handles. The third module uses our *HandleDNSResolver* module to resolve Handles over DNS traffic.

- **Handle Proxy:**

Although, the resolution procedure through the Global Proxy Resolver will also involve proxy servers outside of Europe (due to DNS round-robin), for our evaluation we will only consider the two proxy servers in located in Europe. One of the European proxy servers is hosted at an Amazon EC2 instance located in Ireland, whereas the other one is hosted at GWDG. Currently, within the Handle System infrastructure efforts are being made to replace the DNS round-robin based proxy server selection by anycast server selection. The result of that endeavor will be that in the near future requests made in Europe will be answered by the European proxy servers. Hence, in our evaluation we will already cover the Handle System infrastructure of the near future by only considering the European proxy servers.

- **DNS Proxy:**

To resolve Handles over DNS traffic, we made use of two different DNS resolvers. The first one is an

internal Amazon DNS resolver preconfigured in the EC2 instances. This can be considered to reflect the situation of institutions which make use of their internal DNS resolvers.

In contrast to that, for the second one, we replaced the IP-address of the preconfigured DNS resolver by the address of the public Google DNS resolver, which is reachable via the IP-address 8.8.8.8.

In summary, we have utilized five different resolvers:

- Built-in resolver based on Handle libraries.
- Handle proxy server located in Ireland.
- Handle proxy server located in Germany at GWDG.
- Amazon DNS resolver.
- Google DNS resolver.

### B. Measurements

Figure 8 finally illustrates the measurements for each of the five resolution approaches in the same order as listed above. The measuring process consists of two runs of 25,000 subsequent resolution requests for each approach. The mean resolution times of the first runs are depicted by the white left-sided bars. The right-sided black bars in turn, depict the mean resolution times of the second runs, which is intended to reveal the effect of caching. For all approaches, the bars show the resolution times from the perspective of the load generator application. Moreover, for the resolution through the Handle proxy servers, we were able to retrieve the response times from the logging files. Hence, the contribution of the Handle proxy server and the LHS to the overall resolution time is marked by hatches on the respective bars.

Ultimately, the measurements allow the following interpretations:

- (1) In both runs, the resolution with the Handle libraries is the fastest method. Since this approach directly communicates with the LHS, there is no overhead caused by the involvement of any proxy system. The disadvantage of this approach is the requirement for the implementation of the Handle libraries into the application, which could cause considerable amount of redesign of the application. The intention behind this approach in this evaluation is to provide a measure for the fastest resolution technique.

- (2) The bars corresponding to the resolution through the Handle proxy servers show clearly the high contribution of the latency between the requesting application and the proxy server. This is especially visible by the second runs, whereby the Handle Record is cached at the proxy servers. Since in the second run, there is no communication between the proxy server and the LHS, the resolution time consists of the latency between the application and the proxy server only.

For the Handle proxy server located in Ireland the impact of the latency between proxy server and LHS to the overall resolution time is significant as well. However, by means of caching at the proxy server the impact of the latency between proxy and LHS can be minimized for frequently resolved Handles, which can be seen from the second run.

- (3) The measurements for the Handle proxy hosted at GWDG and the preconfigured internal Amazon DNS resolver are in terms of network latency are quite comparable. The resolution via the GWDG Handle proxy consists to a great extend of the latency between the Amazon EC2 instance and the proxy server. Since the LHS is hosted at GWDG as well, the latency between this LHS and the GWDG Handle proxy is almost negligible. The database lookup at the LHS has still a small impact onto the overall resolution time, which can be seen from the LHS hatch on the bar. In contrast to that, the resolution time with the Amazon DNS resolver primarily consists of the latency between the LHS and the DNS resolver. As can be seen from the second run, the latency between the application and the DNS resolver is vanishingly small.

Moreover, the second run also reveal the real benefit of the approach of resolving Handles through DNS traffic: Since the DNS resolver is in close proximity of the application, the resolution time of cached Handles is even shorter than the resolution time achieved by a direct communication with the LHS (first run of resolution via Handle libraries). This is quite beneficial for institutions which are heavily working with Handles.

Another fundamental aspect which can be deduced from these two measurements is that Handle resolution via DNS does not cause a significant overhead due to the transformation effort needed to map Handle Values into the DNS resource records. Therefore, the resolution times for both resolution techniques are almost identical for similar network latencies between the involved components.

**Fig. 8:** Comparison of resolution times for different resolution approaches

- (4) Although the resolution time with the public Google DNS resolver in the first run is significantly higher than with the GWDG Handle proxy, in the second run, it is the opposite case. Furthermore, the measurements corresponding to the public Google DNS resolver enable to deduce a general strategy to reduce the resolution time for Handles: Each application uses the DNS resolver in its proximity to minimize the latency to the resolver. By means of caching, the communication overhead between proxy resolver and LHS could be eliminated, which ultimately could result in a significant resolution time reduction for frequently resolved Handles. Although, caching is also applied at Handle proxy servers, the fundamental difference is based on the fact that for an individual application there is always a DNS resolver in its close proximity, which is not the case for Handle proxy servers.

## VI. CONCLUSION

Persistent Identifiers are becoming more and more important which is correlating with the explosive growth of research datasets. To ensure a sustainable access to research datasets, they are increasingly registered at persistent identifier systems to be assigned a globally unique and location-independent identifier. However, as the count of persistent identifiers increases, the performance of the corresponding resolution systems is becoming increasingly critical for research data management. In principle, persistent identifiers are quite comparable to domain names, both are registered once and resolved multiple times. For the resolution of domain names there a myriad of globally distributed DNS resolvers. In contrast to that, for persistent identifiers the count of resolvers are only very few. For the Handle System, which can be considered as the most important and established persistent identifier system, there are currently only five geographically distributed resolvers available. Hence, the resolution time for persistent identifiers generally consists to a great extend of the latency between requesting application and the particular resolver. The fundamental idea in this work is therefore to use DNS resolvers for resolving persistent identifiers.

For a realization of this idea, we have first extended the Handle servers with a DNS interface and secondly conceived an algorithm to map the Handle data model into DNS Resource Records. The result of this endeavor is the resolvability of Handle persistent identifiers over ordinary, unmodified DNS resolvers.

Furthermore, by means of an evaluation, we have proofed that the resolution time for Handles could be significantly reduced with DNS resolvers. This is especially significant for Handles which are cached at DNS resolvers. Although, frequently resolved Handles are cached at the Handle resolvers as well, the overall resolution time suffers from the small number of globally distributed Handle resolvers, which is not the case with the myriad of DNS resolvers. In addition, the evaluation has also proofed that there is no performance loss due to the mapping from the Handle data model into DNS Resource Records.

Further research is needed, to conceive a standardized DNS Resource Record, which is specifically tailored to hold meta information about digital datasets. This would ultimately enable DNS to move from a simple resolution system, which resolves human-friendly labels into IP-addresses towards a real data dissemination system.

**Abstract**—System specifications can be modeled using various types of notations and diagrams regarding applications of the particular model. In this paper, we present an overview of the existing solutions, focusing on UML, BPMN and DMN models and the diagrams provided by these notations. We perform a comparison of these approaches and provide examples of representing system requirements in these notations.

**Index Terms**— Software Engineering, UML, BPMN, DMN, Unified Modeling Language, Business Process Model and Notation, Decision Model and Notation

## I. INTRODUCTION

SOFTWARE engineering aims to produce effectively good quality software. Various methods and processes are at the heart of software engineering [1]. In practical software design, parts of systems are specified using visual models. The standard for modeling software applications is Unified Modeling Language (UML). It provides diagrams to capture requirements, collaboration between parts of the software that realize them, the realization itself and models which show how everything fits together and is executed [2].

Business Process Management [3], in turn, is a modern approach to improving organization's workflow, focused on reengineering of processes to obtain optimization of procedures, increase efficiency and effectiveness by constant process improvement. Business Process Model and Notation (BPMN) is the standard for designing business process models. BPMN can get along with with UML [4], but it does not support modeling of some concepts such as rules. Decision Model and Notation (DMN) provides a standard for modeling decisions and supports decision management and business rules.

The rest of this paper is organized as follows: In Sections II–IV, UML, BPMN, and DMN are introduced. Section V presents the comparison of the notations with the focus on the comparisons from the 4+1 view model architecture perspective. Contributions of the paper are summarized in Section VI.

## II. UNIFIED MODELING LANGUAGE (UML)

Unified Modeling Language (UML) is a general-purpose modeling language in the field of software engineering. Modeling is about capturing a system as models [2], which can be depicted as sets of diagrams. Such diagrams describe the system (or a part of it). UML 2 defines a variety of diagrams divided

The paper is supported by the AGH UST grant.

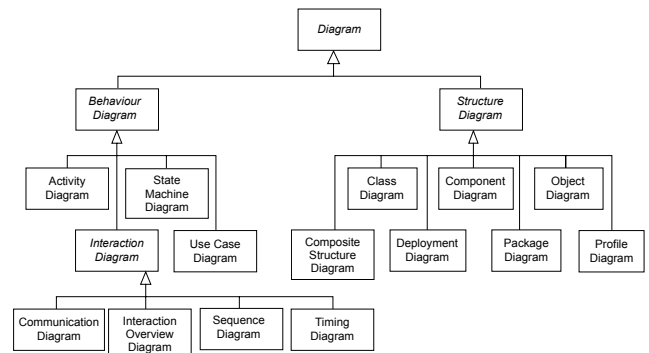

Figure 1: Hierarchy of UML diagram types [5]

into two main categories: *structure diagrams* – containing diagrams representing the structure of a modeled application, and *behavior diagrams* – contain diagrams representing general types of behavior. A tree showing the classification of the UML diagram types [5] is presented in Fig. 1.

The complete system can be described by a number of models describing the system from different angles, often on various levels of abstraction. By design, each UML diagram should be consistent with any other diagram representing the same model. But inconsistency is highly likely to occur in models. Some issues can be resolved using formal methods [6]–[8] or ontologies [9]–[11], but there are also other modeling problems such as exceptions [12] or using reverse engineered models [13].

UML itself is not a design method or a software process. It is only a notation which can be useful within a software process or designing. Another issue is a methodology which indicates how to apply a design. UML itself does not require any specific method, but mostly it is used with an object-oriented design method.

## III. BUSINESS PROCESS MODEL AND NOTATION (BPMN)

Business Process Model and Notation (BPMN) [14] is the most widely used notation for modeling business processes. As the notation is quite complex, it has many application areas that may be found in [15]–[20].

The current BPMN 2.0 specification [21] provides four different types of diagrams:

- 1) Process diagram (describing the ways in which operations are carried out to accomplish the intended objectives of an organization),
- 2) Collaboration diagram (presenting the collaborative public Business 2 Business process),
- 3) Conversation diagram (which specifies the logical relation of message exchanges),
- 4) Choreography diagram (defining the expected behavior between two or more interacting business participants in the process).

In most cases, using only the process model is sufficient. The process model uses four basic categories of elements to model BPs: flow objects (activities, gateways, and events), connecting objects (sequence flows, message flows, and associations), swimlanes, and artifacts as shown in Figure 2.

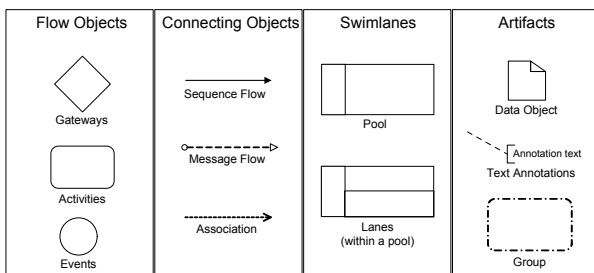

Figure 2: BPMN core elements of Process diagram

In the case of flow object elements, activities denote tasks that have to be performed, events indicate something that happens during the lifetime of the process, and gateways determine forking and merging of the sequence flow between tasks in a process, depending on some conditions. The sequence flow between flow objects is used to model the flow of control in a process. The message flow between selected elements is used to model the flow of messages between participants of a process (which are depicted as different pools).

BPMN 2.0 defines more than 100 elements, thus practitioners differentiate them based on the degree of model detail. Three levels of models can be distinguished [22]: a descriptive level, which is the basic level that uses a very intuitive subset of BPMN to reflect a “happy path” scenario and all major activities in a process; an analytical level, dedicated to analysts, modelers and business architects that use complex structures and elements to design fully representative processes, and an executable level for technicians in which execution details can be captured in the model. Additionally, many different extensions of BPMN were proposed to capture other aspects of business processes [23]–[28].

#### IV. DECISION MODEL AND NOTATION

DMN [29] is a brand new OMG standard for decision modeling. Such a decision determines the result (or selects some option) based on some input data. Its goal is to provide the notation for decision modeling so the decision can be easily presented in diagrams and understandable by business users [30]. The main purposes of the notation are:

modeling human decision-making, modeling the requirements for automated decision-making, and implementing automated decision-making [29]. Such decision models can be integrated with BPMN models or exist separately [31].

There are four types of core elements in DMN: Decision, Business Knowledge Model, Input Data, and Knowledge Source (see Fig. 3). Decision elements are used to determine an output from a number of inputs using some decision logic. Business Knowledge Model elements denote functions encapsulating business knowledge (like decision table, business rules or analytic models). Input Data elements are used for modeling the input of a Decision or Business Knowledge Model when values are defined outside of the decision model. Knowledge Source elements model authoritative knowledge sources in a decision model. These elements can be connected using different requirement connectors. There are three different types of them: Information, Knowledge, and Authority.

Figure 3: The types of DMN elements

The decision model is usually represented as *Decision Requirements Graph (DRG)*. DRG can be split into one or more *Decision Requirements Diagrams (DRD)* presenting a particular view of the model [29].

DMN provides a wide range of tools (various types of decision logic representation, Elements, and Requirements) to implement decision-making, automated or not. It can be easily adjusted and understood. It fills the gap in the market of decision modeling and is often used with BPMN.

#### V. COMPARISON OF UML, BPMN AND DMN

We compare the diagrams of the UML, BPMN and DMN notations using the evaluation Framework for BPM/ISM technique [33] and comparing the diagrams in terms of system specification views, especially focusing on the “4+1” view model architecture [32].

Software architecture deals with abstraction, with composition and decomposition. To describe such architecture, a “4+1” model is often used. The model was designed by Philippe Kruchten and used for “describing the architecture of software-intensive systems, based on the use of multiple, concurrent views” [32]. The views are used to describe the system from the viewpoint of different users (end-users, developers and project managers) [32], [34]. The “4+1” view model supports five main views, as shown in Figure 4 and in Table:

1. *Logical View* – an object model of the design.
2. *Process View* – concurrency and synchronization aspects.
3. *Development View* – static organization of the software.
4. *Physical View* – mapping of the software to the hardware.
- +1 *Use-cases view* – various usage scenarios.

The Logical View (Object-oriented Decomposition) and the Process View are at a conceptual level and are used from analysis to design [35]. This view focuses on realizing an application's functionality in terms of structural element, key abstractions and mechanisms, distribution of responsibilities and separation of concerns. Users-architects use this view for functional analysis [35]. The Process View (process decomposition) [36] captures the concurrency and synchronization aspects of the design. Development View describes the static organization of the software in its development environment [35]. The Physical view (mapping software to hardware) describes the mapping(s) of the software onto the hardware and reflects its distributed aspect [36]. Use case view presents functionality of the system, its external interfaces, and principal users of the system.

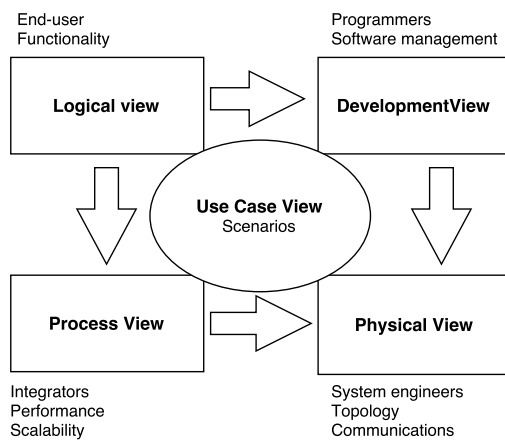

Figure 4: The "4+1" view model architecture

Similarly, the evaluation framework for BPM/ISM [33] is not intended to be rigid, as the lines between depth and breadth of modeling are blurred and hard to be separated.

Our evaluation of the UML, BPMN, and DMN notations in terms of the Giaglis evaluation framework is presented in Table II. Table III presents the comparison of the diagrams in these notations, especially focusing on their application in "4+1" view model architecture [32].

## VI. SUMMARY

This paper has given an overview and provided a comparison of the most popular notations for modeling systems, processes, and decisions, i.e. the UML, BPMN and DMN notations. These results have been presented in terms of the "4+1" view model architecture. Further specification of the contribution is going to be a subject of future research to find the appropriate modeling methods for particular systems.

**Abstract**—The goal of this research is to investigate the process of customer knowledge capturing, specifically knowledge coming from customers. We identified and classified tools and methods of capturing knowledge from customers. Both general tools from knowledge management and specialized ones from marketing research were considered. Besides, we aligned these tools and methods with the contextual factors using case studies from electrotechnical and software development industries, thus, the corresponding decision tree was suggested.

## I. INTRODUCTION

DIFFERENT enterprise knowledge domains (e.g. product/service knowledge, customer knowledge, operations management or strategic management knowledge etc.) have different knowledge characteristics and knowledge types. As a result, different knowledge domains require specific methods and tools (Kudryavtsev, Menshikova, 2016; Kudryavtsev et al, 2017). A number of studies support the idea to differentiate KM methods and tools based on types and domains of knowledge. For example, Jobe and Schulz (Schulz, Jobe, 2001) have shown a positive relationship between the "focused" KM strategy and performance of the company on the basis of empirical research. "Focused" strategy involves the use of different methods of knowledge codification based on the type of knowledge.

Customer knowledge plays an important role in every organization. Researchers and practitioners have focused on customer orientation as a source of competitive advantage for a long time. According to Kohli and Jaworski (1990), customer orientation suggests different activities that are related to information generation, dissemination, and corresponding responses to customer needs and preferences, both current and future ones. For instance, customer orientation is aligned to a degree organization captures and uses information from customers, converts this information into a strategy for meeting customer needs, and implements that strat-

egy by appropriately responding to and meeting customer needs (Hooley and Theoharakis, 2008).

In addition, Narver and Slater (1990) described customer orientation as an important element of market orientation which is linked to organizational performance by multiple studies. Moreover, Saad et al. (2015) state that customer orientation of the firm is a key part of the marketing concept itself. Therefore, the role of customer orientation cannot be overestimated for a modern company.

Consequently, in order to respond to customer needs and requirements and to eventually satisfy them, possessing of relevant customer knowledge is important for an organization. We have chosen to focus on one type of customer knowledge, namely knowledge received FROM customers. So the aim of the paper is to identify tools and methods of capturing knowledge from customers and to understand contextual factors, which influence the choice of a particular tool/method.

The paper is structured as follows. First, we provide a short literature overview with a theoretical background of the research. Then we introduce the methodology of the study. In the following section, we describe the results of the study and discuss implications of the study results.

## II. THEORETICAL BACKGROUND

The present research is built upon marketing (specifically, customer knowledge concept) and knowledge management (knowledge capturing) theories.

Knowledge, as well as customer knowledge, can be tacit or implicit. Therefore, different methods of knowledge capturing should be used for various types of customer knowledge (Nonaka and Takeuchi, 1995). In the next subsections, short literature review of customer knowledge concept and customer knowledge classification, as well as the review of knowledge capturing tools are provided.

### A. Customer Knowledge

Researchers state that the customer knowledge is either the knowledge that an organization has about its customers or knowledge about an organization, its products or services, that customers possess (Campbell, 2003; Mitussis et al., 2006; Lee et al., 2011). Customer knowledge is a comprehensive term and the definition itself depends on a source of knowledge (Nejatian et al., 2011).

Customer knowledge reflects the way the company understands its current and future customers' needs and preferences (Lee et al., 2011). Feng and Tian (2005), based on Gebert et al. (2002) define customer knowledge as "the dynamic combination of experience, value and insight information needed, created and absorbed during the process of transaction and exchange between the customers and enterprise". Campbell (2003) defines customer knowledge as the "organized and structured information about the customer as a result of systematic processing". According to Mitussis et al. (2006), customer knowledge can be defined as a comprehensive type of knowledge, because customer knowledge may be acquired from different sources and channels (Nejatian et al., 2011). Companies usually capture customer knowledge by interactions and dialogues with customers, by observing the ways customers use products or experience service, as well as by analyzing corporate data and information in order to forecast customer behaviour (Wayland and Cole, 1997).

In his research of 108 Fortune 500 companies, Harlow (2008) stated that companies with developed knowledge management approaches and tools have higher effectiveness of innovation activities. It means that use of knowledge management tools allows company to be more successful in terms of new product development.

As for marketing perspective, capturing information or knowledge from customers is traditionally viewed as a part of the market research or, in particular, the customer research. Organizations use different tools and methods to provide this. General methods and tools of capturing knowledge from customers are mainly mentioned in knowledge management literature and toolboxes, such as Asian Productivity Organization knowledge management tools and techniques manual (2010), UNICEF knowledge exchange toolbox (2015), (Gavrilova, Andreeva, 2012); and specialized tools of knowledge capturing from customers mainly used within marketing for market and customer research. Some of the specialized tools are used online.

### B. Customer Knowledge Classifications

There are several classification criteria for customer knowledge. First, customer knowledge can be classified as follows: knowledge about customers; knowledge from customers; knowledge for customers (Gebert et al., 2002; Feng and Tian, 2005). Knowledge from customers has a particular significance for modern organizations, as customers can contribute to the organizations' understanding of current and future products or services, strengths and weaknesses, etc. (Wayland and Cole, 1997; Zack, 2003; Paquette, 2006). Relations with organizations enable customers to have their opinions, thoughts, ideas, satisfied or

non-satisfied needs, and they may share this knowledge with the organization. This knowledge can be used within the organization for different purposes, the main such purposes are products or services' quality improvement, new product development (NPD), market or customer research and other purposes that depend on individual organization (Paquette, 2006; Laage-Hellman et al., 2014).

Second classification of customer knowledge is the split into tacit and explicit knowledge. Helie and Sun (2010) characterized explicit knowledge as "knowledge that can be readily articulated, codified, accessed and verbalized". To put it differently, it is the description of theories, methods, techniques, technologies, machines and mechanisms, structures, systems, etc. Explicit knowledge is stored in the actual physical media (books, paper documents, drawings, diagrams, movies, databases, etc). It means that this type of knowledge is a storage and it is easier to process and use this knowledge.

As for tacit knowledge, it is personal knowledge, inseparable from individual experience. It can be transmitted by direct contact - "face to face" or using special procedures of knowledge extraction.

Customers accumulate the knowledge about products or services they have and use, and they actually may contribute it into company's learning process (Zack, 2003). According to Paquette (2006), customers can provide the organization with unique knowledge that may be used for improving its internal operations, including innovation and new product development. On the other hand, the organization provides a customer with knowledge of its products and services, which makes customer more informed about the company, and, therefore, the customer may become loyal to the company. This two-way flow of knowledge allows company to create a competitive advantage based on relationship, or probably, partnership with the customer.

To summarize definitions and statements mentioned above, customer knowledge may be both:

- Structured information, facts, knowledge that company has about its customers, and their needs, preferences
- Knowledge that a customer possesses in the form of experience, value and insight information. In this case, knowledge is not codified; it is "stored" in minds of customers, so it can be identified as tacit knowledge. It means that it is difficult to acquire this type of knowledge, because it deals with state of mind of customers, however, it is important to consider this type of knowledge due to potential source of insights and ideas (Crié and Micheaux (2006).

Another approach to customer knowledge classification was proposed by Crié and Micheaux (2006). The authors divide customer knowledge into two types, namely: "Behavioral", that may be easily captured and is basically quantitative in its nature (transactional data), and "Attitudinal" that can hardly be captured, but it suggests customer ideas and insights.

However, this research used the following classification (Tseng, Wu, 2014; Gebert, 2002):

- Knowledge FOR customers: knowledge, provided to customers to satisfy their needs;
- Knowledge ABOUT customers: knowledge about customers to optimize customer profiling and segmentation, and campaign management processes.
- Knowledge FROM customers: knowledge possessed by customers and obtained by organizations by interacting with them.

This paper is focused on the third type of customer knowledge, knowledge from customers. As far as the authors know, there are no academic studies related specifically to this type of knowledge. The next subsection covers this type of customer knowledge in detail.

### C. Knowledge FROM Customers

Wang and Yu (2010) state that knowledge from customers refers to the feedback to the company, its products and services, competitiveness, that can be acquired from a customer. Development of technologies provides for increased amount of information that is available to customers, and today, consumers can easily develop their own opinions regarding the company, its products or services (Tseng and Wu, 2014). What is more, customers are paying more attention to the quality of products and services they are consuming, rather than the price (still, the price is also important), and this statement is especially truthful for non-consumable goods (Garcia-Murillo and Annabi, 2002).

According to Fang and Tsai (2005), the companies should consider customer expectations, because it would provide for satisfying service and development of the service quality. Mithas et al. (2005) also stated that through communication and interaction with customers, the company can gain customer knowledge related to new demands about products or services that can be helpful references for improvement; moreover, this process is beneficial for customer satisfaction, customer loyalty and employee productivity. Therefore, the purposes of capturing knowledge from customers are quite various, ranging from new product development and quality of products/services enhancements to conducting comprehensive market researches in order to understand trends, customer needs and wishes, or other things depending on the company and its goals.

In addition, such forms or representations as opinions, feedback, insights, requirements, and ideas may be considered as knowledge from customers.

The object of knowledge from customers (what exactly customers may know about organization) may also vary (Gebert et al., 2002; Paquette, 2006; Laage-Hellman et al., 2014): knowledge about products, knowledge about services, knowledge about brand, knowledge about business processes, knowledge about market, knowledge about partners.

We summarized the review of knowledge from customers in fig. 1.

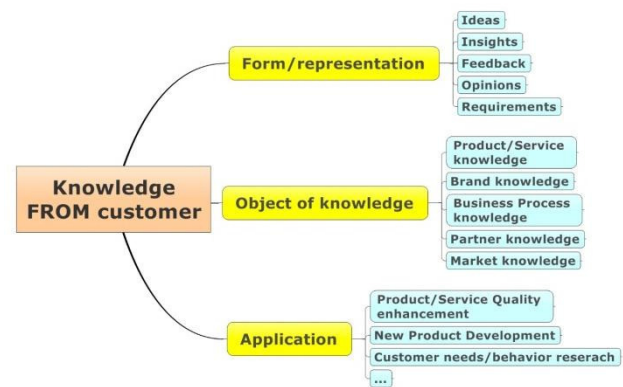

Fig. 1 Overview of knowledge FROM customer

## III. RESEARCH METHODOLOGY

As the aim of the paper was to identify tools and methods of capturing knowledge from customers and to understand contextual factors, which influence the choice of a particular tool/method, research is mostly of exploratory nature, we have chosen a qualitative approach. Literature review, case study, semi-structured interviews and document analysis were employed for our research.

The study was conducted in three phases.

First, literature review was undertaken. Based on the results of the literature analysis, a preliminary classification of tools for capturing knowledge from customers was developed. Since factors, which influence the selection of tools, were also in the focus of the research, a framework for analysis of the context of choosing and using the tools of capturing knowledge from customers was found. The choice fell on 4W framework (Sergeeva and Andreeva, 2014) based on Johns` (2006) "Who? Where? Why? What?" framework. The framework helped to formulate four main questions, answering which allows disclosing the context:

- WHO are the customers of the company?
- WHAT types and forms of knowledge from customers are collected?
  - What are the targets of the company, why it captures knowledge from the customer? (WHY?)
  - What is the company itself, the culture, management style, level of maturity, industry, etc. (WHERE?)

During the second phase preliminary in-depth interviews with 3 knowledge management and strategic consultants were conducted. Preliminary classification of tools for capturing knowledge from customers was demonstrated to them and feedback was collected. These interviews helped to improve classification of tools (see Appendix, Figure A.1) and fine-tune questions for the third phase.

The third phase involved the multiple case study method. 6 companies (cases) from two marketing-driven and knowledge-intensive industries were analysed: 3 electro-technical multinational corporations (companies A, B, C) and 3 software development firms (companies D, E, F). All these companies are operating at Russian market. The primary source of data was in-depth interviews, the secondary source – the companies` web sites, corporate reports and industry analytics. We conducted 6 semi-

structured interviews, which lasted for 60-90 minutes each with experts from these companies. The questions discussed were related to the process of customer knowledge capturing and to the suggested classification of tools. The classification was printed out and given to respondents.

All interviews were tape recorded, transcribed and translated from Russian to English for analysis.

#### IV. RESULTS AND DISCUSSION

Based on the results of the literature analysis and in-depth interviews with 3 knowledge management and strategic consultants, a preliminary classification of tools for capturing knowledge from customers was developed (see Appendix, Figure A.1).

Multiple case study helped to identify contextual factors, which influence application of tools for capturing knowledge from customers within electrotechnical and software development industries.

##### A. *Electro-Technical Industry*

In terms of corporate strategy, all respondents stated that localization of products is a key point for the Russian market (since only multinational corporations were analyzed in this industry). That is why market and customer knowledge is important for them.

We did not find any evidence that management style and organizational culture interrelate with the choice of customer knowledge capturing tools. However, the company that claims to be customer driven and has close relations with customers uses simple and customer-friendly tools and methods such as surveys, feedback forms, etc.

According to all respondents, forms or representations of knowledge may be different: insights, feedback, ideas, and requirements. Almost every form of information from customers that may be used by the company is defined as customer knowledge. However, types of knowledge are different. All companies stated that they used different types of knowledge from customers: product knowledge, market knowledge, business process knowledge.

In this case, product knowledge accumulates all types of information and knowledge about the company's products that customers possess. For example, features of desired products, positive or negative experience linked to a product is referred to as product knowledge. All contacted companies use product knowledge for different purposes.

Here, market knowledge is knowledge of market trends, competitor analysis, customer preferences and trends, etc. There are different reasons for capturing market knowledge from customers: one company uses surveys and questionnaires among its major customers in order to collect market knowledge for opportunity identification, new product development, market penetration. Company B uses market knowledge for market research purposes and orders market research from third parties. Company C, as well as company A, uses surveys and questionnaires for strategic purposes.

Business process knowledge, or knowledge of customer technologies, is used by all companies for different purposes. Company A and C serve large customers with

sophisticated projects where NPD is impossible without considering concrete requirements from customer in terms of business processes and technologies. Company B also uses business process knowledge as well as product knowledge for NPD to satisfy needs of customers (especially from construction industry).

To sum up, types of knowledge and forms of knowledge are quite strong determinants of tools' and methods' selection. However, the type of knowledge alone does not influence the choice of tools and methods; the specific goal of knowledge usage is significant. For example, surveys can be used in both product knowledge for measuring customer satisfaction and market knowledge for identifying market trends.

Reasons and purposes why company captures knowledge from customers is an important determinant for a choice of knowledge capturing instrument. All respondents agreed that before using particular tools or method of capturing customer knowledge, first thing to consider is the purpose of using knowledge from customer. New product development and quality enhancements involve quite different tools. According to respondents, knowledge from customers is used to achieve the following goals:

- Market research;
- New product development;
- Quality enhancements;
- Product localization;
- Customer satisfaction assessment;
- Product requirements and standard clarification;
- Internal business process improvement.

Market research provides for usage of different tools. Company A and company B use different approaches to market research. While company A conducts surveys and sends questionnaires to its customers, company B prefers to use third-party market researches. Like Company A, Company C also uses surveys for its customers.

New product development for sophisticated projects is organized in companies A and C as follows: brainstorming sessions with customer representatives are used for feature discussions, idea generation of needed functions. Company B also uses brainstorming sessions for same purposes.

Product quality enhancements are mostly managed by trial operations or "test drives", where product is tested by customer with succeeding customer's feedback with regard to possible changes or improvements using this tool. Other tools of quality enhancements applied by all companies include feedback forms on web sites, call centers, sometimes, focus groups.

Product localization is closely linked to NPD and quality enhancements, so the tools used for this purpose are the same.

Customer satisfaction assessment is an important sphere or goal of customer knowledge application, as it provides for the opportunity to the company to understand its products' suitability for customers. As for tools and methods, all contacted companies use surveys (NPS score), mailout asking for feedback, feedback forms on web sites, call centers. Company A and C use sentiment analysis in order to identify whether final customers are satisfied or not (mostly for consumer goods, where final customers are people able to leave comments, reviews, feedback on the web, so it is not applicable for business customers). Company B uses

social networks, blogs and forums for this purpose, where it analyzes feedback from final customers as well.

Product requirements' and standards' clarifications are applied by all companies, because they follow their localization strategy, and all new and existing products should be localized for the Russian market. For this purpose, companies contact engineering centers' (design institutions) representatives and conduct interviews or organize workshops, in order to clarify these requirements and standards for products.

Internal business improvement was mentioned just once, in an interview with the company B. They stated that usage of call centers, and web site feedback forms sometimes leads to improvement of internal business processes because customers notice some controversial things need to be improved.

As different industries suggest different type of customers, this dimension may influence the choice of instruments. In author's cases, all contacted companies have two major types of customers: direct and non-direct. Direct ones can be defined as customers that buy products or services from contacted companies. Non-direct customers are defined as influential customers; their knowledge influence companies' decisions.

First, direct customers. Company A, and company C together have b2b customers in the form of distributors, retailers. While company B works directly with its customers who are large maintenance and construction companies, without third parties. In latter case, closer customer relations that include special technical consultant that realizes complex customer care before and after sales, relieves the company from usage of significant number of instruments of capturing knowledge from customers. Company A and company C also work directly with large companies in implementing complex energy networks, processes automation projects, etc. In this case, customer relations are close enough, however they are organized in a bit another way: meetings with customer representatives is major type of communication and knowledge capturing process.

Second, non-direct customers. All contacted companies from electrotechnical industry stated that in order to localize its products for Russian market they also contact so-called engineering centers of design institutions in order to clarify official requirements and standards for products. It is an important step in launching new products to Russian market.

What is more, company A and company C noted that designers, architects and integrators are important non-direct customers too. That is because these 2 companies produce products that are used in design and repair activities in apartments, such as power sockets, counters, switchers, etc. The reason of this fact is quite simple. Interior designers and architects may advise final customers to install products by well-known companies, because they are better quality and design. Therefore, companies are interested in this type of non-direct customers due to insights supply and knowledge that can be used for NPD, product design, etc.

To sum it up, customers as determiners of context of choosing and using instruments and methods of capturing knowledge from customers in electrotechnical industry play moderate role. Type of customer may influence the choice of

instruments and methods, but it depends primarily on how company organizes its customer communication processes.

TABLE 1.  
CONTEXT IN ELECTRO-TECHNICAL INDUSTRY.

Strategy	Localization of products for Russian market
Customers	Direct customers (distributors and retailers; industry companies), non-direct customers (final buyers; engineering centers; designers, architects, integrators)
Forms of knowledge	Insights, requirements, feedback, ideas, thoughts

TABLE 2.  
KNOWLEDGE CAPTURING IN ELECTRO-TECHNICAL INDUSTRY.

Types of knowledge	Applications/ goals	Instruments of capturing knowledge from customers
Market knowledge	Market research	Surveys, Questionnaires, Partner portal
Product knowledge	Quality enhancements	Focus groups
	Customer satisfaction assessment	NPS surveys
Product knowledge, Business process knowledge	NPD	Brainstorming, content analysis, surveys, focus groups, interviews
	Quality enhancements	Test drives (trial operation period); surveys
Product knowledge	Customer satisfaction measurement	Feedback forms on web site; Surveys; call-centers; sentiment analysis
Product knowledge (requirements and standards)	Product localization	Interviews
Product knowledge	NPD (design, features, standards)	Interviews; Blogs

## B. Software Development Industry

There is a significant number of differences with electro technical industry in both tools and methods of capturing knowledge from customers, and basis of these tools and methods' choosing and application.

Development approach defines the whole software development cycle. Two well-known approaches to development used by respondent companies are Waterfall approach and Agile approach.

Waterfall approach, or waterfall model, involves consistent implementation of all phases of the project in a fixed sequence. The transition to the next stage means full completion of the previous phase. The requirements specified during the stage of requirements elicitation are strictly documented as technical specifications and fixed for the period of project development. At the end of each stage, a complete set of documentation is released, and this set shall be sufficient to ensure that the development may be

continued by another development team. Therefore, this approach suggests a lot of documentation and procedures linked to requirements gathering from customers.

Agile approach involves the use of iterative development, a dynamic requirements elicitation, and provision of their implementation by means of constant interaction within the self-organizing working groups, consisting of experts in various fields, and close relations with customers (Agile Alliance, 2015). Therefore, Agile approach means more flexibility, less bureaucracy and documentation, and less application of tools. According to company E and company F representatives, main tools are communication and company specialists' minds.

What is more, company strategy is also significant. For example, company D operates mostly on the Russian market, and it is a large player on this market, while company E and company F are international companies, and their customers are mostly large non-Russian companies. Therefore, their strategy on the Russian market includes finding excellent qualified employees and being attractive employer for them. According to company E and company F representatives, working with large international companies provides that requirements mainly have already been formalized on customer's side, and there is no need to use special tools and methods of capturing knowledge from customers for this purpose.

Meanwhile, working with the majority of Russian customers involves company-based, not customer-based, collecting and formalization of requirements to a product. Therefore, the customers' characteristics are also important in the software development industry. It is not necessarily a rule that Russian companies do not have formalized requirements, when working with software development companies.

As for customers in general, all three contacted companies (D, E, F) stated that they worked with large, enterprise-class companies and state organizations operating in different industries. However, company F focuses mostly on financial, telecommunication, and R&D companies, while companies D and E have no clear industry focus.

All respondents from software development claimed that they needed to know the finest details about customers' businesses. Therefore, business process knowledge and technology knowledge are main focus of knowledge from customers. Sometimes (company D), companies also capture market knowledge that includes knowledge about their former and existing clients and their needs. Alternatively, it appears as potential customer insights and opinions with regard to new service prototypes.

The use and application goals for tools and methods of capturing knowledge from customers in software development industry are quite predictable. Companies collect knowledge from customer to learn which service or product they should develop. All of three contacted companies use service/product requirements for new service/product development. Moreover, the process of development includes trial operation periods where customers test software and give feedback to the company, make changes. Thus, quality enhancements as tools and methods' application are also applied in software development companies.

TABLE 3.  
CONTEXT IN SOFTWARE DEVELOPMENT INDUSTRY.

<b>Strategy</b>	Duplication of company's services to broad market – Non-agile (e.g. waterfall); Being attractive employer, talent acquisition – Agile (e.g., Scrum)
<b>Customers</b>	Large companies; state organizations
<b>Forms of knowledge</b>	Requirements; feedback; opinions; thoughts

TABLE 4.  
KNOWLEDGE CAPTURING IN SOFTWARE DEVELOPMENT INDUSTRY.

<b>Types of knowledge</b>	<b>Applications/ goals</b>	<b>Instruments of capturing knowledge from customers</b>
Product requirements (and product knowledge); Business process knowledge	NPD	Wiki; Brainstorming sessions; Content analysis; Focus groups; Interviews
	Quality enhancements	Test drives (trial operation period); Task trackers; Wiki; Brainstorming sessions
	Customer satisfaction assessment	Surveys; Questionnaires; Interviews
	Beginning of relations with customer	Questionnaires; Interviews
Market knowledge	Market research (probable needs of current and former customers)	Questionnaires
	Market research (collection of opinions and insights of alpha product)	Seminars/webinars; design thinking tools

Customer satisfaction analysis or assessment is important, however, not each company uses tools and methods of capturing knowledge from customers for this purpose. Company D, following the non-Agile approach of software development, uses formal questionnaires to accomplish this task, while companies E and F, following Agile approach, learn about customer satisfaction or dissatisfaction by simple continuous communication process.

Sometimes companies use knowledge from customers to collect insights from potential customers, in order to use them in NPD, or conduct market research, in order to identify needs of their former and existing customers by offering them a different product or service (company D).

Thus, we found out that the approach to software development is an important determinant of knowledge capturing choice. Agile-based methodologies or approaches to software development clearly define usage of tools and methods of capturing knowledge from customers. Findings showed that companies which follow Agile do not simply focus on lots of these tools and methods, for Agile-based approaches do not respect comprehensive documentation, sophisticated processes, and a broad range of tools.

Communication is everything for them. On the other hand, implementation of non-Agile approaches in companies involves these tools and methods.

## V. CONCLUSION

Knowledge from customers plays an important role in customer-oriented business and can be applied for the NPD, improvement of products or services, for market or customer research purposes and other goals.

The classification of tools and methods of capturing knowledge from customers was established during the research. The split into general tools of knowledge management and specialized tools of capturing knowledge from customers was made.

The following determinants of the knowledge capturing tool were identified:

- The strategy of the company; approach to software development (for software development industry), organizational culture and management style (for electro-technical companies). This was used to define, if applicable, internal motives of application or non-application of knowledge from customers and, therefore, tools of this knowledge capture;
- The definition of case companies' customers intended for their classification;
- Forms of knowledge and objects of knowledge to show the exact knowledge from customers received by the case company;
- Applications or goals of using knowledge from customers, to put it differently, why company applies knowledge from customers and capture tools;

The main findings could be summarized as follows:

- For the electro-technical industry, the first step in choosing the tool or method of capturing knowledge from customers is identification of the application goal, while for the software development, the primary thing influencing the choice is the approach or methodology of the software development.

- For the electro-technical industry, determination of the goal of using knowledge from customers is followed by company's decision on which customers should be involved in the knowledge from customer process.

- For the software development industry, when the development approach or methodology is known, the goal or application of knowledge from customers and, therefore, tools of capturing this knowledge should be defined.

The comparison between two industries is revealed and presented as a decision tree (see Appendix, Figure A.2). Decision tree shows the way the most influential dimensions of the context influence the choice of tools among electro-technical and software development industries.

The present paper contributes to the customer orientation theories by providing for the knowledge management perspective. Besides, the study is providing for the context to the knowledge capturing tools analysis. Therefore, the study results are valuable for practitioners interested in customer knowledge capturing techniques. Moreover, the study sheds the light on the underexplored subject of knowledge from customers by providing illustrations of such knowledge for two knowledge intensive and marketing driven industries.

**Abstract**—This article proposes an ontology design pattern leading knowledge providers to represent knowledge in more normalized, precise and inter-related ways, hence in ways that help automatic matching and exploitation of knowledge from different sources. This pattern is also a knowledge sharing best practice that is domain and language independent. It can be used as a criteria for measuring the quality of an ontology. This pattern is: “using binary relation types directly derived from concept types, especially role types or process types”. The article explains this pattern and relates it to other ones, thereby illustrating ways to organize such patterns. It also provides a top-level ontology for generating relation types from concept types, e.g., those from lexical ontologies such as those derived from the WordNet lexical database. This generation and categorization helps normalizing knowledge, reduces having to introduce new relation types and helps keeping all the types organized.

## I. INTRODUCTION

ONTOLOGY Design Patterns (ODPs) are “modeling solutions to solve a recurrent ontology design problem” [1]. A “Conceptual ODP” describes a best practice (BP) for content modelling [1]. Since we only consider ODPs that represent BPs, we use these two terms interchangeably in this article to ease its reading. Many ODPs have been described. E.g., about 160 are registered in the ODP catalog at <http://ontologydesignpatterns.org> which, in this article, will now be referred to as ODPC. Despite these ODPs, most of thousands of existing ontologies that exist are still poorly inter-connected and heterogeneous in their design. It is then difficult for people and automated agents to *compare or match* such independently created knowledge representations (KRs, e.g., types or statements) to know if some KRs are equivalent to others or specializations of others. Thus, it is difficult for people and automated agents to *align and aggregate* – and thus, relate, infer from, search or exploit – KRs or ontologies.

In other words, there is a need for ODPs specifically aimed for knowledge modeling and sharing – as opposed to knowledge exploitation with computational tractability constraints – and, more precisely, specifically aimed for solving the problem of leading knowledge providers to create more matchable and re-usable KRs. As later detailed,

this implies leading them to create more precise, normalized, well related and easy-to-understand KRs. To be adopted, these ODPs should also be easy to follow and easy to use as criteria for automatically measuring the quality of an ontology, to help developing an ontology or selecting ontologies to re-use. Finally, the ODPs – or, at least the knowledge sharing ODPs – should be well inter-related by semantic relations to help people i) know about them and their advantages, and ii) select those they want to commit to. Then, tools can check or enforce these commitments.

This article proposes such a knowledge sharing focused ODP and relates it to other ones, via specialization relations and *gradual pattern* relations. This BP, which in this article will now be referred to as ABP, is: “using binary relation types directly derived from concept types, especially role types or process types”. No ODP catalog appears to include ODPs similar to this one or to any of its parts. Like most BPs, it is domain and language independent. The sections 2, 3 and 4 explain, formalize and illustrate the different parts of ABP. Section 5 relates them to other ODPs and thereby also gives more rationale.

## II. USING BINARY RELATIONS

ABP starts by advocating the use of *binary relations*, i.e., logical statements based on binary predicates. In the RDF model, these statements are called *triples* and binary relation types are called *properties*. In this article, types that are not relation types (RTs) are referred to as *concept types* (CTs), i.e., *classes* in the RDF model. The expression *concept individual* will be used for anything that is neither a type nor a relation.

Since ABP is language independent, this article uses a general terminology, one compatible with those for Conceptual Graphs and RIF-FLD [2], the W3C Framework for Logic Dialects of the Rule Interchange Format. For its formal textual examples, this article uses RIF-FLD PS, the Presentation Syntax of RIF-FLD. Indeed, this notation is both expressive and rather intuitive. For clarity purpose too, in the examples, RT names begin by “r\_” and function names begin by “f\_”. Logical rules are used since RIF-FLD is used and since this shows the direction the implications are expected to be used. However, in each case, a logical equivalence could also be used instead.

\* This work was not supported by any organization.

Following ABP does not prevent using non-binary RTs as long as definitions or rules are also provided to enable the automatic translation of “KRs using non-binary RTs” into “KRs using binary RTs”. Table I illustrates such rules for various kinds of use cases but only the third row is also about the focus of Section 3, i.e., deriving a RT from a CT.

One reason why such definitions or rules are useful for knowledge sharing is that binary relations can be compared while two relations of different arities generally cannot. Two types or KRs are comparable if and only if an equivalence or specialization relation between them has been directly stated or can be automatically inferred. Thus, KRs using binary relations can be ordered by generalization relations,

typically, implications. This is more difficult with KRs using relations of different arities, thus reducing possibilities for knowledge matching or inferences. E.g., as illustrated by Table I, some relations of different arities can be translated into binary relations using a list as destination. Then, they can be compared.

A related reason why such definitions or rules are useful for knowledge sharing is that they make more information explicit. As detailed in Section 5, normalizing knowledge, enhancing its comparability or adding more information have strong relationships.

In practice, with a KR language (KRL) allowing contexts and sets or lists, it is easy to avoid the use of relations with

TABLE I.  
EXAMPLES OF HOW TO DEFINE A GIVEN RT WITH RESPECT TO OTHER TYPES  
(THE RIF-FLD PS NOTATION IS USED IN THE NON-HIGHLIGHTED PARTS; VARIABLES BEGIN BY “?”; “:-” MEANS “<=”)

<p><b>If you wish to (re-)use non-binary RTs, as in</b>  <code>r_spatial_entity_between_3_other_ones ( Jack Joe John Mary )</code>  <code>Exists ?X ( r_spatial_entity_between_2_other_ones ( ?X Joe John ) )</code></p> <p><b>instead of using binary RTs as in</b>  <code>r_list_of_surrounding_entities ( Jack List( Joe John Mary ) )</code>  <code>Exists ?X ( r_list_of_surrounding_entities ( ?X List( Joe John ) ) )</code></p> <p><b>then provide ways to translate the 1st ones into the 2nd ones, e.g.,</b>  <code>Forall ?A ?B ?C ?D ( r_list_of_surrounding_entities ( ?A List( ?B ?C ?D ) )</code>  <code>:- r_spatial_entity_between_3_other_ones ( ?A ?B ?C ?D ) )</code></p> <p><b>since it is then much easier to make inferences, e.g., ?X = Jack</b>  <b>and the above 3rd statement specializes (hence implies) the 4th</b></p>
<p><b>The above approach also works for contextualizations, e.g.,</b>  <code>r_list-of-surrounding-entities_at-time ( Jack Joe John D-Day )</code></p> <p><b>can automatically be translated into the binary relation</b>  <code>r_list_of_surrounding_entities ( Jack_at_D-Day List( Joe_at_D-Day John_at_D-Day ) )</code></p> <p><b>This cannot be specified in RIF PS but something similar can be:</b>  <code>Forall ?A ?B ?C ?time_T (</code>  <code>Exists ?A_at_time_T ?B_at_time_T ?C_at_time_T (</code>  <code>And ( r_list_of_surrounding_entities ( ?A_at_time_T List ( ?B_at_time_T ?C_at_time_T ) )</code>  <code>r_extended_specialization ( ?A ?A_at_time_T r_time ( ?A_at_time_T ?time_T )</code>  <code>r_extended_specialization ( ?B ?B_at_time_T r_time ( ?B_at_time_T ?time_T ) )</code>  <code>:- r_list-of-surrounding-entities_at-time ( ?A ?B ?C ?time_T ) ) )</code></p>
<p><b>Similarly, if you wish to use RTs representing types of processes, as in</b>  <code>r_landing ( Joe Omaha_Beach D-Day )</code>    <code>r_defining ( Joe Square )</code></p> <p><b>instead of using classic primitive binary RTs as in</b>  <code>Exists ?landing ( And ( ?landing # landing // "?i # ?t" &lt;=&gt; instanceOf ( ?i ?t )</code>  <code>r_agent ( ?landing Joe )    r_place ( ?landing Omaha_Beach )</code>  <code>r_time ( ?landing D-Day ) ) )</code>  <code>Exists ?defining ( And ( ?defining # defining    r_agent ( ?defining Joe )</code>  <code>r_object ( ?defining "square" ) ) )</code></p> <p><b>then provide ways to translate the 1st ones into the 2nd ones, e.g.,</b>  <code>r_directly_derived_relation ( Landing r_landing )</code>  <code>r_directly_derived_relation ( Defining r_defining )</code>  <code>Forall ?rel ?process ?agent ?time ?place (</code>  <code>And ( r_agent ( ?process ?agent )    r_place ( ?process ?place )    r_time ( ?process ?time ) )</code>  <code>:- And ( ?rel ( ?agent ?place ?time )    r_process ( ?rel ?process ) )</code>  <code>Forall ?rel ?process ?agent ?object (</code>  <code>And ( r_agent ( ?process ?agent )    r_object ( ?process ?object ) )</code>  <code>:- And ( ?rel ( ?agent ?object )    r_directly_derived_relation ( ?process ?rel ) ) )</code></p> <p><b>since it is then much easier to make inferences,</b>  <b>e.g., for the statement in the next line, a match for ?X is Joe</b>  <code>Exists ?A ( And ( r_agent ( Landing ?A )    r_agent ( Defining ?A ) ) )</code></p>

arity greater than two. A *context*, i.e., a *contextualizing statement*, is a meta-statement specifying restrictive conditions for the contextualized statement to be true, e.g., via temporal relations or modalities. Although RIF-FLD is not restricted to first-order logic, it lacks a construct for expressing contextualizations in simple ways, as in KIF [3] for example. However, the second row of Table I shows how simple contextualizations can still be represented – albeit in a rather cumbersome way – using binary relations. To that end, this example uses an adaptation of the ODP named *Context Slices* in ODPC [4]. It relies on introducing *concept individuals within contexts* and relating them to their context as well as to their context-independent counterpart. This is an alternative to the more common approach of reifying a statement and asserting a relation between the reification and the context. With the reification based approach, handling contexts is a bit more difficult when simple KR management tools are re-used and extended. Both approaches lead to rather lengthy statements and are ad-hoc since they require extensions to inference engines to fully handle them correctly. Therefore, *for the purpose of knowledge modeling and sharing* – as opposed to knowledge exploitation which comes after and may require converting the knowledge into KRLs of reduced expressiveness but which can be handled efficiently – *a BP is to i) use a KRL that handles contexts or use more ad-hoc concise constructs, and then ii) provide or use rules for translating into the various ways to represent contexts in other KRLs. The same idea applies for the many ODPs that deal with the problems of translating “KRs using high expressive constructs” into “KRs using lower expressive constructs”*. E.g., in ODPC, there are many ODP for translations into OWL or from OWL.

To conclude, although formally specifying the semantics of *relations of arity greater than two* requires at least one primitive ternary relation [5], in practice there is no necessity to use such relations for knowledge modelling.

There is no claim here that the idea of “translating non-binary RTs into binary ones or directly using them” is original. Yet, it should be an ODP for various reasons: i) it is useful, ii) some claims seemingly about the necessity of using non-binary relations are actually claims about the necessity of using constructs supporting different kinds of contexts [6], and iii) this best practice is sometimes unknown to users of KRLs allowing non-binary relations.

### III. DERIVING RELATION TYPES FROM CONCEPT TYPES

ABP advocates the use of – or specifications of translations into – binary RTs *directly derived from CT*. A CT may have multiple *directly derived RTs* if they have *uncomparable* signatures, i.e., if none specializes another one. The third row of Table I illustrated a way to directly derive an RT from a CT using a rule and a relation of type *r\_directly\_derived\_relation*. The first two rows illustrate the definitions of non-binary RTs mainly with respect to binary RTs. This is useful as an intermediary step: the final step – deriving these last binary RTs from a CT, e.g., one

named *List\_of\_surrounding\_entities* – was not illustrated in Table I.

Manually or automatically defining each RT with respect to a CT makes additional information explicit and ensures that every distinction in the (subtype) hierarchy of RTs is also included in the CT hierarchy. This last point is important for two reasons. First, it prevents some knowledge providers to develop distinctions only in the RT hierarchy while others develop distinctions only in the CT hierarchy, thus leading to *undetected redundancies* within a shared knowledge base or in different ontologies. Second, it ensures that any distinction can be used – *without losing possibilities of knowledge representation and matching* – with both its CT form and its RT form. More possibilities come from the CT form since i) unlike RTs, CTs can be quantified in many different ways (e.g., “3 landings”, “all landings” or “8% of landings” can only be described via the CT “Landing”, not the RT *r\_landing*), ii) CTs are easier to organize by subtype relations than RTs, and iii) the number of used or re-usable existing CTs is much greater than the number of used or re-usable RTs. Thus, both cases lead to better categorizations in the concept and relation hierarchies.

These advantages of using *defined RTs* come for free when RTs are automatically derived from CTs and hence defined with respect to them. *Furthermore*, such derivations permits a system to display fewer types in the RT hierarchy which is then easier to read and grasp. Indeed, the derived RTs may be left hidden or may not have to be created at all. This last option was used in the knowledge server Ontoseek [7] and is used in the knowledge base server WebKB ([www.webkb.org](http://www.webkb.org); [8]). In Ontoseek, any type derived from the noun-related part of the lexical ontology Sensus could be re-used as a CT or a RT. WebKB also re-uses a lexical ontology derived from WordNet. However, unlike Ontoseek, WebKB only allows the subtypes of certain types to be re-used as RTs. This is defined by specifications that users can adapt. More precisely, this is defined by *relation signatures which are directly associated to certain top-level CTs*. Table II illustrates the approach and then gives rules that would actually generate the derived RTs. The next section complements this framework by giving an ontology of the CTs these rules can be applied to. These RT generation rules permit to formalize the framework. They rely on the functions *f\_type\_name* and *f\_denotation\_of\_type\_name* which are identical to the KIF functions *name* and *denotation* formalized in the documentation of KIF [3]. In WebKB, such rules are not actually executed but a more efficient process relying on the same idea is used. Indeed, during the parsing of statements, whenever a CT is used where a RT is expected, WebKB simply checks that one of the signatures associated to the CT is respected and acts as if the relevant derived RT was actually used. Thus, in WebKB, there is no need to use the actual names of the virtually derived RTs: the CT names can be used directly. As in the framework described by Table II, signatures are inherited along subtype relations between CTs and an error is generated if a CT is associated to two signatures that are *comparable*. This approach and ODP seem original.

TABLE II.  
 RULES FOR AUTOMATICALLY DERIVING A BINARY RT FROM A CT (AND, IF NEEDED, DOING SO FOR ALL ITS SUBTYPES)  
 BASED ON A KIND OF SIGNATURE ASSOCIATED TO THIS CT  
 (NOTE: IN THESE EXAMPLES, THE TYPES CREATED BY THE AUTHORS OF THIS ARTICLE HAVE NO PREFIX TO INDICATE THEIR NAMESPACE).

*Table I gave examples of how a rule can define a RT with respect to a CT. This had to be done for each RT. Here, the approach is simpler. The derived RT does not have to be explicitly defined. Its signature is directly associated to the CT via a relation of type `r__signature_for_derived_binary_relation` or a function of type `f__derived_binary_relation`.*

*Thanks to the definitions given in the next row of this table, the derived RT is automatically created.  
 A CT may have different RT signatures associated to it, as long as the signatures are un-comparable, i.e., as long as none specializes another.*

```

r__signature_for_derived_binary_relation ( Father List ( Animal Male ) )
  //-> associates a signature to the CT Father and derives the RT r__father with domain an Animal and range a Male

Forall ?t ( r__signature_for_derived_binary_relation ( ?t List ( Thing ?t ) )
  :- ?t ## Thing_usable_for_deriving_a_binary_relation_with_that_thing_as_destination
    // "##" means "is subtype of"; "#" means "is instance of"; this rule derives the expected RT for each
    // subtype of Thing_usable_for_deriving_a_binary_relation_with_that_thing_as_destination

Forall ?processType Exists ?r
  And ( ?r = f__derived_binary_relation ( ?processType List ( Agent Object ) )
    Forall ?process ?agent ?object And ( r__agent (?process ?agent) r__object (?process ?object) )
      :- And ( ?process # ?processType ?r (?agent ?object) ) )
  :- ?processType ## Process //this rule derives the expected RT for each subtype of Process

```

*Furthermore, the derived RTs have the same subtype relations as the CTs they derive from. However, to keep things simple, it is here assumed that no RT with the same name as the derived RT has previously been manually created. The RT name is created by taking the CT name, lowering its initial and prefixing it with “r\_\_”. The functions `f__denotation_of_type_name`, `f__type_name`, `f__cons`, `f__cdr`, `f__lowercase` used below are identical to their counterparts (without the prefix “f\_\_”) in KIF.*

```

Forall ?t ?r__t ?t_domain ?t_range ?t_supertype ?r__t_supertype ?t_sup_domain ?t_sup_range (
  And ( rdfs:domain (?r__t ?t_domain) rdfs:range (?r__t ?t_range)
    ?r__t = f__denotation_of_type_name ( f__cons ( f__lowercase ( f__car ( f__type_name ( ?t ) ) )
      f__cdr ( f__name ( ?t ) ) ) )
    ?r__t ## ?r__t_supertype // "##" means "is subtype of"
    :- And ( ?t ## ?t_supertype
      ?r__t_supertype = f__derived_binary_relation ( ?t_supertype
        List ( ?t_sup_domain ?t_sup_range ) ) )
    )
  :- ?r__t = f__derived_binary_relation ( ?t List ( ?t_domain ?t_range ) ) )

Forall ?t ?t_domain ?t_range (
  Exists ?r__t ( ?r__t = f__derived_binary_relation ( ?t List ( ?t_domain ?t_range ) ) )
  :- r__signature_for_derived_binary_relation ( ?t List ( ?t_domain ?t_range ) ) )

```

*Other rules can be built upon these last ones, e.g., this rule for deriving functional binary relations:*

```

Forall ?t ?t_domain ?t_range Exists ?r__t (
  And ( ?r__t = f__derived_binary_relation ( ?t List ( ?t_domain ?t_range ) )
    ?r__t # owl:FunctionalProperty ) // "##" means "is instance of"; owl:FunctionalProperty is a 2nd-order type
  :- r__signature_for_derived_functional_binary_relation ( ?t List ( ?t_domain ?t_range ) ) )

```

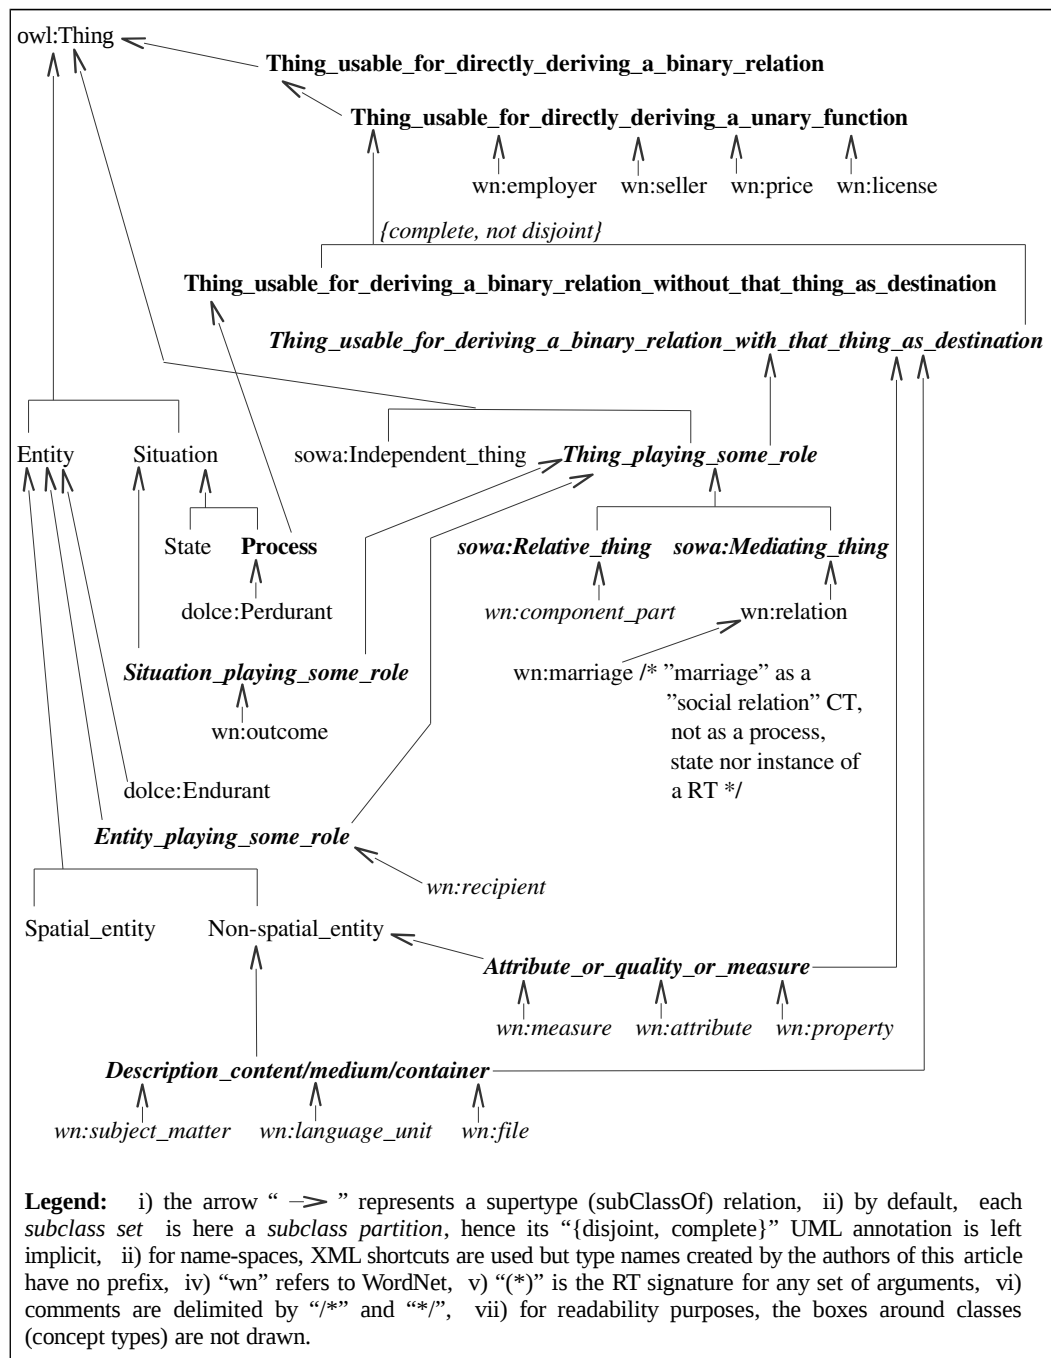

#### IV. DERIVING FROM ROLE TYPES OR PROCESS TYPES

ABP advocates the derivation of RTs from CTs, “especially role types or process types”. The third row of Table I illustrated this for processes. In this article, a *process* refers to a *situation* that is not a *state*, and hence that makes a change. A *situation* is something that *occurs* in a real/imaginary region of time and space. These

conceptual distinctions come from the *Situation Semantics* [9] and are the basis of John Sowa's first top-level ontology [10]. There are re-used in this article for at least the following reasons:

- They are rather intuitive and generalize other well known types. E.g., *Perdurant* from Dolce [11] is subtype of Process.

- They are very adequate for the signatures of thematic relations [12], e.g., `r__agent`, `r__recipient`, `r__cause`, `r__instrument`. Such types are top-level types of relations from a process.
  - In this article, a *role type* (e.g., Agent, Experiencer, Recipient, Cause, Instrument) is a CT which is defined – or could be defined – as being the range of a thematic RT. This informal definition of a role is a bit more general than what is usually thought to be a role type [13] but here it is sufficient: as defined in this article, *processes* and *role* types can be used for deriving CTs into binary RTs.
  - Thematic RTs or their subtypes can also be used for defining most RTs. Thus, doing so normalizes KRs.
  - Most statements implicitly or explicitly refer to a process. Representing it, either directly or via RTs directly derived from a process, strongly normalizes KRs. Not doing so, which unfortunately is the case in many ontologies, amounts to losing precisions and many KR comparison possibilities.
- Fig. 1 compares *CTs usable for directly deriving a binary RT* with other types. The common supertype of these CTs is `Thing_usable_for_directly_deriving_a_binary_relation`. Only its subtypes can be used for deriving binary RTs; this

**Fig. 1.** Slightly adapted UML representation of a subtype hierarchy to compare the type `Thing_usable_for` directly deriving a binary relation with other types.

includes types for processes and roles. Fig. 2 illustrates subtype relations between such derived RTs. Fig. 3 displays common top-level types for relations from a process, most of which are thematic RTs. Fig. 3 re-uses top-level types shown in Fig. 1. All the types in these figures are part of the *Multi-Source Ontology* (MSO [14]) which is accessible and cooperatively updatable via WebKB. Hence, the names in these figures are names accessible via this Web server. However, these figures have not previously been published.

The MSO includes more than 75,000 categories and relates them by more than 100,000 relations, mainly subtype relations. It categorizes WordNet types as well as types from various top-level ontologies (DOLCE included) with respect to the types shown in Fig. 1 or specializations of them. More precisely, about a hundred of top-level WordNet types and some more specialized WordNet types were manually set as subtypes of those in Fig. 1 or specializations of them. Thus, in the subtype hierarchy of the MSO for *things usable for directly deriving a binary relation*, there are currently more than 4800 process types, 2900 role types (for *things playing some role*), 650 types of *attributes or qualities or measures* and 240 types of *description content/medium/container*. This makes more than 8600 types usable for creating relations without having to declare new RTs. The 4800 process types can also be used directly with *relations from a process*. Finally, the types shown in Fig. 3 for these relations can implicitly or explicitly be specialized by types derived from the 2900 role types. To sum up, the proposed approach and the MSO permit people and automated agents to create KRs that are well normalized, inter-related and comparable. Furthermore re-using the approach and content of the MSO to extend other ontologies is eased by the fact that i) the MSO relates, generalizes and specializes types from various other

ontologies, and ii) the MSO can be complemented online via WebKB.

In Fig. 1, the types named *Relative\_thing* and *Mediating\_thing* come from John Sowa's second top-level ontology [15].

To show how rules can be used to associate a signature to a CT and thereby to a derived RT, examples in Table II used a process type and the type of *things usable for deriving a binary relation with it as destination*. Similar rules can be used for other types of *things usable for deriving a binary relation*". Fig. 2 shows how the various relations types – derived or not from CTs – can be related by subtype relations. Organizing relations of different arities is permitted by the use of "\*" in the relation signatures: it refers to any number of arguments. In Fig. 2, a signature is shown as an ordered list of comma-separated arguments, within parenthesis. Both KIF and RIF-FLD allow relations with a variable number of arguments. However, unlike in KIF, there is no special construct in RIF-FLD for definitions, hence for signatures.

ODPC includes the DOLCE+DnS-Ultralite ontology [16] and categorizes it as *Content ODP*. ODPC also includes related but smaller *content ODPs* such those named *ActingFor* and *Agent-Role*. Its *DnS (Descriptions and Situations)* part includes some types which can be seen as subtypes of those in Fig. 3. ODPC proposes many RTs which could be – but, it seems, are not – derived from process types, e.g., RTs with names such as *actsFor*, *conceptualizes* or *defines*. Yet, some of its CTs have been aligned with *OntoWordNet* [17]. Thus, the ontology and approach proposed in this section and the previous one could be used to extend and normalize DOLCE+DnS-Ultralite. This would support more KR comparison possibilities.

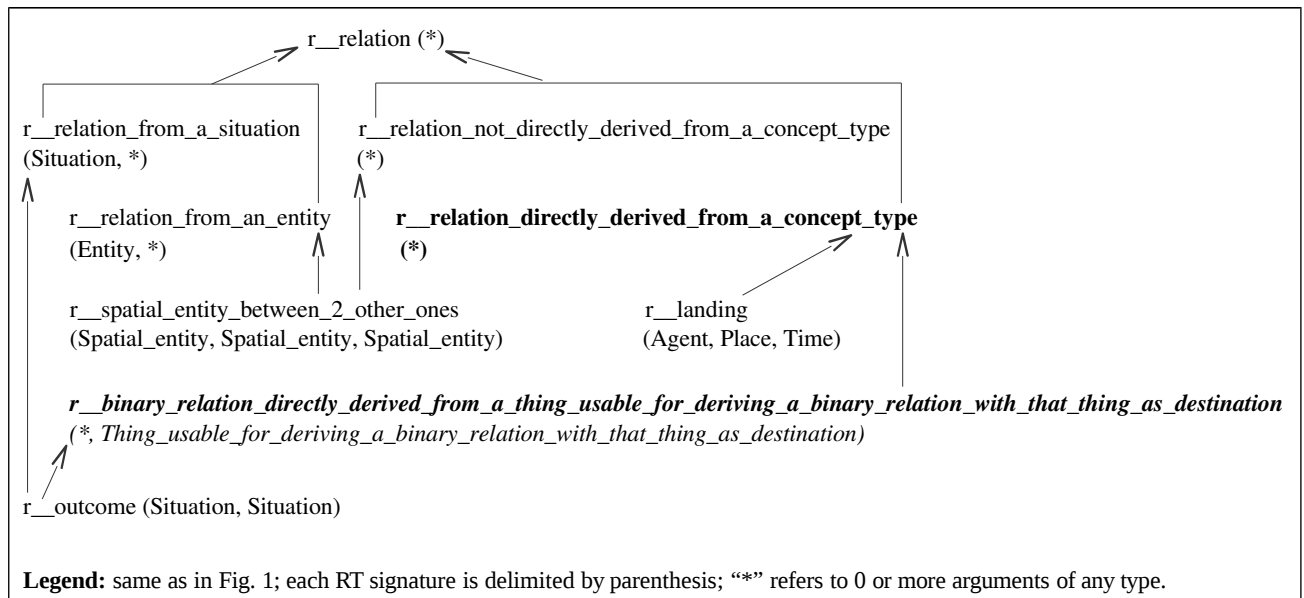

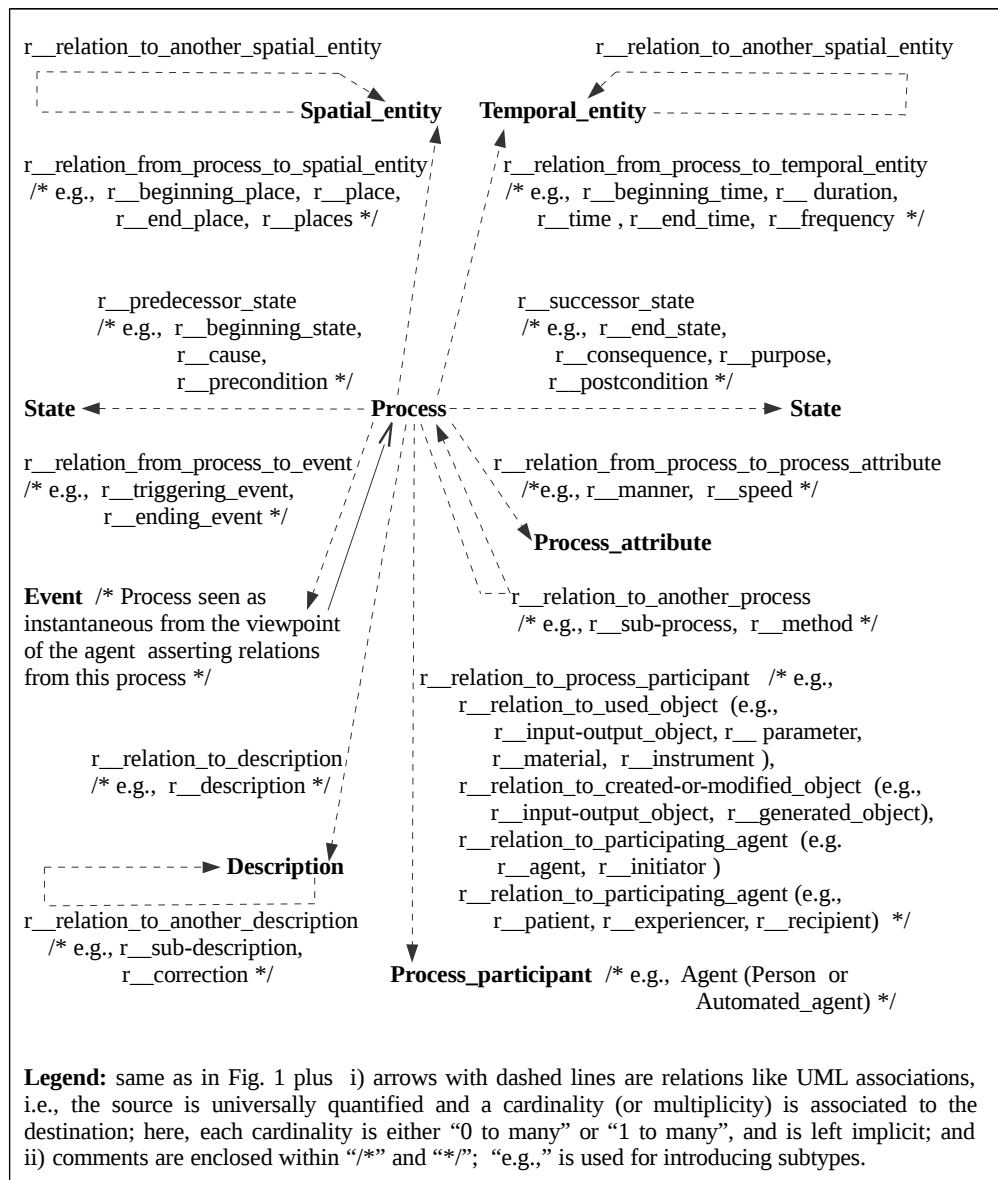

Fig. 2. Subtype hierarchy of some relation types derived from subtypes of the concept type *Thing\_usable\_for\_directly\_deriving\_a\_binary\_relation*.

**Fig. 3.** Examples of common types of relations from a process; most of them are thematic RTs.

## V. RELATING TO OTHER ODPs

To be adopted, knowledge sharing ODPs should be well inter-related by semantic relations to help people know about them and the criteria or advantages they fulfill. Thus, people can search and select ODPs to commit to. Then, tools can check or enforce these commitments, or retrieve ontologies satisfying them.

Thus, ideally, ODPs should at least be organized into categories related by specializations and exclusion relations, as in the hierarchy presented in Fig. 1. However, this is not easy. The most organized of current ODPC or BP repositories [18] seems to be ODPC. It organizes its ODPs into a specialization hierarchy with a first level of six categories. Each of them has 0 to 3 sub-levels. These six categories and their current content are:

- **Content ODP:** 101 ontologies, some having only a few types.
- **Reasoning ODP:** no ODP has yet been submitted in this category.
- **Structural ODP:** 1 ODP in the *Architectural ODP* category – BPs about the structure of an ontology, e.g., the use of subtype partitions, i.e., unions of disjoint types as in Fig. 1 – and 13 in the *Logical ODP* category – translations between constructs from KRLs of different expressiveness.
- **Correspondence ODP:** 12 in the *Reengineering ODP* category – meta-model transformation rules to create ontologies from structured but less formal and semantic sources – and 13 in the *Alignment ODP* category – these ODPs are examples of RTs between elements from different ontologies.

- *Lexico-Syntactic ODP*: 20 linguistic structures for extracting KRs or displaying them, as with a controlled language.
- *Presentation ODP*: no submission of ODP has yet been submitted in this category about the usability and readability of ontologies. It has two subcategories: *Annotation ODP* and *Naming ODP*.

All these categories are not exclusive. An ODP can be placed in several of them. E.g., the ODPs listed in the sections 2, 3 and 4 seem to be architectural ODPs as well as logical ODPs and, for some of them, also Content ODP, e.g., the DOLCE+DnS-Ultralite. The ODPs we gave in Section 5 are Naming ODPs but are also related to Structural ODPs.

Since there are multiple categorization possibilities, different persons will search or add a same ODP in different categories, thus leading to less relations between the ODPs and more *undetected redundancies*, as noted in the previous sections. This structure also does not lead ODP providers to collaboratively build a finely organized hierarchy or graph of ODPs. Such a structure could be obtained by formally representing each ODP as a process, using a same base ontology, e.g., the MSO, hence with the types shown in Fig. 1 and Fig. 3 as top-level types. Most of the subtype relations between ODPs could then be automatically calculated. Although this approach would scale well, such a formal and homogenous representation would be a huge work and would require quite motivated ODP providers.

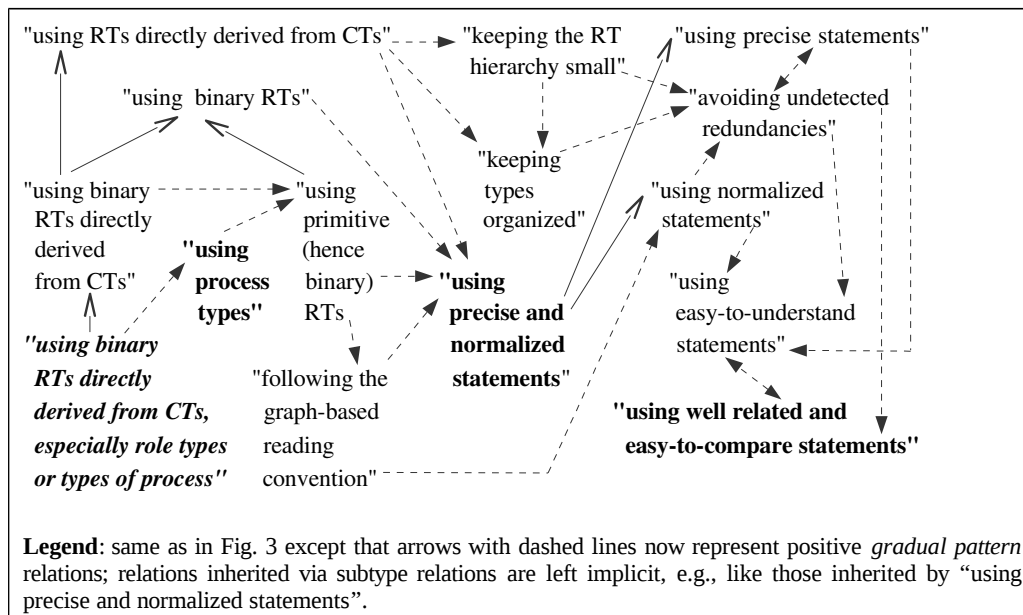

Furthermore, relations to criteria and advantages would still probably not be sufficient since relating ODPs to criteria – or processes representing these criteria – is difficult. Therefore, for the ODPs advocated in this article, another approach has been adopted: i) manually setting subtype relations between ODPs or BPs represented as

process types, and ii) using positive *gradual pattern* relations. Fig. 4 is the result.

These last relations represent rules of the form “the more X, the more Y”. [19] gives a formalization for such relations. Arrows with dashed lines are *positive gradual pattern* relations. E.g., the dashed arrow from “keeping the types organized” to “avoiding undetected redundancies” can be read “the more ‘keeping the types organized’ is achieved, the more ‘avoiding undetected redundancies’ is achieved”.

This last particular rule refers to the idea that was mentioned again two paragraphs ago and which could be rephrased as: “the more a KR (type or statement) has a ‘unique place’ [20] in a hierarchy of KRs, the less chances there are that another person will add an equivalent KR in another place”. E.g., as opposed to subtype hierarchies, taxonomies relate objects (terms, documents, ...) with relations which are neither typed nor formal. Thus, people use these relations for representing subtypes, parts, instances, agents, etc. This leads to hierarchies that are difficult to search and that often have redundancies. When subtype partitions are used, this is far less the case. This is also far less the case when the hierarchy is automatically built based on the definition of each type. Like subtype relations, gradual pattern relations are typed and transitive. Hence, if used correctly, each KR can have a *unique place* [20] in the graph formed by these transitive relations. However, gradual pattern relations do not enable as many automatic checking possibilities as subtype partitions.

Given the explanations provided in the previous sections, the relations in Fig. 4 should now be understandable. The use of gradual pattern relations between ODPs or BPs is original. The direct setting of subtype relations between them also seems original.

**Fig. 4.** Supertype relations and *gradual pattern* relations between ABP (the BP advocated in this article; see the BP name in italic bold characters at the bottom left of the figure) and related BPs.

## VI. CONCLUSION

Knowledge sharing is difficult. It implies satisfying many criteria – and following various BPs – which, as Fig. 4 showed, are inter-related. To provide such BPs and ways to follow them, this article has focused on the idea of deriving RTs from CTs and has shown the relationships between this ODP to other ones for knowledge modeling and sharing. Some of these ODPs were already known, several were original.

This article also provided various *kinds* of ODPs. According to the categories of ODPC, these are architectural, logical, content and naming ODPs. However, given their inter-relations and the focus on derivation mechanisms, it is also true that this article focused on one ODP – the one named ABP – composed of simpler ODPs.

The ODPs we proposed are applied to – and supported by – the MSO which includes more than 75,000 categories and which is accessible and updatable online via the WebKB shared knowledge base server. Together, these resources and tools help people and automated agents create KRs that are more normalized, inter-related, comparable and understandable. Furthermore, the multi-source nature of the MSO would help applying the proposed content ODPs to other ones such as DOLCE+DnS-Ultralite.

Finally, the following of the proposed ODPs can easily be tested, e.g., via SPARQL queries on an ontology or, interactively, within WebKB. For example, it is easy to test if each RT is defined with respect to one CT. This makes these BPs usable as criteria for selecting ontologies.

This work will be extended by relating knowledge sharing techniques, BPs and criteria, via specialization relations and gradual pattern relations. *Negative* gradual pattern relations – “the more X, the less Y” – will also be used. The focus will be on representing various approaches to knowledge sharing, e.g., those based on formal documents, those based on collaborative editing within a shared ontology server and those based on knowledge exchange between ontology servers. Thanks to their organization by specialization relations and gradual pattern relations, the various kinds of ways to share knowledge and their respective advantages and drawbacks should be clearer.

**Abstract**—Recently, many have begun to believe that learning and training approaches known as learner-centered, active learning, and cooperative learning improve learning and practicing performance and are more effective than traditional lectures. Moreover, in addition to paper-based materials such as textbooks, face-to-face co-located communication frequently utilizes digital video and other visual reference materials. However, no previous studies have examined the precise face-to-face behavior of dialogue participants stimulated by video and other reference materials. Therefore, this paper describes the dialogue stimulated by science videos and reference materials based on data from 10 male university students measured while using first-, second-, and third-person view videos, as well as utterances recorded during the measurements.

## I. INTRODUCTION

TEACHERS and instructors in traditional education and training are responsible for defining learning purposes and objective areas of learning tasks, and for designing and assessing learning and training processes. Recently, many have begun to believe that learning and training approaches referred to as learner-centered, active learning, and cooperative learning improve learning and practicing performance and are more effective than traditional lectures [1]–[4]. The concept of collaboration and cooperation includes allowing individuals to enrich their own experience of acquiring knowledge on their own accord.

An important factor enabling these learning approaches is Information and Communication Technology (ICT), which provides learners with many kinds of tools that can be used at schools, including preschools, and business workplaces to enhance the way in which they acquire diversified knowledge, skills, and experiences [4].

Collaboration through digital video-mediated communication has been widely used, and research comparing video-mediated with face-to-face communication has been reported [4]–[6]. For example, O'Mally et al. compared the dialogue in video-mediated communication with that in face-to-face co-location communication. The results showed that

both video-mediated and face-to-face speakers use visual cues to check for mutual understanding. They also suggested that speakers are less confident in their mutual understanding when they are not physically co-located.

Moreover, in addition to paper-based materials such as textbooks, face-to-face co-located communication frequently uses digital video and other visual reference materials. These previous studies have not examined the precise face-to-face behavior of dialogue participants stimulated by video and other reference materials.

Therefore, this paper describes the dialogue stimulated by science videos and reference materials based on data from 10 male university students measured while using first-, second-, and third-person view videos, as well as utterances recorded during the measurements.

## II. METHODS

### A. Dialogue stimulation materials

The following materials were prepared for the measurements:

(1) Video: “Lives of creatures on Earth”

Copyright-free Hi-Vision materials were obtained from the NHK Archives Video Library [7]. Copyright-free BGM materials were obtained from OVA-SYNDROME’s FREE BGM website [8]. All videos of seven creatures were edited using Windows Movie Maker, Microsoft.

(2) Reference materials

The important parts of the video were captured and edited for printed reference materials, which are shown in Fig.1

### B. Participants

The study participants were 10 male university engineering students in their early twenties.

### C. Video shooting views

The first-person view video is that of a participant, and the second-person view video is that of their dialogue partner. The

third-person view video is the viewpoint of a person other than the dialogue pair.

#### D. Measurement procedures

##### (a) Equipment and reference materials

- Wearable video camera for the first/second-person view (Panasonic HX-A500, Japan)
- Digital video camera for the third-person view (Panasonic HC-V360M)
- Personal computer for viewing an instructional origami skill video (Toshiba Dynabook D41, Japan)
- Reference materials: video on the lives of various creatures and video captures.

##### (b) Measurement setup and procedure

Fig. 1 shows the equipment setup. The behavior of the participants was recorded from different viewpoints. Their dialogue was also recorded using a voice recorder. The measurement procedure was as follows:

- (1) A participant wore a wearable camera near his ear.
- (2) Before watching the video (1 minute):  
After distributing printed materials and presenting the discussion theme, "Important creatures on Earth", the dialogue pair started a free discussion after watching the reference material, as shown in Fig.2. The participants did not receive any additional instructions or requests apart from having free discussions during the measurement.
- (3) During the video viewing (4 minutes and 30 seconds):  
The participants had a free discussion on the lives of creatures they watched in the reference video and materials.
- (4) After watching the video (3 minutes):  
The participants continued a free discussion on the lives of creatures on Earth. They re-watched the reference video and materials if necessary.
- (5) After the dialogue was finished, the recorded utterances were transcribed verbatim. The text data were then used to analyze emotional changes during the time series.

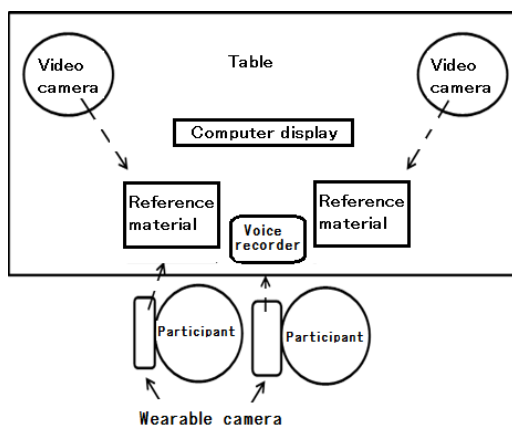

Fig.1 Video shooting arrangement (top-view)

### III. MEASURED RESULTS AND ANALYSIS

Fig.2(a)-(e) shows characteristic behavior images (photos) of Pairs A, B, C, D, and E, respectively.

Fig.3 shows time sequence changes in utterance intentions. The utterance intentions are classified as follows:

Intention 1: Questions and proposals in the dialogue

Intention 2: Agreement or disagreement between partners in the dialogue

Intention 3: Opinions regarding the video themes

Intention 4: Others

Intention 4 of Pairs A and B increased, suggesting that they may reached consensus regarding the initial dialogue theme after watching the video.

### IV. CONCLUSION

The paper described the dialogue stimulated by science videos and reference materials using data from 10 male university students measured using first-, second-, and third-person view videos and utterances recorded during the measurements. Possible strategies for promoting efficient dialogue were described based on the results. The main results are summarized as follows.

(1) Watching videos and other reference materials stimulates face-to-face dialogue.

(2) Dialogue saturation is defined as (i) a decrease in the utterance frequency rate, (ii) an increase in dialogue intent or content that is not directly related to the initial theme.

(3) These behaviors are found regardless of how frequently the participant looks at the dialogue partner.

(4) Monitoring dialogue saturation factors (i) and (ii) in item (2) above could help realize computerized interventions and assistance that would enable face-to-face dialogue and discussions to become fruitful and efficient.

Since (i) and (ii) can be detected by speech recognition and emotion estimation by physical expressions [9], in the future, in conjunction with AI and voice synthesis, computerized interventions and assistance for efficient dialogue could be realized by suggesting dialogue or development themes [10],[11] for further constructive discussion if the dialogue becomes saturated.

To realize this, further investigations on the measurements, analysis and assessments of different dialogue themes by different category subjects are needed so that emerging technologies for learning and training are fully utilized in practice.

**Abstract**—Considering different aspects of knowledge functioning, context is poorly understood in spite of intuitively identifying this concept with environmental recognition. For dynamic knowledge, context especially seems to be an essential factor of change. Investigation on the impact of context on knowledge dynamics or more generally on the relationship between knowledge and its contextual interpretation is important in order to understand knowledge dynamics. The aim of this paper is to research and examine the nature of knowledge transformation (a specific sort of life-cycle), and to identify contextual factors affecting knowledge dynamics.

*terminants*, where each is also classified to a particular type and evaluated to the extent of the awareness level of a particular organization.

The paper is organized as follows. In Section II, we provide two basic definitions. In the next Section, the nature of knowledge transformation is outlined. In Section IV, we introduce the idea of contextual factors. Finally, we provide a working example as an image of the discussed issue, with a conclusion in Section VI.

## I. INTRODUCTION

KNOWLEDGE is valuable – something we all agree on, but this agreement abruptly ends when we attempt to answer the primary question “*what is knowledge?*”. Indeed, in ancient times, philosophers like Plato and Aristotle formulated different theories of knowledge, yet still today there is no common agreement on the definition of knowledge, and even proudly announced proposals are far from rationale, providing poor semantic and biased forms. Nevertheless, this does not discourage live discussions on its nature among scholars and practitioners, the results of which begin from basic definitions and end with complex artificial intelligence (AI) methods and techniques.

In the past few years, authors have been conducting research in the scope of AI, *knowledge discovery from databases* (KDD) and *knowledge management* (KM). One of the emerging issues identified, with far reaching consequences, is *context*, which, by grounding the meaning and understanding of knowledge, enables knowledge to be transformed in particular dimensions, i.e. *space*, *time* or *situation*.

We used content analysis to examine the existing literature in the framed domain and time extent from 2000 to 2016. Our search for the adequate literature embraced various bibliographic databases, e.g. the Association for Computing Machinery (ACM), the ISI Web of Knowledge, Scopus, and Springer Link. Furthermore, the empirical studies and technical reports were analyzed to gather evidence of existing context-aware applications and systems.

In this paper, our contribution includes the following findings. Firstly, there are particular contextual determinants that influence different entities and the process of knowledge transformation; the classification or grouping of determinants is a must in order to elaborate a valid method of knowledge development. Secondly, we observed that knowledge transformation is constructed on *contextual de-*

## II. BASIC DEFINITIONS

### A. Knowledge

In this elaboration, the term “knowledge” has a twofold definition, based on the broad types, implicit and explicit. The former is based on common sense, encompassing a variety of phenomena (e.g. the ability to walk or run), roughly what Polanyi referred to as “tacit knowledge”, which cannot be captured in language as it is tied to the environment and set in culture and relationships [1]. The interpretation of such knowledge can be subjective [2] (when do you walk slow or fast?, and when do you start running?). On the contrary, the latter has a verbal or written form (e.g. procedure) and is relatively easy to communicate, codify, store and distribute; usually, explicit representation uses a predefined notation that enables gathered (generated) knowledge to be expressed consistently and completely [3] (e.g. in the form of the association rule: *if a customer buys wheat bread then he/she also buys skimmed milk*, with support 0,02 and confidence 0,85).

### B. Context

Isaac Newton claims that space is distinct from body and that time passes constantly, with no regard to whether anything happens in the world. For this reason, *absolute space* and *absolute time* are basic properties of the universe, and are the preferred frame of reference – both are the essence of the context’s substance. Some examples of space- and time-aware contextualization can be found in [4, 5, 6].

To understand particular ambiguous terms, at a glance some authors simply provide synonyms for them. In this case, “context” is often referred to as *environment* [7], *location* [8], or *situation* [9]. To these three nouns, we can respectively pin the following questions: <sup>(1)</sup> what resources are you surrounded by?, <sup>(2)</sup> where are you?, and <sup>(3)</sup> who are you with, or what are you doing? However, the context can be known or unknown,

and if necessary may be identified “*manually*” by exploiting the expert (or domain knowledge), or “*automatically*” by using particular types of attributes [10].

### III. THE ESSENCE OF KNOWLEDGE TRANSFORMATION

The *Knowledge Grid* (KG) is a promising new frontier that can be seen as an interpretable resource of information structures treated as a *state* at a specific time and place [11]. In general, this means a static state or a series of states with operations changing this state, which expresses the dynamic aspect of knowledge functioning [12]. Therefore, any development of the knowledge structure is due to a transformation covering its content, form or structure *globally*, (especially including network resources), or *locally* (identified with “granules” of knowledge). *Knowledge transformation* (KT) can be identified by its changes through relevant operators [13]. In a broader sense, we can put forward the entire knowledge life-cycle (divided into specific phases), while in a narrower scope it can be reduced to specific operations resulting in the creation of a new generation of knowledge *content*, *structure* or *form* [14].

There are several different approaches to defining the *knowledge life-cycle* (KLC) [15, 16, 17]. We share the view, along with [18, 19, 20], of the four-phase KLC, namely: (1) *discovering* → (2) *processing* → (3) *sharing* → and (4) *re-using* → (1); with the assumption that the output should present “*new*” (previously unknown, non-trivial) knowledge, further processed and refined, usually in a collaborative way [21], which means moving again towards the cycle [22].

It is generally accepted that the discovery process consists of a sequence of iterative steps of data processing (data cleansing and integration, selection and transformation), data mining, evaluation models and their presentation and visualization [23]. Naturally, to a certain extent, it also requires user interaction with adequate expertise and experience. Some researchers [24] are of the opinion that the stage of knowledge processing is the second KLC phase, where the first one is to *store* and the third is to *transform*. The authors stress that despite the definition of a linear relationship between the phases, in practice, it is not always possible to clearly indicate the end of one and the beginning of the next. Moreover, the situation is complicated by possible different states of advancement of knowledge processed by individuals, groups or the entire organization, that work together in one environment of the knowledge grid. This creates the necessary conditions for the two-way and multilateral exchange of knowledge between entities.

For any organization, the challenge is to acquire new knowledge [25] (e.g. to solve a problem, to know the specifications of the market or to forecast customer behavior), which can be “produced” by employees (sometimes experts), or discovered from data repositories. The next step in the process of knowledge discovery from databases is the *integration* of heterogeneous sources of knowledge and the reinstallation of their combined analysis, which ultimately aims at generating “*new*” resources. This stage requires a

number of problems to be solved such as the partial *formalization* and *standardization* of knowledge, taking into account different levels of detail and the detection and elimination of anomalies.

As part of the knowledge discovery phase, the following operators can be performed: *search*, *capture*, *generation* and *evaluation* [26]. Examples of such operations refer to the preparation of a list of potential contractors of the project including ranking the involved enterprise. Naturally, specific knowledge *evaluation criteria* must be taken into account: about the performers, price parameters, timeliness of performance or quality of service [27].

The *processing of knowledge* in a more elementary approach applies to subsequent operations that in an important way may change its *content*, *form* and *location* [28]. Within this process, we can distinguish: *storage*, *combination*, *separation* and *localization* [29]. Considering the nature of the processing process through a network, each of these operations, representing various forms and possible levels of knowledge aggregation, refer to particular *concepts*, *axioms*, *rules* or *methods* [30]. They include assumptions concerning the criteria for the grouping of companies or the diversification of their characteristics according to their areas of activity. It is also possible to anticipate the need to involve companies essential in delivering services. Results can be in the form of knowledge conglomerates (knowledge of the companies cooperating). In each case, one can deal with the knowledge of the network, located in a variety of *corporate portals* [31].

Operations that constitute the sharing of knowledge are directly related to the participating entities and available resources, and consist of: *selecting*, *locating*, *configuring* and *evaluating* [32]. Each of these operations can be adapted via the *knowledge network*, addressed to specific demands of users e.g. to select specific companies, or the location of knowledge resources on the problem being solved, adequate to the task and evaluation of the generated knowledge.

The last of these life-cycle processes of *knowledge re-use* is a kind of a *bridge* between separate cycles. Its role is the consolidation, adjustment and localization of knowledge. This means, in practice, the improvement of existing and newly discovered resources in terms of their use in new conditions, taking into account aspects of localization.

An example of solutions meeting the requirements formulated in the knowledge life-cycle, and efficiently providing the relevant operations available through network architecture, is definitely the *Knowledge Grid* [33]. The model of KG architecture consists of three layers: the *repository*, *services* and *applications* [34]. The repository layer refers traditionally to the tasks associated with acquiring and storing knowledge. The second service layer allows the use of homogeneous and heterogeneous sources of information. Thus, it is comprised of scattered operations of the knowledge transformation. In the third layer application users can work actively with knowledge resources.

The added value of the use of such a system relates to accessing different knowledge resources i.e. *know-what*,

TABLE I. STRUCTURING THE CONTEXT – DIMENSIONAL ASPECT

Dimension	Type of context
Internal	<ul style="list-style-type: none"> <li>- Organizational infrastructure</li> <li>- Resource oriented</li> <li>- Customer oriented</li> </ul>
External	<ul style="list-style-type: none"> <li>- Political and Social</li> <li>- Economic and Legal</li> <li>- Technological</li> <li>- Environmental</li> </ul>

Source: [37]

*know-who*, *know-how* and *know-why*, which are contextually-dependent [35]. Therefore, the transformation of the knowledge units or knowledge grids can be determined appropriately by the *subject*, *object*, *method* and *motivation*.

#### IV. CONTEXTUAL FACTORS FOR KNOWLEDGE DYNAMICS

Before discussing the role of factors determining knowledge transformation, firstly we discuss the context role in this process. Generally speaking, a context is everything that forces the understanding and interpretation of a given concept [36]. The complexity of the context may be different, from a single concept to a complex description. In other words, any *implicit* or *explicit information about the circumstance or situation which affects an entity* [37].

*Context awareness* is sometimes very intuitive, coming from different environments where entities (people, organizations) can act. Especially when changes in an environment must be considered for actual or future variants of activities. In turn, *contextual factors* seem to be useful as representative of circumstances. More precisely: *contextual factors* (CF) can be defined as *certain characteristics of circumstance or situation*. This concept can be presented in a more detailed way. One interesting approach is proposed in [36], where the authors presented a structured framework of contextual factors, based on two dimensions and a context type, given in Table 1.

CF can be considered for a company by including particular acting entities. Similarly, we may formalize the influence of CF on *effectiveness* or *performance* by including relationships between entities and the like. No doubt contextual factors can be considered as more or less advanced structures.

To structure the context a framework needs to be prepared with well-recognized dimensions: *internal* and *external*.

The above-presented framework describes contextual factors in terms of potential perspectives sharing and using knowledge. For example, knowledge should be prepared to be useful for servicing different customers. Available knowledge should be useful for company activities in the event of changing economic parameters, or modified legal regulations. If any of the assumed contextual factors are modified, as a result, company knowledge must be transformed in order to be useful for new circumstances, such as *organizational*, *economic* or *environmental*.

Such flexibly prepared contextual factors must be coherent with a company's intellectual assets or even personal knowledge. The main quest is in which way contextual factors can influence, directly or indirectly, knowledge transformation. A good starting point is the analysis of tendencies – or better, *determinants* – on knowledge transformation.

#### V. WORKING EXAMPLE

The research was conducted on the problem of knowledge transformation taking place at the university. Following the earlier-presented dimensions of context and context types – the influence of assumed context factors, the influence of the earlier-presented dimension of context is evaluated apart from the required level of awareness. The given examples reflect real cases from the academia sector. The influence on knowledge transformation as well as the required level of its awareness was expressed from low to high. The results are presented in Table 2.

Knowledge transformation typical for changes in organizational infrastructure refers to a redefinition of university hierarchy, in terms of tasks and dependencies among university units (impacts, progressive aspects, educational challenges and specialization requirements). More than that, agreements with staff members should be updated, and duties of particular divisions should be negotiated and accepted. In consequence, the influence of this factor on knowledge transformation is *very high*.

The impact of the second contextual determinant, defined at the medium level, is *resource oriented*. Knowledge about new resources should be delivered (and similarly, a bit changed); however, regulations about library resources usage are not essentially changed. The lowest level of influence of

TABLE II. OVERVIEW OF THE CONTEXTUAL FACTORS INFLUENCING KNOWLEDGE TRANSFORMATION

Context dimension	Context type	Example of context	Influence on knowledge transformation	Required level of awareness
Internal	<ul style="list-style-type: none"> <li>- Organizational infrastructure</li> <li>- Resource oriented</li> <li>- Customer oriented</li> </ul>	<ul style="list-style-type: none"> <li>- Division in faculties and departments</li> <li>- New library built</li> <li>- New specialization offered</li> </ul>	<ul style="list-style-type: none"> <li>- High</li> <li>- Medium</li> <li>- High</li> </ul>	<ul style="list-style-type: none"> <li>- High</li> <li>- Medium</li> <li>- High</li> </ul>
External	<ul style="list-style-type: none"> <li>- Political and social</li> <li>- Economic and legal</li> <li>- Technological</li> <li>- Environmental</li> </ul>	<ul style="list-style-type: none"> <li>- University ranking</li> <li>- Acquired new grants or funds</li> <li>- Accreditation awarded</li> <li>- New IT products implemented</li> <li>- Attractive localization</li> </ul>	<ul style="list-style-type: none"> <li>- Medium</li> <li>- Medium</li> <li>- High</li> <li>- High</li> <li>- Low</li> </ul>	<ul style="list-style-type: none"> <li>- Low</li> <li>- Low</li> <li>- Medium</li> <li>- High</li> <li>- None</li> </ul>

contextual determinants can be defined in the case of environmental aspects. An example of an attractive localization in fact does not change university knowledge. Thus, the influence on knowledge transformation was evaluated at the *lowest level*. The presented influence of contextual factors on knowledge transformation presented for the university can also be valid for companies from different sectors. Knowledge transformation operators should be addressed for particular objects, but the problem of presenting relationships between contextual factors and the knowledge management process seems to be determined by the application domain.

## VI. CONCLUSIONS

Contextual determinants are essential in knowledge transformation, and in particular:

- the transformation of knowledge, considered as several steps of activities, should be correlated with environmental components,
- there are contextual determinants that can influence different entities and processes (including knowledge transformation); some classification or grouping of the determinants is necessary in order to elaborate a successful method of knowledge development,
- tendencies in knowledge dynamics should be correlated with grouped contextual determinants. Synchronization should be kept between the discussed determinants and progress in knowledge transformation.

Future research will be devoted to the improvement of knowledge transformation operators and to the investigation of other relevant grouping methods of contextual factors.

**Abstract**—Looking at the end-to-end processing, typical software-intensive systems are built as a system-of-systems where each sub-system specializes according to both the business and technology perspective. One challenge is the integration of all systems into a single system – crossing technological and organizational boundaries as well as functional domains. To facilitate the successful integration we propose the use of simulation models in parallel to the existing software engineering procedures. As an example we look at the German tolling system for heavy goods vehicles (HGVs) – a liability-critical system consisting of some 60 sub-systems including a fleet of more than 1 000 000 on-board units deployed in the HGVs. Since its start in 2005 the system regularly undergoes changes and updates. To mitigate the associated costs and risks we developed a microscopic discrete event simulation (DES) model of the tolling system and use it to support both the design of planned changes and the monitoring of the day-to-day operations. The model includes the dynamic aspects of the tolling system and HGVs interacting with the system. In the article we discuss the use of realistic simulation models as part of the system design process. Since simulations are heavily used by the design process it is called Simulation Driven Development (SDD).

## I. INTRODUCTION

Historically, software development focused on standalone systems [1] and even there a projects' success was far from guaranteed [2]. Taking these approaches to build interacting systems bears a high risk of inadequate integration of the various systems into a coherent end-to-end system. Of course, problems with the integration of systems tend to surface very late in the software development process with a correspondingly large impact on the schedule and the resources needed.

### A. Complexity Challenge

Modern technical and socio-technical systems consist of a large number of distributed components and are characterized by architectural complexity, dynamic interactions and complex interdisciplinary functionality. The continuing technical advances – e.g. in the field of electronics, where a 50% increase annually can be assumed – are one essential driver but also the emerging systems-of-systems accelerate the growth in complexity. In addition the requirements for these systems evolve rapidly, driven by end-user demands and non-functional aspects (e.g. in safety, accessibility and comfort). However, the efficiency of the existing system design methodologies evolves more slowly, e.g. [3] mentions increases of about 25% per year. This gap between the growth of the systems

under consideration and the design methodologies used in their development has become a familiar terminology since the mid-1990s – the "system design gap" [4]. This effect has been strengthened by shortened system life-cycles and time-to-market periods necessitating novel and improved system design methodologies and tools. In fact, an organizations' capabilities to develop and maintain IT systems are both a competitive advantage and a barrier that is difficult to overcome for any competitor [5].

Regarding the challenges of the system design process most of the critical system design problems originate in the early design stages when specialists are specifying the system under a high degree of variability and uncertainty. The *European Software Process Improvement Training Initiative* (ESPITI) in 1996 showed that the probability of critical problems due to poor design decisions is over 60% in the specification phase. The main reason for this high probability is that either text-based or non-executable model based specifications are utilized. These specifications cannot be validated in an integrated manner at a system level where the overall architecture and dynamic behavior are determined. The system design uncertainty remains high and the probability of errors too. In addition, crucial design steps are not fully automated e.g. enforcing validation after a design change. Hence traditional design processes are high risk and thereby highly expensive development processes [6].

### B. Facing the complexity challenge

To overcome the complexity and integration issues we propose to introduce a holistic executable specification of the overall system accompanying the complete system development process. The executable specification can at any time be validated and optimized against the requirements of the integrated system. The validated specification of the integrated system can in turn be passed on to specialist teams for subsystem development and subsequent integration.

In this manner, integration problems surface in the early design stages rather than in the final test stages. As a consequence the development time and risk are reduced, specification quality and speed increases – albeit at the added expenditure of maintaining an executable specification. However, even after the completion of the product development such executable specifications can be of use in day-to-day operation

(e.g. to predict and monitor the dynamic system behavior) and continued product development (e.g. validating architectural changes in the operational context).

The remainder of this paper is split into four sections. Section II introduces our system design approach where the executable specification transports the knowledge along the design process. Technically the executable specification is implemented as a simulation model, which collects and encompasses the known system requirements as explained in section III. The interplay between the requirements, the simulation model and the requirement management process is discussed in section IV whereas section V gives an example of a system where executable specifications have been applied.

## II. THE SYSTEM DESIGN APPROACH SIMULATION DRIVEN DEVELOPMENT (SDD)

Simulation Driven Development (SDD) is a system design approach for complex distributed systems and processes. It is characterized by applying modeling and simulation technologies during the whole system life-cycle (resp. product life-cycle). At its core is an executable system specification that exists during the whole system life-cycle encapsulating the current knowledge of the system, starting with the systems' conceptual design, followed by the design, implementation and test stages up to the day-to-day operations of the system and further development activities. At any time, the executable system specification represents the virtual prototype of the system to be built, the system under design or the system operated. The executable specification is kept up-to-date even after the real system or a real prototype is available. In that way it is at any time possible to test the system – either under construction or in operations – against its specification. In the SDD approach testing is preventive [7] before the system is constructed or the change is implemented. In a sense, SDD extends the test-driven-development paradigm [8] to the level of the systems' requirements.

In particular SDD emphasizes the integrated system as a whole and the dynamic coupling effects between the subsystems. One consequence of the increased knowledge of the integrated system as well as the system awareness, is a rapid improvement of the specification quality particularly in the very early design stages. This is in turn equivalent to a higher accuracy of the specification, i.e. less errors are expected in later test stages. Overall we expect SDD to increase the design and implementation speed and to reduce the overall development and operational risk considerably.

### A. Executable system specification

In general an executable system specification defines the functional and non-functional properties of a system in a formal, consistent, and self-contained manner to enable processing [9]. Functional properties define the tasks of the system including information processing in relation to data, operation ("what the system should do" [10]) and the systems' behavior ("a behavior that a system will exhibit under specific conditions" [11]). Non-functional properties are more difficult

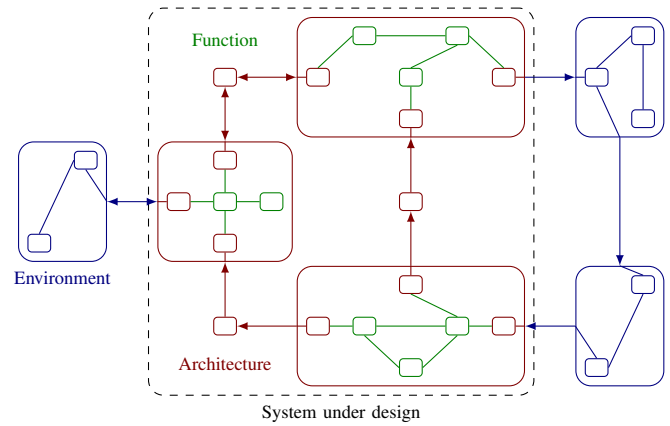

Figure 1. An executable system specification encompasses functional, architectural and environmental components.

to pin down – there is not even a simple consensus on the term and its use [12]. They are used to describe the circumstances necessary to render the required functionality, e.g. the performance requirements, quality properties and constraints (e.g. environmental and implementation constraints, platform dependencies [13] or the typical properties summarized as dependability [14]: availability, reliability, safety, confidentiality, integrity and maintainability).

In contrast to a system specification as a natural language text or non-executable models, executable system specifications are expressed by means of executable models [6]. These models include three component types (see figure 1):

- Functional components: Realization of functional system requirements (e.g. sending toll data at a certain time)
- Architectural components: Realization of non-functional system requirements (e.g. communication protocols and network topology of interacting subsystems, platform limitations)
- Environmental components: Description of operational scenarios with respect to mission objectives, and use cases of the system (i.e. dependability as listed above).

### B. The SDD design process

The SDD design process consists of the typical design phases in system development: analysis/conception, design, implementation and test (see figure 2). However, in the SDD case all phases are accompanied by virtual and real prototypes which in turn are connected to a central requirement repository. This repository of all known system requirements enforces a revision control environment to store and manage prototype versions.

Each phase of the product development has different interactions with the requirements repository: During the analysis phase specifications are derived on a conceptual level concerning the systems' operational scenarios or use cases. Both functional and non-functional requirements are derived from the specification and entered into the repository. This set of requirements is the starting point to implement an

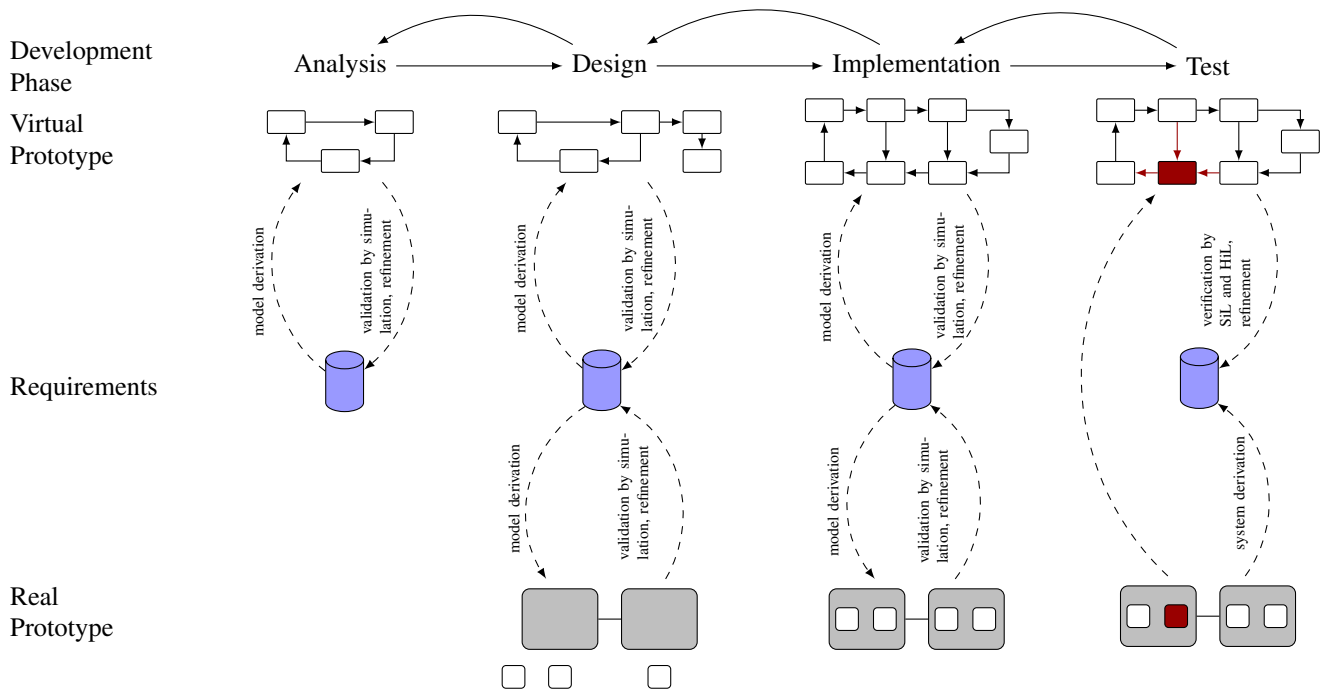

Figure 2. Design process of Simulation Driven Development: The requirements repository (center) provides the baselines for the virtual and real prototypes as well as the real system.

executable specification – a virtual prototype of the system to be developed. The simulation (i.e. running the executable specification with a given set of parameters) aims at validating the specification already at the level of the whole integrated system during this initial phase. In addition, the transition from natural language specifications to executable ones will automatically generate more detailed and rigorous specifications.

The design phase enhances the knowledge of the system under consideration in two directions: The solution space is explored through different virtual prototypes, e.g. to scope varying architectures or behavioral aspects. At the same time, each virtual prototype becomes in itself more specific by adding the necessary behavior and parameters to allow measuring its performance. Depending on the complexity and runtime the optimization can be delegated to an automatic optimization algorithm [15] – in that case properties of the simulation environment become themselves requirements, e.g. the execution performance. At the same time real prototypes are introduced to validate the design resulting in a feedback-loop: the requirements from both sides, the virtual and real prototype, are related and affect each other. The design phase ends when the variability of the potential solutions is reduced to a single solution specification – the starting point for developing the real system.

In the subsequent implementation phase the emphasis shifts from the virtual prototype to the real system under construction. However, the executable specification is kept up-to-date and mirrors the known requirements. In that way simulations are part of the decision making process: Implementation

variants can be explored and compared through simulations. Each design decision is transported to the real prototype via the requirements repository and the executable specification – the latter being a representative of the whole integrated system which itself is still under construction [9]. Similarly design changes from the real prototype are transferred to the virtual prototype via the requirements repository to keep both prototypes consistent.

Finally the test phase is characterized by applying the refined virtual prototype to component tests, i.e. the validation and verification of the components through their defined interfaces [10]. To that end the soft- and hardware components implemented in the real prototype are integrated into a whole working system via the virtual prototype rather than the real world components (or artificial models thereof): So called Software-in-the-Loop (SiL) and Hardware-in-the-Loop (HiL) tests. In addition the virtual prototype is kept to support for the future system development, e.g. when new operational scenarios or new system architectures emerge. In any step, changes to the requirements can automatically invalidate parts of the virtual prototype and are the trigger to adapt and repeat the simulation runs.

### III. HANDLING REQUIREMENTS IN THE SDD APPROACH

Requirements are descriptions of how a system should behave, or of a system property or attribute [10], [16]. However, gathering the right set of requirements is a non-trivial task: In the early design phases the requirements will still be rather abstract and the impact on the real-world system is difficult to gauge. This is a particular problem for non-functional

requirements, e.g. the behavioral aspects of the system [11] or its underlying architecture. Yet it is well-known from software cost models, that the initial investment in choosing the right architecture is important: A NASA recommendation [17] suggests a sweet-spot from the COCOMO II cost-model of dedicating up to 20 % of the software budget to the early analysis and to developing the right architecture.

Addressing the large amount of requirements generated in typical software-intensive systems, requirements are documented at different levels (or layers) of abstraction: The top layer defines why the system is build and what the owning organization hopes to achieve. This type is termed as *business or stakeholder requirements* [11] – an example would be to cut costs by reducing manual steps in a business process. Already at this level-of-abstraction the requirements need to be validated as soon as possible – is the requirement really necessary at the documented level? Seemingly inconsequential numerical targets can have profound effects on the technical solutions, [17] gives the example of 99% data completeness for scientific observations necessitating additional redundancies. The translation of the requirements into an executable specification allows exploring the effects of the requirements on the solution space early on. Vice versa, the virtual prototype transports operational properties of the real-world system back to the solution space potentially modifying or restricting the requirements.

The subsequent levels of detail produce additional layers of requirements where the whole system is defined in terms of an implementable solution. Each layer provides precise means of qualifying the solution and the requirements of a given layer are linked upwards to the next higher layer [18]. To that extend requirements are modeled as uniquely identifiable entities in the same way as all other elements of the prototype model. The resulting links from the different layers of abstraction form an important prerequisite for establishing formal traceability [19].

In SDD, like in the classic V-Model [20], the different types of requirements appear in the distinct development phases:

In the analysis stage very few high-level business requirements exist. They express the overall visions, goals and uses cases of the system under consideration. This initial specification is used to derive executable virtual prototypes for simulations of the system behavior. In light of the cost/benefit discussion above the virtual prototype aims in this stage at clarifying the overall requirements and system architecture – i.e. to identify the essential functionality and to avoid accidental complexity [21] in the overall system and its subsystem.

In the design stage the system architecture becomes more detailed, components emerge and their requirements are formulated. The executable specification helps in drafting accurate requirements and simulation runs yield the resulting dynamic behavior prior to the implementation of the system.

The implementation stage shifts the focus to the real prototype and the system under construction. In this stage the requirements are supposed to remain fixed and only minor adjustments need to be returned to the repository. The simulation model is an executable representation of the state-

of-knowledge and is technically able to integrate a given component into the overall system – especially as long as the whole system is not yet available.

In the test stage, the high-level requirements are used for acceptance tests of the whole system. Usually the development of the virtual prototype precedes the development of the real system. In that case the already implemented components of the real systems are tested using Hardware-in-the-Loop tests. The simulation model provides the still missing ones and allows to test dynamic coupling effects even when not all components of the real system are available. Additionally all requirements in the central repository, which only apply to the real prototype are tested.

The emphasis on introducing an executable specification – e.g. as a simulation model – at the very beginning of the development process is important to connect the abstract requirements to the operational context. In the words of [17] the recommendations are to “raise [the] awareness of downstream complexity” and to “involve operations engineers early and often”. The discussion necessary to bring the initial set of abstract requirements to a set of executable specifications will automatically involve subject matter experts from all fields concerned and yield numerous reviews of requirements, design decisions and the architectural choices taken.

During the whole process all requirements are stored in a central repository. Initially, the repository is populated either manually or by importing them from external resources. As it is the case in any repository, additional meta-data is available to support the development and maintenance process, e.g. by providing information on authors, priorities, costs or authorization.

#### IV. COUPLING THE REQUIREMENTS TO THE SYSTEM SPECIFICATION

Where the prior sections focused on the overall SDD process, this section explains the coupling between the requirements repository and the various systems supposedly implementing these requirements: The virtual and real prototypes, the simulation model and the real system under consideration. At the core of the SDD process is the availability of an executable system at any time during the whole development life-cycle. Together with the links between the executable specification and the requirements at any level-of-detail the validity and correctness of the executable specification is constantly assured by the attached requirements (see section IV-A). To that extent the current system state needs to be captured and compared with the requirements as detailed in section IV-B. In the end, validating the requirements necessitates a dedicated work-flow (see section IV-C) and the creation of dedicated test-functions (see section IV-D).

##### A. Requirements validation

“Treat English as Just Another Programming Language” [22] – requirements start with those people that are responsible for the system: product owners, marketing experts and domain experts whose domain is typically not the software industry.

The requirements may be gathered by specialists but start as a natural language document – fuzzy and open to multiple interpretations [23] – before they are translated into more formal notations.

Many well-documented methods exist to refine and to formalize requirements:

- Formal notations, e.g. the Z-Notation [24], Vienna Definition Language [25], Language of Temporal Ordering Specification (LOTOS) [26] and the B-Method [27].
- Cause-effect graphs [28] provide the relationship between input (causes) and expected output (effect) specified by the requirement [29]. Generators are able to derive test vectors from this model that are fed into the requirements model and into the system under test to compare the results. However, as the number of requirements grows, the size of the cause effect graphs becomes hard to handle.
- Computation tree logic (CTL) or linear temporal logic (LTL) are yet other ways to formalize requirements [30].

Naturally these methods rely on the manual task of translating the natural language into the formal notation chosen. A rigorous approach is rarely taken since the cost is typically only justified for critical systems i.e. ones in which potential financial or human loss would be catastrophic [18]. In addition, these methods are difficult to apply in the very early design stages when the requirements are at a very high level and still a subject to change. Therefore a different approach is necessary.

To address the size of the solution space in the early stages, SDD introduces configurable scenarios, called missions. Each mission is driving the virtual prototypes – the specification becomes executable via a set of parameters or even architectural choices. The dynamic system behavior – at the yet considerable level-of-abstraction – is obtained for a particular scenario by executing the mission as a simulation run. The set of all missions describes the solution space that is considered to adhere to the known requirements. At this point, detailed requirements for the initial subsystems and components are not yet settled or completely absent. Yet the simulations will already give boundaries for the subsystem behavior and the discussions with the subject matter experts will quickly refine the requirements – already within the context of the integrated system.

To validate the requirements, the authors have chosen a method similar to test oracles [31]. A test oracle is a predicate that determines whether a given test activity sequence is an acceptable behavior of the system under test [32]. In this context, a testing activity can be seen as a sequence of stimuli and response observations. To that extent the virtual prototypes are enhanced by dedicated test-function blocks representing test oracles: These functions are used to check if the model state matches the expected as defined by the requirements. Links between the requirements, the virtual prototype and the test-functions provide the traceability in the SDD approach.

Figure 3. Sampling points are embedded into the simulation model to capture event streams

### B. Capturing the system state

One advantage of the virtual prototype running as a simulation is the access to the whole system state – which is not feasible in many distributed systems in the real world. To capture the system state in a simulation run we embed sampling points in the model (see figure 3).

Depending on the placement of the sampling points, different information is recorded: If placed on a connection between two or more components, the event flow of the discrete event simulation model is recorded along the chosen connection. Additionally, each component can be extended so that its local internal state can be sampled. In both cases, every sampling point produces a stream of data as the simulation run produces and processes events over the execution time. Data extraction is read-only, i.e. the semantic of the virtual prototype remains unchanged albeit at a minor performance hit.

The sampling data stream adds the event time and the component to the data sampled at the sampling point. Of course, the interpretation of a given sample value is model and domain specific. The tuples sampled in a simulation run form the stimuli or the responses of the test-functions used to validate the requirements. Any combination is conceivable: A test-function may use a single tuple, i.e. one value at a given simulation time, several tuples at the same or even at different times – opening the possibility to correlate information along the flow of a business process over time. The data processing can itself be performed either synchronously or asynchronously to the simulation run.

### C. Validation work-flow

The SDD approach explores the solution space by maintaining different missions (see section IV-A) corresponding to different virtual prototypes. To validate the requirements all missions are executed as simulation runs, each run produces its sampling data stream to feed the test-functions embedded in the virtual prototype. For each mission the result is a simple boolean “pass” or “not-passed”, a detailed look at an individual simulation run of a given mission will in turn show the boolean result for each embedded test-function (see figure 3). The traceability of all requirements results from the links between various levels-of-abstraction and to the virtual prototype and its test-functions. As a result of executing all missions, it is possible to determine those missions that implement the

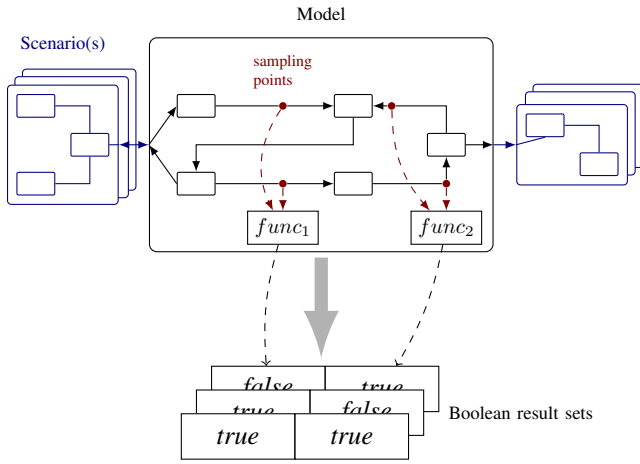

Figure 4. Requirement validation: Different scenarios are used to run the model. The test-functions create an output value for each simulation run, which altogether build the boolean result sets.

requirements successfully. If some requirements in the central repository are not validated – either explicitly as “not-passed” or implicitly when no test-function is available, the traceability allows the automatic high-lighting of these requirements in the repository.

The validation work-flow starts with executing – probably in parallel – all available missions of the virtual prototypes and the subsequent collection of the test results. During the simulation runs, the embedded test-functions are constantly triggered by the events passing through the simulation model resulting in a sampling data stream that is captured and evaluated to return the boolean result set of the used test-functions (see figure 4). Eventually when all simulation runs are finished, all result sets are aggregated allowing to identify valid virtual prototypes and potential problems and their origin by following the traceable links from the test results via the test-functions and the simulation model components back to the individual requirements.

Table I summarizes the possible outcomes at a global level: All test-functions of all missions could return a positive result, some might return a negative result or all of them fail. This global overview concerns the overall solution space since the various missions are equivalent to different possible solutions – it is expected that as the knowledge about the system under consideration progresses more and more potential solutions will fail the added requirements and constraints. The design stage therefore aims at retaining at least one valid virtual prototype where all requirements are successfully verified by test-functions. This approach naturally leads to a iterative spiral-model [33] where the negative test-results will start the search for an incrementally improved solution and the refinement or alteration of the requirements responsible for the negative test result.

The validations work-flow can of course be automated in large parts: New simulation runs are automatically created and executed, the results of the test-functions are mirrored

Table I  
INTERPRETING THE RESULTS OF THE REQUIREMENTS VALIDATION  
WORK-FLOW

Test-Function Results		Overall Rating
All	test-functions in every mission are evaluated to	true } fulfilled
Some		true } partially fulfilled
All		false } violated

to the requirements repository. The search for better virtual prototypes or adjusted requirements remains a human task involving the domain experts as well as the technical experts. Once a change to the existing requirements is identified and submitted, the traceability automatically yields all virtual prototypes and test-functions impacted by the change.

#### D. Implementing a test-function

The SDD approach takes the ideas of test-driven development (TDD) to the very early design stages: The requirements undergo testing prior and in parallel to the system implementation using test oracles as test-functions [34]. As in the TDD case, testing is not the aim of the SDD rather the “driven [...] focuses on how TDD leads analysis, design, and programming decisions” [35]. Of course, technically test-functions need to be implemented to verify the requirements through the correct behavior of the virtual prototype: An obvious implementation is to compare the input events (stimuli) of a particular component in the simulation model with output created (responses) – basically a simple unit test of a component. However, often a single deterministic outcome is not sufficient to determine the success of a test-function. Rather the test-function is used to explore the boundaries of the specification, the statistical distribution of events or correlates information from different components of the virtual prototype at the same time or over time periods.

To that extent, test-functions are again source code potentially with (read-only) access to the whole simulation run and a private data store to retain and correlate data over the runtime. As the complexity of the test-function increases, the risk of program errors increases as well. To mitigate this risk as set of predefined, configurable and proven test-functions is provided ready-for-use. The set may consist of functions, to test whether a value is bound to a specific interval as well as functions to express boolean conditions in the form *if ... then ... else*. With this starting point mathematical relationships are straightforward to implement.

Test-functions are implemented like the other model components using the same levels of abstractions such as nested sub-components, if necessary. The only difference is, that they cannot influence the model semantics or impose any side effects.

#### V. APPLICATION: SIMULATING THE GERMAN AUTOMATIC TOLL SYSTEM

We have applied the SDD approach – in parts – to the ongoing development of the German automatic toll system, a

large-scale autonomous toll system [36] operated by Toll Collect GmbH. The toll system collects the tolls for heavy-goods vehicles (HGVs) driving on federal motorways – at present it is the largest system of its kind in operation, collecting more than 4.6 bn € annually predominantly automatically using the more than 1 000 000 on-board-units (OBUs) deployed at present.

#### A. Challenges of the development process

As a typical system-of-systems the toll system consists of a multitude of sub-systems for the various domain-specific tasks. Wherever possible, sub-systems are designed around existing commercial off-the-shelf applications and very few are custom-developed (the most notable one is the hard- and software of the OBU). Most often the development and operations of the sub-systems is outsourced to technology partners – at least the system specification and later on the system integration remain as a core competency [37].

The common software or system development practices suffice to address most aspects of the liability-critical system: Following a V-Model approach, requirements are documented prior to the system design and implementation, all of which create test cases for the subsequent verification in different stages. However, the more than 1 000 000 OBUs deployed in HGVs pose a particular challenge. They form a ‘distributed system’, i.e. “one in which the failure of a computer you didn’t even know existed can render your own computer unusable” [38]. In addition the OBU behavior depends on the user interaction which is in large parts not known due to technical restrictions and data privacy protection.

To address these challenges posed by the OBU-fleet, additional test stages are added using tens of OBUs in a lab environment, hundreds and up to a few thousand OBUs in dedicated test fleets. Yet these tests are still at a scale below 1:100 and occur only at the end of the development once the software change has been implemented and tested in unit and component tests. Scaling based on past experience from the real-world system is of course possible when the changes are minor and the operational context remains unchanged.

Major changes to the software of the toll system cannot rely on past experience: Even recourse to expert advice is known to be problematic – experts tend to be over-confident [39], a well-known cognitive bias that needs to be mitigated by the system design process. Besides, given time, the cost-of-operations dominates over the initial system development costs. I.e. the validation of the requirements – *did we build the right system?* – can only be answered in the context of the daily operations of the whole system at a scale of 1:1.

#### B. Adding simulations to the development process

To overcome the challenges mentioned above we developed a simulation model of the automatic toll system that incorporates the most important processes – collecting tolls and providing updates to the fleet – at a scale of 1:1 (figure 5, upper part) and a model for the temporal behavior of the user interaction (figure 5, lower part, for details see [40], [41] and references therein). Having this executable specification of the

Figure 5. The simulation model includes a model of the technical system (above, dashed) and a model of the user interaction (below).

automatic toll system we derive missions corresponding to the system in operations either at present or in the near future. Simulation runs based on these missions predict the dynamic operational behavior over weeks or months, e.g. the propagation of software updates across the fleet. Where possible, the predictions of the simulation runs are compared with data observed in the real-world system and the parameterization is calibrated accordingly.

This realistic, microscopic simulation model of the real-world toll system is the starting point to change the software development process to *simulation driven*: As the software development starts, the virtual prototype of the existing toll system is forked to reflect the proposed changes. In that way the proposed system is accompanied from the very beginning with a simulation model: The very early design stages start with an executable specification that transports much of the existing operational context to the newly drafted requirements. Design decisions are from the start *driven* by the simulation results where the simulation takes into account the system operations at a 1:1 scale. Consequently the initial draft of the new requirements – typically a document using natural language descriptions – quickly becomes more precise and the discussions are anchored in the real-world operational context.

## VI. CONCLUSION

A realistic simulation model of a software-intensive system-of-systems is the natural extension of the test-driven development approach: The development process is at any time driven by the results *as observed in the real-world operational context*. The core of this idea is to create an executable specification of the known requirements in every development phase and to trace changed requirements from the beginning with a focus on the real-world effects. In this article we have outlined our approach – Simulation Driven Design – and briefly mentioned the case of the automatic German toll system. There the effects of proposed changes are from the beginning measured against the (simulated) effects in the integrated system at a scale of 1:1. The effect of SDD is twofold: Simulation runs predict the effects of a proposed change and creating the virtual prototype drives the development process with the focus on the systems’ operational context.

□

**Abstract**—The paper proposes a methodology for the development of a marketing decision support system using Big Data technology and data mining techniques. The approach was inspired by the CRISP-DM methodology, which is not oriented towards Big Data projects. Therefore, we have modified this methodology with respect to the purpose and technological requirements of the project. The proposed methodology was tested during development of RTOM (Real Time Omnichannel Marketing) project. Project tasks focus on the analysis and exploration of large and heterogeneous data sets. The paper presents the phases of the project implementation according to the extended CRISP-DM methodology, taking into account the specifics of the analysis and exploration processes of large real-time marketing databases. Examples of project steps are also provided to illustrate the approach.

## I. INTRODUCTION

DATA exploration is a process of automatic detection of non-trivial, unknown, and potentially useful relationships, rules, patterns, similarities, or trends in large data sets [1]. Generally speaking, the task of exploration is to analyze data and processes it in order to better understand and use it in decision-making processes. Data mining is a multi-disciplinary area that integrates a range of research fields such as information systems, databases and warehouses, statistics, artificial intelligence, parallel computing, operational research, visualization, and computer graphics. Exploration systems use a broad range of information and communication technologies, Web technologies, information retrieval methods, and geolocation techniques, as well as signal processing and bioinformatics.

In this paper, an approach to development methodology of the analysis and exploration of marketing data is presented, adopted in a Real Time Omnichannel Marketing (RTOM) system. In the project, the data is collected mainly in real time and huge sets of data are processed, with high heterogeneity of data sources, formats, volume, and intensity of inflow. The user of RTOM (manager, marketing analyst, etc.) expects acquisition of non-trivial, new and useful knowledge that can be used in the decision-making process. In addition, the knowledge, extracted from the collected data, should be used automatically in customer communication processes to optimize the selected parameters of business process such as

purchase probability, customer satisfaction, customer retention risk, product margin, and more. Therefore, our project is not a typical task for most classic Business Intelligence systems, whose implementation is relatively well known [2].

Taking into account the complexity of the project, its innovative character as well as the multiplicity of skills and competences involved in it, and the inherent application of modern information technologies, it was necessary to adopt a uniform methodology of project implementation. In literature, a wide range of descriptions of data mining algorithms applied to generate insightful business analyses can be found, but there is much less information about the methodology of Big Data exploration [1], [2]. This methodology supported by software should enable teams to more efficiently and effectively implement projects entailing real-time knowledge acquisition from very large databases.

So far, several data mining methodologies and process models have been developed. They have achieved varying degrees of success in business applications. According to Gartner, in 2015, 85% of Fortune 500 organizations failed to execute Big Data projects! Those who succeeded were characterized by a high degree of organizational maturity and a good methodological approach [3].

Recent studies of the usage of methodologies in large database exploration projects indicate that the CRISP-DM methodology, proposed by MIT, dominates (42% of applications), followed by own methodologies (19%), while the SEMMA methodology proposed by SAS ranks third (13%) [4]. The other methodologies such as KDDProcess, My Organizations, and domain-oriented methodologies accounts only for a few percent of the market [3],[5]

When selecting the methodology for our project, the following considerations were taken into account:

- 1) the specificity and complexity of the project, in particular the process of exploring large databases in real time,
- 2) the need for a pragmatic approach to deliver an application focused on specific sales management and marketing issues,

□ This work was supported by Regional Research Program, Wrocław, Poland. Grant RPDS.01.02.02-02-0079/15-00

3) organizational maturity and competence of Unity S.A. in the areas of Big Data applications, modern analytical tools and information technology.

As a result of the studies and discussions, we chose the CRISP-DM methodology as a framework. Despite many usage areas, it is not a methodology oriented towards Big Data projects. Therefore, this methodology has been modified to meet our needs, the purpose of the project as well as its technological requirements in mind. In the following sections of this paper, we describe in detail the phases of the project development process, taking into account the specificity of the analysis and exploration processes of large real-time marketing databases.

## II. RTOM PROJECT OUTLINE

Real-Time Omnichannel Marketing (RTOM) provides automated and personalized real-time consumer interaction based on the collection and processing of empirical consumer data in a multi-channel sales and marketing model using artificial intelligence and geotargeting algorithms.

The basic assumption of a multi-channel sales strategy is based on the fact that a single customer transaction can be carried out using more than one customer contact channel with the supplier. In a classic multi-channel approach, the seller has multiple customer-facing channels (e.g. bricks & mortar shopping centers, website, on-line commerce systems, mobile application, contact-center, and many more). The omnichannel approach is intended to improve the customer experience. Deployment of the omnichannel approach requires full integration of off-line channels with those on-line at the business and IT level. Today's Consumer Journey involves a variety of activities and it is carried out in multiple communication channels, as shown in Figure 1.

Omnichannel is a big business and IT challenge, but first of all a chance to fully understand customer needs and behaviors (see [6], [7]). Therefore, data mining tasks and Big Data technology must be employed to attain the full implementation of the strategy [10]. The basic requirements for the RTOM system are the following:

- 1) Building a unified customer profile based on the Master Data Management concept [11], with various types of references between entities implemented, e.g.:
- 2) Shopping preferences: what size of clothes the customer buys, what colors / styles they choose, their favorite brands, etc.,
  - Channels in which the customer contacts the retailer / purchases products / picks products up / gives feedback,
  - Time of purchase (e.g. birthday / occasions, holiday, particular season, etc.)
  - Final receiver (whether the client buys for themselves, partner / spouse, child, another person).
- 3) Ability to seamlessly incorporate new artificial intelligence models. Currently available recommendation are based mostly on statistical analysis or simple association rules. In RTOM, we will implement unsupervised learning methods: various clustering algorithms, multi-level associative rules, and also supervised learning methods such as classifiers and predictors. The system must allow the final user to design their own predictive models.
- 4) Ability to perform analysis of behavioral data not only describing store transactions, but also characterizing the way visitors navigate the website, perform searches and filter data, etc., and how they interact with off-line channels (store visit records, complaint registers, communication with contact centers). The analysis is supported by domain-specific knowledge of the industry / characteristics of the products offered by a selected retail network, for example:

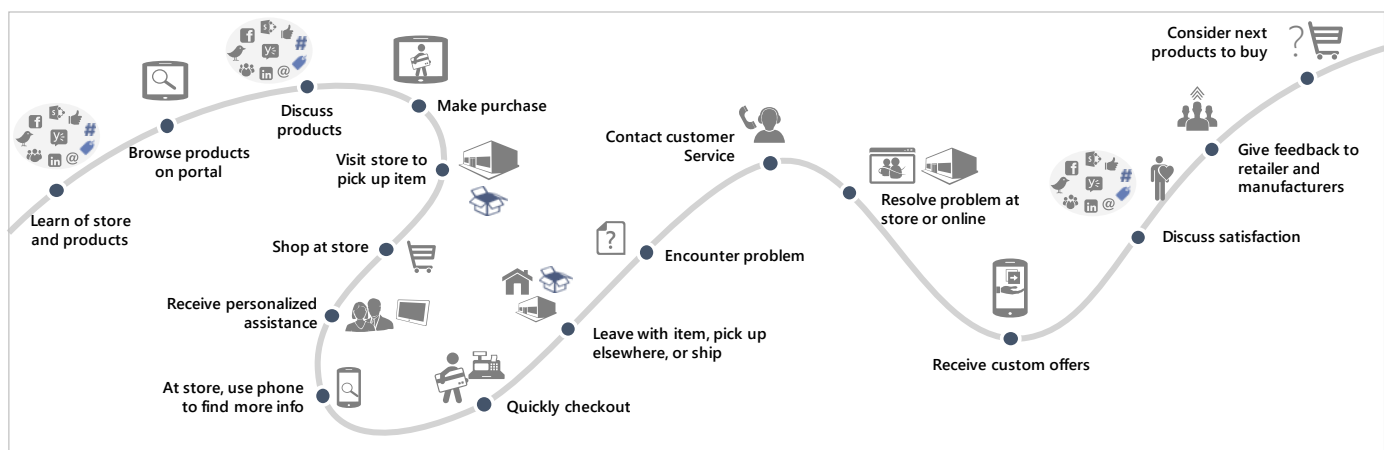

Fig. 1. Customer Experience Journey Map

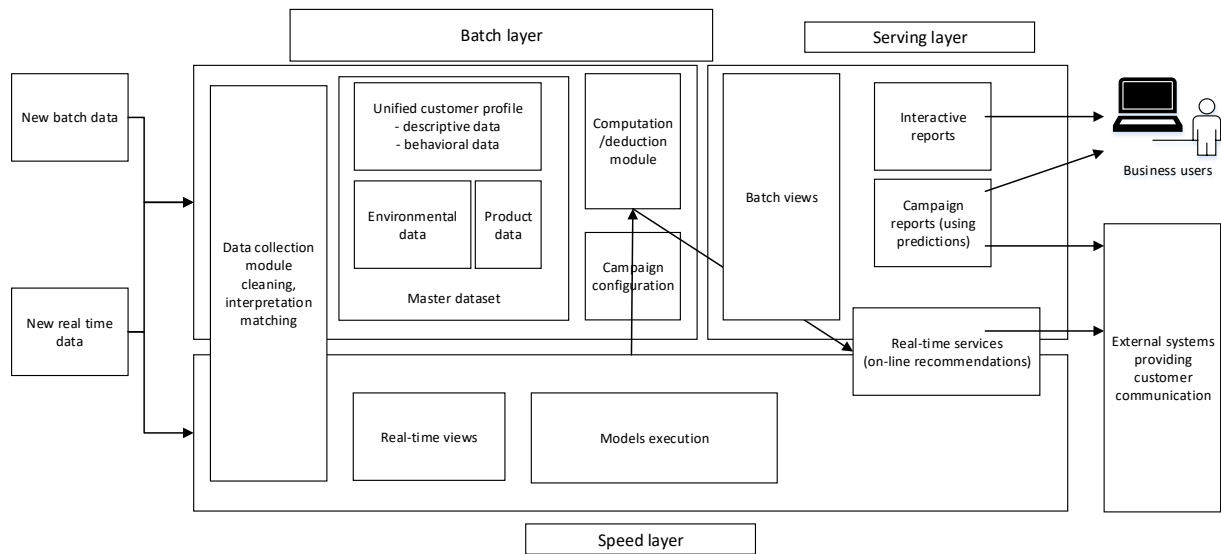

Fig. 2. RTOM general architecture

- Product should be identified by its characteristics rather than on SKU (e.g., the information that the client viewed white running shoes of a given size and brand is far more important for us than the fact that the product's id was 343202043)
- Product's designation e.g. the season regards to casual shoes or jackets, and is irrelevant in regard to a wallet and maybe partly relevant to a skirt or t-shirt.
- For whom the product is designed (male, female, youth, infants), which matters in the case of clothes or books, but not for TV sets.

The project is intended to provide a retailer or a client with real-time recommendation of a product purchase, discount or marketing activity in order to maximize a selected customer experience factor (purchase probability, customer satisfaction, customer retention risk, product margin). The recommendations should be delivered by models based on the knowledge gathered from collected data sets and supported by experienced specialists' expertise.

The project also includes features of generating knowledge from collected data in the form of:

- interactive reports facilitating confirmation or denial of hypotheses,
- recommendations for marketing messages directed to individual customer segments resulting from the predictive model but not necessarily generated in a real-time,

Considering the heterogeneity of data sources mentioned earlier, the enormous amount of data and the need to generate real-time response, we decided to base the RTOM architecture on Lambda architecture. Lambda is a reference

architecture for scalable real-time data processing systems [9], [10]. As shown in Figure 2, the platform consists of 3 layers typical for Lambda architecture, namely:

- batch layer - storing immutable append-only set of raw data, describing: customer features and customer's behavior (a unified customer profile). This collection is called the master dataset from which we generate batch views. This repository is based on Apache Hadoop and HDFS file system. We use Hadoop based data retrieval mechanisms mainly:

- Hive<sup>1</sup> (data warehouse software),
- Impala<sup>2</sup> (low latency and high concurrency analytic database for BI/analytic queries on Hadoop)
- HBase<sup>3</sup> (non-relational, distributed database inspired by Google's Bigtable approach),
- Cassandra<sup>4</sup>, (distributed NoSQL database) etc..

- serving layer – storing indexed batch views, which enables to generate reports in a low-latency and ad-hoc way. It also stores predictive models defined in our project.

- speed layer - real-time views storing recent data only to compensate the batch views with real time data.

The Lambda Architecture aims to satisfy the needs for a robust system that is fault-tolerant, both against hardware failures and human mistakes, being able to serve a wide range of workloads and use cases, and in which low-latency reads and updates are required. The resulting system should be linearly scalable, and it should scale out rather than up [12]. Although we are aware that Lambda Architecture is questioned [13], we decided to use it as a reference architecture but we carefully follow its indicated drawbacks to avoid potential problems.

### III. CRISP DM METHODOLOGY – PROPOSED EXTENSIONS

Many of the mentioned methods and technologies were used to analyze marketing data for the purposes of the project and implementation of the RTOM platform. Unlike most existing CRM systems, we were more focused on analyzing heterogeneous, semi-structured data available in real-time. This required not only broad adoption of Big Data technology, artificial intelligence, and the mobile technology, but also consistent assumption of the appropriate methodology for the design and implementation of the platform. As we noted, the adopted methodology is largely founded on the CRIPS-DM methodology.

The CRISP-DM methodology assumes that each data mining project develops in a specific lifecycle. Unlike the original CRISP-DM version, where the process of project development is divided into six phases, in our approach two stages of CRISP-DM: understanding and data preparation are integrated into one. Figure 3 shows a diagram of the RTOM platform development process. The arrows in the diagram shown below indicate the relationships between the different phases. It should be pointed out that improvement and enhancement of the existing solutions usually follows the five phases. The circle surrounding them symbolizes the continuous adaptation of the solutions to new environments.

The **first phase** consists in defining and understanding the project requirements from a business perspective and pre-planning activities to achieve the project goal. Understanding business considerations includes:

- clear formulation of the goal and requirements of the project using business terminology,
- use of defined objectives and constraints to detail the problem,
- formulation of the initial hypotheses and methods of their validation,
- collection of opinions about the proposed solutions put forward by managers, shareholders and domain experts,
- identification of sources of data acquisition and the scope of required data,
- identification of the necessary tools and information technologies,
- definition of the initial schedule of activities to be undertaken so as to achieve the goals.

In the approach, we assume that the formulated hypotheses are pre-validated on a sample of source data by a data analyst, using the Orange <sup>5</sup>data mining platform. The analyst should document their work and provide the first version of the models with an I/O description (including the definition of variables and required data preprocessing).

The milestone of this phase is the elaboration of documentation containing answers to the above-mentioned points and documentation of the pre-model (models) developed on the Orange platform.

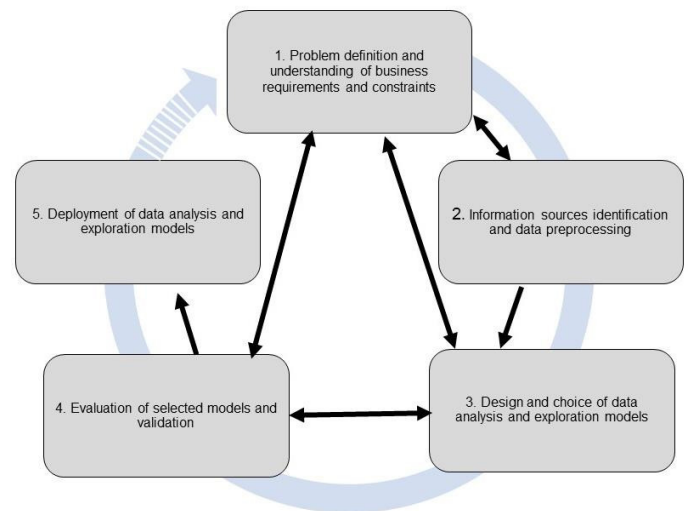

Fig. 3 Phases of the platform development methodology

To illustrate the approach, we apply the example of one of the tasks solved on the RTOM platform, i.e. customer clustering. In this application, clustering can concern customers, products, transactions, and customer contacts with store web pages. For example, in our database we have several thousand customers, each described by several dozen attributes of various importance. The goal of clustering is to find clusters of similar customers to whom we can send an offer or whom we can target when promoting specific products. We require clusters to have specific statistical characteristics (such as minimum variance) and usefulness in marketing decision making (e.g. determining loyal customer groups). Clustering is expected to ensure that promotion of store products becomes more effective, which will be specifically expressed in sales profitability ratios. In this phase, the data have to be identified; in our case, they are transactional systems, CRM, geolocation data, social networks and logs of store web services.

Working on the problem, it is extremely important to formulate preliminary hypotheses and to assess the proposed methods of achieving the goals set by the company's managers, shareholders and domain experts. What is innovative, in terms of methodology, is to develop a prototype of a model and perform initial validation on a simplified case, using an easy-to-use data mining tool. One such tool is an open source visual programming platform Orange. The clustering process diagram is shown in Fig.4.

The obtained results together with the cluster visualization allow one not only to better understand the problem and to clarify business objectives, but also to perform an initial validation of the solution.

<sup>5</sup> The Orange platform is an easy-to-use data mining tool with a rich graphical interface and functions for data analysis, classification, clustering and prediction. The visual design of the data exploration process together

with the ability to expand functions in Python make Orange a tool used very often by analysts. More information about Orange can be found on the web site of the University of Ljubljana <http://orange.biolab.si>.

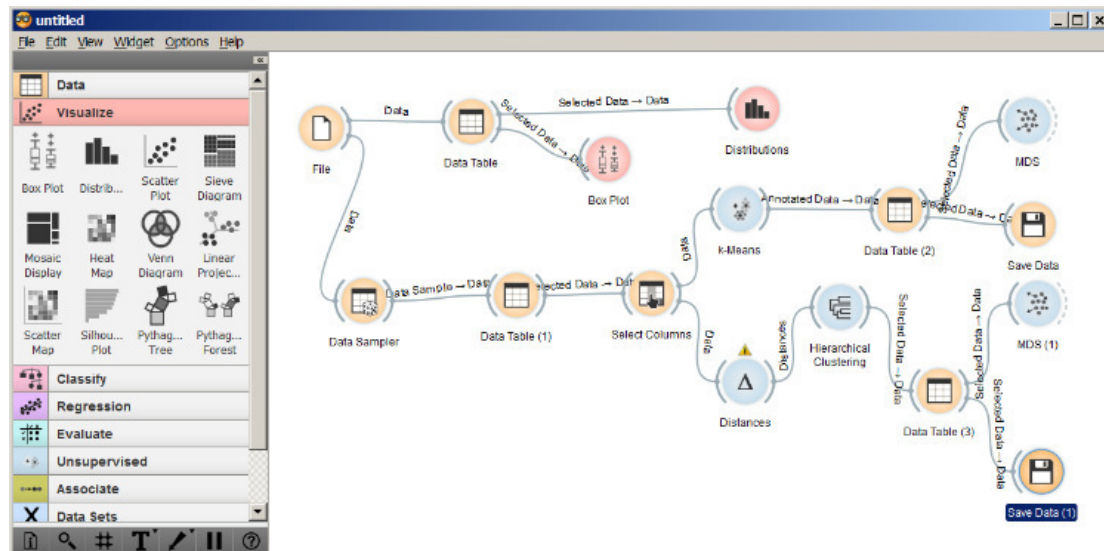

Fig. 4 Visual diagram of customer clustering

The **second phase** concerns the identification, understanding and preparation of data. In our approach, compared to the original CRISP-DM, we integrated two stages: the understanding and preparation of data. From all the phases, it is the most iterative and time consuming work. The main task is to collect pre-process data to be used by the tools and data mining algorithms. In the context of Big Data technology, the data is collected in so-called data sandboxes. Technically, a data sandbox consists of massively parallel processors, extensive memory, and I / O mechanisms that ensure the scalability of the data collection processes and the independence of the operational database systems [14]. Thanks to this, the sandbox provides the ability to carry out complex data analyses without interrupting the operation of the company's information systems. The collected data may be of heterogeneous types; they can come from transactional systems, mobile devices, OLAP cubes, telephone logs, Web logs, and the Internet. It should be taken into account that the size of a data sandbox may exceed many times the size of a company data warehouse.

It should be noted that although the sandbox data is shared by data analysts and exploration modules, at the same time the sandbox platform has to ensure data security and confidentiality.

The second important task of this phase is the preparation and transformation of data according to the Extract-Load-Transform (ELT) scheme. The value of the ELT is that it preserves data in its original form in the database. Therefore, the analyst may freely convert it or leave it unchanged. As far as this job is concerned, it is important to control the quality of the collected data and provide statistically useful measures. The last task is to organize and design the transformation process of raw data. Typical transformation operations include attribute analysis, data cleaning and normalization, completion of missing information, etc.

In the project, the data sandbox platform is run under Linux; we apply the NOSQL database technology available

on the Hadoop platform, and processing compliant with the MapReduce paradigm available in the Spark engine [15].

The phase milestones are the development of technical documentation and the creation of the sandbox for RTOM. For example, in the RTOM project, the main source of data is the transaction processing system and customer logs with the store's web application. The database schema is illustrated in Fig.5.

In addition to transactional data, the sandbox collects data from all marketing channels, which include customer geo-location data or data pertaining to customer activity in social networks.

The **third phase** of the process focuses on the design and choice of the data mining model. While in the previous phase we were concentrated more on data quality, at this phase we undertake the problem of discovering the relationships between variables in the area of specific business problems. We use the documentation of the preliminary version of the model (models) previously prepared on the Orange platform. It is important here to engage the domain experts who might suggest variables that can influence the solution and to accept or reject the hypotheses defined in the first phase. In particular, it may concern interpretation of correlation and causal relationships.

The choice of attributes is crucial for the performance of data exploration. The analyst must be open to the prospect of examining various algorithms, their parametrizations, and the composition of the input vectors. The design of the input vector and the data mining models is an iterative process. Model learning and testing on all possible variables is usually impractical. In order to reduce the dimensionality of space, analysts can consult the experts who will suggest important variables or use algorithms that rank variables according to criteria such as the Gini index, information gain,  $\chi^2$ , ANOVA, or the rate of entropy reduction.

There are many data mining models. Generally, they fall into three categories: classification, prediction and

clustering<sup>6</sup>. In the RTOM project, we restricted the offer to the models available in Apache Mahout<sup>7</sup>, Spark MLlib<sup>8</sup>, Tensorflow Core<sup>9</sup> and Pandas<sup>10</sup> [16], [17].

To provide an example of our work, we applied the clustering models available in Apache Mahout<sup>11</sup>, Spark MLlib and Tensorflow Core libraries [8], [15]. From the available clustering models, the k-means model [1], [10] was chosen. The following fragment of the code illustrates a part of the model specification

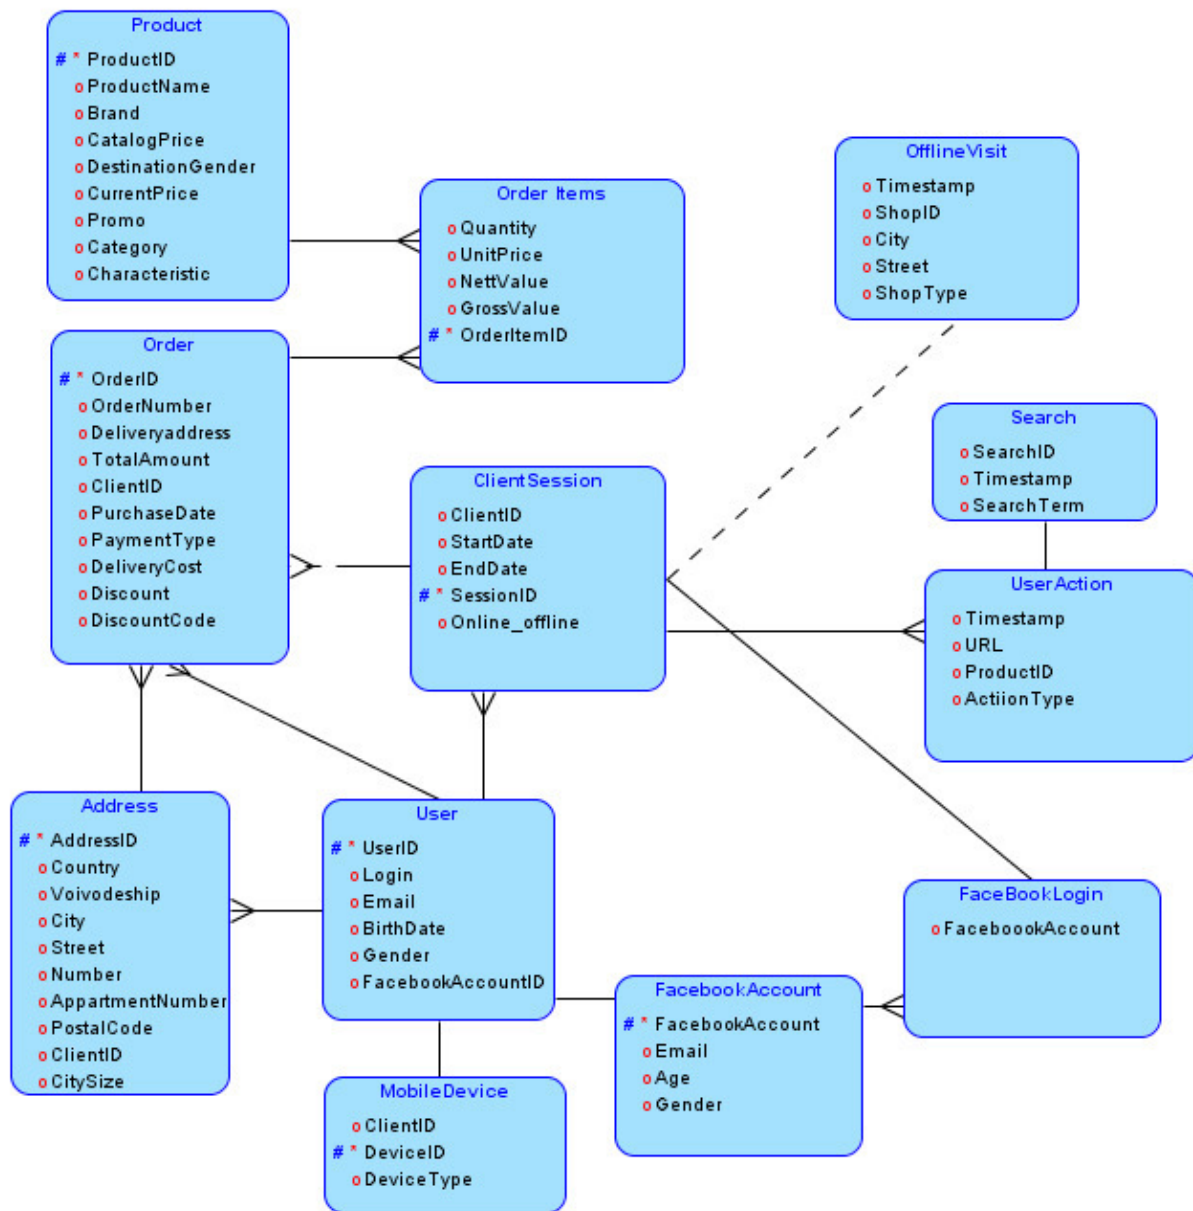

Fig. 5 Conceptual diagram of the database

Presented model code is intended to build clustering model of customers. Before we start we need to calculate aggregate values describing clients' behavior. In the input dataset one row represents one client for whom we select his or her

birthday, gender and we calculate the date of the first client's order, number of orders and their total values in 2016 and 2017 as well as discounts in 2016 and 2017.

<sup>6</sup> Classification and prediction are very similar and generally related to the type of data used to build a given model. If the decision attribute is categorical, then the predicate problem of the value of such an attribute is presented as a classification problem. If the decision attribute is continuous (numeric), the problem is called a prediction problem.

<sup>10</sup> <http://pandas.pydata.org/>

```

%%spark -o vector_df
from pyspark.ml.feature import VectorAssembler
from pyspark.ml import Pipeline

def create_vector_assembler(col):
    vector_column_name = 'v_' + col
    input_cols = [col]
    return VectorAssembler(inputCols=input_cols,
outputCol=vector_column_name)

columns = [
    'min_order_place_date',
    'birth_date',
    'number_of_orders',
    'promotion_counts',
    'sum_2016',
    'avg_disc2016',
    'sum_2017',
    'avg_disc2017',
    'gender'
]
vector_columns = map(lambda c: 'v_' + c, columns)
vector_assemblers = map(create_vector_assembler,
columns)
pipeline = Pipeline(stages=vector_assemblers)
vector_df = pipeline.fit(df).transform(df).select(vector_columns)
vector_df.cache()
from numpy import array
from math import sqrt

from pyspark.mllib.clustering import KMeans,
KMeansModel

def to_training_point(data_frame):
    return array([getattr(data_frame, column_name)
for column_name in column_names])

column_names = d.columns
training_data = d.map(to_training_point)
clusters = KMeans.train(training_data, 8,
maxIterations=10,
runs=10, initializationMode="random")

```

To interpret the obtained clusters of customers, we built a decision tree using the library *pyspark.mllib.tree*. The tree rules allowed interpretation of customer groups in marketing terms. The following fragment of code illustrates the process of decision tree generation.

```

from pyspark.mllib.tree import DecisionTree,
DecisionTreeModel
from pyspark.mllib.util import MLUtils
from pyspark.mllib.regression import LabeledPoint

ttd=sc.parallelize(map(lambda(p,l):
LabeledPoint(l,p),cl))

tree=DecisionTree.trainClassifier(ttd,numClasses=8
,categoricalFeaturesInfo={},impurity='entropy',
maxDepth=5,maxBins=4,minInstancesPerNode=10,
minInfoGain=0.1)
names = dict(map(lambda(k,p): ('feature
{}'.format(k), '{} {}'.format(p,k)),
enumerate(d.columns)))
res = tree.toDebugString()
print(res)

for f,t in names.iteritems():
    res = res.replace(f,t)

```

```

mytree =
sqlContext.createDataFrame(sc.parallelize([res,])
), ['c'])
mytree.show()

```

The milestones of the phase are documentation of data exploratory models, a set of models along with specifications of the data used in the learning, testing and validation processes.

The aim of the **fourth phase** is the assessment of the quality of the developed data mining models. The prerequisite for the task is to clearly define the evaluation criteria. The evaluation problem is a multi-criterial one [18]. In addition, however, it often happens that managers, shareholders, and experts impose supplementary priorities during the model evaluation.

In general, the models should be evaluated in terms of quality and efficiency before being implemented on a sample of sandbox data. Two-step model testing is recommended here: first – on a pilot trial, later – on full information resources. As a result, the cost / modification time of the model can be reduced due to simple errors or oversights, thereby diminishing the risks associated with testing and validating the production version of the platform. It is advisable to gradually extend the scope of assessment, e.g. to product categories, selected sale channels or market regions. When launching a model in the real life environment, the assessment should first focus on detecting anomalies in the input data before running the model. The model's performance is evaluated not only in terms of quality and efficiency but also in terms of mutual cooperation with other platform resources. This action permits one to formulate operational recommendations for the model deployment under real conditions

It is very important to prepare datasets for model building and evaluation (model learning, testing and validation.) The quality of selected models is assessed according to predefined business criteria and generally accepted assessment criteria for each category of data exploration models.

In the example discussed here, the proposed clustering models were evaluated. In general, the measures of evaluation can be divided into two categories: internal assessment of clustering results and evaluation based on external criteria.

Using the internal criteria, we evaluate the clustering hierarchy taking into account the similarity of instances within clusters and the similarity between clusters. The following measures can be applied [1],[18]:

- Davies-Bouldin index

$$DB = 0.5n \sum \max ((\sigma_i + \sigma_j) / d(c_i, c_j))$$

where  $n$  is the number of clusters,  $c_i$  and  $c_j$  are cluster centers,  $\sigma_i$  and  $\sigma_j$  are the standard deviations, and  $d$  is a distance between cluster instances and centroids.

The algorithm that generates the lowest value of the DB index is considered the best according to this measure.

- Dunn index

$$D = \min (d(i, j) / \max d'(k))$$

where  $d(i, j)$  is the distance between clusters  $i$  and  $j$ , and  $d'(k)$  is the distance measure within clusters  $k$ .

Dunn's index focuses on cluster density and the distance between clusters. Algorithms preferred by the Dunn index are those that reach high values of the measure.

In external evaluation methods, clustering results are assessed using external data, not taken into account during the clustering process. For instance, such data concern the customers who were previously assigned to the clusters by experts. In this case, the clustering results generated by the algorithm are compared with the clusters determined by the experts. The following can be cited among the measures :

- cluster homogeneity index calculated according to the formula:

$$WJK = 1/N \sum \max |m \cup d|$$

where  $M$  is the number of clusters created by the algorithm, and  $D$  is the number of the expert's clusters.

- Jaccard index measures the similarity between two sets of observations according to the following expression:

$$WJ = TP / (TP + FP + FN)$$

where  $TP$  means True Positive,  $FP$  False Positive and  $FN$  False Negative rates.

For two identical sets  $WJ = 1$ .

- Rand index is sensitive to false clustering decisions and calculated according to the formula:

$$WR = (TP + TN) / (TP + FP + FN + TN)$$

The Rand index, as the previous ones, is based on a comparison with benchmark classes given by the expert. It provides information about the assessment of similarity between the correct decisions of the clustering algorithm and those on the benchmark.

Apart from these metrics other measures can be also applied, such as F-score, Fowkes-Mallows index, etc.

Marketing analysts often map clustering results in the form of Multi-Dimensional Scaling (MDS) diagrams; an example is shown in Figure 6. The MDS diagrams not only ensure easy visual assessment of clusters and their dispersion, but also indicate outliers. The described measures allow determining whether the selected models meet all the business requirements and demonstrate the hypotheses defined in the first phase of the methodology. In the event of positive evaluation by managers, shareholders and analysts, it is possible to deploy the model and disseminate the results.

The milestone of this phase is an evaluation report of data mining models containing the above described indexes and their interpretation.

The final phase of the methodology is the deployment of positively assessed models and the RTOM platform. The deployment takes place in two steps. First, the pilot version of the platform is implemented in the real production environment and the results are evaluated in terms of content, usability and performance. The reports are assessed by managers and business analysts for their correctness, completeness, and usefulness in decision-making. At the same time, the platform is monitored by designers and future system administrators. The monitoring is mainly about the computational efficiency, and the use of computational and memory resources. Earlier validation of the pilot version allows us to limit the risk of the full version's interference with all other components of the company's information system. It also provides time for adjustments and fine-tuning before implementing the full version of the platform.

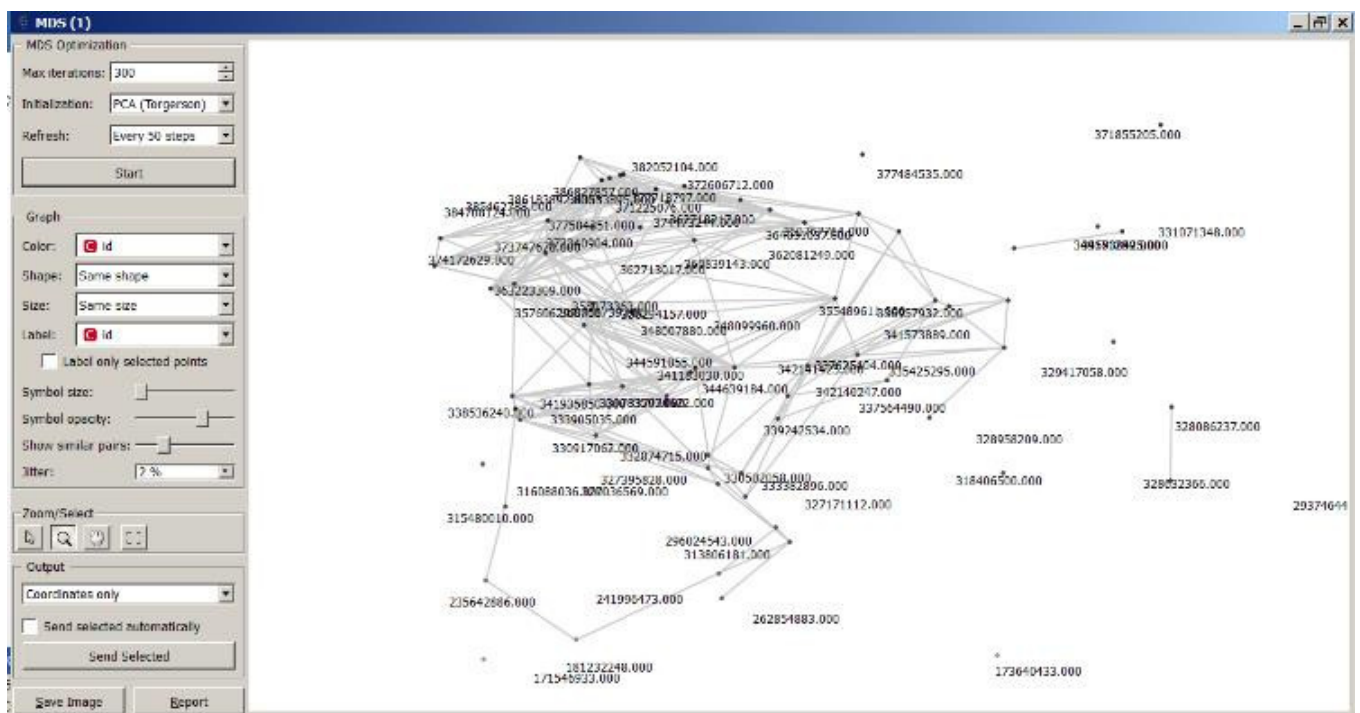

Fig. 6 MDS diagram of customers

In the second step of this phase, the platform runs in a full production environment. Performance results are disseminated to users, who often have to undergo additional training. Also, new organizational roles are then defined and new specialists are employed. It should be pointed out that the new business and technological solutions are revolutionizing the marketing practices and data processes hitherto in use.

The process of improvement of decision making systems never ends. With the advancement of new information technologies, the data mining methods impose improvements of information systems. Therefore, after the deployment, we should think and plan future updates and enhancements. In Figure 1, further development of the platform is illustrated by the dashed arrow leading to the first phase of the process.

The main milestones of the phase are the following:

- the application deployment plan and dissemination of results
- the schedule of platform monitoring and maintenance,
- the final report and technical documentation.

#### IV. SOME COMMENTS ON BIG DATA IN THE CONTEXT OF THE PROPOSED DATA MINING METHODOLOGY

The proposed methodology was presented in the context of the RTOM development, entailing Big Data technology and real-time business data processing. The phases of exploration discussed above show that the approach is different from that applied in Business Intelligence type solutions. In these systems, despite apparent resemblance, we do not deal with massive data streams coming in real time [10], neither do we have to solve technological problems related to the scalability of the application and the heterogeneity of data. The problem of integrating various software components and the efficiency of the exploration processes is also less important. Therefore these aspects were what we tried to emphasize in the methodology adopted for the development of the RTOM platform.

Summing up, certain key issues for the RTOM platform development have to be highlighted: namely:

- Data quality and volume of data. The studies have shown that as the data streams from different sources increase, their quality deteriorates. Therefore, the processes of data collection and preparation are extremely important in the RTOM project. In consequence, data quality determines the quality of exploratory models as well as the usefulness of the generated results. This particularly applies to cleaning and noise filtering processes and algorithms for completing the missing data stored in the sandbox.
- Availability of models. Today most algorithms and models of data exploration are available in software libraries, some references were cited in this paper. Therefore, there was no need for presenting a full specification of models and programming them from scratch. More important from the user's perspective was to describe algorithm profiles *with their* parameterization

and interface for various, useful components of the RTOM platform, for example related to model evaluation or visualization of data and results.

- Hadoop, the open source Apache product, is not a data mining platform; it is one of the tools for management and operation on very large data sets [14]. Undoubtedly, Hadoop, MapReduce and HDFS components improve the performance of systems on large, distributed datasets. It should be noted, however, that Hadoop works well on linear case studies, while most business applications are nonlinear problems. Therefore, in our methodology we extensively used, among other things, Apache Mahout and Apache Spark MLlib, which provide efficient data mining tools using Hadoop.
- Interpretation of results and their use in decision-making. any of the data mining models are rated for quality, accuracy and performance. In business applications, we must take into account the economic criteria of the cost, and the specific measurable and non-measurable effects of the model. Apart from those, features also important for managers include the ease of understanding and interpretability.

# Software Systems Development & Applications

**S**SD&A is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to the discipline of software engineering. The SSD&A area emphasizes the issues relevant to developing and maintaining software systems that behave reliably, efficiently and effectively. This area investigates both established traditional approaches and modern emerging approaches to large software production and evolution. Events that constitute SSD&A are:

- IoTM'17 - 1<sup>st</sup> Workshop on Internet of Things, Process Modelling and Microservices
- IWCPs'17 - 4<sup>th</sup> International Workshop on Cyber-Physical Systems
- LASD'17 - 1<sup>st</sup> International Conference on Lean and Agile Software Development
- MIDI'17- 4<sup>th</sup> Conference on Multimedia, Interaction, Design and Innovation
- SEW-37 - The 37<sup>th</sup> IEEE Software Engineering Workshop

# 4<sup>th</sup> International Workshop on Cyber-Physical Systems

**P**ROLIFERATION of computers in everyday life requires cautious investigation of approaches related to the specification, design, implementation, testing, and use of modern computer systems interfacing with real world and controlling their surroundings. Cyber-Physical Systems (CPS) are physical and engineering systems closely integrated with their typically networked environment. Modern airplanes, automobiles, or medical devices are practically networks of computers. Sensors, robots, and intelligent devices are abundant. Human life depends on them. Cyber-physical systems transform how people interact with the physical world just like the Internet transformed how people interact with one another.

The event is a continuation and extension of 2006-2010 Real-Time Software FedCSIS workshops and 2013, 2015, 2016 IWCPSS. The objective of the workshop is to serve the community with main interest in CPS.

The workshop will accept papers in the following areas:

- Control Systems
  - real-time/embedded/networked
  - wireless sensing/actuation
  - process control & cloud computing
- Internet of Things
  - system organization/implementation
  - device security
  - impact on business
- Scalability/Complexity
  - modularity
  - design methodologies
  - legacy systems
  - tools
- Interoperability
  - concurrency
  - models of computation
  - networking
  - heterogeneity
- Validation and Verification
  - safety assurance & certification
  - simulation
- Cyber-security
  - intrusion detection
  - resilience
  - privacy
  - attack vectors
- Applications of CPS
  - intelligent measurements in medicine, environment, etc.
  - robotics, manufacturing
  - intelligent/autonomous cars
  - transportation, ITS
  - power systems including smart grids
  - smart cities
  - military
  - smart consumer devices
- CPS Education
  - curriculum development
  - on-line and virtual laboratories
  - academic courses
  - pedagogy issues

**Abstract**—In this paper, the problem of short-term prediction of traffic flow in a city traffic network is considered. This prediction is performed in order to provide input data to a dynamic control system for street lighting. The forecasting is done by a multi-layer using artificial neural network. Because of the limited number of sensors, the data is insufficient to describe the relation between the traffic intensity at a given point and the points in which the flow intensity is measured. The proposed approach is tested by using data from the centre of Kraków. The prediction error turned to be low.

## I. INTRODUCTION

**E**NERGY savings due to outdoor lighting optimisation have tremendous impact on a city's economy. This is due to the effect of scale: an average city operates several thousand light points. For security and safety reasons, as well as compliance with standards, these light points are on all night long. Reducing power consumption by even one watt at each luminaire translates into substantial savings. This can be achieved by optimising lighting infrastructure design (through altering lamp placement and parameters [1], [2]) and by introducing intelligent, dynamic control which adjusts lighting levels to the actual needs.

This paper focuses on the latter aspect, i.e. increasing energy savings with use of dynamic control. Dimming is performed using sensor data, with traffic intensity being one of the main factors. However, traffic sensors are not deployed at each intersection. Therefore, other methods must be used to estimate the intensity on streets not equipped with measurement facilities. This way, the control system can cover a wider area which leads to more energy savings [3].

The research described in this paper is part of an innovative lighting infrastructure modernisation project in the city of Kraków, Poland. The project involved replacing almost 4,000 HPS (high-pressure sodium-vapour) lamps with LED ones, equipped with a central management system to provide low-level communications. On top of that, a prototype dynamic control system has been developed to derive and transmit

This work was supported by the AGH University of Science and Technology grant number 11.11.120.859 and by the AGH University of Science and Technology, Faculty of Geology, Geophysics and Environmental Protection, as a part of the statutory project.

control decisions to each lamp in real time. An outline map of the project is presented in Figure 1.

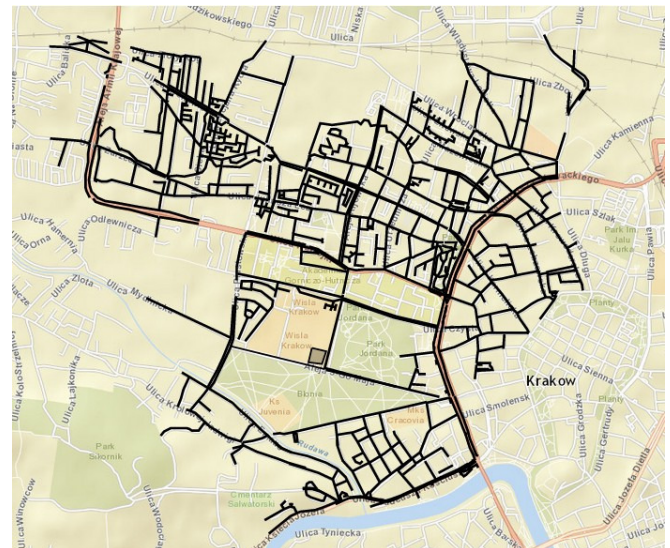

Fig. 1. Outline map of the dynamic lighting project in Kraków.

## II. MOTIVATION

The concept of Smart Cities is based on the idea of applying technological solutions, mainly IT-based, to areas such as transport, energy, healthcare, water and waste management, with a projected market of \$400 billion by 2020 [4], [5], [6], [7], [8]. It is closely related to the vision of Internet of things (IoT) [9], which involves various systems communicating in a semantic and secure manner to allow interchange of information between devices and systems. According to a report by the International Energy Agency [10], lighting consumes 19% of the electricity produced globally. Therefore, even though lighting affects many areas within the Smart City concept – including safety, comfort and transportation – the main contribution to this paper lies in the field of energy.

Questions may arise as to whether utilisation of renewable energy-powered lighting may be an alternative to the presented

Fig. 2. An off-grid autonomous lamp, equipped with a solar panel and an underground battery. Image courtesy of Wichary Technic, <http://www.wicharytechnic.pl/en/>.

approach. In fact, off-grid, renewable-based luminaires are being produced and used in many places around the World. An example of such luminaire is presented in Figure 2. Such devices are ideal for locations with no power infrastructure or as temporary lighting for events, etc. However, their large-scale utilisation for urban street lighting has two problems:

- The cost. Autonomous, self-sufficient off-grid devices must be equipped with means of generating energy — usually a solar panel and/or a wind turbine — as well as some energy storage devices. That makes the cost of an individual lamp much higher than with traditional, grid-connected hardware.
- Lighting standards (such as CEN/TR 13201-1:2004 [11]) strictly define the parameters of light to be fulfilled to achieve a given so-called lighting class, and conditions when a given lighting class should be applied. Off-grid devices may be inherently unable to provide adequate lighting due to possible insufficient generation and storage capacity. Recent advances in off-grid device operation optimisation mainly focus on replacing a simple, reactive strategy with a more advanced dispatch plan, based on foreseen power generation capabilities and output (lighting) requirements, with methods including simulation [12] and a hybrid neural network/fuzzy logic

approach [13]. Therefore, the strategy used to control off-grid lamps is based on providing satisfactory lighting as long as possible, not to always fulfil the requirements of the norm, which is the case in this paper.

In the Smart City context, utilisation of renewable sources is much more efficient with dedicated, more centralised installations of solar panels or wind turbines. Of course, that may cause problems on other levels, such as integration with the existing city power grid or with vehicle charging stations [14]. This paper concerns only grid-connected light points.

Outdoor lighting optimisation can have a significant impact on economy [15]. As mentioned in the introduction, it is due to two factors. First, lights stay on all night, which translates to over 4,000 hours of operation in a year. Second, the number of light points is significant, which gives an effect of scale.

Research indicates that there is a need for intelligent control systems for street lighting. There have been multiple experiments and assessments conducted so far. These include highway lighting [16], tunnels [17] and urban areas [15], [18]. However, there still is much room for improvement.

Technically, so-called Central Management Systems (CMSs) are commonly used to provide communications with the fixtures, support inventory and monitor their operations. They are very efficient in providing insight into the operation of lighting systems and providing basic control of the infrastructure, actually moving it towards the aforementioned concepts of Smart Cities and the Internet of things. Most major manufacturers of lighting equipment now provide CMSs integrated with their products. An example of such a system — Owllet Nightshift by Schröder — has been presented in Figure 3.

CMSs, however, do not support dynamic control: lamps operate according to a predefined schedule rather than sensor readings. However, a schedule must assume a worst-case scenario, and that may lead to a solution far from optimal due to large variations of traffic intensity on different days (see Figure 4). Therefore, an external decision system has been developed to generate control signals and transmit them to the lamps via the CMS's API (Application Programming Interface).

Among available sensor data, traffic intensity has the biggest impact on lighting control. From the economic point of view, deploying traffic sensors solely for the purpose of street lighting might be not feasible. Although most cities already have a sensor infrastructure fit for this purpose as part of their Intelligent Transportation Systems (ITSs), the data produced is used mostly for controlling traffic lights at junctions. Of course, the applications of ITS systems are much broader and mostly concern traffic flow optimisation, with advanced, state-of-the-art systems being able to analyse and simulate traffic at a very high detail level [19]. Usually, a city will already have several intersections at which traffic intensity is already measured. However, there are many “white spots”, especially in areas with little or no traffic lights. The main motivation for this paper is therefore to propose a viable traffic flow prediction algorithms which in turn can be used

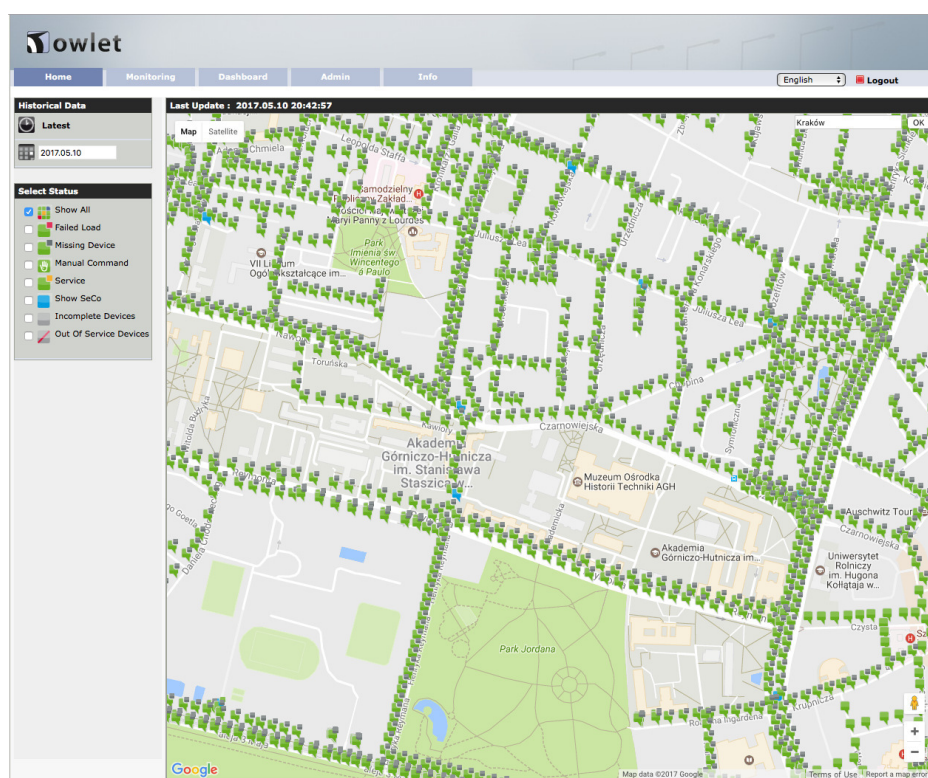

Fig. 3. Owlet Nightshift as an example of an operational lighting Central Management System. Image courtesy of Schröder Polska Sp. z o.o., <http://www.schröder.com/pl-pl>.

Fig. 4. Traffic intensity registered on different days in one of the streets within the Kraków project area. Horizontal lines denote the traffic level thresholds which allow switching from the main lighting class (ME2) to a lower one (ME3b or ME4b). Lighting classes as defined by the CEN/TR 13201-1:2004 standard [11].

by an intelligent street lighting control system to minimise energy consumption.

### III. STATE OF THE ART

Traffic flow prediction is a problem which has been intensively studied for a long time [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33]. Both the traffic on highways and the traffic in city networks is considered. Usually, the traffic intensity is predicted by using historical data. In this approach, however, a few problems appear. First of all, there number of traffic sensors in roads and streets is still insufficient. Furthermore, random events, both on-road and off-road, can impact the flow intensity [21]. Therefore, the method which turned to be effective in traffic flow prediction in a given place can be useless in other locations. For these reasons, intensive studies are being carried out, concerning new methods of prediction as well as application of known methods in new places and contexts. Statistical tools as well as artificial intelligence can be used to solve these problems.

In San Francissco [21], an autoregressive model was used to predict traffic load in San Francisco in two time horizons: five minutes and thirty minutes. The method was tested by using a traffic flow simulator. The errors varied from 2% for five-minute prediction to about 12% for thirty-minute prediction.

A support vector machine (SVM) regression algorithm was used for traffic flow prediction under both typical and untypical traffic conditions, where the term *untypical* denotes holidays or traffic accidents [22]. The approach was tested by using data from California state, USA.

A support vector regression model was also applied for short-term traffic flow prediction in combination with the ant colony optimisation algorithm [25]. The approach has been tested on data from Taiwan.

Many authors reported the application of artificial neural networks for traffic flow prediction [23], [27], [28], [32]. A standard multi-layer perceptron trained by using the Levenberg-Marquardt algorithm with input data preprocessed using the hybrid exponential smoothing method was applied to predict short-term traffic conditions on the Mitchell freeway in Australia [23]. The error varied from 6% to 12% and was significantly smaller than for the reference methods: a wavelet neural network and a Bayesian neural network.

In the paper [32], an interesting idea of application a genetic algorithm is presented. It is used for optimal selection of both the representation and the characteristics of the traffic flow data. Furthermore, the genetic algorithm is also applied to choose the optimal structure and training parameters of the multi-layer neural network used for prediction.

A hybrid fuzzy-neural approach to traffic flow prediction in a city network is described in [33]. The system consists of two modules. The fuzzy module is responsible for clustering of the traffic patterns into sets of similar characteristics. The neural module finds relationships inside the clusters. The effectiveness was tested using real data from Hong Kong. The maximal prediction error was equal to four vehicles per minute.

In the paper [26], deep learning methods for big data were used for sixty-minutes traffic flow prediction at the roads. The used method allowed the authors to detect nonlinear both the spatial as well as the temporal correlations in the traffic data.

### IV. PROBLEM STATEMENT AND METHODOLOGY

In this paper, the following general problem is considered. The traffic flow at point  $A$  should be predicted provided that the traffic flows at other points at the preceding time points are given. The data is insufficient to create an analytical formula which describes traffic flow intensity at point  $A$  as a function of flows at the points for which data is given. This means that junctions with other roads are situated between  $A$  and other points. The problem is solved by using a multi-layer neural network.

This general problem is considered for a small fragment of Kraków city traffic network. The geometry of the studied fragment is shown in Fig.5. The flow is predicted at the point  $A$ . Two following tasks have been put forward.

- 1) The workday is divided into 48 half-hour time intervals. The traffic flow is predicted at point  $B$  using data from sensors at points  $F$  and  $G$  – see Figure 5. Two versions of the input vector have been tested. The first one had the following form:  $[t, F_{t-1}, \dots, F_{t-n}, G_{t-1}, \dots, G_{t-n}]$ , where  $t \in \{1, \dots, 48\}$  denotes the time interval in which the flow is predicted,  $F_k$  and  $G_k$ , denote the traffic flow intensity at the points  $B$  and  $C$  respectively, at the time intervals  $k \in \{t-1, \dots, t-n\}$ . In the second version, the number of the day  $d$  was given as an additional component of the input vector.
- 2) Each day of the week is divided into ninety-second time intervals. The traffic flow is predicted at the point  $B$  by using data from the sensor at point  $A$  or  $F$  – see Figure 5. The input vector had the following form:  $[d_c, t, A_{t-1}, \dots, A_{t-m}]$ , where  $d_c$  encoded the type of a day: Sunday, Saturday or ordinary day and this data was optional;  $t \in \{1, \dots, 960\}$  denotes the time interval of the day in which the flow is predicted and was optional as well,  $A_l$ ,  $F_l$  denote the traffic flow intensity at the point  $A$  or  $F$  at the time interval  $l \in \{t-1, \dots, t-m\}$ .

Let us remark that according to the geometry of the street connections, the traffic flow at point  $B$  in which the flow intensity is predicted does not depend directly on the flows at the point in which sensors  $A$ ,  $F$  and  $G$  are situated.

### V. RESULTS

Each experiment was done by using a multi-layer neural network with one hidden layer and one output neuron. In the hidden layer the neurons had sigmoidal activation function whereas the output neuron was linear. In the description of experiments the components of the input vector are specified as well as the mean error i.e.  $e := \frac{|y-z|}{N}$ , where  $y$  is the measured number of vehicles at the point  $B$ ,  $z$  is the predicted number at the point  $B$  and  $N$  denotes number of events. Furthermore, the correlation coefficient  $r_{y-z}$  between  $z$  and  $y$  is specified as well. The input vector is denoted as  $x$ . In each

Fig. 5. Geometry of the studied fragment of the city traffic network. The points in which sensors are situated are marked by filled circles whereas crossings are marked by empty circles. Sensors G, F and A are situated at the three-lane fragment of a one-way road, each at the separate traffic lane. Sensors G and F are at the lanes from which cars can go only straight ahead whereas sensor G is at the lane from which buses and taxi cars can go straight ahead whereas other cars have to turn right. Sensor B is situated at the one-way road which has two traffic lanes. It is at the lane from which all vehicles have to turn right.

experiment several trials with neural networks having various number of neurons in hidden layer have been performed. The results are described for the most effective neural network. In each experiment the intensity of the traffic flow at the point  $B$  at the time  $t$  is predicted.

In the frame of the task 1 – see section IV (a workday is divided into 48 half-hour time intervals) – the following experiments have been performed with input vectors ( $\mathbf{x}$ ) as stated.

- 1)  $\mathbf{x} = [t, F_{t-1}, F_{t-2}, F_{t-3}, G_{t-1}, G_{t-2}, G_{t-3}]$ ,  $t \in \{1, \dots, 48\}$ .  
The number on neurons in the hidden layer was equal to 10.  
Mean error  $e = 6.7$ ,  $r_{y-z} = 97\%$ .
- 2)  $\mathbf{x} = [d, t, F_{t-1}, G_{t-1}]$ ,  $t \in \{1, \dots, 48\}$ ,  $d \in \{1, 2, 3, 4, 5\}$ .  
The number on neurons in the hidden layer was equal to 10.  
Mean error  $e = 5.2$ ,  $r_{y-z} = 98\%$ .
- 3)  $\mathbf{x} = [d, t, F_{t-1}, F_{t-2}, G_{t-1}, G_{t-2}]$ ,  $t \in \{1, \dots, 48\}$ ,  $d \in \{1, 2, 3, 4, 5\}$ .  
The number on neurons in the hidden layer was equal to 10.  
Mean error  $e = 4.3$ ,  $r_{y-z} = 99\%$ .

In the frame of the task 2 – see section IV (a workday is divided into 960 ninety-seconds time intervals) – the following experiments have been done performed input vectors ( $\mathbf{x}$ ) as stated.

- 1)  $\mathbf{x} = [A_{t-1}, A_{t-2}, A_{t-3}, A_{t-4}, A_{t-5}]$ ,  $t \in \{1, \dots, 960\}$ .  
The number on neurons in the hidden layer was equal to 12.  
Mean error  $e = 1.12$ ,  $r_{y-z} = 68\%$ .
- 2)  $\mathbf{x} = [d_c, A_{t-1}, A_{t-2}, A_{t-3}, A_{t-4}, A_{t-5}, A_{t-6}, A_{t-7}, A_{t-8}, A_{t-9}]$ ,  $t \in \{1, \dots, 960\}$ .

The number on neurons in the hidden layer was equal to 18.

Mean error  $e = 1.10$ ,  $r_{y-z} = 70\%$ .

- 3)  $\mathbf{x} = [d_c, t, A_{t-1}, A_{t-2}, A_{t-3}, A_{t-4}, A_{t-5}, A_{t-6}, A_{t-7}]$ ,  $t \in \{1, \dots, 960\}$ .

The number on neurons in the hidden layer was equal to 20.

Mean error  $e = 1.04$ ,  $r_{y-z} = 72\%$ .

- 4)  $\mathbf{x} = [d_c, t, A_{t-1}, A_{t-2}, A_{t-3}, A_{t-4}, A_{t-5}, A_{t-6}, A_{t-7}, A_{t-8}, A_{t-9}]$ ,  $t \in \{1, \dots, 960\}$ .

The number on neurons in the hidden layer was equal to 18.

Mean error  $e = 1.02$ ,  $r_{y-z} = 74\%$ .

- 5)  $\mathbf{x} = [d_c, t, A_{t-1}, A_{t-2}, A_{t-3}, A_{t-4}, A_{t-5}, A_{t-6}, A_{t-7}, A_{t-8}, A_{t-9}, A_{t-10}]$ ,  $t \in \{1, \dots, 960\}$ .

The number on neurons in the hidden layer was equal to 30.

Mean error  $e = 0.95$ ,  $r_{y-z} = 78\%$ .

- 6)  $\mathbf{x} = [d_c, t, A_{t-1}, A_{t-2}, A_{t-3}, A_{t-4}, A_{t-5}, A_{t-6}, A_{t-7}, A_{t-8}, A_{t-9}, A_{t-10}, A_{t-11}]$ ,  $t \in \{1, \dots, 960\}$ .

The number on neurons in the hidden layer was equal to 30.

Mean error  $e = 0.99$ ,  $r_{y-z} = 77\%$ .

- 7)  $\mathbf{x} = [d_c, t, F_{t-1}, F_{t-2}, F_{t-3}, F_{t-4}, F_{t-5}, F_{t-6}]$ ,  $t \in \{1, \dots, 960\}$ .

The number on neurons in the hidden layer was equal to 10.

Mean error  $e = 1.70$ ,  $r_{y-z} = 95\%$ .

- 8)  $\mathbf{x} = [d_c, t, F_{t-1}, F_{t-2}, F_{t-3}, F_{t-4}, F_{t-5}, F_{t-6}, F_{t-7}, F_{t-8}, F_{t-9}, F_{t-10}, F_{t-11}, F_{t-12}, F_{t-13}]$ ,  $t \in \{1, \dots, 960\}$ .

The number on neurons in the hidden layer was equal to 25.

Mean error  $e = 1.90$ ,  $r_{y-z} = 92\%$ .

## VI. CONCLUDING REMARKS

The experiments have shown that the proposed method yields very good results even with little reference data.

Moreover, the algorithms are quickly saturated with regard to the length of the history provided. For task 1, the optimal number of time units provided is 2; for task 2, no significant improvement is noticeable beyond 10 historical time units.

It must be noted that the presented research is performed with a well-defined application in mind, which is dynamic control of street lighting. In particular, the algorithms are used to provide accurate estimates of traffic intensity in streets not equipped with sensor devices. The presented work does not try to compete with Intelligent Transportation Systems, as they have a different purpose. In particular, the algorithms do not attempt to optimise urban traffic; they are only used to try to reflect the actual situation. However, the proposed methods can find broad application to predict flows in any graph-like structures.

Since deployment of traffic intensity sensors is a costly operation, such methods play a crucial role in lowering the energy consumptions of lighting infrastructure. They allow for a vast increase of the scope of dynamic control, thus leveraging the effect of scale. As most energy used in Poland (as well as many other countries) originates from fossil fuel-based power plants, any reduction of its consumption leads to significant reduction of carbon dioxide emission. Furthermore, saving energy also has obvious economic benefits. It should also be noted that the estimated traffic intensity data can also be used for other types of Smart City solutions.

**Abstract**—IoT applications has some characteristics that set it apart from other fields mainly due to the multitude of different types of sensors producing data. In monitoring applications, data processing requires real-time or soft real-time responses in order to aid systems to make important decisions but also predictive analysis to leverage the potential of IoT by data mining vast datasets. This paper presents an architecture developed to efficiently process and store data coming from an huge number of distributed IoT sensors. The back-end of SeeYourBox services is currently based on the proposed architecture that has proven to be stable and meet all the requirements.

## I. INTRODUCTION

The ubiquitous presence of interconnected devices with sensing and communication abilities has brought us to the era of the Internet of Things (IoT). RFID tags, sensors and actuators are only a few examples of components that enable embedded devices and mobile phones to create a network of things that collect and transmit data from the environment they are placed in [3]. Data in IoT applications has some characteristics that set it apart from other fields. We shall go through them as presented by Li et al. [16]. With information flowing from a multitude of different types of sensors data is heterogeneous, with a direct impact on how it's organized within the data storage solution. Reduction in sensor cost, miniaturization and advances in wireless technologies and techniques contributed to the pervasive distribution of connected objects [13]. This leads the design of the application to take into consideration the factor of scale in the early stages of development. Added value is given to recorded data by defining location or context-awareness [18].

Data collected from distributed sensors can be enriched by a multitude of sources. Common examples are city traffic or emotional status of people [20]. Devices can have more than one sensor, effectively requiring multidimensional data management [8]. The most evident consequence of these characteristics is that data itself shapes and influences the design of an IoT system architecture. Organization of data storage and processing technologies and techniques are the two main aspects to consider [24]. In monitoring applications data processing requires real-time or near real-time responses in order to aid systems to make important decisions [25]. On the other hand predictive analysis can leverage the potential of IoT by data mining vast datasets [15]. Management of IoT data

can be seen and considered from two view points i) Processing and ii) Storing the IoT data.

In the typical IoT scenario millions of devices constantly feed a data ingestion system with data sourced by integrated sensors. The system must be able to handle and process incoming data with as low as possible response times to avoid building system bottlenecks. The challenge is to design a system capable of processing requests that can have real-time requirements [19]. On the other hand, the volume of data produced by the average IoT system over time quickly translates into ever growing datasets. These can be used for historical reasons only or for creating predictive analysis systems that use data mining for extracting valuable information. The speed with which these datasets grow requires a system that is capable of handling big data from it's early stages.

It is common to consider these two main aspects of IoT system as separate and a way to refer to them is *hot-path* or online processing and *cold-path* processing. The former term is used to refer to data that is processed before being stored. The latter, or offline processing, is used to refer to analysis that is performed after data is stored. Typical examples are statistical analysis, reporting and data mining. In the following sections we will dive into common strategies that revolve around data stores to support these requirements in an efficient way. Both aspects require the support of a data storage solution capable of managing the challenges of IoT data. Both will need to face common challenges but with different goals.

The challenges that big data generate in IoT systems are [6]:

- Variety, with things equipped with multiple sensors and things that serve different purposes, data in an IoT system is typically unstructured and varies rapidly over time to adapt to dynamic environments and tasks.
- Volume Lower costs, smaller dimensions and better battery life achieved by embedded systems in recent years has enabled the IoT to become more popular and pervasive [13]. The widespread availability of connected things constantly transmitting data generates a demanding amount of data to process.
- Velocity, while processing speed and performance is usually sought as a positive quality of any data processing system, in the IoT it has direct implications on how things can react to the environment and events. It is not

uncommon for IoT systems to be required to meet real-time constraints.

- Veracity, the power of unleashing computation and sensing capabilities to devices that can blend with their environment without direct supervision raises issues regarding the trustworthiness of data. Dealing with trustworthiness and reputation, also the problem to define a strategy that minimize the attachment cost is a relevant problem [7]
- Value, the ability of sourcing data that would be otherwise unavailable and the simplification of creating telemetry systems offers tremendous opportunity to generate value by analyzing data both online and offline.

The characteristics of big data are the most influencing aspects in designing a system that handles it. However, solely focusing on database management systems is not the only aspect that needs to be addressed when designing a system that needs to manage big data and this paper deals with them.

A key component of an IoT system (or a big data system in general) is the *middleware software layer* that interfaces things and *application back-end* [3]. By abstracting backend implementation and details it allows application developers to focus on delivering value based solutions faster and more efficiently without having to be concerned with technology details of the infrastructure they rely on.

The massive volume of data processed, performance requirements and robustness that are demanded from industrial applications translate often into a system that is able to be distributed and replicated across multiple machines and locations. A carefully engineered middleware allows a system to scale horizontally effortlessly. In this paper we present an architecture designed to collect, elaborate and store information of IoT system. In section II we discuss the different solutions presented in literature. In section III we reason about the motivation to design a new and personalized solution. Section IV discuss the proposed architecture; in particular, in this section we present the solution adopted to collect and store the vast amount of data produced by an IoT system. Finally, Section V presents some conclusive remarks.

## II. RELATED WORK

In this section we will go through the state of the art of current technology and research in the field of system architecture. In respect to system architecture we will analyze the solutions adopted by two of the major cloud computing providers, Amazon AWS and Microsoft Azure, for creating a specific IoT platform. The recent IoT revolution has raised attention for scalable applications and storage solutions. Mileage might vary a lot between different yet similar applications and there is no silver bullet for solving all classes of problems.

The impact of big data in IoT raises questions on how to manage and store data efficiently. A commonly accepted solution still hasn't emerged as a de facto standard and it is left to system architects and developers to come up with a solution that can provide adequate performance [18]. The challenges to face are numerous and often each is best dealt with different database management systems. NoSQL databases,

with their dynamic schema and support for horizontal scaling aid developers in handling scale and heterogeneity of IoT data. However, lack of strong ACID compliance and often lack of support for complex queries, results in reasons to not exclude traditional SQL databases from the possible candidates. Ultimately it's difficult to set guidelines that can define a common solution for dealing with IoT data in an effective and successful way. Small differences in data structure and processing can lead to very different results and approaches.

Since the public announcement of Amazon EC2 cloud computing platform in 2006 [4] an array of companies started to offer on-demand computing solutions. Examples are Google App Engine and Microsoft Azure. These platforms allow flexible pay-to-go solutions to implement an all-in cloud computing infrastructure that is able to scale according to the applications they run. The rich suite they often offer allows developers and designers to customize the architecture to fit the requirements of their applications. However since 2015 two of the major cloud providers, Amazon and Microsoft, launched specific IoT oriented cloud platforms. Other than commercial or marketing reasons, that will not be addressed in this work, targeting a specific field such as IoT is a reasonable move from a purely technological prospective since many of the requirements and problems are recurrent and standardized. IoT telemetry is usually characterized by hot-path and cold-path data analysis. While the first is bound with real time concerns and constraints, requiring event handling and device control, in the cold-path response time is set aside in favor of scale and big-data management. A common solution is to separate these two flows in order to optimize each one accordingly without having to surrender to compromises. Powering virtual cloud environments with optimized messaging paradigms and protocols eases composability of highly optimized modules. The IoT targeted solutions focus greatly on providing data ingestion, routing and processing capabilities.

1) *IoT Amazon AWS*: Amazon AWS is a suite of cloud computing services offered by Amazon since 2006. Two of the most popular services are Amazon Elastic Compute Cloud (EC2) and Amazon S3 (Simple Storage Service). Both active since 2006, they offer respectively an on demand solution for deploying virtual servers and storage in the cloud. Launched in October 2015 AWS IoT is Amazon's answer to the growing IoT industry that requires secure, bi-directional communication between Internet-connected things and the cloud [5]. The core of Amazon AWS IoT is a publisher-subscriber pattern. To enable the developer to control communication, the platform offers multiple communication protocols that include MQTT, HTTP and MQTT over Websockets. Since internet is not always available for IoT devices (ZigBee or Bluetooth) it's possible to interface these devices with physical gateways. From a device view point AWS offers a dedicated SDK implemented in a variety of languages, such as C, Javascript or Arduino. Particular attention in AWS IoT is dedicated to connectivity and its characteristics in the IoT field. Aside from using protocols optimized for publisher-subscriber communication it offers solutions for managing the

high latency or unstable connectivity that often characterizes WSNs and IoT in general. The message broker offers three different solutions: MQTT AWS IoT offers a customized MQTT (Message Queue Telemetry Transport) message broker implementation, HTTP The message broker also supports a pure publishing protocol as a REST API over standard HTTP and MQTT over Websockets. By implementing MQTT over Websockets AWS IoT enables browser based and remote application to interact with the connected devices using AWS credentials.

Message handling and delivery is augmented by a Rules Engine that enables the use of business logic rules for event handling and message routing. Rules can be applied to specific devices or groups of them. The engine is a key component in the Amazon AWS ecosystem as it allows integration with the comprehensive tool set offered by Amazon and allows devices to directly interact with all components of the application. Rules can be defined by using SQL syntax to filter messages received by the broker and examples of associated actions triggered by a rule could be writing to a database or invoking lambda functions.

The Thing Registry, supports the need of a representation of a device or logical component in the cloud. Information regarding a thing is memorized in JSON files that contain a device identifier and attributes. These could be a serial number or manufacturer code. While not mandatory, a registry entry eases management and search of things. Using the AWS IoT console or CLI it's possible to create, update and search things within the registry. Non reliable networking and intermittent connection result in a not always connected device. Such behavior could be enforced also by power saving strategies. To simplify interaction with things Amazon AWS offers a component called Thing Shadow. This feature enables the developer to manage the state of a thing and applications to read messages and interact with it at all times. The underlying system takes care of publishing data when possible. A thing shadow is implemented with a JSON document and acts as an intermediary between actual devices and applications.

Finally, while good security policies are never a bad feature to claim in an information system, in the IoT where things can directly interact with the physical world, they acquire particular importance. Connected devices are required to have credentials to access the messaging broker and the traffic must be encrypted using Transport Layer Security (TLS). Authentication is provided with the use of AWS method (called SigV4) or by using X.509 certificates.

**Pricing** In Amazon AWS IoT is based on a pay per use structure and priced on the number of messages published from and to the platform. To encourage new customers and developers there is a free tier that allows 250,000 messages per month for 12 months. In this pricing model a message represents a block of data counted in increments of 512 bytes.

2) *Azure IoT platform:* Microsoft's counterpart to Amazon's AWS IoT is the Azure IoT platform. It allows an organization to connect, store, and analyze device data in both large scale or hobbyist IoT environments. The architecture

follows four guideline principles: heterogeneity, security, hyperscale and flexibility [10]. Only outbound connections are allowed and security protocols are implemented at transport and application level. The system allows for direct and indirect connectivity, the latter used for non IP capable devices and can be built on top of AMQP, MQTT or HTTP communication protocols. Devices and gateways can implement edge intelligence and analysis to provide reduction of transmitted data and local decision making. Incoming connections and transmission protocols are managed by the cloud gateway. It enables remote communication between field devices and the cloud and can make use of multiple application level messaging protocols. High-volume telemetry ingestion and device control is supported by message brokering systems. This allows decoupling the edge from the cloud for performance, composability and scalability. Additionally, the platform offers a dedicated solution for high-volume ingestion only scenarios called Azure Event Hub. Devices can connect by direct connectivity, agents or by using client components provided in the form of libraries or SDKs.

Once data has reached the cloud gateway its flow is directed by data pumps and analytic tasks. Microsoft Azure offers the possibility to use a Stream Analytics service or custom event processing solutions. Common tasks that can be performed at this stage are data aggregation or enrichment. Another feature that can be implemented is a rules engine to dynamically execute data driven rules that can be activated or deactivated accordingly. Output produced at this stage can be forwarded to a storage solution or an event handling hub, called Event Hub.

In Azure IoT platform the cloud gateway is the entry point to the cloud infrastructure and enables communication between devices and the application. It's responsible for connection management, authentication and authorization. It usually implements brokered communication model to support event handling and decoupling of components. Multiple application level messaging protocols are available for data routing and management. Azure IoT offers two alternatives in respect to the cloud gateway technology: Azure IoT Hub and Azure Event Hub. The former offers high-performance bidirectional traffic support by combining telemetry ingestion with command and control traffic. The latter is an ingestion only gateway capable of handling heavy concurrent sources at high data rates.

A Device Identify Store offers a direct lookup means for device identity and cryptographic secrets used during authentication procedures. Identity and device registry are kept separate also for performance and security concerns. The identity store can be internal to Azure Hub or implemented as an external component with an array of options such as Azure DocumentDB, Azure Tables, Azure SQL database or third-party solutions. A Device Registry Store keeps information for discovery and reference data related to the device. Metadata associated to devices is contained in this resource and the main difference between this and operational data is that the former is slow changing. The device registry can be implemented in

different ways:

- DocumentDB: each device is described by a document and the id corresponds to the device id. This solution is suited for registry function because it accepts arbitrary data structures.
- SQL database: this solution uses a hybrid approach by storing properties as columns or as JSON or XML objects if they represent complex data.
- Third-party solutions: third-party solutions are allowed (e.g. MongoDB or Cassandra), however the actual schema will represent a variation of the previous two options.

Azure Iot provides a Device State Store. It contains operational data relative to the device and is separate from the registry. While in the Amazon AWS the device shadow is a core component in Azure the device state store is optional. Data can be pushed directly to storage. An array of implementation options are available for the device state storage: Azure Data Lake used as distributed data store for relational and non relational data, Azure Blob storage that allows to store raw data and Azure Tables to manage device records and values.

The brokered nature of the communication architecture allows for flexible data flow management. Data entering the cloud through the gateway may flow across different data pumps or analytics tasks. This feature allows for efficient parallel data processing. Examples are raw telemetry for registering data from a sensor, hot-path analytics for pattern recognition or alert triggering. The implementation can make use of Azure's stream processing services or custom third-party solutions to also create complex rules engines and event processors.

Pricing Microsoft Azure IoT uses a completely different pricing model compared to Amazon AWS IoT. In place of a flexible pay-per-use, Microsoft offers four tiers that set a ceiling to the maximum number of messages that can be processed per day and their size.

The two IoT cloud solutions presented share some similarities, such as a brokered message management but are quite different in the way they implement it. This is mainly due to the underlying protocols they use, AMQP for Microsoft and MQTT for Amazon. However they both support HTTP, a protocol that is commonly used within cloud based systems. They also take two different approaches on the interactions between things and the cloud platform. In Amazon AWS IoT interaction revolves around the concept of state with the device shadow, a feature that is supported but not mandatory in Azure IoT.

Features supported by security protocols and SDKs are comparable for both solutions. On one side Amazon AWS IoT offers a highly focused platform that defines clearly the architecture of the system. Combined with the rich feature set of the popular Amazon AWS suite it is easy to deploy and integrate the IoT platform within large scale existing systems. On the other hand Microsoft Azure IoT offers a much higher level of customization and will attract interest of designers that are in need of a higher degree of control. This is also reflected by the richer feature set that the AMQP protocol exhibits [22].

Ultimately the pricing models differ a lot. The Amazon model is based on million messages exchanged while Microsoft's on the concept of a Hub and the maximum number of messages it is able to handle. It's difficult to compare these different approaches in a general way since final pricing depends a lot on customer needs, volume and payload size of messages exchanged (AWS's messages are priced in 512B increments).

### III. MOTIVATION

In the previous section we analyzed the potential of cloud based IoT platforms for data ingestion and processing. The offerings from Amazon and Microsoft are specially tempting for small to medium scale projects or ones that have to be integrated within an existing system. We can imagine for instance an IT company developing an IoT branch of development to find these solutions particularly attractive as they reduce the R&D costs by offering a reliable turn-key solution that is scalable. The biggest concern remains however focused on two of the major arguments on opting for a cloud based solution or an in house system: costs and control over data

Regarding costs, for a company that founds on IoT its core business and that expects to scale to millions of active devices transmitting constantly every day, the yearly fees can quickly translate into six figure invoices. This is sufficient to require deep investigation on developing an in house solution.

Regarding control over data, when working with high-value and mission critical information it is not infrequent for a customer to require that data is not sent or stored on cloud systems that are not under direct control of the company offering a service. Furthermore, government laws of different countries can apply and require that data is stored in a certain matter.

These two reasons forced us to investigate and build an in-house cloud infrastructure and develop from the ground up a cutting edge architecture that could handle the volume of data generated by a ultra-large-scale IoT project. Investigation of the state of the art in database management systems led to a deep understanding of how data shapes the architecture of a system and what are the true guidelines to take into consideration when designing an IoT processing system. The most valuable outcome was that a high performance large scale system could not rely on a centralized data storage solution for the whole system, and furthermore, on a single DBMS engine for the different components of the system. Research pointed into this direction and preliminary prototyping confirmed that by combining different DBMSs it was possible to achieve performance levels otherwise unreachable with a single shared engine. Additionally, research and empirical evidence demonstrated that performance of a DBMS is heavily related to data structure and the way that it is manipulated. With this in mind and with an openness to reshape dataflow within the system it is possible to expand the array of possible candidates that can match the requirements for data storage. Ultimately the freedom that results from this allows a company to consider

the choice of a DBMS not only under the concern of raw performance but also from the points of view of licensing, learning curve, expandability and availability of development tools.

When designing the architecture of a system that needs to process IoT data, one of the first challenges that a designer has to face is how to manage scaling to possibly millions of devices transmitting data simultaneously. Founding an application onto a scalable cloud based infrastructure can represent a viable strategy as it allows designers to focus on core technology without the burden of managing in-house legacy IT systems [1]. Cloud technology has also a very important impact on the financial lifecycle of a startup as it enables companies to capital infrastructure expenses into variable costs [4]. There are also some important points to consider when evaluating a cloud computing platform in place of an in-house infrastructure. Evaluating extensively advantages and disadvantages of cloud computing systems is beyond the purpose of this work. However in respect to the specific class of systems we are considering, it has to be said that immense flexibility that platforms like Amazon AWS IoT or Azure IoT offer comes at a price.

Where developers pay this price is in the limited control over the whole process and the inability to fine tune the system to their specific needs. Where the companies pay the price is in the potentially ever growing running costs that reflect the horizontal scaling of the system. As an alternative a bespoke system where all components are carefully designed and integrated, can potentially offer much better performance. The ability to tailor fine details and control over data are just a few of the reasons that *See Your Box* took into consideration when deciding to develop an IoT server architecture from the ground up in spite of the tempting aspects of PaaS and IaaS services. Most of the research and work was focused on four aspects:

- Define an architecture for hot-path and cold-path data analysis
- Design a scalable private cloud infrastructure
- Distribute computational load
- Managing big-data.

*See Your Box* is a real-time monitoring service where the telemetry pattern sustains dynamic business logic applied to incoming data. Hot-path is used for detecting specific events that clients want to monitor while cold-path data feeds a predictive analysis machine learning system. With a goal to scale up to millions of devices transmitting data simultaneously the system must be able to scale quickly and easily. The five key characteristics of the system that influenced the architecture design are:

- Flexibility, in the *See Your Box* system two devices can be sourcing different types of data and require to encode it differently. Once received by the servers it must be processed and handled according to business logic rules customized for each client.
- Edge computing - *See Your Box* devices are not only

sensors with a transmission module but an active re-programmable OTA smart sensing devices capable of data processing and event detecting. The system must provide a bidirectional communication means to control the devices.

- Scalability - While not subject to extremely variable and bursty traffic spikes, common for websites and social networks, the system must be able to replicate, distribute and scale over the private cloud network.
- Integration *See Your Box* provides APIs to allow customers to integrate their systems with its monitoring platform.
- Security Privacy laws and regulations require the company to have full control over data, especially where it is stored.

Since early stages of development it was evident that the scale of data involved and the level of flexibility required would make the data storage the most critical part of the system. If not well engineered it would soon become the bottle neck of the system. By analyzing data flow it was also evident that different parts of the application had different requirements when accessing databases. This pointed to a strategy of combining multiple databases [14]. This aspect together with the desire of developing a scalable system brought *See Your Box* to design a totally modular system where each component could be fine tuned and optimized for its task.

#### IV. ARCHITECTURE

The whole architecture is based on a fully scalable infrastructure based on virtual machines that are responsible of fulfilling specific tasks. A lot of research and effort was invested in creating an efficient self load balancing system that could use the full potential of the available hardware. This allows the system to take advantage of instant and dynamic vertical scaling driven by the actual load of the system. The resulting architecture is summarized in figure 1 The system is

Fig. 1. *See Your Box* Architecture

subdivided in three main component:

- Gateway, accepts incoming requests from devices, authenticates and decrypts data, forwards data within the system and delivers messages to devices.
- Engine, devoted to analyze collected data

- Databases, to store data.

By separating responsibilities over multiple machines it is possible to scale them (horizontally or vertically) separately and selectively. Performance, however, is not the only concern that motivates such architecture. Spatial redundancy, for instance, can be achieved by replicating machines within the system for increased security and availability. Performance and behavior of a distributed system is only as good as the efficiency of the underlying protocols that enable communication between its components. Traffic exchanged between the telecommunications infrastructure and the servers travels over the HTTP protocol. While many other more specialized alternatives exist (as seen with AWS IoT and Azure IoT), the simplicity of the HTTP protocol and the availability of tools that enable diagnostic and manipulation make it a valid candidate for cloud based solutions. Additionally, its popularity and widespread usage allow a simpler process of integration of the APIs developed and distributed by the company to its clients. In the following sections we will go through the different key components that define the architecture, highlighting findings and elements that led See Your Box in its design related decisions.

In the following subsection we present only the Gateway and the Databases solution used in the system. The Engine is out of the scope of this paper. It is structured in two components, the Rules Engine, that applies business logic to incoming data, providing real-time analysis for event detection and data processing and the Actions engine, that implements the event handling logic by processing actions such as sending e-mails, connecting to external APIs or producing messages to send to other devices.

#### A. Gateway

HTTP protocol allows the gateway to expose its services and APIs with a single protocol simplifying development and maintainability of the system. Implemented with a lightweight Python framework it can take advantage of many best practices and policies that have emerged in the last years with the rapid widespread of web applications. The gateway was developed using Flask, a Python simple yet extensible micro framework serving APIs through an nginx web server. Data is returned to the client in the form of JSON files.

When using a web application to deliver content for HTTP requests it is common practice to enclose all code to manage the request inside the same module that processes the request and provides a response. While this is an intuitive way to handle HTTP requests it does have its drawbacks. There are times when the processing of a request and the corresponding output can be decoupled. In figure 2 a device is sending data to a server that has to be processed and subsequently stored in a database. In a fully sequential synchronous approach response time to the device depends on processing time of the tasks associated to incoming data introducing a delay in the response. In figure 3 instead, by decoupling server and workers it is possible to keep short response times to the device

Fig. 2. Synchronized approach

Fig. 3. Not Synchronized approach

requests while deferring heavy workloads to other actors of the system. Many are the reasons to investigate this choice:

- Scaling is possible to distribute over multiple nodes the computation related to incoming data and time consuming operations.
- Power management, usually IoT devices are battery powered and enforce heavy power management policies. A common strategy is to power on transmission related hardware when only strictly necessary. Short response times translate in smaller windows of time when transmission modules are powered on.
- Resource management The dynamic vertical scaling of the infrastructure allows to distribute resources instantly as needed by the single components, maximizing performance.

In this scenario the main question concerning this matter was what information really does the device need in the response sent by the server. If data processing in the system is viewed as single action the response usually indicate the processing status. If however, we breakdown processing into steps it becomes evident that by operating a separation of concerns the most important piece of information that must return to the device is the confirmation of successful reception of data by the gateway. What the server does to that piece of information is generally not a concern of the device. Since it is possible to let the API quickly return the outcome of gathering the incoming data. To rephrase the last concept, the main purpose of the return message is to inform the device if the transmission was successful, regardless of what happens when the system will process the data. However See Your Box is not only a pure telemetry system. Device flexibility and edge computing are only two features that clearly require bidirectional data exchange between things and the server. The design of the system calls for only outbound connections from devices, so, for instance, any data directed to a device

will require an initiative of the device. To solve this issue, in asynchronous systems, we use a message box where data to be sent to the device is stored until emptied. Two options were evaluated in designing the system: internal or external message box. An internal message box is advisable in those

Fig. 4. Message box as a component of the gateway

situations where the content of the message box is produced from the gateway itself. Examples could be to store the status of the execution of the worker and request a re-transmission. Messages can be cached in volatile memory and reduce the overhead of having to initiate yet another transaction as shown in figure 4. Whilst using an external message box (figure 5) the gateway must forward a request to the service that implements this function and the added latency clearly impacts the response time to the device. We opted for an external message box contained into the Device DB. By doing so the gateway only needs to query once an external service that returns both messages directed to the device and the metadata needed to authenticate and forward the incoming data to the rules engine.

Fig. 5. Message box as a separate component

Ultimately the main operations performed by the gateway when it receives data from a device are:

- 1) Decode incoming data
- 2) Query the device DB for metadata and pending messages
- 3) Forward data and device metadata to the rules engine
- 4) Return messages to the device

The complete sequence diagram of a generic request to handle data from a device is highlighted in figure 6. Due to the limited size of data packets involved we will neglect the time necessary to perform the decode phase. This leaves most of the responsibility on the efficiency of the communication protocol (delegation to worker) and performance of the Device DB data storage.

1) *Communication protocol*: Splitting the execution of a task and distributing its load over multiple threads requires a form of coordination and interprocess communication. A common way to do this is by using messages queues. They offer an

Fig. 6. Sequence diagram of the Gateway

asynchronous communication protocol, allowing senders and receivers to exchange messages without directly interacting with each other. Tasks are submitted as messages to an inbox and are eventually read and executed by a worker when ready. See Your Box Gateway uses Celery, an open source task queue based on message passing. Its architecture abstracts from the underlying communication protocol and it can be implemented with a number of different options. The main components of a task queue are [12]:

- 1) Messages Tasks are submitted to the queue in the form of messages. These could be binary objects, strings or JSON files.
- 2) Broker is the component that actually stores the messages. Acts as a middle man between producers and consumers. Examples of message brokers are Redis or RabbitMQ.
- 3) Producer is the portion of application generating the tasks. This could be an API endpoint that requires the execution blocking or time consuming operations.
- 4) Consumer Commonly referred to as a worker, it is the component that will actually execute the operations associated with the task.

There are a number of things to consider when implementing a task queue system for asynchronous processing. The first is regarding persistence of messages on disk or in memory. This is an important decision that influences directly the performance of the system. When evaluating what strategy to adopt we considered that the main reason that could motivate the adoption of a permanent storage solution is to avoid losing messages due to an unexpected power down or crash of the system. Upon reboot the system could ideally continue executing the tasks associated to messages delivered before the event. What was discovered was that in case of unexpected crashes or hardware failures the risk of corrupting the disk under the heavy write and read load was very high. The benefit of being able to possibly recuperate messages stored in queue upon a crash was minimal compared to the potential gain in performance when implemented as a in memory message broker. Efficiency of the system depends on how fast the workers are able to process the incoming messages. To take full advantage of the scalable infrastructure it is also necessary for the application to monitor system load and performance and automatically deploy new workers within the system.

Finally, when configuring a message queue, and specifically a task queue, it is important to take into consideration ordering of task execution and completion. The broker will generally work as a FIFO (First In First Out) queue. Tasks, or messages, are delivered to the broker in temporal order and executed by any of the available workers. An alternative is to configure

Fig. 7. Message handling order with single queue

the system with a FIFO queue for each worker. Messages are delivered in order to the broker and the corresponding worker will execute the tasks associated with the messages in the same order. There are a few aspects to consider when choosing one configuration over the other.

- 1) Load distribution. A single queue implementation results in a simple load balancing mechanism, where tasks are distributed to free workers as they become available. In a multi-queue configuration load balancing depends a lot on how the messages have been distributed to the broker. The producer has the added responsibility to distribute messages accordingly onto the queues. Uneven delivery would result in some workers being overloaded while others remaining in an idle state.
- 2) Queue distribution A single queue configuration results in a single point of failure. If the node that contains the message queue becomes unavailable due to a system crash, for instance, the whole task queue comes to a halt until a recovery strategy kicks in. Distributing the queue on more machines allows the system to contain the effects of a node failing.
- 3) Completion order In a queue messages, and the respective tasks, are executed in order. However no guarantee can be given on the required execution time of a single task. This could result in a queue populated by short and long tasks as shown in figure. Assuming a three worker scenario, tasks TA1, TB1 and TB2 will start executing shortly one after the other. However the smaller task TB2 could complete before TB1, effectively braking the order.

In a multiple queue scenario, where one worker is dedicated to a single queue the execution of a task necessarily follows the completion of the preceding task. In other words, when a single worker is dedicated to a single queue, delivery, execution and completion order coincide. Configuration of the message broker and how queues and workers are deployed within the system has to take into consideration load balancing, distribution and message ordering. It is important to consider carefully the specific problem to solve. In the See Your Box system message ordering was a fundamental requirement as it reduces greatly the need of storing additional data for hot path

analysis. A lot of the conditions that are typically monitored in IoT systems have direct correlation to temporal evolution of variables and occurrence of events. When data is provided to the system out of order it has to be stored provisionally and subsequently retrieved and reordered for analysis. A very simple way to make queries faster is not to run them at all. Enforcing temporal order of processed messages allows the system to use incremental and cumulative analysis that is able to support almost the majority of monitoring scenarios. This resulted in multiple queues, one for each worker, and a simple yet very efficient algorithm for distributing tasks generated by a device always to the same worker.

## B. Databases

As seen in the architecture overview, it was not convenient nor feasible to use a single database management system to serve data processing in the whole system. The strategy adopted was to focus on the single interactions step by step and define what were the most important requirements for each one of them. This architecture results in a data storage solution that has to cover three key components:

- Device DB. This must be a high speed and robust data store optimized for reads and updates. It contains metadata associated to the device producing incoming data and an inbox for messages to deliver in return. The faster the system can read from this source the quicker it can serve a request.
- Business DB The system must be able to serve thousands of clients, handle accounts, ACLs and financial transactions.
- Data points DB This database collects data points of processed data. To minimize processing time this database must be optimized for inserting data, however the main concern over this database is horizontal scalability and ability to manage big data.

In processing incoming data we have two goals: in the first place ensure the fastest possible response to the device and in the second place optimize processing time as a whole along both the hot path and the cold path. The approach followed was in reality very simple. The idea is to define clearly hot and cold paths and break them up into stages. For each stage define what the critical component was and optimize it. As a rule of thumb the quicker both hot and cold paths are traversed by incoming data, the smaller the fraction of shared resource for time unit is necessary to process a request. Smaller fractions will result in a smaller infrastructure that allows the company to optimize costs. Quick analysis on prototype architectures revealed that the bottlenecks were database interactions. It was clear that it was necessary to optimize reads and updates in the hot path and writes in the cold path. Sporadic writes in the hot path and offline reads in the cold path were not to be taken into account in the optimization phase and choice of solutions.

Business DB is used for storing crucial data such as accounts, customer's options and financial data. This database is generally not directly involved in data processing during

either hot-path or cold-path. During the lifetime of an active device generally the system will need to interact with this database only during power-on, poweroff and special maintenance procedures. For this reason its impact on the overall performance is limited. The main requirement for this data storage are support for transactions and consistency. For this reason, and because data contained exhibits strong relations it was decided to use a relational database management system. Research on related work pointed to two possible candidates, PostgreSQL and MySQL. While the former has an extensive and powerful feature set and PostgreSQL was already used inside the location service of the company, its complexity limited the obtainable performance. MySQL on the other hand was a proven database with which the team had significant experience. A concern was raised regarding the costs of licenses that can have a high impact on yearly operational costs of the system.

Despite the support and service provided as benefit of the annual subscriptions, once again similarly to what happened when evaluating cloud providers it was necessary to consider alternative solutions. In 2009 before the acquisition of MySQL, an open source fork of the original project was released under the name MariaDB.

The deviceDB contains metadata related to the device and messages that need to be sent to the device. This storage must be optimized for read and update speed. The DeviceDB has a crucial role in the system and its performance influences mostly processing time of incoming data. Following the general architecture of the system, this is the component that required most attention from the R&D department of the company. The DeviceDB contains two important components that are necessary for handling incoming data. These are the message box for data to be returned to the device and the metadata associated to it. The latter is used by the rules engine to know how to interpret data, actions to be performed on it and state of the device. The requirements of this storage:

- Flexibility - Metadata related to a device can vary a lot. Smart sensing devices can monitor a large number of parameters with different encoding schemes. It must be possible to embrace this difference and not be limited by a fixed scheme.
- Performance As previously noted, read operations must be extremely fast in order to obtain low response times. Write performance is less crucial since this would happen with a low frequency.

The first database management system that went under examination for this task was MongoDB. The main reason was the required flexibility of the data structure used to describe metadata. Repeated tests demonstrated however that its performance wasn't up on par with the high speed key-value NoSQL database or MariaDB tables powered by a TokuDB engine. Redis was taken into consideration due to the fact that it minimizes disk access by keeping the database in memory. This is a problem for scalability since the size of the database is limited by the quantity of available RAM.

Furthermore some form of persistence on disk needed to be provided, since the stored data isn't short lived. Additionally it was found that read performance wasn't very different from an optimized MySQL/MariaDB database for comparable queries. Similar results were confirmed in literature [18]. These findings quickly made us discard Redis as a possible candidate. Ultimately one of the company policies was to keep the set of adopted technologies as narrow as possible in order to favor interoperability of expertise of the team. Ultimately this led us to explore what we defined as a hybrid solution that was to use a SQL database as a key-value storage and use a text field to store a JSON files representing metadata and message inbox. Each row would represent a device and would be indexed upon the device id. This unorthodox approach to data management proved over time one of the most valuable decisions in the design of data storage support to the system. Performance wise we were achieving read and update speeds comparable to the top class key-value memory based data storages and flexibility was on the same level of the NoSQL databases thanks to the adoption of JSON objects. However, the most important benefit was that, while braking some of the ACID properties for the data contained inside the JSON fields, these were guaranteed for the other fields. This allowed us to integrate the DeviceDB tables with the BusinessDB, enforcing all consistency benefits of a traditional SQL RDBMS. Not being able to query single fields of JSON files such as in MongoDB was not a problem since each incoming packet would require all the data contained inside the row and never a part of it.

Once incoming data has traversed all the processing path in the system and has been augmented by external data and real time manipulation it must be stored in a database management system for offline analysis and visualization. Write operations at this stage are very well defined if not unique. Conceptually the only storing procedure that is necessary is saving a data point. This piece of information is essentially a collection of sensor readings and location photographed at a given moment in time. However the structure of a data point is extremely dynamic and heterogeneous.

Evidence in literature coupled with advice provided by IT consulting companies pointed in the direction of a document based NoSQL database, particularly MongoDB. The widely recognized features of this database were soon confirmed in the prototyping stage of the architecture. The document based nature of MongoDB allowed for a simplification of data representation across the system. It uses BSON, a binary representation of JSON files. The latter was the format under which data was managed across the system and particularly fed through the customer accessed APIs. While it might appear as a trivial detail, it allowed for a more compact code base that would reduce the abstraction and translation layers across systems. For a developer a data point is created, manipulated, stored and finally returned to the client API in the same format: a simple semi structured JSON file. This allows for much faster integration, debugging and analysis of the system, particularly data flow. Ultimately, but most importantly, it was

the support for massive scale dataset that confirmed MongoDB as the key solution. Support for auto sharding and distribution reduced the need of designing a complex mechanism for horizontal scaling of the system. The only true challenge that was encountered when developing this component was the interference of the read and write operations. Sudden slowdowns and reduction in performance was experienced when these two operations would happen at the same time. The solution was to implement a semaphore system that would lock writes when a read operation was performed.

## V. CONCLUSIONS

The IoT industry has experienced an exponential growth in the last years. It has been pushing the boundaries of conventional architectures by challenging developers with massive quantities of data to be processed with near real time requirements. Scale, heterogeneity and velocity of data have an immense impact on the system design. We analyzed how two of the major cloud computing providers tackled the challenges of the IoT in their comprehensive service suites. With a strong focus on modularity, composability and horizontal scaling they both offer valuable solutions for an array of scenarios. The commodity of a turn-key cloud based platform comes at a cost that could potentially grow out of control, impacting the finances of a company quite heavily. Costs don't always grow linearly with the scale of the system due to the nature of some computational operations that are performed on data or on pricing model.

Cloud based platforms enable startups to quickly penetrate the market. However, for young companies it is not only a matter of balancing NRE and operating costs. Turn-key solutions like Paas and Iaas allow startups to focus on building a team with skills closer to the business core technology and penetrate the market faster and more effectively. Ultimately deciding for a cloud based solution or an in-house one requires balancing interests from different points of view that are not strictly IT related. According to the specific application scenario a bespoke system with a custom architecture, despite a significantly higher NRE can represent a better solution.

The proposed architecture is a brokered task queue system distributed over a private cloud infrastructure. Incoming messages from devices are paired with metadata stored in a hybrid SQL data storage that combines the flexibility of NoSQL key-value or document based DBMSs and reliability and ACID compliance of an SQL traditional relational database management system.

Ultimately the designed system, presented in this work, has been implemented and released onto the market. After 12 months and over 1 million data points collected, the system has proven to be stable and meet the preset requirements, enabling the company to expand its business and acquire new clients.

**Abstract**—The transition towards a cyber-physical energy system (CPES) entails an increased dependency on valid data. Simultaneously, an increasing implementation of renewable generation leads to possible control actions at individual distributed energy resources (DERs). A state estimation covering the whole system, including individual DER, is time consuming and numerically challenging. This paper presents the approach and results of implementing a simplified state estimator onto an embedded system for improving DER monitoring. The implemented state estimator is based on numerically robust orthogonal factorization and used on a set of state equations of a generic wind turbine generator (WTG). The simplified state estimator is tested by simulating a generic WTG model and evaluated based on its execution time and estimation accuracy. Results show its fast execution time, its accuracy in handling normal measurement error and its ability to provide reliable data in the case of gross errors in the set of measurements.

## I. INTRODUCTION

THE traditional power system is mainly composed of large centralized power plants, but since the turn of the century, countries worldwide have increased the integration of renewable energy sources (RES) [1]. At the same time, control methods utilizing distributed energy resources (DERs), to ensure a reliable delivery of electricity, have been proposed and included in grid codes [2], [3]. To manage the decentralization of control decisions, investments in advanced information and communication technology (ICT) infrastructure are made, increasing the data acquisition and improving the visibility of power system operation [4], [5].

Relying more on monitoring and control of DERs and having a more complicated technology mix on both sides of generation and consumption, the power system is transitioning into a cyber-physical energy system (CPES) [5], [6], [7], [8].

Historically, the process of state estimation has been used to remove measurement error within the boundaries of the power system [9], but within the larger and more complex CPES, centralized state estimation becomes computationally demanding and numerically challenging. Instead, the physical system at the boundaries of the power system could be observed and used for local state estimation purposes, removing gross measurements and assisting in the decision-making process of determining appropriate distributed control actions. The aim

of this paper is to utilize this theory and implement a DER monitoring system onto an embedded system and determine its accuracy compared to that of raw measurements.

For this purpose, the generic wind turbine generator (WTG) model described in [10] is modelled in Simulink and analyzed with the purpose of developing a simplified state estimation model. Considering the limited resources of an embedded system, the simplified state estimator is implemented on a commercially available embedded system. In this work, the embedded system chosen is a National Instruments (NI) compact-RIO (cRIO) 9074.

In previous work of applying state estimation techniques to wind power plant monitoring [11], [12], the aim has been to investigate the dynamics of the WTGs, for testing and developing control designs, and improving the transient performance of WTGs. For these purposes, comprehensive dynamic models of WTGs are necessary to give the required level of detail. In this paper, the goal is to validate measurements in DER supervisory control and data acquisition (SCADA) systems to provide an accurate picture of the static operation of the DERs that can be utilized from a system operations perspective. Therefore, the accuracy and complexity of the WTG model can be decreased to enable execution of the simplified state estimator on an embedded system.

Results from testing the capability, accuracy and performance of the monitoring system, show that the state estimator is simple enough to be implemented onto an embedded system and execute within appropriate timing, is fairly accurate when normal measurement error is present and offers higher accuracy compared to the utilization of raw measurement data when gross measurement error is present.

The rest of the paper is organized as follows. In Section II the chosen state estimator algorithm is described, followed by a presentation of the derived state equations from the WTG Simulink model used in the state estimator. The section ends with a description of how the simplified state estimator was implemented on the embedded system using LabVIEW software. Section III presents the objective, analysis and evaluation of three test cases used to test the monitoring system. Section IV concludes this paper.

## II. METHOD

The concept of state estimation in power system application was presented in [9]. The purpose of the state estimation is to reduce measurement error  $\mathbf{e}$  by estimating a set of state variables  $\mathbf{x}$  related to the set of measurements  $\mathbf{z}$  by a set of state equations  $\mathbf{h}(\mathbf{x})$  as shown in Eq. (1).

$$\mathbf{z} = \mathbf{h}(\mathbf{x}) + \mathbf{e} \quad (1)$$

Since the concept was introduced, numerous different algorithms have been proposed in literature, some of which are described in [13]. Most of these methods are based on the formulation of a set of non-linear equations, where the solution is found by solving a weighted least squares (WLS) problem [14]. The WLS problem is formulated as a optimization problem as described in (2).

$$\text{minimize} \quad J(\mathbf{x}) = 1/2 \sum_{j=1}^m \left( \frac{r_j^2}{\sigma_j^2} \right) \quad (2)$$

where  $J(\mathbf{x})$  is the weighted sum of square residuals,  $m$  is the number of measurements,  $r_j = z_j - h_j(\mathbf{x})$  is the residual and  $\sigma_j^2$  is the variance of the  $j$ -th measurement. The variance of the measurements is based on the characteristics of the measurement devices. As measurement are devices are less than 100% accurate, it is assumed that its error is normal distributed with zero mean and variance  $\sigma^2$  [14].

As the objective of this paper is to implement the state estimator on an embedded system, two requirements for the state estimation method are considered. The chosen methods have to 1) be numerically robust, as rounding errors are more likely in the embedded system compared to a control center computer, due to the limited bit number of the embedded operating system (OS) compared to general purpose OS, and 2) ensure an accurate convergence within the timing requirements set by the system.

The state estimation method used in this work is formulated around an iterative process where the updated state variables are calculated using orthogonal factorization, also referred to as QR factorization, which has been widely accepted in practice [14]. The stability of the factorization method comes from avoiding the formation of the gains matrix and thereby alleviating the numerically ill-conditioned state estimation problem. In [15] a comparative study has shown that the QR factorization is the most numerically robust, but at the same time has the highest computational requirements. To ensure convergence within the timing requirements, the complexity of the state equations, representing the WTG, is formulated from a trade-off between accuracy and computation requirements.

An added feature in power system state estimators, that improves the removal of measurement error, is the threefold process of bad data detection, identification and elimination that together form a bad data detector.

### A. Bad data detection, identification and elimination

Mili, Van Cutsem and Ribbens-Pavella defined the task of the bad data detector, in the content of state estimation, as "Its task is to guarantee the reliability of the data base generated through the estimator." in [16, p.3037].

Bad data can occur in a monitoring system because of faulty measurement devices, faulty communication or even interference from adversaries [7]. In [17] measurement error has been characterized into three groups based on their magnitude compared to the standard deviation of the measurement device. Normal measurement error is expected to have a magnitude of up to  $5\sigma$ , gross measurement error has a magnitude between  $5\sigma$  and  $20\sigma$ , and extreme measurement error has a magnitude larger than  $20\sigma$ .

There exist multiple different bad data detection algorithms in literature [16], [18], [19]. In this work, a simple bad data detector is implemented and designed to run after each iteration of the state estimation algorithm. The detection algorithm chosen is introduced in [9] and based on the concept of hypothesis testing and  $J(\mathbf{x})$  tests. The method is based on an assumption that the weighted sum of square residuals,  $J(\mathbf{x})$ , follow a chi-square distribution,  $\chi^2$ , with a degree of freedom,  $f$ , equal to the number of measurements  $m$  minus the number of state variables  $n$ .

By analyzing the chi square probability density function,  $P$ , a probability,  $\alpha$ , is chosen between 1% and 10% as a trade-off between the number of false positives and negatives [20] as indicated by Eq. (3).

$$P [J(\mathbf{x}) > K | J(\mathbf{x}) \sim \chi^2] = \alpha \quad (3)$$

where the weighted sum of square residuals,  $J(\mathbf{x})$  is calculated using Eq. (2).  $K$  is characterized as the  $(1-\alpha)$  quantile of the chi-square probability distribution with a degree of freedom equal to  $(m-n)$  and is calculated using Eq. (4) [20].

$$K = \chi_{(m-n);\alpha}^2 \quad (4)$$

The hypothesis of whether or not bad data is present in the set of measurements  $\mathbf{z}$  is evaluated by comparing  $J(\mathbf{x})$  to the detection threshold  $K$  with a chosen  $\alpha$ -value. If  $J(\mathbf{x}) > K$  bad data is detected and vice versa. In the case of bad data being detected, the process of bad data identification is initiated. A widely used identification method of sorting the weighted residuals in  $J(\mathbf{x})$  in a descending order and determining the measurement with the largest weighted residual as the bad measurement, is implemented in the bad data detector [18].

After detecting and identifying the bad data, the bad measurement must be eliminated to make sure the state estimator will converge towards an accurate solution. There exists multiple different techniques in eliminating bad data, with different computational requirements [16], [19]. As DERs are operating in a highly dynamic system, the process of simply replacing the bad data by the measurement from the last period is unreliable. Instead a similar approach as the one used in [19] is utilized, where the bad measurement is replaced

by a pseudo measurement based on the estimated value and the gains matrix. In the simplified state estimator, the gains matrix is avoided, therefore the identified bad measurement is calculated using Eq. (5).

$$z_b^{new} = z_b^{old} - \text{sign}(z_b^{old} - h_b(\mathbf{x})) \cdot |a| \quad (5)$$

where the subscript  $b$  represents the index of the identified bad data, and  $|a|$  represents the absolute value of a normal distributed random number with zero mean and a standard deviation of  $\sigma = 0.01$ . The idea behind the value subtracted from the bad data to form the new data in Eq. (5), is that the sign of difference between the bad data and the estimated value is assumed to represent the sign of the difference between the bad data and the correct data. By simply pushing the bad data in the direction of the estimated value, the new data should be closer to the correct data, assuming the estimated value is closer to the correct data.

After safely eliminating the identified bad data, the state estimator executes its algorithm once again and the process of bad data detection, identification and elimination is repeated. It might be necessary to execute the bad data detector several times until the hypothesis of bad data being present is thrown.

### B. WTG state model

The state estimator of the WTG generic model requires the three sets composing Eq. (1):

- A set of measurements  $\mathbf{z}$
- A set of state variables  $\mathbf{x}$
- A set of state equations  $\mathbf{h}(\mathbf{x})$  relating the state variable to the measurements and the measurement error  $\mathbf{e}$ .

The SCADA system of a single wind turbine communicate more than 150 different values including temperature measurements, alarm state signals, and mechanical as well as electrical measurements of the wind turbine and the equipment connecting it to the collector system [21]. For the generic WTG model, 9 relevant mechanical and electrical properties are listed in Table I and used as inputs for the state estimation model.

TABLE I  
WIND TURBINE SCADA MEASUREMENTS IN THE WTG STATE ESTIMATION MODEL

Mechanical			Electrical		
Signal	Description	Unit	Signal	Description	Unit
$V_w$	Wind speed	[m/s]	$P$	Active power	[W]
$\theta$	Pitch angle	[°]	$Q$	Reactive power	[var]
$\omega_r$	Rotor speed	[pu]	$U_{rms}$	Phase a rms voltage	[V]
			$I_{rms}$	Phase a rms current	[A]
			$U_a$	Phase a voltage	[V]
			$I_a$	Phase a current	[A]

For the DER monitoring system implemented in this work, a measurement frequency of 1 Hz is chosen as it complies with the normal practice in SCADA systems [22], [23]. Simultaneously, this entails that the timing requirements of the

state estimator is well below 1 second, as the embedded system has to acquire the measurement signals before executing the state estimator, and allow time for data communication and processing at control centers.

For all the measurements in Table I the normal measurement error is assumed to have zero mean and a standard deviation of  $\sigma = 0.01$ , which corresponds to the measurement error introduced by measurement transformers for the electrical measurements and the errors entailed when measuring the mechanical system [24]. From the set of measurements in Table I, an appropriate set of state variables is identified. From state-space analysis theory [25], the state variables have to enable an estimation of all the input signals at any instance in time  $t$ . In the mechanical system, there is a relationship between the wind speed, the turbine rotational speed and the geometry of the wind turbine. If a steady wind is blowing, the tip speed ratio  $\lambda$  defines this relationship through a constant  $K_b$  as shown in Eq. (6).

$$\lambda = \frac{K_b \cdot \omega_r}{V_w} \quad (6)$$

For this project, the parameters given for a General Electric (GE) 1.5MW DFIG in [10] are used to represent the generic WTG. Due to the simplicity of the generic WTG model, a single mass model is used to represent the shaft connecting the rotor hub to the generator as recommended in [10].

The tip speed ratio can be used to estimate the pitch angle of the blades  $\theta$ . According to [26] the aerodynamic design of the wind turbine blades and their pitch angle has a certain relationship with the power coefficient  $C_p(\theta, \lambda)$ . These power coefficient curves are confidential and extremely difficult to access, therefore [10] has defined a relationship used in the generic GE 1.5MW DFIG WTG representation.

The built-in pitch controller of the generic WTG model attempts to maximize the power output according to the tip speed ratio. At very low wind speeds, the pitch controller keeps the pitch angle at 0°. When the wind speed increases, the pitch controller regulate the appropriate pitch angle in order to keep the power output at rated power. To get the relationship between tip speed ratio and pitch angle expressed as an equation, the WTG model is implemented in MATLAB Simulink, and simulated with a gradually increasing wind speed. Fig. 1 shows the resulting pitch angle as a function of tip speed ratio. At  $\lambda > 6$ , the pitch angle is 0.

From this discussion, it can be argued that from the wind speed and the rotational speed, it is possible to estimate the blade pitch angle. Therefore, the first two state variables of the state model are chosen as  $x_1$  referring to  $V_w$  and  $x_2$  referring to  $\omega_r$ . In the electrical system, assuming availability of accurate voltage and current angles through phasor measurement units (PMU) [27], all the input signals can be estimated from the root-mean-square (rms) current and voltage. Therefore  $x_3$  is chosen equal to  $U_{rms}$ , likewise  $x_4$  is chosen equal to  $I_{rms}$ .

To improve the reliability of the state estimator, all the measurements are converted into the per unit (pu) scale, which decreases the differences in the non-zero elements of the

Fig. 1. Simulation results of the generic WTG model in MATLAB Simulink with graduate increasing wind speed, giving a relationship between pitch angle,  $\theta$ , and tip speed ratio,  $\lambda$ .

Jacobian matrix of the state equations. All measurements are converted into per unit using the base values shown in Table II.

TABLE II  
PER UNIT BASE VALUES OF THE WTG MEASUREMENTS

Mechanical		Electrical			
Signal	Base value	Signal	Base value	Signal	Base value
$V_w$	12 m/s	P	3 MVA	$I_{rms}$	2 886.75 A
$\theta$	10.42 °	Q	3 MVA	$U_a$	346.41 V
$\omega_r$	1 pu	$U_{rms}$	346.41 V	$I_a$	2 886.75 A

The per unit base values of the mechanical system are chosen based on the parameters of the GE 1.5MW WTG from [10], Eq. (6), and the relationship between  $\lambda$  and  $\theta$  illustrated in Fig. 1.

For the electrical system, the apparent power and voltage per unit base values are chosen based on the test system shown by the one line diagram in Fig. 2, created based on the benchmark tests performed in [10] and the cable data found in [28].

Fig. 2. Single line diagram of test grid used to simulate the WTG model connected to an external grid.

The highest rated equipment is the 230/34.5 kV transformer with an apparent power rating of 3 MVA. From the second transformer, it can be observed that the terminal voltage in line to line rms is 0.6 kV. Therefore the per unit values of the electrical system are calculated as in Table II.

After defining the per unit bases, the  $\lambda$ ,  $\theta$  relationship found in Fig. 1 is converted to per unit and analyzed through the MATLAB curve fitting tool to give the four term Gaussian function representing the state equation in Eq. (8).

$$V_w = x_1 \quad (7)$$

$$\begin{aligned} \theta = & 2.778 \cdot \exp \left( - \left( \frac{x_2}{x_1} - 0.4469 \right)^2 \right) \\ & + 0.8212 \cdot \exp \left( - \left( \frac{x_2}{x_1} - 0.8423 \right)^2 \right) \\ & + 0.4885 \cdot \exp \left( - \left( \frac{x_2}{x_1} - 1.037 \right)^2 \right) \\ & + 0.2784 \cdot \exp \left( - \left( \frac{x_2}{x_1} - 1.169 \right)^2 \right) \end{aligned} \quad (8)$$

$$\omega_r = x_2 \quad (9)$$

$$P = x_3 \cdot x_4 \cdot \cos(\phi) \quad (10)$$

$$Q = x_3 \cdot x_4 \cdot \sin(\phi) \quad (11)$$

$$U_{rms} = x_3 \quad (12)$$

$$I_{rms} = x_4 \quad (13)$$

$$U = x_3 \cdot \sqrt{2} \cdot \sin(2\pi ft + \delta) \quad (14)$$

$$I = x_4 \cdot \sqrt{2} \cdot \sin(2\pi ft + \beta) \quad (15)$$

The equations in Eq. (7) to (9) are the mechanical state equations and together with Eq. (10) to (15), they form the complete set of state equations  $\mathbf{h}(\mathbf{x})$ . The set of electrical state equations, in Eq. (10) to (15), are found from power system theory [29].

### C. LabVIEW implementation

The DER monitoring system is tested by implementing a simulation model of the WTG onto the cRIO through the LabVIEW programming tool. The Simulink WTG model is built as a C code, using the compiler in Simulink, and implemented on the cRIO through the model interface toolkit (MIT) in LabVIEW.

The added computational burden on the cRIO is considered by lowering the simulation of the WTG model. To include necessary details of voltage and current waveforms from the WTG model, the simulation frequency is set to 2500 Hz. On the cRIO, each simulation step will be executed 25 times slower than real time, this will however not affect the execution time evaluation of the state estimator.

With the Simulink model implemented on the cRIO, the simplified state estimator and integrated bad data detector are programmed in LabVIEW, as described in Section II and II-A, and shown in the process diagram in Fig. 3, which contains additional information about the inter-process and inter-target communication.

To allow control of the wind speed, a real-time (RT) target process is created to simulate wind speed according to the model described in [30]. The wind speed  $V_w$  and WTG simulation model are executed in synchronized while loops on the RT target to make sure that the calculations are executed in a deterministic fashion. Before executing the state estimator in the process of Fig. 3, each Simulink signal is distorted by a normal distributed measurement error with zero mean and variance equal to  $\sigma^2 = 10^{-4}$ . After completing an iteration of the state estimation process, the updated state variables are

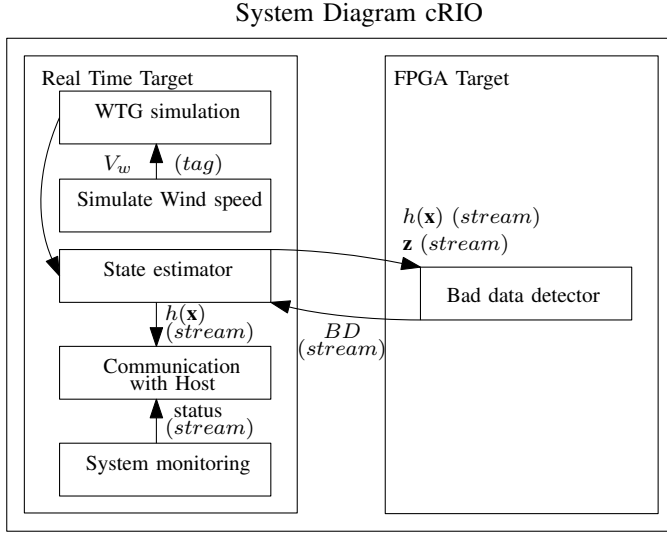

Fig. 3. System diagram of the cRIO with the Simulink model of the generic WTG implemented in LabVIEW.

communicated to the field-programmable gate array (FPGA) target where bad data is detected and identified.

The information about bad data is returned to the state estimator, which eliminates the bad measurements through Eq. (5). When the Euclidean norm of the state variables have converged below the tolerance  $x_{convergence}$  and no bad data is detected, the information is returned to the host and visualized for the system operator.

### III. RESULTS

To evaluate the application of the embedded system for DER monitoring the following three factors are considered:

- 1) Its ability to solve the WLS problem within a short time frame.
- 2) Its accuracy in estimating the solution to the state estimation model compared to raw measurements when subject to normal measurement error.
- 3) Its performance in terms of detecting, identifying and eliminating gross measurements errors.

Each factor is evaluated through a test scenario. In the following, three test cases are introduced, the results are analyzed and the system is evaluated.

#### A. Test 1: Execution time

The purpose of the first test is to evaluate how fast the simplified state estimator with integrated bad data detector can solve the WLS problem. This objective is reached by implementing tick counts in the LabVIEW data flow before and after the state estimator and bad data detector process in Fig. 3.

Under normal conditions, with a standard deviation equal to the assumed measurement device accuracy of  $\sigma = 0.01$ , the QR factorization algorithm only requires a single or two iterations to solve the WLS problem. To evaluate the execution time of the DER monitoring system at different number of

Fig. 4. Average, minimum and maximum execution time of the state estimator, with integrated bad data detector, as a function of the number of iterations needed before converging.

iterations, the standard deviation of the measurement error is increased to  $\sigma = 0.02$ . This results in a higher chance of the measurement error causing a detection of bad data, while using a detection probability of  $\alpha = 5\%$ , and thereby increases the number of iterations needed to solve the WLS problem.

The cRIO is run for a time series where the state estimator executes in total 162 times. The resulting execution time data is separated based on the number of iterations needed before finding a solution to the WLS problem, reached after the Euclidean norm of the change in state variable value between two iterations is below the convergence threshold chosen as  $x_{converge} = 0.01$ .

The number of iterations ranges from 0 to 13. In the case where no iterations are needed, the first solution of the state estimator is close enough to the final solution of the previous execution, used as the starting point for the following execution. The minimum, average and maximum execution time is calculated and presented in Fig. 4 as a function of the required number of iterations before converging.

A linear relationship between the number of iterations and the average execution time is observed in Fig. 4. For the executions with 1 to 3 executions, the maximum observed execution is around 5 ms slower than the average execution time. At the same time, the average value is observed closer to the minimum execution time, which indicates that the occurrence of large execution times is rather limited.

From Fig. 4 the execution time of the embedded DER monitoring system can be evaluated. As previously mentioned, the system is intended to run between acquisition and communication of data, and the added timing requirements of validating the data should be low enough to allow further data handling. For an iteration count between 0 and 13, the execution time varies from around 5 ms to 45 ms.

Considering the case of two iterations, the average execution time is calculated in Fig. 4 as approximately 10 ms, this corresponds to an execution frequency of 100 Hz. An execution frequency of 100 Hz satisfies current SCADA requirements

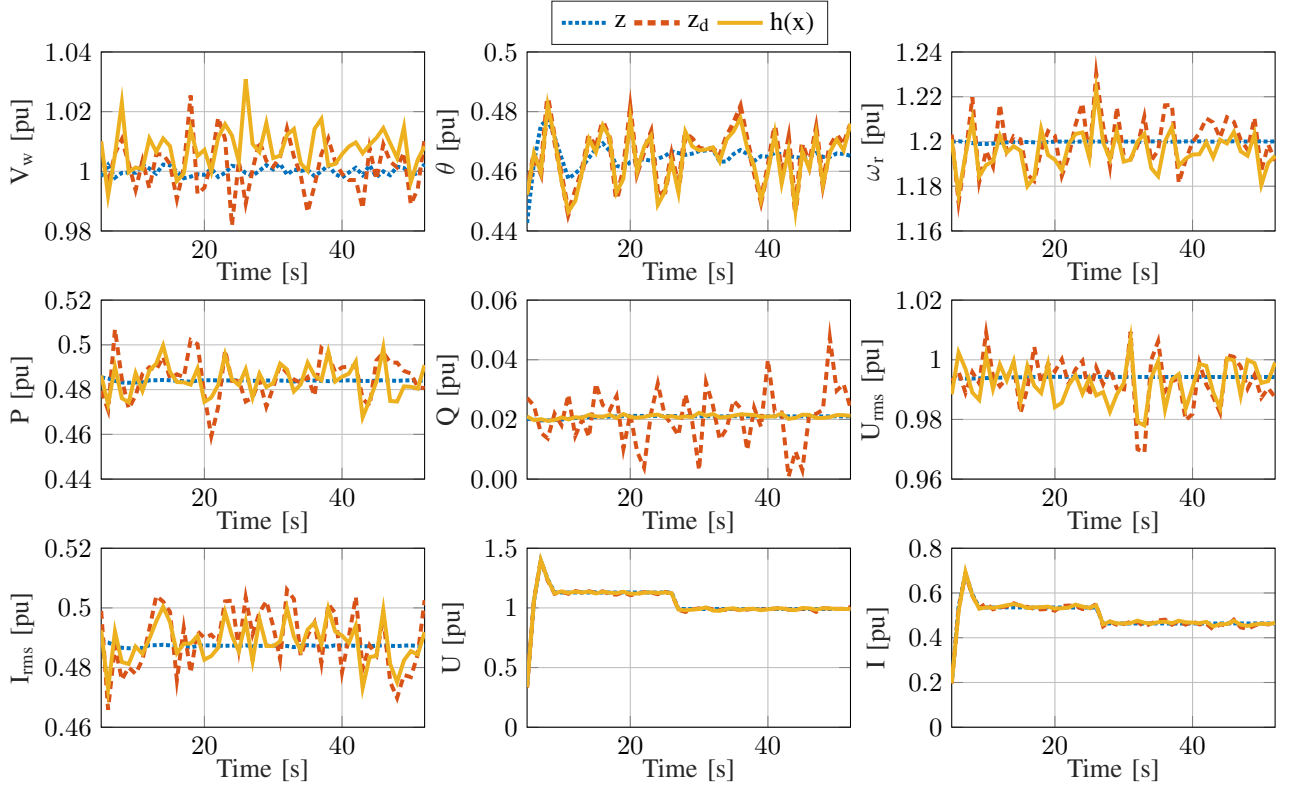

Fig. 5. The value of the nine measurements in  $\mathbf{z}$ , represented by the true simulated signal (blue line), the distorted signal (red line) and the estimated signal (yellow line).

and offers possibilities in terms of allowing a faster data acquisition for future SCADA systems.

### B. Test 2: Estimation accuracy

In the second test, the objective is to compare the accuracy of the estimated and disturbed signals to the correct signals from the Simulink model. In this test case, all measurements are disturbed by normal measurement error with zero mean and  $\sigma = 0.01$ .

The cRIO is run and the accuracy of the simplified state estimator is analysed by comparing the estimated signals  $\mathbf{h}(\mathbf{x})$  to the correct simulated signals  $\mathbf{z}$  and the distorted signals  $\mathbf{z}_d$ . These three results are found for each measurement in Table I represented by their per unit value corresponding to Table II, and shown in Fig. 5.

From the nine plots in Fig. 5 the dynamics of the system are observed from changes in  $\mathbf{z}$  during the time period. This is especially visible for the wind speed  $V_w$ , the blade pitch angle  $\theta$  and the instantaneous voltage  $U$  and current  $I$ . For all the measurements,  $\mathbf{h}(\mathbf{x})$  is closer to or similarly distanced from  $\mathbf{z}$  compared to the disturbed measurements  $\mathbf{z}_d$ .

A numerical comparison of the results in Fig. 5 is performed by calculating the average Euclidean error (AEE) over the executed time period  $\tau$ , using Eq. (16), as introduced in [31].

$$AEE(d_i) = \frac{1}{\tau} \sum_{t=1}^{\tau} \|d_{t,i}\|_2 \quad (16)$$

where  $\mathbf{d} = \mathbf{z} - \mathbf{v}$ ,  $\mathbf{v}$  is a set of values who's difference from the correct measurements is desired, and  $i$  is the index of the measurements in Table I. The AEE is calculated for both  $\mathbf{z}_d$  and  $\mathbf{h}(\mathbf{x})$  and is shown in Table III.

TABLE III  
AVERAGE EUCLIDEAN ERROR OF ESTIMATED AND DISTURBED VALUES  
FOR THE TIME SERIES RESULTS IN FIG. 5

$\mathbf{v} =$	$\mathbf{z}_d$	$\mathbf{h}(\mathbf{x})$
$i = 1$	0.0067	0.0085
$i = 2$	0.0067	0.0064
$i = 3$	0.0095	0.0074
$i = 4$	0.0074	0.0055
$AEE(d_i)$ $i = 5$	0.0070	0.0004
$i = 6$	0.0061	0.0057
$i = 7$	0.0090	0.0052
$i = 8$	0.0084	0.0056
$i = 9$	0.0085	0.0053

The small values of all the AEE results in Table III show the similarity of the average error of  $\mathbf{z}_d$  and  $\mathbf{h}(\mathbf{x})$ . Evaluating the accuracy of the simplified state estimator based on these results gives an indication that  $\mathbf{h}(\mathbf{x})$  offers similar accuracy in situations with normal measurement noise as the raw measurements. The state estimator could be improved by utilizing a more detailed set of state equations as in [11] or [12], however this would simultaneously change the execution time as the

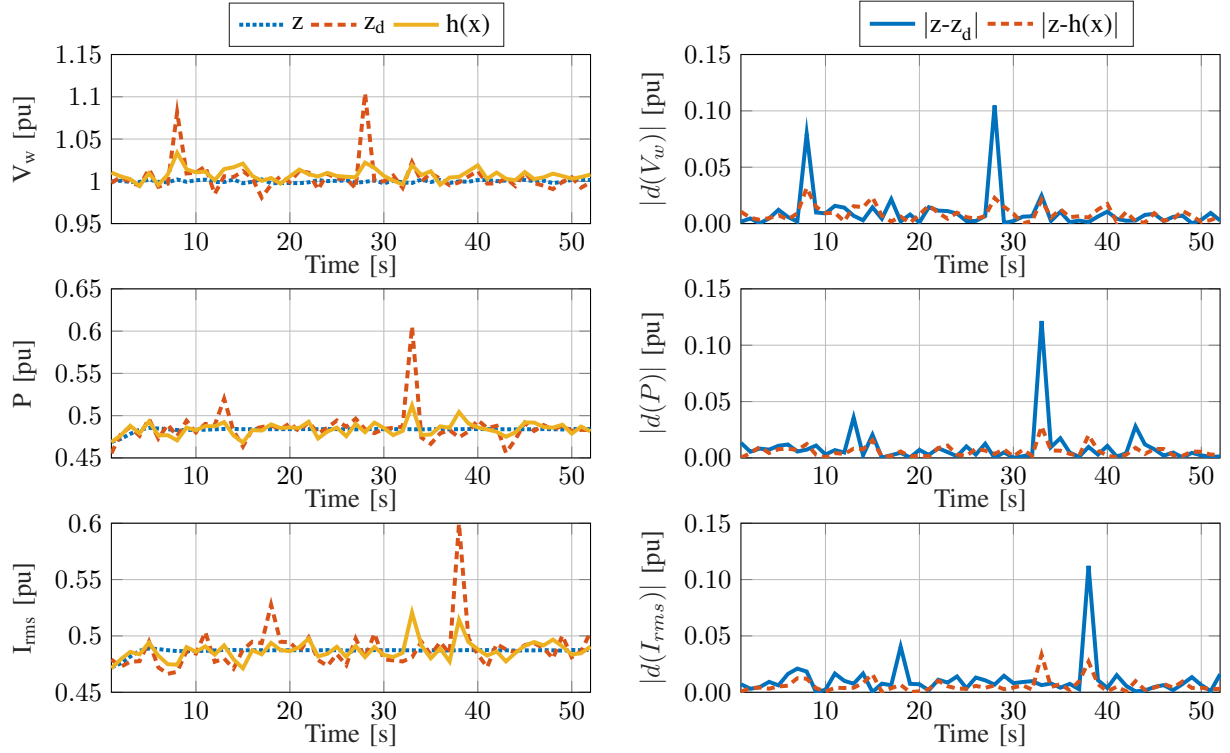

Fig. 6. Left: The wind speed, active power and rms current in per unit when subject to gross measurement error. Right: The absolute error between the true simulated signal and the distorted signal (blue line) and the estimated signal (red line), for the three measurements subject to gross error.

detailed model requires an increased number of calculations in finding the solution to the WLS problem.

### C. Test 3: Gross error performance

After testing the accuracy of the state estimators when measurements are subject to normal measurement error only, this test case evaluates the performance of the embedded DER monitoring system when gross measurement errors are injected into a set of target measurements. For this purpose, a testing interface is implemented in the LabVIEW user interface that allows specification of scalar measurement error and the index of the target measurement.

Three different measurements are chosen as targets and injected with the gross measurement error  $\varepsilon$  at the time  $t_\varepsilon$  as presented in Table IV.

TABLE IV  
GROSS MEASUREMENT ERROR INJECTION SCHEDULE FOR TEST CASE 3.

$t_\varepsilon$	8 s	13 s	18 s	38 s	33 s	38 s
$z_i$	$V_w$	$P$	$I_{rms}$	$V_w$	$P$	$I_{rms}$
$\varepsilon$	$5\sigma$	$5\sigma$	$5\sigma$	$10\sigma$	$10\sigma$	$10\sigma$

From Table IV the magnitude of the gross measurement error injected is chosen as 5 and 10 times the standard deviation of all the measurements  $\sigma = 0.01$ . The schedule is used while running the cRIO, giving the results illustrated in Fig. 6.

In Fig. 6, the left hand side shows the pu value of the wind speed, the active power and the rms current during the time period of execution. From these plots,  $z_d$  is clearly affected by the gross measurement error injected two times for each measurement. In comparison to  $z_d$ , the estimated results in  $h(x)$  are closer to the correct measurements,  $z$  for each injection of gross measurement error.

In the right hand side plot of Fig. 6, the absolute error between  $z$ ,  $z_d$  and  $h(x)$  is shown for each of the three measurements. Here the performance, of the simplified state estimator, in handling gross measurement errors is easily visible, as it is able to detector, identify and eliminate the error and estimate a better signal value than the raw measurements.

The error in  $I_{rms}$  after 33 s in the right hand side of Fig. 6, equal to approximately 0.04 pu indicates room for further improvements of the system. The cause of the large error is that the embedded monitoring system first correctly identifies the active power as the bad measurement, and after eliminating the error, it wrongly identifies a bad data at the rms current as well. This increases the difference between the pseudo measurement value and the correct value. This could possibly be avoided by finding the optimal trade-off between false positives and negatives, thereby fine tuning the detection threshold  $K$ , or refining the methods used in the bad data detector.

Besides the false identification of the rms current as containing a bad data, the results confirm the added accuracy of using the embedded DER monitoring system compared to

using raw measurements when monitoring the performance of DERs. This accuracy could be valuable when considering the utilization of measurements in determining control actions in the CPES.

#### IV. CONCLUSION

The growing implementation of distributed energy resources and the increased focus on distributed control of these resources entails added challenges in the cyber-physical energy system. With the added dependency on distributed control comes dependency on valid data from distributed energy resource measurement systems.

This paper describes the development, implementation and testing of a simplified state estimator, capable of efficiently removing gross measurement errors from distributed energy resource data measurements. The simplified state estimator is implemented on an embedded system and simulated in connection to a simulation model of a generic wind turbine generator. With the embedded system implementation, the measurements from the distributed energy resources can be processed and validated between data acquisition and data communication.

Simulation results show that the simplified state estimator has a fast execution time which offers utilization in current and future measurement systems. Compared to utilizing raw measurement data, the simplified state estimator has similar average Euclidean error as normal measurement error and can remove gross measurements, which shows its application potential in the cyber-physical energy system.

For future work, the bad data detector of the embedded monitoring system could be improved in terms of its ability to accurately identify bad data. A second proposed further research could be to try and validate the efficiency of the simplified state estimator by using real wind turbine measurements, and in the end, try to implement the system on a real wind turbine. A third possibility is to test the generality of the monitoring system by replacing the WTG state estimation model and applying the system on a different type of, such as a photovoltaic system.

**Abstract**—In this paper the authors present the results of research to develop the visual system for autonomous flying agent. The core elements of the vision system which were designed and implemented in the earlier stage of the project are brought together. The second aim is to show capabilities of a simulation environment designed and developed by the authors in order to enable testing of the vision systems (dedicated for Unmanned Aerial Vehicles) in the artificial environment. The first section of the paper introduces the testing (simulation) environment for MavLink-protocol-based autonomous flying robots. Next, the core elements of a vision system, designed for Unmanned Aerial Vehicle (UAV), are discussed. This includes pre-processing and vectorization algorithms, object recognition methods and fast three-dimensional model construction. The third part introduces a set of algorithms for robot navigation, solely based on vision and altitude sensor and compass. The paper concludes with the description of the tests and presentation of results where designed simulator was applied to show mentioned vision system elements operating together to execute complex task.

## I. INTRODUCTION

THE SIMULATION has always been important in the development of advanced robotic systems. Such a need is driven by a number of factors. The key one is the cost of the robotic solutions. Utilizing such environments for testing of the early versions of elements of the system, such as vision system and navigation algorithms, may help avoiding costly accidents [1]. Additional benefit of using artificial testing environments lays in short time between bug discovery, patch implementation and re-testing. This can lead to greatly minimized overall development and testing time.

The key questions that arise during the development of advanced UAV systems may be:

- 1) Are we sure how the robot will response to the input from navigation procedures and sensors?
- 2) Will it be able to accomplish the task within given time regime?
- 3) What are the limitations of communication protocol?
- 4) How will robot react if emergency situation, such as loss of communication with navigation module, occurs and how procedures for such event will work?

Artificial testing environment can help minimize the risk associated with these questions. Nevertheless, some uncertainty is related specifically with communication protocol which is utilized between navigational module (which includes

AI functions) and autopilot module which is responsible for execution of low-level tasks, such as robot's movement, power management, basic sensors reading (such as barometer, GPS, gyroscope). There is a number of existing simulators for particular UAV controllers and, on the other side, more general approaches, where testing environment is designed for abstract robot, not associated with particular communication protocol or controller model [2], [1]. The challenge is to create the testing environment which directly incorporates the communication protocol (such as MavLink) that will be used in real UAV. In such scenario the AI module sends the instruction directly to the navigation module utilizing the given communication protocol, but the system can be connected either to the emulated or real UAV.

The solution presented in this paper introduces an approach, which enables testing solutions that are ready to be applied on real UAV. It faces that challenge by combining emulation of robot which communicates via MavLink protocol with visualization of the simulated environment. The MavLink protocol (Micro Air Vehicle Communication Protocol) is one of the most popular protocols for communicating with robots' control stations (also called *autopilots*), sending commands and exchanging telemetry information. It is a lightweight, header-only protocol utilized by controllers such as Pixhawk PX4 (see <https://pixhawk.org/>), APM 2.6 (see <http://ardupilot.org/copter/>) or SLUGS Autopilot [3], [4]. Such approach in the design of UAV simulator allows not only to test a considerably wide range of solutions but also to directly use existing code to connect to real UAV, utilizing MavLink protocol, immediately after finishing simulated tests. This can be accomplished by simply changing the connection from the server representing emulated UAV to a real robot connected to PC via telemetry transmitter/receiver.

Such simulator can be applied in various scenarios. The most basic one would be testing of robot's reactions to movement requests, sent from the controlling application, where a graphical interface would allow observation of potential responses of the real robot and tracking unexpected behaviors. This simulator can be applied for testing of more sophisticated solutions. One of the typical classes of algorithms that can be tested in such simulator are object recognition [5], [6] and scene analysis [7], [8]. These problems are widely studied in

robotics and can contribute to the solution of more complex tasks, such as scene understanding and robot localization [9], [10].

The paper is structured as follows. Section II discusses the design and functionalities of the proposed simulator. Next section (see III) describes the core elements of scene analysis system. It briefly introduces algorithms for vectorization of the images, recognition of the objects in the scene and three-dimensional model building. In section IV the authors propose the set of methods for navigation of a UAV to allow operating in an urban environment, utilized in tests for the solution. Section V is dedicated for presentation of test showing capabilities of scene analysis system as well as the simulator. The scenario of the tests is based on the idea of UAV, equipped with visual sensor, operating in an urban environment. The main task of this robot is to locate predefined object in the scene and build a three-dimensional model of the located building (later in this paper the terms *object* and *building* will be used interchangeably due to assumption that the robot operates in an urban environment). The last section is dedicated for concluding remarks.

## II. ARTIFICIAL TESTING ENVIRONMENT

In this part the environment for simulating execution of a real UAV's tasks is introduced. The designed system is dedicated for testing UAV which utilizes MavLink protocol. The solution is based on combination of lightweight SITL (Software In The Loop) simulator and scene model which is generated in OpenGL environment. The whole system was implemented in Python language. The SITL simulator is provided alongside with libraries for communicating in MavLink protocol. It is aimed to allow simple tests of sending command to the robot and receiving telemetry information from it. When the simulator is started as a server in local machine it responds to the input as if it was a physical UAV using MavLink protocol. This is enough for testing simple commands of movement and receiving information from the robot. To allow the simulator to execute more complex tasks it was combined with OpenGL module which enables visualization of actions executed by a simulated UAV. The important outcome of this is the possibility to use OpenGL camera to work as a visual sensor of the robot. The input from that virtual camera is a source of information that can be provided to the complex scene analysis algorithms. By combining these two elements the researchers and developers are allowed to directly switch from using simulator to executing actions on real MavLink-enabled UAV, equipped with visual sensors.

The overall design of the simulated environment is shown in Fig. 1. In this system, the *UAV module* and *Image processing module* operate together as the central control unit. It processes information from sensors (video feed from OpenGL in the presented simulated environment), executes complex tasks related to image processing and conducts interaction with a physical flying robot or a simulated one (*SITL simulator*) like it is presented in this paper. Practically, this control unit is the main part of an unmanned flying agent responsible for

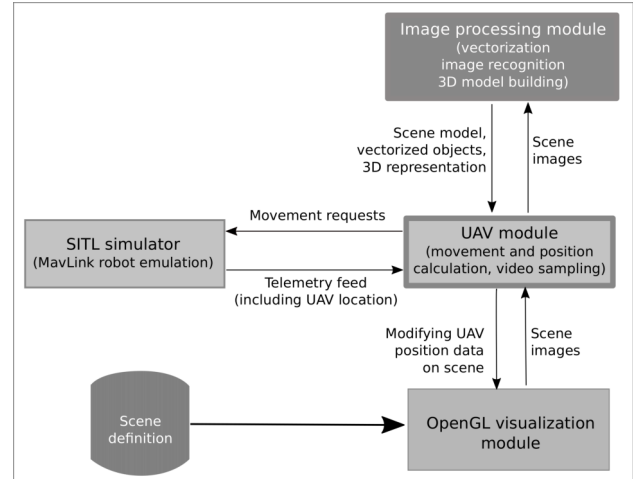

Fig. 1: Overview of the system modules and communication in the simulated environment.

all higher level functionalities over those that are ensured by *autopilots* such as PX4 or APM 2.6 and communicates with the *autopilot* with a use of the MavLink protocol.

## III. SCENE ANALYSIS ALGORITHMS

This section is aimed to briefly introduce a set of scene analysis methods that were combined to form a complete task for a UAV, tested in the simulator. These algorithms were designed and implemented in another part of the project to create the core elements of visual system for autonomous flying agent. More details about these methods and their possible applications can be found here [11], [12], [13]. These algorithms can also be utilized for solving more complex problems, such as cognitive approach to scene analysis and recognition [14]. Let us briefly introduce these algorithms below.

### A. Vectorization method

This method is aimed to obtain memory-efficient, vector representation of objects in the examined scene. The amount of information describing the shape of an object is limited to a list of points in Euclidean space which are located in the corners of the object. The steps which lead to creation of that representations are:

- 1) **Pre-processing.** As the pre-processing of the images is outside of the scope of discussed project it is assumed that objects that are subject for analysis have distinctive colors. This allows extracting objects from the image by filtering specific colors from predefined set.
- 2) **Border extraction.** The result of pre-processing which consists of extracted color shapes on the black background are subject for edge detecting process. To extract edges of the shapes, a recursive algorithm for two-dimensional edge detection is used [15].
- 3) **Point sequence generation.** A dense sequence of points, located along the edge of each object, is generated. The

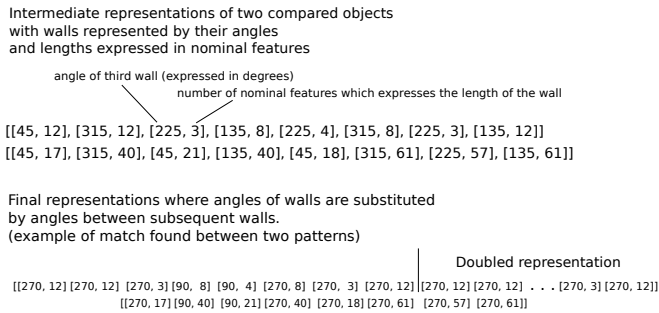

Fig. 2: Representation obtained from vectorized object, used for recognition process.

points are evenly distributed and the distance (calculated in number of pixels from original image) between them depends on predefined parameter. The distance has impact on shape description accuracy and the greater distance is, the less accurate description can be obtained with the increase of efficiency of the algorithm at the same time.

- 4) **Removing redundant points.** Some points are redundant in the sequence if they lay on the same line or change the path insignificantly. To remove them the Ramer-Douglas-Peucker curve simplification algorithm [16], [17] is utilized.

The final step is the enrichment of the object representation with information about its color. To do this a pixel located inside the outline of examined object is selected and its RGB color description saved along with the vector representation. Further it will be used to prepare images for 3D object model construction. The particular images, showing examined building from various sides (see section III-C) will be filtered to select only this color which is associated with the color of the object which was first vectorized and recognized based on the image taken from above. This is done to ensure that the contours that are discovered in the images taken during examination of the building belong to the desired (examined) object.

### B. Object recognition

For object recognition a syntactic algorithm was proposed. It allows a rotation and scale invariant matching which is crucial for UAV application as altitude and direction of flight may differ from one scenario to another.

In Fig. 2 the representation used in matching algorithm is presented. To allow rotation invariant matching, the representation of first object is doubled as it is highly probable that starting corner (first in vector representation) of one object is different from the one that belongs to the representation of compared object. More comprehensive information about this algorithm can be found in [11].

### C. Three-dimensional model building

Another application where the vector representation described above is utilized is three-dimensional object model

construction. Such a representation can be used in various applications. As an example we can consider ground inclination and obstacle shape approximation [18] and objects shape modeling for collision-free navigation and inspection tasks in an urban environment [13]. Such model is built using projections which are obtained from images taken from three sides of the examined object - top, front, right. This allows to create a simplified model carrying information about overall shape of the object as well as configuration of separate walls and features such as holes in object's structure. The process of model construction is divided into steps in which particular walls of the resulting 3D structure are derived separately, based on *reference* projection and two other projections which are cut into fragments and adjusted to form the third dimension. In Fig. 3 a process of single wall creation is presented, where a *reference* projection is the right one and top and front ones are being cut.

## IV. NAVIGATION METHODS

Some of the most important tasks for a UAV are target position calculation and path planning. They are exceptionally critical when operating in urban environment and during inspection tasks. In such applications robot is required not only to avoid obstacles (even when flying on high altitude) but also to position itself precisely to execute given tasks [10], [19], [20]

The scenario presented in section V require utilization of precise navigation as well. To support UAV with necessary capabilities the following methods were provided:

- 1) Calculating position of Points Of Interest (later referred to as POI) in the area photographed from high altitude. The POIs are related with objects (buildings) that, in subsequent steps, are subjects for recognition in order to find the specific one which shape is similar to one's that was initially stored in the robot's memory. Each POI has to be visited in order to collect an image revealing the exact shape of the object observed from position straight over it.

This calculation is done by a function *calcMoveTo-TargetHorizont()* executed for each POI. The function returns distance to North and East to a point in the photo, given as an argument. First the distances along *X* and *Y* axis (in pixels) are calculated with reference to the center of the photo which represents the point over which the UAV is currently located. Next, using information about drone's altitude (read from barometer sensor) given as an argument, those *X* and *Y* values are converted to real distances in meters. Finally the function uses drone's heading direction (read from compass) to count the real shift to North and East (as the image of the scene is not necessarily taken while the drone is facing North).

- 2) Calculating target position to collect images necessary for building three-dimensional representation of an object. This is executed once the UAV is positioned straight over the building which is recognized as the one to be examined.

(a)

(b)

(c)

Fig. 3: Steps of creating walls in 3D model building, (a) - cutting from projections, (b) - projecting onto a plane, (c) - intersection of intermediate walls

To accomplish this, the function *calcHeadingChangeForImage()* was introduced. It chooses the place and direction for the front and right-side photo of the building. The idea is to calculate the smallest rectangle that can be circumscribed on a figure of a building. For the *front* image we choose the side of the building associated with one of the longer edges of obtained rectangle. It is done so, because the *front* image is supposed to give the best overview of the examined building. After the front side is identified, the distance from the building is calculated

Fig. 4: Bitmap image of searched object provided to UAV.

using the camera's vertical and horizontal angles of view. The position for the second photo is set in front of the side of the building associated with shorter edge of the circumscribed rectangle. It means that direction in which camera has to be pointed is perpendicular to the direction in which the *front* side is photographed.

Finally, it is checked if any of two chosen points collides with any other object on the scene. If so, another possible point is searched. It means that the opposite side of the building is selected or distance from the building is changed if opposite side also gives colliding position. If there is no collision, the function returns heading changes and coordinates for both of the chosen spots.

## V. TESTS

This section presents the results of the tests to show capabilities of the simulator introduced in this paper. These test also bring in action the scene analysis algorithms discussed in previous sections - vectorization, image recognition and 3D model building. Test scenario is revealed step by step in this section and supported by figures showing most essential output. Let us briefly outline the scenario:

- 1) First, the UAV is provided with an image of the object (taken from above) which is going to be searched in the simulated environment.
- 2) The robot, using the image of the scene taken from high altitude, locates objects in the scene and calculates route to take more detailed pictures of each of them.
- 3) It flies over each object and takes detailed images from lower altitude. Each photographed object is compared with the searched one.
- 4) Once the searched object is located the UAV performs closer investigation of the building to collect images necessary for 3D model building.

In Fig. 4 and 5 a searched object and its vector representation is presented. This object is provided to the UAV to be located in the simulated environment. The vectorized object will be an input for image recognition algorithm discussed earlier in this paper.

Fig. 5: Vector representation of searched object.

Fig. 6: Scene generated in simulated environment, photographed by the UAV from high altitude.

Fig. 7: Vectorized image of the scene. Calculated destination points to take precise images are marked.

Fig. 8: Detailed image of yellow building.

The next figure (see Fig. 6) shows the first image taken by the UAV and represents whole scene with four buildings. To take this picture the UAV climbed up to predefined altitude of  $h = 45$  meters. In the following figure (see Fig. 7) the same scene is shown vectorized. This vectorization is done to allow UAV to find all structures in the scene and calculate target positions from where it will be possible to take more precise images. These images will further be compared with searched object to find the one for which the 3D representation will be built.

In the next step the destination points were added to the list. It was then provided to UAV module to initiate a task of visiting each point. After reaching each of the points from the list (at predefined altitude of  $h_2 = 20$  meters) a detailed image was taken (see Fig. 8, 10, 12, 14), vectorized (see Fig. 9, 11, 13, 15) and provided to image recognition algorithm.

The following figures (see Fig. 14 and 15) show the image and vector representation of the building that was recognized in the scene as the one that was searched. During this step, when the object was recognized, its RGB color code is stored along with vector representation. It will be used in next steps for proper extraction of objects photographed horizontally against other objects in the scene.

In this particular test it turned out that the *red* building was the last on the list and all buildings were visited before this

one. In more general scenario it is not necessarily the case as the searched object can be found earlier and the task of flying over all targets can be terminated.

After the searched object was recognized the UAV initiates next task to scan the object and build 3D representation. To accomplish this, the following target locations are calculated and provided to simulated UAV:

- 1) position over the building with UAV heading set to take a proper image which will be used as one of three projections (the *top* one).

Fig. 9: Vector representation of yellow building.

Fig. 10: Detailed image of purple building.

Fig. 13: Vector representation of blue building.

Fig. 11: Vector representation of purple building.

Fig. 14: Detailed image of red building.

- 2) turn the camera from pointing downwards to front in order to take horizontal images. In real UAV it can be done with the use of gimbal stabilizer.
- 3) position on the front side of the building to take *front* projection.
- 4) position on the right side of the building to take *right* projection.

Figures 16, 17 and 18 present images of the examined object taken by the robot from the above mentioned positions respectively.

In the next set of figures (see Fig. 19, 20 and 21) there

are vector projections of the examined object, obtained from above mentioned images. The RGB color code (red tint in this case), stored with vector representation of *top* projection, is utilized in this step in order to properly extract shapes of the objects in the images taken horizontally. This is done in image pre-processing by filtering out all colors that are different from the stored one.

The final step is the creation of three-dimensional representation of the object that has been found and closely examined. Figures 22 and 23 show the final result of three-dimensional model building algorithm.

Fig. 12: Detailed image of blue building.

Fig. 15: Vector representation of red building.

Fig. 16: Image of examined object taken from above. Direction is the same as for front image which makes it directly suitable for 3D model building.

Fig. 19: Vector representation of the object photographed from above.

Fig. 17: Image of examined object taken from frontal position of UAV.

Fig. 20: Vector representation of the object photographed from frontal position of the UAV.

Fig. 18: Image of examined object taken from the right side of the examined object.

Fig. 21: Vector representation of the object photographed from the right side.

Fig. 22: The result of three-dimensional model building algorithm.

Fig. 23: The result of three-dimensional model building algorithm presented from a different angle.

Fig. 24: The route of the UAV executing tasks in simulated environment. The locations from which the robot took images of examined object are marked.

Fig. 25: The route of the UAV shown from different angle.

Additional functionality of the presented simulator is the tracking of movement of the UAV. Figures 24 and 25 show the path that was followed by the UAV during the tests. It can be noticed that the robot started from the middle of the scene and immediately climbed to high altitude to take overview image of the scene (shown in Fig. 6). Then, on a lower altitude, all objects on the scene were visited in the sequence: *yellow, purple, blue, red*. Additionally, in Fig. 24 the points from which the UAV took images for 3D model building are marked.

## VI. CONCLUSION

In this paper the authors discussed the simulator for Unmanned Aerial Vehicle. Its characteristics, including MavLink protocol utilization, were introduced. The design of the simulator allows to connect AI both with navigation module directly to a real UAV which can shorten the time between development of the robotic solution and its implementation on a real UAV. The authors also introduced the vision system which was tested on the proposed simulator. The aim of the tests was to show that the vision system modules, such as object recognition and three-dimensional model building, can be combined to allow execution of complex tasks. The test results show the capabilities of the vision system which was applied for searching and analysis of the objects in the modeled scene.

The further work will be focused on extension of functionalities of the simulator. It will include monitoring of the UAV state, based on telemetry information send via MavLink protocol. Also, the visual module of the simulator will be developed to simplify switching from OpenGL view of the simulator to a vision sensor of a real UAV. In terms of vision system the cognitive module for close inspections will be developed. It will allow a robot to identify features and shape details of the examined objects and utilize the obtained information for navigation close to the structures.

# 1<sup>st</sup> International Conference on Lean and Agile Software Development

THE evolution of software development life cycles is driven by the perennial quest on how to organize projects for better productivity and better quality. The traditional software development projects, which followed well-defined plans and detailed documentations, were unable to meet the dynamism, unpredictability and changing conditions that characterize rapidly changing business environment. Agile methods overcame these limits by considering that requirements are not static but dynamic, while customers are unable to definitively state their needs up front. However, the advent of agile methods divided the software engineering community into opposing camps of traditionalists and agilists. After more than a decade of debate and experimental studies a majority consensus has emerged that each method has its strengths as well as limitations, and is appropriate for specific types of projects, while numerous organizations have evolved toward the best balance of agile and plan-driven methods that fits their situation.

In more recent years, the software industry has started to look at lean software development as a new approach that could complement agile methods. Lean development further expands agile software development by adopting practices from lean manufacturing. Lean emphasizes waste elimination by removing all nonvalue-adding activities.

## TOPICS

The objective of LASD'17 is to extend the state-of-the-art in lean and agile software development by providing a platform at which industry practitioners and academic researchers can meet and learn from each other. We are interested in high quality submissions from both industry and academia on all topics related to lean and agile software development. These include, but are not limited to:

- Combining lean and agile methods for software development
- Lean and agile requirements engineering
- Scaling agile methods
- Distributed agile software development
- Challenges of migrating to lean and agile methods
- Balancing agility and discipline
- Agile development for safety systems
- Lean and agility at the enterprise level
- Conflicts in agile teams
- Lean and agile project management
- Collaborative games in software processes
- Lean and agile coaching
- Managing knowledge for agility and collaboration

- Tools and techniques for lean and agile development
- Measurement and metrics for agile projects, agile processes, and agile teams
- Innovation and creativity in software engineering
- Variability across the software life cycle
- Industrial experiments, case studies, and experience reports related to all of the above topics

# Selecting Requirements Documentation Techniques for Software Projects: a Survey Study

Aleksander Jarzębowicz, Katarzyna Połocka

Department of Software Engineering, Faculty of Electronics, Telecommunications and Informatics,  
Gdańsk University of Technology, Gdańsk, Poland  
Email: olek@eti.pg.gda.pl, k.polocka@gmail.com

**Abstract**—A significant number of techniques dedicated to requirements specification and documentation is described in the available sources. As there is no purpose to use all of them, a selection has to be made, taking into consideration the context of a given software project, for example its size, usage of agile approach or stakeholders' technical competency. This paper is intended to provide guidelines for such selection. We reviewed several sources (mainly industrial standards) to identify the general approach to requirements specification and specific techniques they recommend for this purpose. We also proposed a set of attributes describing project's context. Then, we conducted a survey study involving 42 Polish IT industry professionals, asking them to select techniques applicable to different projects. The survey was followed by two interviews with experienced business analysts to interpret its results. The main contribution of the paper are selection recommendations based on results of survey and interviews.

## I. INTRODUCTION

Requirements Engineering (RE) is a part of the overall development process, which relies on interacting with customer representatives and other stakeholders and results in defining and maintaining system/software requirements. RE comprises of several activities, including discovering, eliciting, developing, analyzing, determining verification methods, validating, communicating, documenting, and managing requirements [1].

In recent years, a term of Business Analysis (BA) emerged, which is defined as the practice of enabling change in an enterprise by defining needs and recommending solutions that deliver value to stakeholders [2]. In case of software projects, it can be said, that RE is a part of BA, as the scope of BA is wider and includes activities focusing on financial and organizational issues affecting the customer.

Regardless of the names and definitions accepted, RE and BA are considered to be among most important areas of any software project, as they provide basis for all further activities and failures/omissions in this area result in serious problems affecting the overall development process and project outcome [3]–[5]. The significance of RE/BA resulted in publishing a significant number of sources describing processes and recommended practices. Such sources include international norms ([1], [6], [7]), industrial standards ([2], [8]–[10]) and books ([4], [11]).

The practices recommended include techniques to be used for particular activities e.g. elicitation or specification of requirements. A notable observation can be made, that despite the fact RE/BA has a long tradition and is considered to be a more disciplined (“heavier”) process, the influence of lean and agile approaches is becoming visible. Several titles known for years as established sources of information on RE/BA, in their more recent editions/revisions list techniques adopted from Agile methodologies (e.g. user stories, backlog management, on-site customer representative) [2], [4].

The number of RE/BA techniques listed in the sources mentioned above, as well as others, is very significant. The intent is usually to describe the tools available to business analysts, system analysts or other professionals responsible for RE/BA and to leave the choice up to them. To some extent, several complementary techniques can be used together e.g. different requirements specification techniques cover static, process or user interface aspects of the developed system. In general, however, techniques are usually at least partially redundant and a selection is necessary. Such selection should take into consideration the context of a given software project e.g. team size or development methodology.

In the research reported in this paper we focused on techniques dedicated to requirements specification and documentation, leaving out techniques used in other RE/BA activities (elicitation, validation, management etc.). We intended to provide a guidance on selection of such techniques in various project contexts. We also wished to include (among others) the specifics of agile projects to determine applicable specification techniques. Our general approach was to utilize the experience of business analysts (and other IT professionals working with requirements) for this purpose. The main research method was a Web-based survey study, additionally we interviewed two experienced business analysts to validate the study, as well as to analyze and further interpret the results.

The remainder of the paper is structured as follows: in Section II we describe the related work on applicability of RE/BA techniques and related practices to specific projects, tasks or purposes. Section III provides a background on requirements specification and documentation definitions in the available standards. The next Section IV describes our

preparatory research activities: first a set of requirements documentation techniques is selected for further consideration, next a list of attributes determining project's context is proposed. Section V presents the survey study conducted and its results. In Section VI we describe how the results were validated through follow-up discussions with the interviewed business analysts. Section VII concludes the paper with discussion of the findings and limitations of our study.

## II. RELATED WORK

The main group of related research is focused on selection of RE/BA techniques for a particular purpose or evaluation of such techniques with respect to their applicability.

The only work specifically focusing on requirements documentation techniques is reported in [12], where 8 such techniques were evaluated (by the authors) with respect to their potential expressed by inherent characteristics e.g. availability of graphical representation, ability to represent requirements' priorities, independence from a specific development methodology.

A wider study covering techniques from all RE/BA areas (including requirements documentation) is described by Jiang et al. [13]. They propose attributes to assess each technique's potential, a set of characteristics describing software projects and rules for selecting techniques in different contexts. It is a complex and mature approach, however documentation techniques considered by them differ significantly from those recommended in current standards, as they use e.g. formal notations like Z or more general methodologies like object-oriented analysis.

Hickey and Davis [14] conducted interviews with known software engineering experts, about applicability of RE/BA techniques for a number of hypothetical cases of software project contexts. Their study however considered requirements elicitation techniques only.

Also, several other papers on evaluation of RE/BA techniques with respect to their characteristics (e.g. abstraction level, effort, required skills), are available. They however focus on techniques from other areas, mostly requirements elicitation [15]–[17], but also analysis [18] or validation [19].

As we intended to cover some aspects of lean and agile development by e.g. considering projects involving smaller teams, following an agile methodology etc., the other area of related work concerns the application of RE/BA techniques and related practices to agile projects.

An initial assessment of RE/BA techniques to agile projects is described in [20]. Empirical analyses on usage of particular agile requirements practices in the industry, as well as related benefits and problems, were reported in [21]–[23]. A literature review based summary of agile requirement approaches (extracted from more general papers on agile practices) is presented in [24]. According to our knowledge, no work dedicated to systematic investigation on application

of various requirements documentation techniques in agile development was published.

## III. BACKGROUND

We use the terms of requirements specification and requirements documentation interchangeably and understand them as writing down the requirements using a suitable representation to capture their essentials. The terms however are not so obvious, considering the differences between standards. In this section we summarize how this aspect is described in norms and industrial standards. A summary of terms used by different standards is shown in Table I.

TABLE I.  
SUMMARY OF TERMS USED IN STANDARDS

Term	ISO/IEEE	BABOK	REQB	IREB	PMI Guide
Documentation				X	X
Analysis	X	X	X		X
Specification	X	X	X		
Modelling		X	X	X	X

The main international norm on requirements engineering is ISO/IEC/IEEE 29148 [1]. It superseded earlier documents [6] and [7], which however are still referenced by current industrial standards (e.g. [8]). These sources recognize the need of unambiguous requirements specification, but do not provide the detailed definition of specifying/documenting requirements activity. Instead, they provide the contents of system/software requirements specification documents.

Business Analysis Body of Knowledge Guide (BABOK) [2] defines a “Specify and Model Requirements” task, included in “Requirements Analysis and Design Definition” (one of six main areas listed in this standard). It therefore does not distinguish between specifying and modelling.

Requirements Engineering Qualifications Board syllabus (REQB) [8] lists “Requirements Specification” as one of main RE sub-processes, which concerns both requirements representation (as diagrams, user stories etc.) and contents of System Requirements Specification document. The available notations and forms of representing requirements are however described more thoroughly in “Solution Modelling” section, being part of “Requirements Analysis” process.

International Requirements Engineering Board syllabus (IREB) [9] introduces “Requirements Documentation” as one of four main RE activities. It also distinguishes “Model-based Documentation of Requirements”, where several modelling techniques are listed.

“Business Analysis for Practitioners. A Practice Guide” issued by Project Management Institute (PMI Guide) [10] in turn defines a major activity of “Requirements Elicitation and Analysis”, which includes (among others) the documentation-related tasks: “Model and Refine Requirements” and “Document Solution Requirements”.

TABLE II.  
REQUIREMENTS DOCUMENTATION TECHNIQUES IN BABOK AND PMI GUIDE

#	Technique name (and alternative names)	BABOK	PMI Guide
1	Business Rules Analysis (Business Rules Catalog)	+ (10.9)	+ (4.10.9.1)
2	Data Dictionary	+ (10.12)	+ (4.10.10.3)
3	Data Flow Diagrams	+ (10.13)	+ (4.10.10.2)
4	Data Modelling (Entity Relationship Diagram)	+ (10.15)	+ (4.10.10.1)
5	Decision Modelling (Decision Table, Decision Tree)	+ (10.17)	+ (4.10.9.2)
6	Functional Decomposition (Decomposition Model)	+ (10.22)	+ (3.5.2.2)
7	Interface Analysis (System Interface Table, User Interface Flow)	+ (10.24)	+ (4.10.11.2, 4.10.11.3)
8	Organizational Modelling (Organizational Chart)	+ (10.32)	+ (3.3.1.2)
9	Process Modelling (Process Flow)	+ (10.35)	+ (4.10.8.1)
10	Prototyping (Wireframes, Display Action Response)	+ (10.36)	+ (4.10.11.4)
11	Root Cause Analysis (Fishbone Diagram)	+ (10.40)	+ (2.4.4.2)
12	Scope Modelling (Context Diagram)	+ (10.41)	+ (4.10.7.3)
13	State Modelling (State Table, State Diagram)	+ (10.44)	+ (4.10.10.4)
14	Use Cases and Scenarios (Use Case Diagram, Use Case)	+ (10.47)	+ (4.10.7.5, 4.10.8.2)
15	User Stories	+ (10.48)	+ (4.10.8.3)
16	Acceptance and Evaluation Criteria	+ (10.1)	
17	Business Capability Analysis	+ (10.6)	
18	Business Model Canvas	+ (10.8)	
19	Concept Modelling	+ (10.11)	
20	Glossary	+ (10.23)	
21	Non-Functional Requirements Analysis	+ (10.30)	
22	Roles and Permissions Matrix	+ (10.39)	
23	Sequence Diagrams	+ (10.42)	
24	Stakeholder List, Map or Personas	+ (10.43)	
25	Ecosystem Map		+ (4.10.7.2)
26	Feature Model		+ (4.10.7.4)
27	Goal and Business Objectives Model		+ (4.10.7.1)
28	Interrelationship Diagram		+ (2.4.4.2)
29	Report Table		+ (4.10.11.1)
30	SWOT Diagram		+ (2.4.2)

Also, “Analyze Requirements” task explicitly refers to selecting a suitable requirements representation/model to work with.

#### IV. PREPARATORY RESEARCH ACTIVITIES

In this section we describe preparatory steps necessary to conduct the survey study. Preparation included two main activities: analyzing the available sources to extract particular requirements documentation techniques and

defining the attributes which characterize the context of software projects.

#### A. Requirements Documentation Techniques

International norms (ISO/IEC/IEEE 29148, IEEE 830, IEEE 1233) provide guidance on RE/BA processes and contents of system/software requirements specification documents, but not on particular RE/BA techniques (in fact techniques are rarely mentioned and only as examples). We therefore turned to industrial standards mentioned in Section III. Due to limited resources, we decided to use BABOK and PMI Guide to identify state of the art techniques of requirements documentation. REQB and IREB proved to be much more difficult to use. The initial review of their contents revealed that techniques are not explicitly listed (the whole text would have to be carefully scanned) and their descriptions are rather brief (if any at all – many techniques are only mentioned, not described).

The analysis of the contents of two sources: BABOK and PMI Guide resulted in identifying 30 requirements documentation techniques, together with their definitions/descriptions. Table II provides a summary of our findings, including references to the relevant sections of sources. Despite the fact that these two sources often use different names and sometimes include different variants of similar techniques, it was possible to match 15 out of 30 techniques as common to both sources. Short descriptions of these 15 techniques are given below, for more details and for definitions of the remaining techniques, the readers of this paper are directed to the source documents.

- **Business Rules Analysis** – A business rule is a specific, testable directive that serves as a criterion for guiding behaviour, shaping judgments, or making decisions [2]. Business rules analysis is used to identify, express, validate, refine, and organize the rules that shape day-to-day business behaviour and guide operational business decision making [2]. Business rules can be organized into catalogues which describe each rule using e.g. a unique ID, its type/category, description and references to related documents [10].
- **Data Dictionary** - A data dictionary is used to standardize a definition of a data element and enable a common interpretation of data elements between stakeholders [2]. A data element can be described e.g. by name, aliases, description, allowable values, validation rules [2], [10].
- **Data Flow Diagrams** - A data flow diagram illustrates the movement and transformation of data between externals (entities) and processes [2]. It identifies data inputs and outputs for processes, but does not specify the timing or sequence of operations [10]. It also includes the temporary or permanent repositories within a system or an organization (named data stores or terminators) [2].
- **Data Modelling** - A data model describes the entities, classes or data objects relevant to a domain, the attributes that are used to describe them, and the relationships among them [2]. It usually takes the form of a diagram that is supported by textual descriptions [2]. Entity Relationship Diagram can be specifically used for data modelling purposes [10].
- **Decision Modelling** - Decision models show how data and knowledge are combined to make a specific decision (straightforward or complex) [2]. Straightforward decision models use a single decision table or decision tree to show how a set of business rules that operate on a common set of data elements combine to create a decision, while complex decision models break down decisions into their individual components [2], [10].
- **Functional Decomposition** - Functional decomposition helps manage complexity and reduce uncertainty by breaking down complex systems and concepts into their simpler constituent parts and allowing each part to be analyzed independently [2]. This technique can be applied to decompose e.g. processes, systems, functional areas, organizational units, work products [2], [10].
- **Interface Analysis** - Interface analysis is used to identify where, what, why, when, how, and for whom information is exchanged between solution components or across solution boundaries [2]. An interface under consideration can be a user interface for humans interacting with software/hardware but also an interface between IT systems or processes [2]. System interface tables and report tables are more concrete tools for this purpose [10].
- **Organizational Modelling** - An organizational model is a visual representation which defines how an organization or organizational unit is structured [2]. It should describe the boundaries of the unit, the formal relationships between members (who reports to whom), the functional role for each person, and the interfaces (interaction and dependencies) between the unit and other units or stakeholders [2].
- **Process Modelling** - Process models describe the sequential flow of work or activities. Models can depict business processes (flow of task and activities within an enterprise) or system processes (control flow within an IT system) [2], [10]. Process models include activities, events, participants and decisions points [2], [10].
- **Prototyping** – A prototype is a representation of a system used to validate elicited requirements and to identify missing or incorrect requirements [2], [10]. Prototypes can be non-working models, working representations, or digital depictions of a proposed

solution. Various types of prototypes exist e.g. user interface drawings, mock up websites, partially working constructs of the system [2].

- Root Cause Analysis - Root cause analysis is used to identify and evaluate the underlying causes of a problem (or an opportunity) [2], [10]. It applies an iterative analysis approach in order to take into account that there might be more than one root cause contributing to the effects [2]. Specialized approaches like Fishbone Diagram or Five Whys are used to guide such analysis [2], [10].
- Scope Modelling - Scope models define the nature of one or more boundaries and place elements inside or outside those boundaries [2]. Scope models are typically represented as a combination of diagrams, matrices and textual explanations [2]. The name of context diagram is also used instead of scope model [10].
- State Modelling - State modelling is used to describe and analyze the different possible states of an object, allowed transitions from one state to another and internal activities within a given state [2], [10]. State diagrams and state tables are used to express such aspects [2], [10].
- Use Cases and Scenarios – They describe how a person or system (so called actor) interacts with the solution being modelled to achieve a goal [2]. Scenarios are written using a structured text as a series of steps performed by actors or by the solution [2], [10]. A use case usually describes several scenarios [2], [10]. A use case diagram can also be used to visualize relationships between use cases or use cases and actors [2], [10].
- User Stories - A user story represents a small, concise statement of functionality needed to deliver value to a specific stakeholder [2], [10]. A typical format of a user story is “As an <actor>, I want to be able to <function> , so that I can <business reason>” [10].

We made a decision to restrict the survey only to such common techniques (rows 1-15 in Table II). The reason was to keep the scope of the survey realistic. Our earlier experiences clearly indicate that it is difficult to find respondents to a survey with numerous and/or complicated questions and even more difficult to prevent them from dropping out before completion.

#### B. Attributes of software projects

Our aim was to prepare a list of attributes describing the context/situation of software projects. We intended the list to be short, in order to limit the number of questions in the survey. This approach was different if compared to e.g. [13], where 21 project attributes (each one with several possible values or ranges of values) were defined. Also, we wished to consider software projects from business analyst's point of

view and focus on issues essential to RE/BA activities, not software development or project management in general.

We reviewed several sources which proposed software project attributes or classifications of projects [4], [25]-[27] and used them as ideas to develop our proposals. The resulting list of attributes was:

- Development methodology used in project;
- Time available for RE/BA activities;
- Size of the team responsible for RE/BA;
- Level of quality expectations;
- Technical competence of stakeholders;
- Availability of stakeholders;

Please note that some attributes refer to the general constraints of the project (e.g. development methodology, quality expectations), but the others are narrowed down to RE/BA activities (e.g. time available for RE/BA instead of project's duration time or size of business analysts' team instead of project team size). The reason is that we considered such factors as more important for selection of RE/BA techniques.

## V. SURVEY STUDY

### A. Questionnaire development

Both sets obtained during preparation activities (i.e. the set of documentation techniques and the set of project attributes) were used to design survey questionnaire. In each question respondents were supposed to select documentation techniques, which they regarded as suitable for a given situation. As mentioned before, we intended to avoid complicated questions, so we derived those situations from project attributes by assigning specific values to attributes. For example, considering attribute “Development methodology used in project”, we decided to use two values: “Agile methodology” and “Formal, plan-driven methodology” (which does not have to be waterfall approach, but generally a “heavier” documentation-based process). Consequently, two separate questions about techniques applicable to projects using each of methodologies were included in the questionnaire.

In general, each question was phrased like “Which requirements documentation techniques would you use in the following situation: ...?” and referred to 12 situations of software projects:

- A project developed according to an agile methodology (*Agile Meth.*);
- A project developed according to a more formal, plan-driven methodology (*Formal Meth.*);
- Enough time for business analysis in a project (*More Time*);
- Time available for business analysis is short compared to anticipated scope (*Less Time*);
- A larger team (more than 3 persons) of business analysts (*Larger Team*);

- A smaller team (up to 3 persons) of business analysts (*Smaller Team*);
- High level of product quality expectations (with respect to e.g. reliability or ergonomics) (*Quality*);
- Stakeholders with high technical skills/competence (*High Skills*);
- Stakeholders with low technical skills/competence (*Low Skills*);
- Good availability of stakeholders, who can dedicate their time to the project (*Good Avail.*);
- Low availability of stakeholders, who can spare little time to the project (*Low Avail.*);
- Survey participant's free choice - if he/she was able to choose techniques according to his/her own preferences (*Own Pref.*).

Expressions in parentheses are identifiers of questions. They are used in the remainder of this text when referring to questions, especially in tables and figures.

It can easily be spotted that for each of project's attributes two situations were defined. The only exception is "Level of quality expectations" - we only asked about a situation of high expectations (e.g. high integrity systems). An additional question about respondent's preferences regarding documentation techniques was included instead, as we expected that such factor can influence answers to other questions.

Our target group of survey participants were IT professionals from Polish industry (business analysts and others involved in RE/BA activities). We did not decide to expand the study to include professionals from other countries, because of anticipated problems of reaching out to

them. The language used in questionnaire was Polish, all questions and answers cited in this paper are translations.

A questionnaire was prepared using a web-based Typeform tool. It was divided into two parts: the first gathered context information about survey participant's background (age, gender, job position, experience in RE/BA), in the second part questions about selection of requirements documentation techniques for various situations were included.

Each question about techniques' selection was a multiple choice question. Survey participant was allowed to choose any number of techniques he/she considered applicable in a given context (including none or all of them). 15 techniques (see Section IV.A) were available as possible answers. The participant was also able to choose "Other techniques" option and enter technique(s) in addition to the ones selected among the predefined ones. The design of the questionnaire ensured that possible answers were displayed in randomized order. The reason was to stimulate more awareness of survey participants and reduce mechanical answers. The survey was anonymous, but optionally a participant could enter his/her e-mail address to receive summary survey results.

The questionnaire was verified in a pilot survey involving 3 test participants of different background (junior analyst, senior analyst, product manager). Their feedback (e.g. concerns about clarity of some questions) was used to improve questionnaire contents. The full scale survey was delayed until all 3 test participants approved the modified questionnaire.

TABLE III.  
SURVEY RESULT SUMMARY – SELECTIONS OF DOCUMENTATION TECHNIQUES FOR PARTICULAR PROJECT CONTEXTS

	Agile Meth.	Formal Meth.	More Time	Less Time	Larger Team	Smaller Team	Quality	High Skills	Low Skills	Good Avail.	Low Avail.	Own Pref.
Business Rules Analysis	11	29	36	5	28	12	28	15	13	26	6	12
Data Dictionary	12	26	28	7	23	13	17	18	15	21	8	14

User Stories	38	7	18	34	16	29	16	9	35	16	26	4

### B. Survey study and its results

We started the survey by publishing the questionnaire in the Internet and inviting participants. We invited them using personal contacts, direct mailing and online discussion groups dedicated to business analysis topics.

Answers were collected during an approximately two-month period. In total 42 persons participated in the survey. Most of them (25) were employed as analysts (business analyst, system analyst, IT analyst – different names of job positions were declared). Other most frequent job positions included managers, developers, consultants and testers.

Table III presents summary results of the survey. Its rows represent documentation techniques, while columns represent questions about particular situations (using symbols introduced in Section V.A). Numbers in table cells indicate how many survey participants decided to select a given technique in a given context.

As there were very few cases when “Other techniques” were suggested by survey participants (literally 3: Story Maps for *Agile Meth.*, Enterprise Architecture Modelling for *Formal Meth.* and Glossary for *Low Avail.*), we do not present them in Table III nor include in further analysis.

We analyzed the answers for particular questions (table columns) to identify the most and least frequently selected techniques. We used quartiles for this purpose. Techniques from the first quartile (techniques among 25% of least selected) are highlighted using red color, while techniques from the third quartile (25% of most frequently selected) using green color. As the numbers of answers in columns differed (due to multiple choice questions used), the quartile values are significantly different as well.

A number of observations can be made with respect to survey results:

- In general, more techniques were selected for situations where business analysts are not restricted in their work (*More Time, Good Avail.*) or a need for a more documented approach is recognized (*Formal Meth., Larger Team*). It is a rather intuitive and not surprising result.
- Quite surprisingly, Use Cases and Scenarios were frequently selected in literally all situations. The reason could be that this technique can be applied on different levels of detail - from structured, scenarios including detailed interaction steps, pre&post conditions, exceptions, alternatives etc. to simpler descriptions of user's goal and brief interaction summaries [28]. Also, such choice can stem from respondents' preferences, as this technique was the most preferred one (*Own. Pref.*).
- User Stories were selected for Agile contexts, both in terms of assumed methodology (*Agile Meth.*) and typical conditions (*Less Time, Smaller Team*). However, our participants recognized this technique more applicable in case of low stakeholders' availability (*Low Avail.*), while rather the opposite

(*Good Avail.*) is assumed for Agile development (e.g. customer representative on site).

- The second preferable technique (Prototyping) was among the most frequently chosen ones for agile-like situations, but not for other contexts.
- Process Modelling was also declared as applicable in almost all contexts, with a clear exception for the situation of very limited time for BA (*Less Time*). As for high quality demands (*Quality*), it just narrowly did not make to the third quartile.
- Most of other techniques based on models and graphical notations were either not found applicable by survey participants (State Modelling) or found applicable only in limited number of situations (Data Flow Diagrams, Data Modelling, Organizational Modelling).
- Techniques based on causes and consequences analysis (Decision Modelling, Root Causes Analysis) were generally not considered usable by our respondents. A possible explanation is that such techniques are important for specific classes of systems (e.g. the cause and consequence analysis as input for risk estimation in case of high integrity systems), but not necessarily very popular outside such context.

The data from Table III can be processed and used to visualize applicability of techniques to a given situation. Examples are presented in Figures 1-7, the other graphs cannot be included here due to space limitations, but all of them are available in a report published on line [29]. The numbers in each figure indicate how many respondents selected a given technique for the context given in figure caption. Moreover, colors are used to visualize quartiles (1<sup>st</sup> - gray, 2<sup>nd</sup> - light blue, 3<sup>rd</sup> - dark blue).

## VI. INTERVIEWS

We planned interviews as a way to assess the validity of the survey study and its results. Moreover, we expected discussions leading to interpretation of results (especially more surprising ones). Validation interviews were conducted with two experienced business analysts, of the following background:

- Analyst 1 – 10 years of employment as business analyst in several software companies. Main experience in: business processes improvement and development of customer-tailored systems for various business domains, including: insurance, finances, courts of law, electronics and telemetry. Involved mainly in projects using plan-driven, formalized development methodology.
- Analyst 2 – 8 years as a business analyst, mainly in projects using agile methodologies. Main professional experience in: requirements elicitation, business process modelling and reengineering. Work history in: finances, e-commerce and transportation application domains.

Each interview was conducted in a separate and independent manner. Before each interview, a report summarizing survey results and analyses was sent to the interviewed analyst. The interviewees were asked to consider the following issues:

- Is the report comprehensible or does it contain any ambiguous fragments?
- Was the survey and analysis of its results conducted in correct and valid manner?
- Is the analysis of results complete or should the data be processed in different way?
- What further directions would be recommended in this research on documentation techniques?

It should be noted, that both analysts represented industry practitioner's point of view and provided answers from such perspective, not e.g. research methodologist's perspective. This was however intentional, as we wished to confront our research with the reality of IT industry and its needs.

Analysts 1 and 2 first provided their answers in writing, then face to face meetings with each one took place to discuss their opinions. Both analysts confirmed that they consider survey results as a useful source of information, providing possible support for techniques selection in real-life projects. Both of them however also stressed that survey results cannot be solely used as selection criteria, because there are more factors influencing such selection, which should be taken into consideration.

They had no concerns about survey validity and concluded that in general the results are consistent with their perception of techniques' applicability. There were however some exceptions, the greatest concern was about "Use Cases and Scenarios", which (according to survey participants) was found applicable to all specified situations.

Analyst 2 suggested, that results could be biased by answers of inexperienced practitioners, who made their choices on the basis of their expectations rather than real experience and job history. To verify such possible explanation, additional analysis was conducted. As the raw data (exported by Typeform tool) included the necessary information (one of the introductory questions was about professional experience in RE/BA), we were able to divide answers into sets according to respondents' declared experience. Then, we used quartiles to identify most frequently selected techniques within each set. No particular differences were found for situations questioned by Analyst 2 between the answers of less (<2 years of experience in RE/BA) and more experienced (2-5 years, >5 years) survey participants.

No other concerns questioning validity were raised, the general feedback was positive and the outcome of the discussion consisted mostly of possible future research. Suggestions about the issues related to requirements documentation techniques that would be interesting to the interviewed analysts were included in our directions of future research (described in concluding Section VII).

## VII. CONCLUSIONS

We conducted a survey study dedicated to the selection of requirements documentation techniques in different software project contexts and situations. The study was preceded by preparatory activities: we identified a number of techniques recommended by industrial standards and established a set of software project attributes, later used as a basis for defining project context/situations. The survey targeted practitioners from Polish IT industry (mainly business analysts) and was completed by 42 respondents. Its results were processed, analyzed and validated through interviews with two RE/BA experts. These results can be used to support business analysts who face the problem of techniques' selection for a specific project. The results cannot however be treated as the only possible criteria, disregarding any other factors.

The results can be used as guidance or practical tips for business analysts. If such analyst determines the context of his/her software project with respect to the methodology used, time available for analysis and other aspects described in Section IV.B, he/she can refer to Table III and/or more convenient visualizations (Figures 1-7, additional report [29]) to identify a set of techniques most suitable for such project. For example, in case of a plan-driven project with sufficient time and a small team of analysts, "Use cases and Scenarios" and "Process Modelling" would be recommended (1<sup>st</sup> quartile in each situation). The decision about using one or both techniques would have to be made by the business analyst, also taking into consideration: (1) project needs (e.g. are there complex business processes to understand and describe); (2) how redundant candidate techniques are.

Our study obviously had several limitations. Some of them are simply the effect of decisions made during study's design

– we restricted the number of documentation techniques, the number of project attributes and furthermore the number of situations derived by assigning particular values to such attributes. As result, none of these sets can be considered exhaustive i.e. covering all possible relevant options. The survey used a Web-based questionnaire and was intended to be anonymous (requiring personal data is problematic on legal grounds and a good way to discourage potential respondents), therefore we cannot have absolute certainty that our respondents provided true information about their background. Also, we cannot be sure that the surveyed group is representative in the context of Polish IT industry. As the survey was limited to one country only, its results cannot be simply generalized for European or worldwide software industry (even though IT industry in Poland is not significantly different compared to other European countries).

A number of directions for future research can be considered. A more complete identification of project attributes and their values can be attempted. We are aware that it is rather impossible to list all potential factors influencing business analyst's choices, but an effort can be made towards improving this aspect of our research. It is also possible to expand the set of documentation techniques (by including items 16-30 from Table II and/or techniques recommended by other sources). We do not find this direction very promising though – our survey participants could manually enter additional techniques they considered useful and only 3 such cases were found (for 42 respondents, each answering 12 questions). However, considering variants of already included techniques e.g. particular notations for Process Modelling or distinguishing between brief and detailed Use Cases could provide more insight. Another direction is an attempt to capture not only decisions about techniques selection, but also the rationale behind each such decision. It however would require a different kind of study, based on interviews rather than questionnaires. Moreover, a wider survey study, involving respondents from different countries can be conducted.

Email: {pawel.markowski, mrp}@pjatk.edu.pl

**Abstract**—The aim of this paper is to show the strengths and the weakness of process mining tools in post-delivery validation. This is illustrated on two use-cases from a real-world system. We also indicate what type of research has to be done to make process mining tools more usable for validation purposes.

## I. INTRODUCTION

THE lean department of a real-world company asked us to check the control system of a production line against the expected cycle of manufacturing. This is the usual process of validation in lean manufacturing and software development [1], [2], [3] — since in such methodology there is no up-front design, one evaluates in the working environment whether the implemented system meets the expectations and needs of the principals. The lean department is responsible for production process optimization that leads to overall increase in efficiency. They focus on layout optimization and usability development to ensure best environment to work and high throughput. They decided to try new methods of material flow analysis by leveraging process mining features. Our evaluation is aligned with lean thinking adopted by the company.

We gathered the data from the warehouse management system and production line (presented in Table I) and used them to discover the real process that was followed by the mechanical parts manufactured on the production line. Our main tool in process-discovery [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], [15] was an open source platform ProM [16] with various plugins (i.e. Directly-follows Graph, IVM, Discover Graph). After examination of the discovered processes by the principals, serious anomalies were discovered, which led to the reimplementation of the system. However, not all of the processes were actually discovered *correctly*. Despite feeding them with information about the duration of each action in the process, the mining algorithms were unable to discover correctly the parallelism of the actions. Consequently, they produced large clumsy and meaningless diagrams. This shows the limitations and weakness of the currently available methods.

The paper is organized as follows. The next section describes the gathered data and the platform that was used to mine processes. In Section III we describe the use-case of warehouse moves and the corollaries of our analysis. In Section IV we deal with a use-case containing parallel actions and show that contemporary algorithms fail to mine a useful

model. The paper is concluded in Section VI, where we also suggest some further research in the area of process discovery.

## II. DISCOVERING PROCESSES

Discovering processes from event logs requires a collection of events with timestamps and case ID, which identifies instance of executed process. Timestamps allow process mining algorithms to transform the data into diagrams, which represent discovered models. According to a given set of parameters model accuracy can be different. By leveraging more features it is possible to i.e. receive a less accurate graph, which may be easier to analyze or interpret. For the validation of the system we used ProM software (version 6.6). We split tests into two parts — the first one is the classic process discovery with events triggered sequentially. In the second case, some of the actions were executed in parallel. It requires proper approach, which will be able to identify specific flows with parallel actions.

There are many methods and forms of storing event logs of information systems. Each solution may have own approach how to collect and store event logs. When an event occurs, the system generates a set of data about the action that triggered the event. Information included in it can be stored in a specified location, like raw file or a database record. There are often special rules that indicate, which information should be stored in the log. Many systems have different levels of log detail, which can be setup during configuration. To start working with process mining tool ProM, we have to deliver an unified log file. ProM allows conversion from CSV to XES format — an XML uniform format of data recognized by the platform. It has a dedicated creator module that allows a user to easily perform transformations. The greatest issue here is the quality of data stored in log files.

## III. CASE: WAREHOUSE MOVES ANALYSIS

We focused on warehouse movement analysis. The system was modified to record each move performed in the warehouse area. It ensured better understanding of daily basis operations and, hopefully, will help in further optimization processes in the department. We collected event logs (shown in Table I) that describe actions with precise timestamps. Case ID reflects single pallet of goods.

A discovered model of the process, shown on Figure 1, has accuracy comparable to human expert knowledge about the

real model of the process. The discovered model distinguishes two areas, which have different starting points.

The first one is a warehouse responsible for storing inbound components. Most of part numbers have additional quality control, which is performed by internal laboratories. Quality inspectors control incoming wares and change status after measurements. Prototypes and parts conforming to the standards and specifications are stored in warehouse racks and shelves. Production department order trigger move in warehouse that leads to release of a proper number of parts.

The area that is responsible for the shipments (outbounds) is described on Figure 1. It starts from “produced” action. Produced goods are stored in outbound warehouse. Goods can be put into specified rack or can be directly moved to carriers’ truck. When the truck arrives, warehouse employees use terminal that gives them information about, which pallet have to be loaded into the track. The system enforces compliance with FIFO methodology.

Streamlining just in time production is one of the most

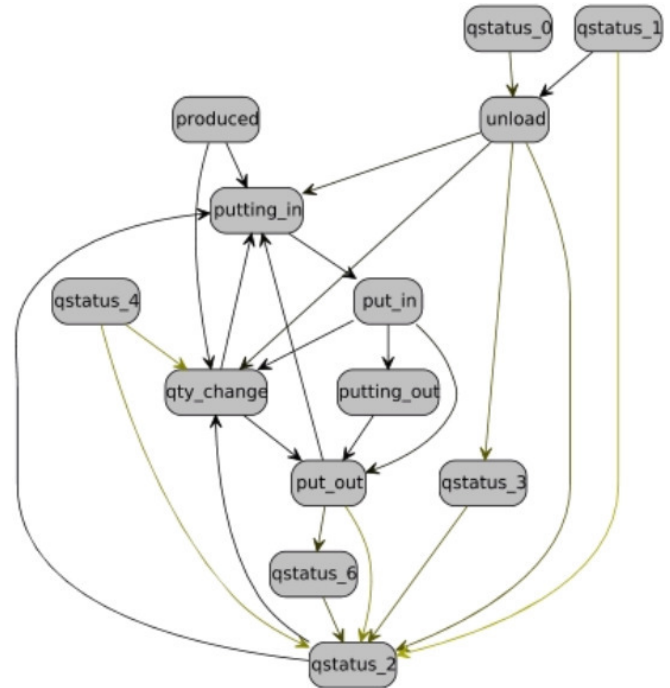

Figure 1. Process discovered by ProM Casual Activity Graph from event log presented in Table I.

valuable optimization for the company. Improvement will be apparently visible in key process indicators. Parts are stored in warehouse in a racks after production what is presented on Figure 2. Storing wares on shelves leads to freeze assets that could be used to gain competitive advantage. Figure 3 mined by Inductive Visual Miner presents goods flow in a warehouse. It gives a possibility to monitor moves on the animation with a time-line and filters. Presented activities can be tracked and verified. The company has to focus on production plans and on reorganization of the transports, which leads to downsizing time that stored staff spends on shelves. Modern process mining algorithms, implemented in ProM software, can perfectly reflect process model [17], [18], [19], where actions are not performed in parallel.

#### IV. CASE: PRODUCTION TRACEABILITY LOGS WITH PARALLEL EVENTS

Most of the production lines have specialized, dedicated software solution, which is responsible for collecting production events log. This kind of solution is required for most demanding and restrictive areas like pharmacy or automotive. This functionality gives an opportunity to recall from the market specified batch of defective items. Without traceability and its archive module company won't be able to specify, which item batches have to be removed from the market.

The production line has dedicated traceability database: Microsoft® SQL Server® 2008 R2 SP2 – Express Edition. In this paper we analyze a part of the line from the perspective of human ↔ machine interaction, which is realized by parallel

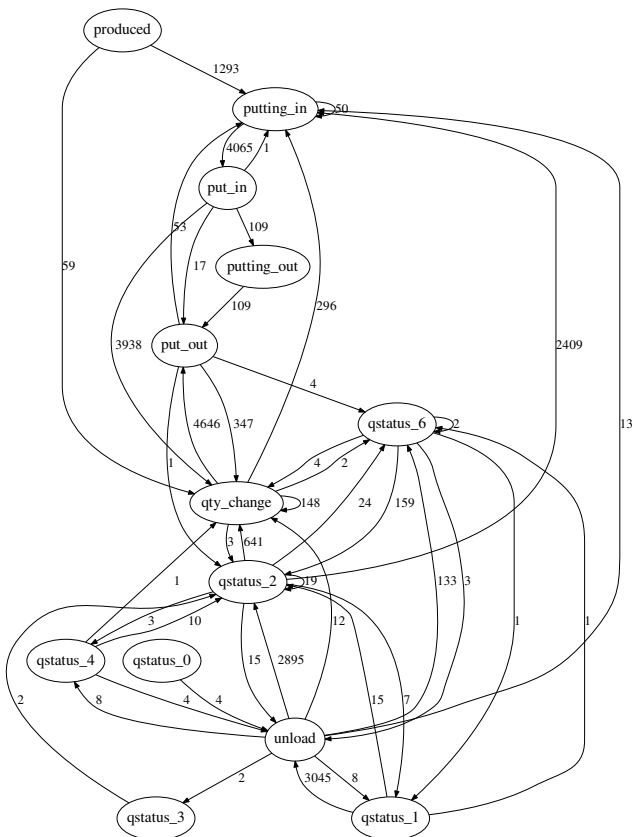

Figure 2. Process discovered by ProM Directly Follows Graph from event log presented in Table I.

quality inspection tasks. Operator activity records are stored only when a person rejects a given part during a specified operation.

An operator is a person responsible for supervising process performed on the station. Visual inspection of the components that are loaded to a machine and final product check are crucial and can minimize scrap costs. When operation is done, operator checks an item to minimize risk of defectiveness / incomplete produced item. If an item has been rejected earlier, the organization covers a lower cost of the scrap. The cost includes i.e. production time, components used during production process, energy, machine utilization, spare parts and so on. During quality validation operators can mark part as rejected (not valid) with an error code, which describes rejection reason.

Operations performed on a machine are recorded in a separated database table. This database contains identifiers of produced parts or its batches. Additionally, there are attached operation parameters and sensors values, which describe the results of each operation.

From the process mining perspective, there are interesting parallel activities between a machine and an operator involved in the production step.

Logs from each operation are stored in independent tables. To ensure proper model recognition consistent file log is required. Source log file has to be combined from extracted data tables. One of the tables contains information about visual inspection performed by human.

HMI panel is installed on the machine 605. This device allows operator to mark an item as rejected. It occurs when the item does not meet quality restrictions during visual inspection. During production process events together with their parameters are stored in the database archive. Operations OP605 and OP605HMI are parallel activities whose time of execution is the same.

In this case, timestamps with information when each single item was completed on the stations are the same. Unfortunately the discovered process was flattened and its actions were shown as if they had been performed sequentially. Figure 4 represents graph, where operations OP605 and OP605 HMI are executed one after another. This flow is not align to the existing process implemented in the production process.

## V. PARALLEL ACTIVITIES

For the validation, a subset of production line was checked by the algorithms implemented in ProM tool. The production line logs stored in the database have a various number of columns. These columns contain information about serial numbers, specified models, item status/error codes, cycle times and lot of parameters measured during a specific operation. We calculated the starting time of actions using the ending time of operations and the cycle time. Information about intervals was loaded to ProM XES file. The Start Time and Completion Time have been entered in PROM CSV to XES converter. The result of this operation was similar, because discovered process diagram had the same sequence. A single action was split into two separated actions (i.e. OP605 Start and OP605 Completed).

Results of the generated model (Figure 5) compared to the layout elaborated by a team of engineers do not reflect parallel operations performed at the set of machines.

## VI. CONCLUSIONS AND FURTHER WORK

This paper describes some aspects of a validation of the process of manufacturing mechanical parts on the production line, which is aligned with lean thinking adopted by a real-world company. We successfully applied available process mining algorithms to validate the production line and provided valuable suggestions to the lean department. On the other hand, the algorithms were of no use when it came to the discovery of highly parallel processes. Moreover, feeding the algorithms with additional knowledge about the duration of each action in the process did not help. This suggests that to make process mining tools more beneficial for the validation purposes, further research should focused on parallel process discovery (with and without additional information about duration of the actions).

Wrocław, Poland

Email:

stanislaw.plebanek@lean.org.pl

**Abstract**—The paper investigates whether the user-interface interaction can be shortened with the use of process improvement methods. Similarities between office or factory work and interacting with a user interface have been noticed. Based on that a relevant process improvement method has been selected and applied to analyze different cases of interactions between a user and an interface. This analysis has shown that process improvement methods enable identification of interface elements to be modified in order to shorten the user-interface interaction. Additionally, the method has been found to be a way for facilitating identification of ideas for new services.

## I. INTRODUCTION

AS users of devices, we deal with User Interfaces (UI) every day: switching the TV channels, setting the temperature in a car or buying things through vending machines. Some of these interactions with interfaces are more memorable than others. Especially when the interfaces are so poorly designed that while using them one can easily notice the waste of time caused by steps or screens displayed at the digital interface which are irrelevant for the current customer. This experience is even worse when one interacts with a poorly designed interface when being under time pressure. As a result of using an interface with a poor usability the users get frustrated, can make errors [1] and thus the interaction takes more time than it could.

On the other hand, there is a well-developed body of knowledge that deals with process improvement. Organizations like factories, banks, design offices, hospitals, accounting and others strive to improve their processes. They use standardized work [2], SMED [3], TWI-JM [4], MTM [5] and other methods to improve safety, increase productivity or improve process quality.

Being a user who interacts with UI's and being a bank or factory employee – the similarities exist. In both cases, the person executes some kind of a process. According to a definition process is “a series of actions or steps taken in order to achieve a particular end”. Therefore selecting

certain icons on the screen or any other user-interface interaction which leads towards achieving the desired goal is also a process. And if it is a process, it leads to a question: can the user-interface interaction be improved with the use of process improvement tools? Which process improvement tools should be applied in order to improve the user-interface interaction?

## II. PROCESS IMPROVEMENT

### A. Methods for improving user-interface interaction

Improving user interactions is part of improving the usability of an interface. For that purpose several methods have been already developed including: customer journey map [6], service blueprinting [7] or the GOMS model [8]. Additionally there has been work conducted on applying Lean Management principles to improve User Experience [9]. Out of the above mentioned methods only the last one is somehow related to the process improvement tools. However it focuses on how to manage the product or service design process and does not go into detail on how to identify improvement potential at the level of interactions between the user and the interface of a device.

### B. Training Within Industry

Out of identified process improvement methods one is relevant to improve the work with the machine interface: the Training Within Industry – Job Methods [10] which is part of the original Training Within Industry (TWI) program.

The whole TWI program was created during II World War by the United States Department of War. It was developed for the American industry which started running short of personnel because of a large number of men in productive age fighting in the war. Industrial companies had to start to employ women as welders, riveters or milling machine operators even though they were not skilled for those positions. The program was dedicated to mid- and low-level managers. Its aim was to quickly develop new, talented production employees in order to achieve increase in productivity and quality [11].

The research leading to these results has received funding from the European Union Seventh Framework Programme (FP7/2007- 2013) under grant agreement n° 609143. The paper reflects only the author's views and that the Union is not liable for any use that may be made of the information contained therein.

TWI program focuses on developing Five Needs of supervisor: knowledge of work, knowledge of responsibility, skill in instructing, skill in improving methods, and skill in leading. These needs have been taught in relevant parts of the training: Job Instruction, Job Methods, Job Relations, Union Job Relations and Program Development [13]. Training Within Industry – Job Methods (TWI-JM) is the element of the program that helps to develop the supervisor's skill in improving work methods. It is an analytical tool that helps to understand the current state of a process and give insights how it can be improved in terms of productivity, quality [11], and also safety, ergonomics and comfort. The TWI-JM method consists of 4 steps. Step number 1. "Break down the job" helps to answer the questions: How the activity is performed? What are the subsequent steps? and is concluded with a list of steps. Step number 2. "Question every detail" answers why the activity is performed that way. In this step 5W1H questions (Why is it necessary? What is its purpose? Where should it be done? When should it be done? Who is best qualified to do it? How is the 'best way' to do it?) are being used. Step 3. "Develop the new method" helps to understand if there are other ways the work can be performed in a better way in terms of effort, quality etc. There are four types of improvements possible: elimination of unnecessary details, combining details, rearranging them for better sequence and simplifying details. This step concludes with a proposed new method written down to the level of subsequent steps. Step 4. "Apply the new method" helps to get final approval of all employees concerned including other operators and a manager. It concludes with the method being in use. [14]

### III. TWI-JM FOR IMPROVING USER-INTERFACE INTERACTION

TWI-JM has been selected to be a methodological base for improving user-interface interaction. In order to meet this purpose the method has been adapted and is presented in Fig. 1. Improving a user-interface interaction bases always on existing products or services. Therefore the method should be applied for a specific product or service. It cannot be applied for a product idea or concept nor for a generic product. Like the first principle of Lean Management [15] the developed method focuses on the customer – it does not enhance improving the interaction from other perspective than the users' one.

The method starts with selecting a process that will be analyzed and improved. The user may interact with an interface of one device for multiple reasons – the method requires selecting one of those reasons and a process associated with it. Processes differ from each other and can be analyzed one at a time. Changes in the interface may

positively impact one process, but they may negatively influence the other ones. Therefore it is important to start the analysis from those processes which are most important to the specific users' group. Selection of those processes should be done together with the users. The most important processes may be ones that take the most of the time a user interacts with the product. These may also be those processes that strongly influence the quality of the work being done with the use of the product (e.g. setting processing parameters at a machine). These may also be activities that most significantly prevent the product from being used the way the user would like to use it (e.g. activities preventing a manufacturing machine from producing, like changeovers or maintenance). The most important processes may also be ones that don't take a lot of time but are done at the time where there is an accumulation of tasks (e.g. preparing the discrepancies report at the end of month by an accountant).

After selection the process needs to be deeply understood. It is done by observations at the place where it is conducted and by breaking it down into steps. In this step filming the process may be of help. It enables people using the method to repeat watching certain steps of the process in order to better understand what has been done and reflect on it.

After breaking the process down the way the process is conducted needs to be questioned. 5W1H questions are being used at this step. They help to understand if there are other ways the interface could be organized in order for the interaction to be shorter or to provide better quality. It is important to ask these questions in the order provided (Why is it necessary? What is its purpose? Where should it be done? When should it be done? Who is best qualified to do it? How is the 'best way' to do it?). That is because if one questions the aim of the step and has the idea to eliminate it there is no need to think how to conduct that step in an improved way. The results of this detailed analysis are insights on what prevents the product from better meeting the user needs in terms of efficiency, ergonomics or more generally in terms of usability.

The last stage of the method is the definition and selection of improvements. The steps which have been questioned during 5W1H analysis are being brought to attention. For each of them brainstorming should be organized in order to generate improvement ideas. In order to decide the implementation scope and order each of the ideas should be assessed whether it's easy or difficult to implement and whether it is perceived by the user as of high or low effect. After deciding which improvements should be implemented (first the easy ones with high effect) the last part of the method is to put the ideas in life and apply the new way the interface is interacting with the user.

Fig. 1 Method for improving user-interface interaction for a certain product/service

## IV. RESULTS

The above described method has been applied in various scenarios: from buying a train ticket via a vending machine, through a changeover of an electric-discharge machine to entering address in a car navigation system. These cases have been selected because a relatively significant portion of user time is spent on active interaction with the user interface. In these cases the user needs to take a decision,

press a button, set a value etc. in contradiction to waiting for the device to process an information or conduct a process without or with a relatively small amount of user activity. The method provides best results for those types of user-interface interactions. Below buying petrol at a self-service petrol station has been described in detail in order to describe the method in practice. It has been selected as it is not a complex nor a long process and therefore it is good to

TABLE I.  
JOB BREAKDOWN SHEET FOR PAYMENT FOR FUEL AT A SELF-SERVICE PETROL STATION eMILA.

No.	Steps of the current method	Part of interface	Why? What is the aim?	Where?	When?	Who?	How?	Ideas	Eliminate	Combine	Rearrange	Simplify
								Write below, do not try to remember.				
1.	Press „Press to start the transaction” button	Touch screen	X					Why does the whole operation not start from step 2 (fuel pump selection)?	X			
2.	Select fuel pump no. by pressing button „1” (also available „2”)	Touch screen					X	Buttons on the touch screen could be larger – it would be easier to hit them. If nobody has fueled a car the next would be step 3. If one would press a number where receipt has not been printed yet after fueling the next step would be step 10.				X
3.	Select that you don’t have a discount code by pressing “No” (also available “Yes”)	Touch screen			X	X		The majority of customers do not have such a code (according to the spokesman of eMila). A button „Discount code” in the corner of the screen in step 2 should be enough.		X	X	
4.	Select that you don’t have an eMila card by pressing “No” (also available “Yes”)	Touch screen			X	X	X	The majority of customers do not have such a card (according to the spokesman of eMila). A small button „eMila card” in the corner of the screen in step 2 should be enough. If the question about the eMila card is necessary (to provide data for the invoice) two buttons could appear: “Enter the eMila card” and “I don’t have an eMila card”.		X	X	X
5.	Select payment method: “Payment with card” (2 more available: „Banknotes” or “Payment with contactless card”)	Touch screen			X		X	This could be done by simply entering the banknotes or card and a text on the screen: „Enter a payment card or a banknote”.		X		X
6.	Select payment limit (for card payments) - press “20” (other available: “50”, “100”, “150”, “200”, “250”, “300”, “Other”)	Touch screen				X		If payment method would be selected by entering the card or banknotes than this step should be after the card or banknotes are entered.			X	
7.	Enter card and confirm with PIN code (only if „Payment with card” was selected in step 5.)	Card terminal										
8.	(after fueling the car) Select „Print receipt” button	Touch screen	X					Is this step necessary? Step 9 could be shown after 7.	X			
9.	Select fuel pump no. by pressing button „1” (also available „2”)	Touch screen					X	Like in step 2.				X
10.	Collect the receipt	Tray					X	The light could be on the outside of the tray.				X

explain the method. It is also a good example of a case where the method could be applied because a vast majority of users of self-service petrol stations have one goal – fuel up their cars. So there is one main goal the interface should enable to obtain. And for such cases the method suits best.

#### A. Buying petrol at a self-service petrol station

Self-service petrol stations are not the most common ones. Petrol companies prefer to have a store at the station so they can sell a variety of items and not only fuel. However there is a group of customers who do not buy additional items while at the petrol station and who do not like to waste their time staying in a queue when other customers who are before them order hot beverages or buy other items. Self-service petrol stations are for them. However as this group of people values their time it is important for the station to provide services as seamlessly as possible and without any unnecessary activities required from the user.

The process of buying the fuel at such a petrol station has been analyzed from a perspective of a person who uses the station from time to time. The purchase was done with a card and for a limited, predefined amount of money. The study does not cover the process of fueling up the car. The analysis has been presented in Table I. After purchasing the fuel and filming it all the steps have been described one by one (“Steps of the current method”) and described whether this step was done at the touch screen, card terminal or at the tray (“Part of interface”). The next step of the method is to ask 5WH questions and provide a vast number of improvement ideas basing on answers to those questions. In columns “Why? What is the aim?”, “Where?”, “When?”, “Who?” and “How?” in a case where there is an idea how to organize a step in a better way according to these questions an “X” is placed to mark in which way the status quo is being challenged. In the column “Ideas” all the improvement ideas related to previously marked “X” have been noted. And finally (“Eliminate”-“Simplify”) out of all the ideas the ones that are relevant, have a business potential and are feasible have been selected for implementation and an “X” has been placed in the relevant row and column.

In this single case the time of buying fuel (without fueling up the car) could be shortened from around 63 seconds down to around 47 seconds which equals to 25% time reduction. This data is based on a video analysis. This can mean more satisfied customers due to shorter service time but also increased revenue in the case of queues to pumps due to shorter pump occupation by a single customer.

#### V. DISCUSSION

The research has shown that a process improvement method may be applied to improve user-interface interaction. The TWI-JM has been adapted and used to identify areas where the time of this interaction can be shortened. This way the overall usability of the analyzed product or a service may be improved. Based on different cases out of which each was

conducted only by one user it has been observed that the interaction time could be shortened from 20% to 74%. Assessing more accurate values would require analyzing a larger sample of similar cases.

The research described in this article has been limited only to one method. No deep assessment of the method against predefined criteria has been done. The increasing role of usability in the overall perception of products and services implies further research. Work on comparing the method with the other methods that enable improving the user-interface interaction is required in order to develop a framework which would help to select tools in accordance to problems being solved.

The adapted method is applicable only for existing processes, or at least for those that can be observed in real settings and broken down into steps. Another disadvantage of the method is that it enables to analyze only one process at a time. The adapted TWI-JM enables benchmarking of competitive products or services however one needs to analyze them in a similar way and compare step by step.

**Abstract**—The notion of success is unsubstantial, complex and domain-specific. Software companies have been exploring its different aspects and aiming to put forward measures to capture and evaluate them. In this paper three main dimensions of success have been elicited based on previous industrial studies: project quality, project efficiency along with social factors and stakeholder's satisfaction. By investigation of their assessment criteria in commercial context a set of metrics and measures was determined and adapted to provide a structured evaluation approach for projects developed in academic setting. Professionalizing teaching and assessment process is an attempt to close a gap between workforce's expectations towards new graduates and the outcomes of their university education.

## I. INTRODUCTION

GRADING system of students' work was born at the most prestigious universities in the world and dates back to eighteenth century: the first grades were issued at Yale in 1785 [1] while the concept of grading students' work quantitatively was implemented by the University of Cambridge in 1792 [2]. These grading systems were straightforward and measured on a given scale the learning outcomes and extent of assimilation of knowledge. Although a shift to project-based learning has been made ever since, no wide-known elaborate framework that would privilege assessing different dimensions of success of students' projects has been published.

While much research has addressed the definition and measurement of success in industrial software engineering undertakings [3], [4], [5], so far little attention has been paid to the same problem in academic context.

This article explores how assessment criteria used for IT deliverables can be translated into an academic grading context and aims to introduce a set of metrics, and measures for evaluation of projects developed by students.

A thorough literature review reveals three main criteria of project success [3], [5], [6], [7], [9]:

- project quality – source code and product quality,
- project efficiency – resources utilization and productivity of the team,
- social factors and stakeholders' satisfaction – team cohesion, morale; students' satisfaction and learning outcomes.

The presented paper is structured as follows: applicability of the proposed evaluation framework is discussed in section two,

while the three dimensions and their measurement methods are detailed in sections three, four and five respectively.

## II. ACADEMIC SETTING

While commercial projects are carried out according to the rules of a certain software development approach – ranging from plan-driven (Waterfall), through evolutionary (Spiral) to iterative and agile (Scrum, XP), academic projects do not always adhere to any formal processes. They could however, follow certain phases of development as software projects do:

- *requirements engineering*, usually in the form of functionality imposed by the lecturer that needs to be analyzed by students,
- *design*, when architecture and the technology stack of the project are defined,
- *implementation*, in form of coding that involves the most effort relative to the rest of the project,
- *testing*, which allows students to internally verify adherence to functional requirements and encompasses tutor's evaluation.

The project life cycle in a commercial context acts as a structure that allows for coordination and management, efficient allocation of resources, risk assessment and mitigation and a common and shared vocabulary [6], [7]. While the evaluation framework provided in this article is not tailor made for a particular development approach, it requires application of distinct project phases.

## III. PROJECT QUALITY

Paul Ralph and Paul Kelly [3] investigate the dimensions of software engineering success, yield 11 different themes with project being the most important and central concept. In this article two types of quality are explored:

*Internal quality* aspects vary depending on the chosen software development methodology and include [8]:

- requirements documentation – in the form of user stories for Agile approaches and written communication for traditional ones,
- detailed design documents – applicable in traditional models,
- the code and adherence to continuous integration practice – also comprised in Agile models.

*External quality* aspects are observable outside the development team and are assessed by client in commercial projects and professor in academic ones. They encompass both:

- documentation materials – presentation, user manual, installation guide [8] and
- software's characteristics – adherence to functional requirements, user-friendliness, robustness and reliability.

These software quality attributes account for four out of six areas covered by the quality model proposed by ISO/IEC 9126.

#### A. Internal quality

As mentioned, there are two major factors that influence the internal quality of a project: source code and extent of adherence to continuous integration practices. Studies have shown that more complex code, or "spaghetti code", produced by undergraduate students in particular, is difficult to understand, more prone to produce errors than a well-designed and coded module [12].

1) *Code complexity and size measure: Cyclomatic complexity (CC)* is a measure of complexity of a program and is determined by counting the number of decisions (linearly independent paths) made in a given source code. It is a commonly used metric in the industry and according to McCabe Software Company [11] it meets three qualities of a good complexity measure. It is:

- descriptive, as it objectively measures something – decision logic in the case of CC,
- predictive, as it correlates with something important – errors and maintenance effort,
- prescriptive as it guides risk reduction – testing and improvement.

While Cyclomatic Complexity proves to be a good indication of quality, the Software Assurance Technology Center (SATC) at NASA [13] found that the most effective evaluation is a combination of size and complexity. Source code of significant size and high complexity bears very low reliability. Likewise, software with low size and high complexity, as it tends to be written in a very terse fashion, renders the source code difficult to change and maintain [14].

An additional success criterion of students' projects is its quality of Object Oriented Design. This is a core of any computer science related course and a paradigm that is applied to a majority of students' future undertakings [36]. As suggested by SATC [13] a pertinent evaluation is the Weighted Methods per Class, introduced by Chidamber and Kemerer [15]. WMC is the sum of the complexity of the methods of a class and a predictor of how much time and effort is required to develop and maintain the class [13], which is particularly important for students as they share the code with other team members.

2) *Continuous integration*: Continuous Integration is a concept first introduced by Booch [17] whose aim was to avoid pitfalls while merging code from different programmers and thus reduce the work and time effort required for the project.

Though initially employed only in a commercial setting, CI has gained popularity in the students' undertakings, as effective teamwork requires use of a version control system on regular basis. In a Technical University of Munich study [9], continuous integration was perceived as beneficial according to 63% of a sample of 122 students and only 13% did not agree with that statement.

To measure adherence to this practice in a large-scale agile transformation in multiple companies, Olszewska et al. [18] propose a metric called *Pacemaker: Commit pulse* by counting the average number of days between commits and aiming at keeping it as low as possible. Evenly distributed workload and regular merges reduce the complexity of integration and decrease the pressure related to issues of meeting a deadline, which is a frequent challenge in students' undertakings.

The metric is applicable to both plan-driven and agile settings as data can be collected and evaluated with respect to any significant time frame, e.g. sprint, month, or semester.

The three aforementioned metrics can be easily elicited from source code written in any major programming language [10], [16] and give meaningful insight into a product's internal quality.

The calculation method of *Cyclomatic Complexity*, *CC* is given by:

$$CC = \sum_{i=1}^n E_i - \sum_{j=1}^{nm} N_j + 1,$$

where:  $N$ : number of nodes – logic branch point, such as *if*, *while*, *do*, case statements in *switch*,  $E$ : number of edges – an edge represents a line between nodes.

The calculation method of *Weighted Method per Class*, *WMC* is given by:

$$WMC = \sum_{i=1}^n c_i,$$

where:  $C$ : given class,  $M$ : methods defined in a class,  $c$ : complexity of a method.

The calculation method of *Pacemaker Commit Pulse*, *PCP* is given by:

$$PCP = \sum_{i=1, j=i+1}^{n, m=n-1} (C_j - C_i) / N$$

where:  $C_i$ : timestamp of a commit,  $C_j$ : timestamp of the following commit,  $N$ : total number of commits in a given period.

#### B. External quality

While in commercial environment the testing phase is an elaborate process carried out by dedicated personnel and lasting weeks, in the academic setting, it involves mostly a rudimentary test campaign performed by students to ensure that the requested functionality is in place before assignment completion. The tutor performs additional ad-hoc tests to evaluate functional conformance and judge his overall satisfaction level with the results. What additionally differs between the two contexts is that the latter often lacks a framework for defects categorization and tracking. In this article a minimal formal process for testing is proposed so that the external quality factor can be incorporated into the project success evaluation.

1) *Orthogonal Defect Classification*: Businesses provide considerable effort to analyse and improve their software development life cycle process; one of early adopters of a formalized approach was IBM. Chillarege et al. [32] introduce an Orthogonal Defect Classification (ODC), a conceptual framework using semantic information from defects to extract cause-effect relationships in the development process. It involves classifying defects according to different attributes at two points in time:

- once by a submitter, who evaluates the functional correctness of software,
- once the defect has been fixed or responded to by a technical team member, who identifies the type of problem origin.

In order to keep the classification simple and the overhead added minimal, only the first phase is retained as part of the proposed framework. When a defect is detected, it needs to be classified according to three attributes [33]:

- *Activity*, which refers to the actual process step (code inspection, function test etc.) that was being performed at the time the defect was discovered.
- *Trigger*, which describes the environment or condition that had to exist to expose the defect.
- *Impact*, which refers to either perceived or actual impact on the customer.

#### IV. PROJECT EFFICIENCY

From a classical project-management point of view the underpinning of a process's success is respect of underlying budget and time constraints. Indeed, a systematic literature review of 148 papers published between 1991 and 2008 [27] revealed that Effort and Productivity were defined as success indicators in 63% of studies of process improvement initiatives. In the simplest terms, effort is the time spent by the team during the development process and productivity is its output size in terms of KLOC (*kilo lines of code*) [28]. In this paper, more nuanced ways of evaluating project efficiency and team productivity are investigated as motivation to produce significant amounts of code can be detrimental to the quality and is not representative of delivered software value.

##### A. Defining measurements units

An antagonistic approach of measuring functional size was introduced by Middleton et al. [30], who invented a method called *Function Point Analysis (FPA)*. Ever since, multiple recognized standards and public specifications were defined based on the notion of *Functional Points*. In parallel, other size-based estimation models emerged, such as *Use Case Points* [31] or story-based estimation in Agile techniques. While complex frameworks might yield precise results, they require experience that students lack and are frequently time-consuming.

*Function Point* will thus be understood as an informed high-level estimation of an underlying piece of functionality (known as *Early Function Point Analysis*). Professors are encouraged to provide the estimates along with the specification of projects

or assist and share their knowledge with students if the estimation process is within the assignment scope.

In order to adopt a reference unit, students need to track the time spent on the project. Abrahamsson [29] suggests collecting effort for each defined task with a precision of 1 minute using paper/pen and predefined excel-sheet as the primary collection tools. While feasible in a commercial setting, students are required to estimate their effort with a precision of 15 minutes. This number is more suitable to a working environment that is characterized by irregular efforts and little attention to one's own time tracking.

##### B. Productivity and efficiency metrics

The definition of effort and reference unit sets the ground for the evaluation of project efficiency through the application of multiple metrics. The first one, suggested by Olszewska et al. [18] is *Hustle Metric: Functionality/Time spent*, which measures how much functionality can be delivered with respect to a certain work effort. It is calculated by dividing function points of a task, module or even an entire project by total amount of implementation time spent by the students.

The calculation of *Hustle Metric: Functionality/Time spent*, *HM* is given by:

$$HM = \sum_{i=1}^n F_{pi} / \sum_{i=1}^n T_i,$$

where:  $F_{pi}$ : number of functional points of an artefact (task, module etc.) considered,  $T_i$ : overall time spent by the team implementing the considered functionality.

The evaluated efficiency facet of this metric is overall global productivity of the team.

Processing interval is calculated as a subtraction of a timestamp when the feature is fully implemented and uploaded to a repository ( $T_{ship}$ ) and a timestamp when the feature is accepted for implementation ( $T_{acc}$ ). This metric mirrors the efficiency of the implementation process as one can monitor the technological or functional cumbersomeness of a certain feature and team's capability to tackle encountered problems.

The calculation of *Processing Interval: Lead-time per feature*, *PI* is given by:

$$PI = T_{ship} - T_{acc},$$

where:  $T_{ship}$ : timestamp when the feature is fully implemented and uploaded to a repository,  $T_{acc}$ : timestamp when the feature is accepted for implementation.

A related metric was tracked at Timberline Inc. [29] – *Work In Progress (WIP)* – defined as a sum of function points of features that are currently under development. As observed in the study, large amounts of work in progress can translate into many unidentified defects, which would be discovered eventually. It can also mitigate a potential risk of another harmful phenomenon: cherry-picking features that are most interesting to the team or perceived as the simplest ones.

The calculation of *Work In Progress*, *WIP* is given by:

$$WIP = \sum_{i=1}^n F_{pi},$$

where:  $F_{pi}$ : function points of a task currently in progress.

## V. SOCIAL FACTORS AND STAKEHOLDERS' SATISFACTION

In their study, Hoegl and Gemuenden [19] express three principle factors that influence the success of innovative projects: team performance, teamwork quality, personal success.

Teamwork quality is a measure of conditions of collaboration in teams; according to Hoegl and Gemuenden [19] it consists of six facets: communication, coordination, balance of member contributions, mutual support, effort and cohesion.

Team cohesion is defined as the "shared bond that drives team members to stay together and to want to work together" [22]. As stated in [20] cohesion is highly correlated with project success, critical for team effectiveness [21], and leads to increased communication and knowledge sharing [22].

A final dimension of project success is satisfaction and personal accomplishment of its participants. Although it might not be apparent to students, it is their learning outcomes and improved skills that are of paramount importance in that subject matter. Employers emphasize that both technical and soft skills are essentials for implementation of successful software projects. A study by Begel et al. [34] on struggles of new college graduates in their first development job at Microsoft finds that they have difficulties in communication, collaboration and cognition areas; Brechner [35] suggests they should participate in dedicated courses in Design Analysis and Quality Code as part of their education.

## VI. CONCLUSIONS AND FUTURE WORK

This paper provides professors and faculty members a framework for evaluation of Software Engineering projects' success. Its different dimensions are elicited and further divided into sub facets so that they can be addressed with a specific metric or measure. Exploring assessment criteria used for IT deliverables in commercial setting helps professionalize computer engineers' university education and more aptly prepare the graduates to join today's workforce.

Future work will consist of application of the framework to University courses so that students' perception can be taken into consideration and possibly some of the measures adjusted. By employing the proposed evaluation scheme, roadblocks can be identified along with supporting tools to minimize the potential overhead.

# Making agile retrospectives more awesome

Adam Przybyłek, Dagmara Kotecka

Gdansk University of Technology, Faculty of Electronics, Telecommunications and Informatics

Narutowicza 11/12, 80-233 Gdansk, Poland

Email: adam.przybylek@gmail.com, dagkotecka@gmail.com

**Abstract**— According to the textbook [23], Scrum exists only in its entirety, where every component is essential to Scrum's success. However, in many organizational environments some of the components are omitted or modified in a way that is not aligned with the Scrum guidelines. Usually, such deviations result in missing the full benefits of Scrum [24]. Thereby, a Scrum process should be frequently inspected and any deviations should be corrected [23]. In this paper, we report on an Action Research project conducted in Intel Technology Poland to revise the work practices related to the Retrospective. During the focus group discussion in the company, retrospectives were generally judged ineffective because “the same things are discussed over and over”. To cope with this challenge, we revitalized retrospectives by adopting collaborative games. The feedback received from three Scrum teams indicates that our approach improved participants' creativity, involvement, and communication, and produced better results than the standard retrospective.

## I. INTRODUCTION

OVER the years agile methods have become extremely popular in the software industry. Among them, Scrum is the most adopted one [26]. Nevertheless, when examined more closely, by phrase “we are doing Scrum”, organizations often mean, “we are using some parts of Scrum” [5, 6, 7]. Following the Scrum framework only partially or modifying it in a way that is not aligned with the principles of Scrum is commonly referred as ScrumBut [22]. Such misalignment almost always hides one or more inadequacies or dysfunctions which, if addressed and removed, would allow the company to take full advantage of Scrum [24]. In this paper, we focus on Scrum deviations related to the Sprint Retrospective.

Retrospective is a time-boxed meeting where the team inspects the past Sprint, learns from the experience and plans for improvements in the next Sprint. It should be held after the Sprint Review and prior to the next Sprint Planning [23]. During a retrospective meeting, the following questions should be answered [16, 21]:

- What worked well that we might forget to do in the next Sprint, if we do not discuss it?
- What did not work and how to do it differently next time?
- What did we learn?

Retrospectives address one of the principles of the Agile Manifesto [12]: “At regular intervals, the team reflects on how to become more effective, then tunes and adjusts its

behavior accordingly”. However, running an effective and enjoyable retrospective meeting is a challenge due to at least two factors: (1) Scrum does not prescribe techniques or best practices on how to do it; and (2) if this meeting is repeated in the same way over and over again, it becomes flat and may seem to be a waste of time.

In this work, we try to facilitate Sprint retrospectives by adopting collaborative games. Collaborative games refer to several structured techniques inspired by game play but designed for a purpose beyond pure entertainment, typically to develop a better understanding of a problem or to inspire new ideas about solving a problem. To keep participants focused on a specific purpose, collaborative games usually involve strong visual activities like drawing pictures, moving sticky notes, or assembling things. These activities challenge participants who are normally quiet or reserved to take a proactive role [14]. Furthermore, numerous studies have suggested that fun is a powerful tool in unleashing creativity [13, 19], and facilitating collaboration [10, 20, 25]. Our main interest in this research is to investigate whether the promised benefits of collaborative games are materialized during retrospectives.

The rest of the paper is structured as follows. The next section covers related work. Section III explains the research method and describes the research settings. Section IV reports the steps taken to carry out the research project. Section V presents and discusses the results. Finally, Section VI concludes the paper.

## II. RELATED WORK

Although collaborative games are not new [1], their application to support software development processes has not received much attention yet. An important cornerstone for this research area were innovation games introduced by Hohmann [13] as market and product research techniques.

Trujillo et al. [25] adopted a game-based approach as a strategy to support the Inception phase of a project. They found that collaborative games increase stakeholders' involvement and improve collaboration between stakeholders and the development team. Gelperin [9] defined six collaborative games to facilitate requirements elicitation. He also defined a mapping system to help developers choose the best game to play. Ghanbari et al. [10] employed online collaborative games for gathering requirements from

distributed software stakeholders. Their approach allowed less experienced individuals to identify a higher number of requirements.

Derby & Larsen [4] presented the agenda with five type of games that could be used sequentially in the same retrospective meeting: set the stage, gather data, generate insights, decide what to do and close the retrospective. Gonçalves & Linders [11] and Caroli & Caetano [3] described respectively 13 and 44 games that can be used to facilitate retrospectives. Krivitsky [18] presented 16 games that can be combined in numerous retrospective agendas. He also provided the details to the games based on the team mood, size, proximity. Jovanović et al. [16] gathered retrospective games from various sources and established a new classification of games based on the four stage group development model proposed by Tuckman.

In our previous work [20], we proposed an extension to Open Kanban, which contains 12 collaborative games divided into four categories in compliance with four Open Kanban principles. This extension may help inexperienced teams better understand the principles of Kanban and support their teamwork.

To summarize, our work differs from [9, 10, 25] in that we use collaborative games to stimulate developers while they used collaborative games to foster customers' engagement in the software development process. In turn, Derby & Larsen [4], Gonçalves & Linders [11], Caroli & Caetano [3], Krivitsky [18], and Jovanović et al. [16] proposed catalogues of collaborative games that can be used to facilitate retrospectives, but they did not study how these games work in practice. Our study can be seen as a continuation of their work, since we evaluate some games from their catalogues. Finally, our previous work [20] concerned Kanban teams, while in the current work we support Scrum teams.

### III. RESEARCH METHOD

Our study was conducted as Action Research [2]. Action Research is a partnership of the researchers with the study participants who use an iterative process to initiate improvement and study it. The researchers bring their knowledge of action research while the participants bring their practical knowledge and context. Action Research simultaneously assists in practical problem solving, expands scientific knowledge, and enhances participants competencies. A precondition for Action Research is to have a problem owner willing to collaborate to identify a problem, engage in an effort to solve it, analyze the results, and determine future actions [8]. The problem owner in this research was Intel Technology Poland. The company was interested in auditing its software development process and improving identified deficiencies. Three teams that participated in our research are characterised in Table I. These teams were coached by Grzegorz Reglinski who was one of the main Scrum Masters in the company. Grzegorz

worked in close collaboration with us, acting as a co-researcher.

Action Research always involves two objectives: solving organizational issues and expanding scientific knowledge [2]. In this study, the practical objective was to revise the work practices related to the Retrospective, while the research objective was to explore how collaborative games may support the Retrospective.

TABLE I.  
PARTICIPATING TEAMS

Team	Description
T1, 9 people	The team had worked on the project for 18 months, when we started our research. Team members had typically 2 years of Scrum development experience.
T2, 3 people	The team had just joined a new project, but all team members had over 3 years of experience with Scrum.
T3, 8 people	The team had worked on the project for 7 months. All team members had over 3 years of experience with Scrum.

### IV. ACTION RESEARCH IN INTEL TECHNOLOGY POLAND

#### A. Identification of ScrumButs

We started by inspecting the Scrum process in a focus group. The aim was to investigate the practical implementation of Scrum and how it deviated from the textbook version. The focus group consisted of 12 professionals from the three teams. As shown in Table II, the participants had a range of experience. The discussion was structured around a set of 8 main questions and a few supplementary questions to each main question. However, herein, we only present questions and feedback related to retrospective meetings (all questions and feedback can be found in [17]). The questions were as follows:

- Which Scrum meetings do you find to be useful and which not?
- Why do you think so?
- Which Scrum meetings are you attending in your project?
- Which are you skipping?
- Why are you attending or skipping them?

TABLE II.  
FOCUS GROUP CHARACTERISTICS

Role	Experience in IT
Scrum Master	10 years
Product Owner	2 years
Design Lead	10 years
Senior Developer	6 years
Developer x7	2 - 3 years
Developer Intern	6 months

Only 3 out of 12 participants agreed on the importance of all Scrum meetings. They also believed that all Scrum elements must be implemented to effectively adopt the approach. A few others said that they attended all Scrum meetings just because the meetings had been already

implemented at the company when they had joined. The majority perceived only Daily Scrum and Sprint Planning to be useful and they declared that if it had been up to them they would have attended only these two meetings. They also admitted that they did not fully understand Scrum and probably that was the reason why they did not see the point in attending other meetings. However, they were often forced to attend, which resulted in an aversion to the unwelcome duty. Finally, two participants hated Scrum and considered all Scrum ceremonies to be a waste of time.

The most unappreciated meeting was Sprint Retrospective. It turned out that some of the participants knew this meeting only in theory, but they had never experienced it in practice. On the other hand, the majority of those who experienced retrospectives considered them useless because no added value ideas came up. It was also noticed that usually a few team members did not actively participate in the meeting but were only listening. Nevertheless, one participant advocated the Retrospective as a way to improve the team and the development process.

Based on the feedback from the focus group, we concluded that the analyzed teams encountered common problems related to the Retrospective. Indeed, findings presented in the literature [6, 7, 15, 27] suggest that retrospectives are often judged ineffective and dropped because the same old things come up every time instead of insightful ideas.

#### *B. Selection of collaborative games*

We decided to freshen our retrospectives by leveraging collaborative games. After reviewing the available literature [3, 4, 11, 16], we came up with over 100 retrospective games. However, most of these games turned out to be complementary activities that can be run either to warm up the team and promote group interaction, or to help participants know more about each other and build the team. In turn, we were interested in games that directly focus on retrospective activities and allow participants to identify positives, negatives and learning. In addition, as advised by the Scrum Master, we tried to choose games that require participants to write things down on sticky notes before the discussion starts. The motivation for this recommendation was twofold. First, many people do not feel comfortable expressing their vulnerabilities verbally. Second, a few vocal people may dominate the discussion, while others, less vocal, prefer to blend in the background even though they have profound views on things. Taking into account the above, we analyzed the description of each game and chose the most suitable ones. At the end of the day, we had a set of 4 games, which we present below.

**The Sailboat game** [11] allows a team to think about their impediments, risks, good practices, and where they want to go. The game starts by drawing a sailboat, rocks, wind, and an island. The island represents the team's objectives/vision. The rocks represent the risks the team might encounter along

the way. The anchor is everything that slows them down on their journey. The wind represent everything that helps them to reach their objectives. Next, participants write ideas on sticky notes and then post the ideas into the different areas according to the picture. Then, they discuss how to continue the practices that are written on the clouds/wind area, how to mitigate the identified risks, and what actions can be taken to fix the problems [20].

**Mad/Sad/Glad** [4] helps release a heavy emotional steam and gather data about feelings during the Sprint. Before the game starts the facilitator divides a board into three areas or hangs three posters labeled:

- Mad – frustrations, issues that have annoyed the team and/or have wasted a lot of time;
- Sad – disappointments, issues that have not worked out as well as was hoped;
- Glad – pleasures, issues that have made the team happy.

The game starts with everyone writing on sticky notes the issues that made the mad, glad or sad during the Sprint. When the timebox expires, participants post their sticky notes on/under the appropriate poster/area. Then, the team groups related sticky notes into logical themes. In the end, each theme is discussed, a consensus is found, and corrective actions are proposed.

**The Starfish game** [11] is an evolution of the typical retrospective questions. The game board comprises a circle divided into five equal areas:

- Stop Doing – activities or practices that have not brought value, or even worse, have been hindrances to progress;
- Less Of – activities or practices that have been done and have added value but have required more effort than really needed;
- Keep Doing – activities or practices that the team is doing well and wants to keep;
- More Of – activities or practices that are useful but not fully taken advantage of; and the team believes that they will bring more value if are done even more;
- Start Doing – activities or practices that the team wants to bring to the table.

To play the game, team members write their ideas on sticky notes, and then proceed in a manner analogous to that for Mad/Sad/Glad.

**The 5Ls game** [17] handles both the positive and negative aspects of the Sprint but also brings forth the continuous improvement. Before the game starts, the facilitator divides a board into five columns or hangs five posters labeled:

- Liked – what did the team really appreciate about the Sprint?
- Learned – what new things did the team learn during the Sprint?
- Lacked – what things could the team have done better in the Sprint?
- Longed For – what things did the team wish for but were not present during the Sprint?

- Loathed – what things did the team dislike in the Sprint?

Again, the next steps are analogous to those of Mad/Sad/Glad.

### C. Adoption of collaborative games

We collaborated with the Scrum Master to properly adopt the games into the teams. Before a game was run for the first time, it was explained to the team. Table III shows an overview of the deployment process. The bottom entry in each cell indicates the game that was deployed, the top entry identifies the Sprint number when the deployment took place, while the time devoted to the retrospective session is presented in the middle. After each retrospective session, we used a questionnaire to collect feedback from the participants. Then, the results were analyzed and discussed with the team. In particular, we tried to track down the sources of both satisfying and dissatisfying experiences.

After two iterations, we reflected that our question set needed to be refined, since it did not captured all essential aspects of the conducted games (readers interested in the original questions and received feedback are referred to [17]). The work that had been done so far was considered as Phase I.

After revising the questions (the new question set is presented in Table IV), we started Phase II in which we followed the same research procedures as in Phase I. In the meantime, our preliminary results were appreciated by the senior management and we got a permission to coach a new team (T3) in adopting collaborative games. Unfortunately, we had to stop coaching team T1 after its 36th Sprint due to internal reorganization.

After the second implementation of Mad/Sad/Glad, we reflected that this game did not have a potential to improve retrospective meetings, because it was too similar to the standard approach. Therefore, together with team T2, we attempted to enhance this game by adding two new categories, named “flowers” and “ideas”. Flowers express appreciation to colleagues who have done something magnificent for the team or a particular team member. In turn, ideas are suggestions how to improve the teamwork or

the process. We named the new version “Mood++”. Figure 1 shows a photo of the whiteboard taken during the game.

Figure 1. Mood++

## V.RESULTS

Table IV summarizes the survey results. Participants reported their level of agreement or disagreement with each statement on a scale of 1 to 5, where 1 was “Strongly Disagree”, 2 was “Somewhat Disagree”, 3 was “Neither Agree nor Disagree”, 4 was “Somewhat Agree”, and 5 was “Strongly Agree”. For each question, we first took the average per retrospective session, then based on these averages we took the average per team, and finally per game. All games except Mad/Sad/Glad were evaluated positively with respect to all categories. Even if they hardly scored above 3 for one category, they scored around 4 for other categories. They also generated very tangible output that was found to be valuable by most of the participants and the Scrum Master. Nevertheless, those who hated Scrum and perceived the meetings as a waste of time, also did not like our games.

TABLE III.  
OVERVIEW OF THE DEPLOYMENT PROCESS (M/S/G = MAD/SAD/GLAD)

	Phase I		Phase II						
	31st, 90 min, Sailboat	32nd, 105 min, Starfish	33rd, 80 min, Sailboat	34th, N/A	35th, 70 min, Sailboat	36th, 105 min, Starfish	N/A	N/A	N/A
Team T1									
Team T2	1st, 45 min, Sailboat	2nd, 70 min, Starfish	3rd, 45 min, Sailboat	4th, 45 min, Starfish	5th, 40 min, M/S/G	6th, 35 min, Mood++	7th, 55 min, 5L's	8th, 45 min, 5L's	9th, 55 min, Mood++
Team T3	N/A	N/A	19th, 50 min, Sailboat	20th, 50 min, M/S/G	21st, 70 min, Starfish	22nd, 50 min, Mood++	23rd, 50 min, Sailboat	24th, 50 min, 5L's	25th, 80 min, 5L's

TABLE IV.  
SUMMARY RESULTS

<b>Rating scale:</b> 1 – Strongly disagree, 2 – Disagree, 3 – Neutral, 4 – Agree, 5 – Strongly Agree					
	Sailboat	Starfish	Mad/Sad/Glad	Mood++	5L's
The game:					
– produces better results than the standard approach	4.0	4.0	3.0	3.7	4.0
– should be implemented permanently instead of the standard approach	3.0	4.3	3.2	3.4	4.0
– may be considered as complementary to the standard approach	3.5	3.6	4.2	4.0	4.2
– fosters participants' creativity	3.3	3.7	3.7	3.9	4.0
– fosters participants' involvement	3.8	4.1	3.2	3.9	4.4
– improves participants' communication	3.5	3.1	2.3	3.7	4.2
– is easy to understand and play	3.2	4.0	4.2	4.1	4.0

#### A. The sailboat game

Although the participants agreed that Sailboat produces better results than the standard approach, they believed it should not be used too often due to three reasons. First, it would be boring to consider the vision and risks every time because they rarely change through the project. Second, using a sailboat as a metaphor for the team was too abstract for some participants, so the game was not perceived to be easy to play. Finally, the participants missed a good discussion on how to improve the teamwork and the process. On the other hand, they appreciated that the game fostered their involvement and created a friendly environment where they were able to express and discuss their frustrations in a constructive manner.

#### B. The starfish game

Starfish performed well in all categories except one (i.e. “communication among team members”) that was not affected. Since the game covers all topics of classical retrospective and fosters participants' involvement at the same time, the participants advocated the substitution of the game for the standard approach. They also appreciated that the game helped them to understand each other perceived value on the way they worked.

#### C. Mad/Sad/Glad and Mood++

Although Mad/Sad/Glad was considered the easiest to understand and play, overall it performed the worst due to the reasons mentioned in Section IV-C. In particular, its impact on communication between team members was rated negatively. The reason for this was probably that the game is too simple and does not cover all topics that are usually addressed during a retrospective. Nevertheless, after enriching the game with two new categories, the communication aspect was significantly improved, while the new version performed overall as well as the Starfish game.

#### D. The 5L's game

Generally, 5L's received high marks in each category and outperformed all other games. When compared to Starfish and Mood++, it also covers all aspects of the Retrospective, but was considered superior especially in improving participants' communication. The other strong point of the game is that the participants' involvement was fostered. While playing this game, the participants even started to compete against one another to post the highest number of sticky notes.

## VI. CONCLUSIONS

This paper reports on an Action Research project in which we freshened retrospectives to be more engaging and insightful and to avoid monotony. In particular, we adopted five collaborative games and examined the ways in which these games could benefit retrospectives. The received feedback indicates that the adopted games improved participants' creativity, involvement, and communication. Besides, playing together created a type of glue that bonded a team together and made team members more comfortable to participate in the discussion.

We found out that there is no single collaborative game that would give the best result in all cases. Since the issues that a team deals with can be different in each Sprint and project, the Scrum Master should have a set of possible games to be able to pick the most effective one depending on the situation at hand. Moreover, playing the same game over and over would be boring. Furthermore, we observed differences in performance on particular aspects between the games.

The adopted games had proved so successful that not only did the participated teams continue to run them after the project finished, but they also spread their knowledge about the proposed approach and collaborative games started to be implemented in other teams that had not participated in the research. Accordingly, we believe that the usage of collaborative games in Agile Software Development is an

emerging area of research, while our work represents only the beginning of the road. We thus call for further studies to examine other collaborative games and evaluate how collaborative games may support other Scrum ceremonies. We also hope that our research will inspire practitioners to adapt collaborative games and make their retrospective meetings more awesome.

**Abstract**—Knowledge is seen as one of the main resources for organizations providing knowledge-intensive services. Therefore, sharing and reusing are the main goals of the modern knowledge management (KM) approach, driven by information and communication technologies (ICT). However, one must ask for the details in order to provide the means and tools to design and deploy an environment able to fulfil these two goals. We observed that the interactions occurring on knowledge resources can be reduced to a directional flow, and further described by distinguished internal phases. In our research we put forward two research questions: (1) what are the main entities in the knowledge flow supported by ICT? and (2) what are the main phases of the knowledge flow? In this paper we introduce the generic lemniscate knowledge flow model, which, grounded on recognized theory, learned principles and gathered practices, provides foundations to solve the above problem.

### I. INTRODUCTION

KNOWLEDGE is a wide and abstract term, which has been the subject of epistemological discussion among western philosophers since times of ancient Greece. Since the second half of XX century, it has been widely studied in numerous research papers, reaching many definitions, contexts and phenomena and in the end, leading to a legitimate new scientific discipline, defined as *knowledge management*.

These days, people and machines produce countless volumes of data and information, consciously and intentionally transformed into knowledge. All of the aforementioned are important assets in knowledge-driven environments and the last is by far the most labour- and time-consuming. In consequence, some employees spend the majority of their working hours in manual and high-demanding intellectual work, supported by computers processing and manipulating large amounts of data as an input, and producing information or even knowledge as an output [1, 2]. As a result, a new concept of an employee was coined: a *knowledge worker*, whose job primarily involves the creation, distribution or application of knowledge [3]. By many, Peter Drucker is credited to be the first to use this term in his 1959 book, “*Landmarks of Tomorrow*”.

Data sets encoded in a computer memory differ in format, size and type. In general use, there are two primary data formats: binary and text, and four primary data types: text,

drawing, movie and voice. Ordered sequences of characters, images and spoken words are perceived as explicit and unique information objects. Here, we can point out objects that are in everyday use such as documents, presentations and spreadsheets, email-, voice- and video- messages, web-blogs, forums, and pages. Each object processed and interpreted by an individual human mind, applicable and legitimate in a specified environment, where the consequences of an application are known or can be predicted, is considered to be a knowledge object. All of them, gathered and redacted, cleaned and re-processed, organized and integrated in one consistent repository, along with a user interface that facilitates CRUD operations (an acronym for *search, create, read and delete*), constitute a unified system for knowledge workers. In present times, the most popular adjective in the research area “big” is naturally added when “big data” is involved and to underline the scale of the discussed problem (e.g. big management [4]). The ability to process massive data volumes entails other mandatory requirements against the system, such as *efficient, fault-free* and *cost-effective*. If we also take into account the human factor, the notion of the *system* is replaced by the *environment* to indicate additional performers and actions involved.

Now, we consider the problem of the design of an environment that will not only serve as pure technology but also provide interaction with other humans and available knowledge resources. We observed that the occurring interactions can be reduced to a directional flow, and further described by distinguished internal phases. In this context, we put forward two research questions: (1) *what are the main entities?* and (2) *what are the main phases?* Answers to these questions are embodied in the form of the generic lemniscate knowledge flow model and its detailed description, which, grounded on recognized theory, learned principles and gathered practices, provides foundations to solve the above problem.

The rest of the paper is organized as follows. The related work is presented in Section 2. In Section 3 we introduce the knowledge flow model. The research background is presented and referred to in Section 4. Final conclusions are included in Section 5.

## II. RELATED WORK

The recent interest in knowledge management, observed both in business and science, is nothing new. However, it is not a secret that nowadays, information and communication technologies are the basic means to efficiently support every phase of the KM process. For this reason, we only present the state of the art directly concerning knowledge management embedded in the context of ICT, as well as a general retrospection of its existence in the research areas of computer science and management.

Thinking in terms of computer science, our knowledge is materialized in so-called *knowledge bases* (KB) [5]. Bearing in mind the natural attributes of knowledge (e.g. aging, context, source) in order to fully illustrate the constraints and obstacles in the process of codifying, sharing and refining its resources, we should also point out other cons like: subjective burdens, mistakes, false assumptions, unreliable data mining techniques and methods or incomplete and imprecise data. Therefore, the necessity and urgency of knowledge verification and evaluation appear in the foreground in order to ensure its *correctness*, *timeliness* and *objectiveness*. This has been a subject of our previous and current research interests, generally focused on the area of knowledge management, where varied experiments have been performed on acquired resources from experts [6] or discovered frequent sets from web server log files [7].

In another work [8], we introduced the first multi-dimensional *knowledge space model* (including entity-relationship schema), implemented as a part of the developing system, designed to efficiently distribute and manage knowledge resources. We view our model as the foundation of a *knowledge grid* platform, where two significant aspects are considered: education- and research-driven. Some aspects of applying an ontology in transforming and processing knowledge were widely discussed in [9], along with the related standards, terminology and languages; based on theoretical developments [10, 11, 12], and managerial and organizational practice [13, 14, 15]; we also referred to the generic model of the knowledge life cycle and its internal phases, revisiting conditions, constraints and obstacles in the context of the knowledge grid assumptions.

Knowledge may be represented by a variety of forms. In [16] Kapłański *et al.* used a novel feature of the *Ontorion* system [17], that allows for describing knowledge and interacting with the user in *semi-natural language* [18], expressive enough to describe rich and complex things, groups of things, and relations between them. To present such capabilities, a stand-alone experiment was designed and executed. A software process simulation based on the multi-agent approach was performed in order to imitate social behaviours in the software testing phase.

From the management panorama of the knowledge-based organization, Zack [19] distinguished four characteristics, summarized as a *process*, a *place*, a *purpose* and a

*perspective*. A process consists of intra-organization activities engaged in the production of goods and delivery of services. A place includes the organization of boundaries in which knowledge is created, shared and refined. A purpose is defined by a mission and strategy which are considered in the frame of customer satisfaction. Finally, a perspective is related to beliefs, culture and religion, which may have an influence on decisions-makers. This abstract view of such an organization may be considered as a starting point for the analysis, design and organization of actors, tasks and resources, engaged in knowledge creation, sharing and evaluation [20].

The pure nature of the knowledge management process undoubtedly describes such values as: sincerity, impartiality and veracity. Mercier-Laurent *et al.* [21] classified socio-cultural aspects as the most important in KM, which allow and empower knowledge creation and sharing. Besides this, the authors emphasize the role of the *technical environment* in the deliberate development and maintenance of key knowledge management processes and its influence on *strategic management*. In a similar way, Fazlagić *et al.* indicated the role of *corporate portals* (so-called intranets) in developing the processes of knowledge management, realized through a set of functions such as: internal services (concerning administration, finance and human resources), *digital workspaces*, *unified communication facilities* and *document repositories* [22].

To sum up and close this section, in the long-term, effective knowledge management may constitute a competitive advantage. Dominiak and Leja rhetorically ask “*Does university need a strategy?*” [23], and after an affirmative answer, later claim that in order to build, unfold and deploy a strategy, university ought to begin with a *vision*. To create a successful projection of the future, organization members should also directly embody all processes engaged in knowledge management in agreement and cooperation with all stakeholders. Generally speaking, the three main functions of management i.e. planning, organizing and controlling (the action-decision function will not be considered because it is commonly known) are intra- and inter-related, penetrating and utilizing the available resources, where the most important are *intellectual capital assets*. Likewise, for business organizations, Teece [24] also argues that superior profits stem from intangible assets such as customer relationships, know-how and superior business processes.

## III. KNOWLEDGE FLOW MODEL

Some believe in the sense of knowledge management and some do not. However, each organization to some extent, be it smaller or greater, utilizes knowledge in some way, intentionally or not. Nonetheless, we all must agree that the human memory, by nature, is imperfect because over time we unconsciously tend to rewrite some of its parts irrevocably or we are simply unable to retrieve them again.

To bypass those limitations, nowadays knowledge is explicitly codified in a computer mass-storage memory, which lets us create solid backups and, what is the most important, retrieve and share knowledge on request at any time and in any place. On the other hand, the present-day environment is highly dynamic and productive, and as a consequence, knowledge ages rapidly. As an example, let us consider emerging financial and stock markets, legal regulations or even the solar system – indubitably, today we know something about them that may not be true anymore tomorrow.

In our methodical approach, firstly we specify the main goals, and secondly we design the process by determining particular phases in such a way that the sequence of their execution ultimately leads to satisfying each goal.

The main goals of knowledge management are to *share* knowledge with others, and to *reuse* it when necessary. From our point of view, the process itself consists of seven chronological phases where knowledge is (1) *gathered*, (2)

*codified*, (3) *shared*, (4) *verified*, (5) *enhanced* (from the knowledge sender perspective), and (6) *understood*, (7) *evaluated* and shared again (from the knowledge recipient perspective). Such a directional knowledge flow occurs between three entities: knowledge *sender* (KS), *machine* and knowledge *recipient* (KR), where each of them plays a distinct role; however, direct or indirect interactions frequently occur between them. While KS and KR are both humans, the machine is an abstract term representing a set of information and communication technologies (ICT), generally referring to operating hardware (computers, networks and other physical devices) and software (applications, tools and systems). In this case, knowledge is a set of intangible assets, stored in a computer memory, represented by non-trivial plain-text or binary data structures. The underlying assumption, however, is not one based on viewing data as the raw material from which knowledge is created.

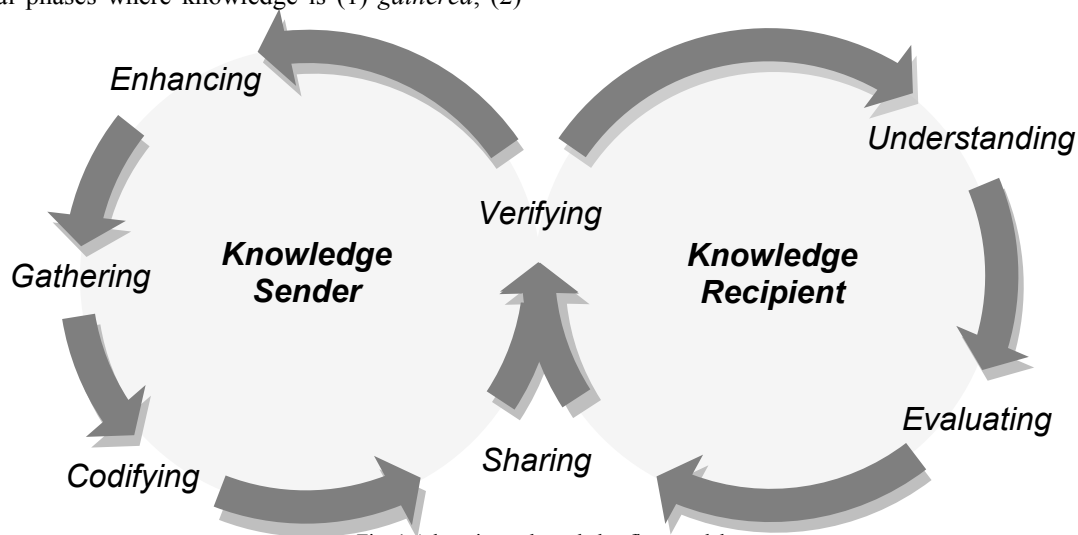

Fig. 1 A lemniscate knowledge flow model

The knowledge sender gathers, processes and combines relevant resources at some point in time. If the composed resources of knowledge are complete and consistent for a given discourse of the universe, then they are codified (articulated), which in turn leads to the creation of the real-world meaning of concepts and relations explicitly and precisely. On the other hand, knowledge codification can be a source of value creation, “reused” either by the knowledge recipient or other knowledge creators. Undoubtedly, an efficient IT system plays a decisive role in the application of the codification strategy. Knowledge sharing is an activity that aims to exchange particular resources among the knowledge sender and their recipients. An efficient and useful technology should support contexts like localization and the knowledge form, hardware capabilities and requirements, language skills, on-the-fly content recommendation and the recipient’s learning predisposition. Simultaneous verification of knowledge takes place during

its exchange by both a sender and a recipient. The perception and understanding of knowledge incorporates cognitive processes, beliefs and human intelligence, as well as the tacit knowledge currently possessed by the involved individual. At the same time, the knowledge is evaluated, which means that each consistent part is checked to fulfil such criteria as *reliability*, *applicability* and *significance* [25]. Feedback given from a knowledge recipient may reveal some errors, inaccuracies or gaps in shared knowledge resources. On the other hand, which seems to be even more important, it may spontaneously trigger valuable expertise, up to that point deeply concealed in a recipient’s mind. Such reactions might indicate and advocate possible changes, supplements or withdrawals of particular knowledge resources. In this case, knowledge refinement may lead to its higher quality, described by attributes such as *adequacy*, *effectiveness* and *productiveness* [26].

Generally speaking, in regard to knowledge “visibility”, classically, knowledge resources are divided into two types: *explicit* or *tacit* [27], while the former by assumption is not cognitively biased. For this reason people naturally tend to share knowledge with others to evaluate its veracity, based on given feedback, and afterwards to consolidate and codify it. On the other hand, any body of knowledge might be codified to a certain extent, where skills and competence are hardly transferable.

#### IV. RESEARCH BACKGROUND

Among the numerous tasks given to students to perform, were those where they needed to actively collaborate in separate groups in the classroom or at home, and exhibit the means and tools to exchange data, information and knowledge. In this manner, we provided the preliminary results of our observations and conducted short interviews, which, synthesised together, allowed us to formulate a set of facts, specified below. Obviously, the elementary means of close communication was *oral dialogue* or *open discussion*. However, a few members reported obstacles in effective group work, such as the “*sucker effect*”, or intrapersonal factors (also recognized and described in [28]). At a distance, instant messaging tools over the Internet (e.g. *Skype*) were preferred to the phone. Group members used a variety of other software tools to explicit and codify gathered or possessed information. In peer-to-peer communication, *Facebook Messenger* was the most preferable tool. In the store-and-forward model, *emails* were sent occasionally to announce some general assumptions, share documents (via attached files) or one asked others to evaluate or accept changed settings.

#### V. CONCLUSIONS

The elaborated knowledge flow model (fig. 1) is an abstract view of the process of *knowledge management*. To our best belief, it seems to be *complete* (definite starting and ending points), *computer-aided* (various ICT are employed) and *generic* (not biased by any domain); the indicated sequential iterations, where the *bi-directional, spoken* or *written exchange* of observations takes place, demonstrate its unfolded nature.

“*We have a conviction to learn during our whole life*” – this straightforward sentence reflects the nature of a human life in present times.

# Enterprise Architecture Approach to SCRUM Processes, Sprint Retrospective Example

Jan Werewka, Anna Spiechowicz

Department of Applied Computer Science

Faculty of Electrical Eng., Automatics, Computer Sci. and Biomedical Eng.

AGH University of Science and Technology

al. Mickiewicza 30, 30-059 Kraków, Poland

werewka@agh.edu.pl

**Abstract**—Enterprise architecture supports a holistic approach used to optimize various activities of a company. Software development companies frequently use a popular agile approach, and the most popular agile methodology is Scrum. A sprint retrospective is a Scrum process which is supposed to enable self-development and improve communication among team members. Unfortunately, the reality is usually different. The aim of the paper is to identify problems with retrospectives and to use enterprise architecture models to help different stakeholders to understand the problems of agile approach and to find reasons why sometimes it does not meet its goals. Next, the authors try to find solutions for the identified problems on the basis of a persona concept.

**Index Terms**—Scrum; agile; retrospective; team work; enterprise architecture; ArchiMate

## I. INTRODUCTION

ENTERPRISE architecture may be used for an efficient development of a company. To optimize the structure and behavior of a company, a holistic approach should be used in which the company architecture should be modelled in a uniform way. One of the reasons why it is worth pursuing this approach is the fact that it offers different company stakeholders a clear understanding of what is going on. In the literature these problems are closely related to integration and interoperability of enterprise architecture [1]. Other important ideas regarding enterprise architecture evolution are standardization and harmonization [2].

There are many examples of processes that do not work so efficiently as expected. A clear understanding is useful not only to people taking part in the process, but also to people observing the process. So, there is a need to describe the behavior of a company in a uniform way. The structure and behavior of a company can be modelled in ArchiMate [3] language, which supports strategy, motivation, business, technology and physical layers concepts. Developing such models is especially valuable for companies developing software (software houses).

Software houses usually apply a mix of different methodologies, e.g. agile or classic. In these companies service

orientation and continuous improvement seem an important goal. To obtain a full picture of the company, it is important to distinguish services in the software production, and to show how these services are supported by processes.

In the paper an ArchiMate model is proposed for iterative software development based on Scrum. The model is based on a more general model of the Scrum framework for teams and a more detailed one for a sprint retrospective. Scrum Guide [4] is a widely accepted reference publication for Scrum.

A sprint retrospective is a meeting that takes place during the last stage of the sprint. During the meeting the participants discuss the finished sprint, focusing on the team and its problems. The main topics of the conversations during a retrospective focus on what went well, what difficulties occurred during the sprint, and how to take corrective actions to avoid similar problems in the future. In Scrum, a sprint retrospective is an integral part of control and adaptation processes, without which the team cannot develop and improve the efficiency of its work.

In many Scrum team members' opinion, a retrospective is a fragile process. To check this view, a survey was conducted by the authors of the paper in which they collected information on the most common problems raised up during a sprint retrospective. Unfortunately, its results do not lead to optimistic conclusions. The main research question was why most teams using an agile approach do not conduct such meetings at all or end them with negative results. Answering this question can be followed by additional questions: Are the authors of Scrum and the authors of books praising the advantages of retrospectives incurable optimists? Are they misled in their assertions? Or maybe the way of conducting a retrospective leads to mistakes?

There are many books, papers and blogs which describe how to conduct a retrospective in a proper way. Usually their authors are experts in coaching agile teams. However, it is difficult to find a common and uniform understanding of a retrospective process. That is why a more general approach is proposed based on an enterprise architecture model. To understand its idea better, a retrospective motivation model and a concept of UX (user experience) are proposed.

The structure of the paper is as follows. After the introduction in the first chapter, an enterprise architecture view of Scrum is proposed in the second chapter, and selected literature concerning a retrospective is analyzed in the third chapter. In the fourth chapter a base motivation model of a retrospective is proposed, while in chapter five common problems of a retrospective are investigated based on a survey, whose results are discussed in the next chapter. The success of a retrospective depends on people taking part in it, and that is why personas and retrospective roles are discussed respectively in chapters seven and eight, which are followed by chapter 9 discussing ways of improving a retrospective. Conclusions are devoted to future research concerning the integration of enterprise architecture and models of agile methodologies.

## II. ENTERPRISE ARCHITECTURE APPROACH TO SCRUM

Enterprise architecture is used to obtain a holistic view of the company. From this point of view, the most suitable enterprise architecture definition is the one given by Lankhorst [5] as “a coherent whole of principles, methods, and models that are used in the design and realization of an enterprise’s organizational structure, business processes, information systems, and infrastructure”. The second important point is competitive development of a company, which is best defined by Gartner Group [6] “Enterprise architecture (EA) is the process of translating business vision and strategy into effective enterprise change by creating, communicating, and improving the key principles and models that describe the enterprise’s future state and enable its evolution.” In the paper both definitions of enterprise architecture are important: the one regarding the company’s holistic view and the one regarding its competitive evolution.

The developers of agile methods try to differentiate them from other methods by different means. There is no essential reason why integrating Scrum into enterprise architecture could not be possible. Literature offers some examples of such proposals, e.g. [7], [8]. The development of enterprise architecture can be proposed for different fields [9]. IT enterprises running projects in different heterogeneous environments integrate classical and agile project management methodologies. Paper [10] discusses the problem of alignment of two project management methodologies based on two ontologies: a classical one represented by PMBOK [11] and an agile one represented by Scrum [4]. In [12] the problem of selecting a suitable agility framework is discussed, and the analysis ends with the conclusion that the investigated methodologies were inconsistent.

To describe project management methodologies or agile frameworks, a common meta-model may be proposed. In the area of software engineering, different meta-models for harmonizing different standards and solutions are offered. In the domain of software development, harmonization is proposed for ISO standards based on the Software Engineering Metamodel for Development Methodologies (SEMDM) described in ISO/IEC 24744 standard. For example, in [13] a proposal of such harmonization is based on Ontology Pattern Language.

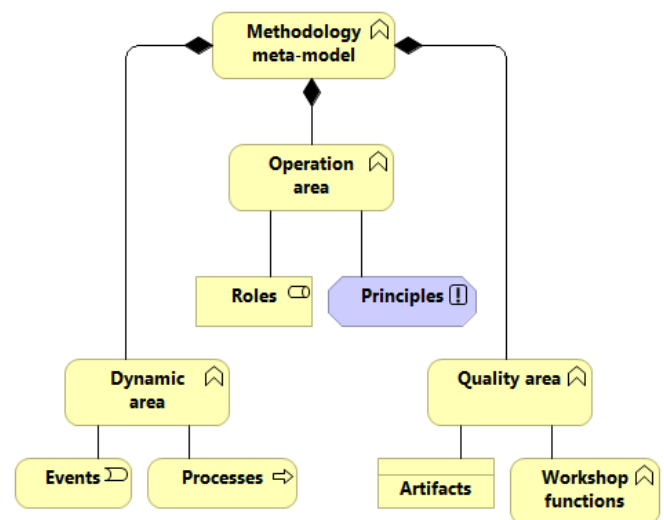

Figure 1. Meta-model of project management methodologies

The paper proposes an approach which harmonizes the project and product development methodologies using enterprise architecture concepts. The proposed meta-model is simple and distinguishes the following areas (Fig. 1): dynamic (describing activities), operation (describing active elements, like roles and principles governing the methodology), quality (depending artifacts, i.e. inputs and outputs of processes) and workshop functions (e.g. the application of selected tools, techniques, and practices).

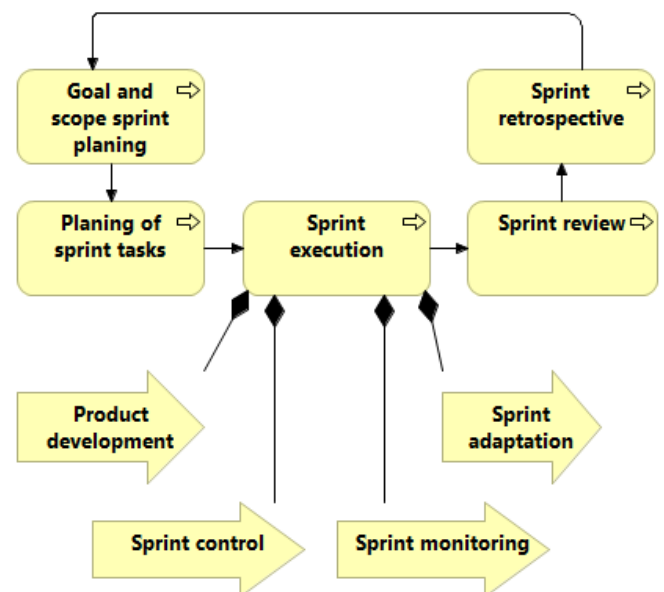

Figure 2. General Scrum process model

In building a Scrum model, Scrum processes should be considered at first. ArchiMate is one of the best known languages used for describing enterprise models. A simple example of a model of processes in Scrum with triggering and composition relations is given in Fig. 2. Sprint, the Scrum

iteration, contains planning, execution, review and retrospective processes. The sprint execution process consists of composite sub-processes: product development, sprint control, monitoring and adaptation. These sub-processes are running parallel during sprint execution.

The full Scrum model based on the meta-model is presented in [14] from two viewpoints: the team's viewpoint and the business owner's viewpoint.

### III. STATE OF THE ART ON A SPRINT RETROSPECTIVE

A sprint retrospective is the last meeting during the sprint. Its main objective is to facilitate the development and self-improvement of the team. During a retrospective its participants discuss the events that have taken place, their impact on their work and how they may be able to deal with problems in the future. The retrospective process is discussed and described in detail in different publications. The Retrospective Handbook [15] shows ways of running more effective retrospectives by addressing certain practical challenges.

A retrospective should not be conducted in a chaotic way. It is very important to prepare, conduct and close a retrospective properly. It is assumed [7] that for a one month sprint, a retrospective should last up to 3 hours. The authors of [16] suggest dividing a sprint retrospective into five phases of varying lengths:

- 1) Setting the stage. The first phase involves familiarizing the group with the timetable and retrospective goals, and, additionally, doing exercises that will make it easier for shy people to express their opinions later.
- 2) Gather data. The data collection is intended to remind the group of events taking place during a sprint. During this phase the team should recall all events that occurred during a sprint, such as meetings, decisions, milestones, integration meetings, rotation of team members as well as adaptation of new technologies. The Timeline [17] exercise may be proposed here.
- 3) Generate Insights. Through brainstorming the team members try to notice the correlation between the events and the quality and effectiveness of their work. Through this analysis, it will be possible to identify which events help and which make it more difficult for the team to achieve the goal. Exercise that can help during brainstorming is called 5 Whys method, which may be used in software development to prevent recurrence of the same problems [18].
- 4) Decide what to do. During this phase, while working in groups, team members create a detailed list of actions to be performed during the next sprint. The most important element of this stage is the selection of 2-3 most important factors that affected the last sprint issues, in which the "Planning Game" [19] exercise may be helpful.
- 5) Close the retrospective. In the end, the leader will gather feedback on the meeting. It is important to collect the

results of the analysis, the list of decisions made and to create a common picture in the form of a poster.

On the basis of this proposal, phases and their goals can be described in ArchiMate model as shown in Fig. 3. The sprint retrospective process consists of sub-processes realizing different goals. The person preparing the meeting is obliged to prepare the place where a retrospective will take place. A good choice will be a location in which the team usually works or an isolated room allowing participants to arrange chairs in a semicircle so that everyone can see one another. The room should offer a possibility to post posters or draw graphs and timelines. This will create a proper atmosphere for the discussion.

Sometimes a retrospective always performed in the same way becomes boring for some team members or for the whole team, however, it is possible to revitalize retrospective meetings. In [20] seven principles serving this purpose are defined: (1) Rotate leadership. It seems natural that the Scrum Master should take leadership of a retrospective, but rotating leadership among team members can bring good results. (2) Change the question. By asking standard questions, we usually obtain the same answers. (3) Vary the process. Some tools may be proposed to structure the process. (4) Include different perspectives. Take into consideration the viewpoints of different stakeholders. (5) Change the focus. Change the focus to e.g. social communication, organization or engineering issues. (6) Try appreciative inquiry. Consider good results obtained in the past to explore how to use them in the future. (7) Analyze recurrent themes. If the same themes occur, try to influence the situation or change the plans.

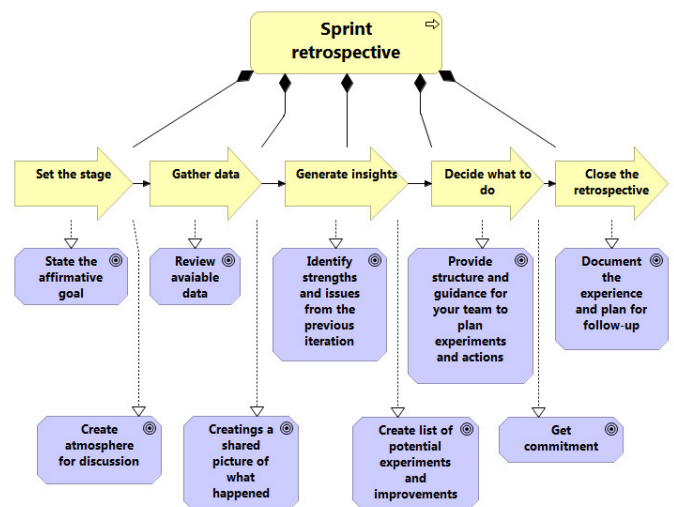

Figure 3. Retrospective phases and their main goals

There are some works offering exercises facilitating a retrospective. Book [21] contains many practical exercises aimed at becoming more proficient in performing retrospectives. Similarly, [22] provides a tool set of activities to transform a group of people into an effective team by keeping the participants amused and providing a setting where they can reflect, discuss and have fun. Another issue is team networking, which is performed outside a retrospective, and for which collaborative games may be proposed, e.g. [23].

#### IV. ENTERPRISE ARCHITECTURE APPROACH TO A SPRINT RETROSPECTIVE

A case of a retrospective process will be investigated here in more detail. A sprint retrospective takes into account (Fig. 4) such inputs as: work progress during the sprint (represented by sprint burn down charts), delivered product at the end of the sprint, product development recommendation made during a sprint review, team capability and retrospective recommendations from previous sprints. A burn down chart, product development and retrospective recommendations are Archimate business objects. A sprint retrospective triggers a process of retrospective recommendation realization.

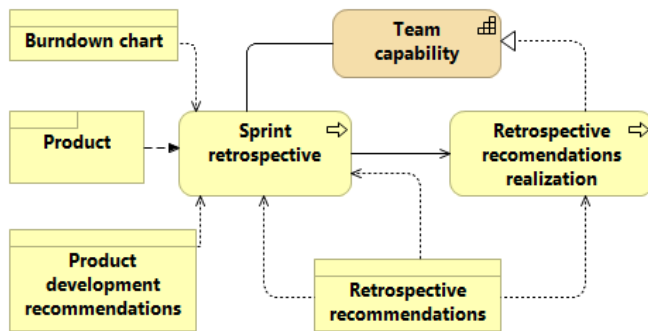

Figure 4. Model of a sprint retrospective

In building an enterprise model a motivation layer should be developed in the first place. Fig. 5 presents retrospective motivation using the following ArchiMate concepts: stakeholder, driver, assessment, principle, requirement, constraint, goal and value. The motivation model for this simplified detail level may be used for a quick check of what the reasons to perform a retrospective are.

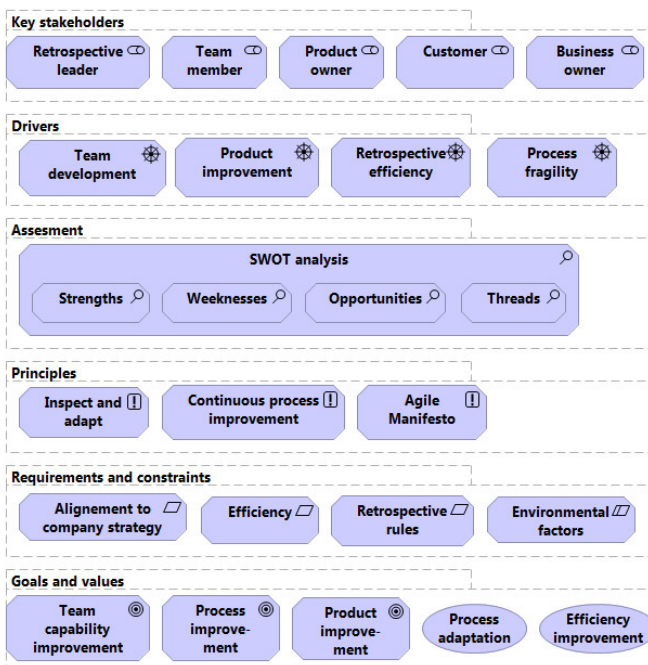

Figure 5. Motivation model of a sprint retrospective

In a full Scrum model the motivation elements are tied to other kinds of motivation, a business layer, and strategy elements.

#### V. COMMON ISSUES DURING A SPRINT RETROSPECTIVE

Obtaining and maintaining a holistic view is an important issue in developing enterprise architecture, but in architecture evolution harmonization and efficiency become the most important goals. The problem can be defined as follow: is a retrospective the best way to develop and improve efficiency of team work?

In order to determine the problems related to a sprint retrospective, a written questionnaire was distributed among people working in Scrum projects. The survey was conducted between May and June 2016 in Cracow and its neighboring areas, which are the largest outsourcing center in Europe [24]. 32 survey participants selected for the survey were members of different Scrum teams from different companies. Their job positions were as follow: 59% were software developers, 38% quality assurance engineers and 3% business analysts. Their work experience ranged between 0-5 years (66%), 6-10 years (21%), 11-15 years (105) and 16-20 years (3 %).

The first part of the survey concerned the position and the work experience of the respondents. In the second part general questions regarding retrospective were as follow: Does the team in which you are working conduct sprint retrospectives? How long does an average sprint take in your project? What is the average duration of a retrospective in your project? Do you prepare for a retrospective? How many exercises does your team perform during a retrospective?

Then, in the third part of the survey the respondents were asked to what extent they agreed with the following statements: (1) I know why a retrospective is carried out. (2) I understand the meaning of a retrospective. (3) A retrospective is a necessary meeting during the sprint. (4) During a retrospective we discuss important things from the team's and project's points of view. (5) A retrospective brings a lot of changes to the team. (6) During a retrospective I make many observations. (7) I want to share my observations during a sprint retrospective. (8) I feel that my participation in a retrospective is important. (9) A retrospective takes the appropriate length of time. (10) A retrospective is interesting. (11) A retrospective drives the team to action. (12) A retrospective is not used to indicate the person responsible for the success / failure of the sprint. (13) A retrospective improves communication between team members. (14) A retrospective improves the team's work organization. (15) A retrospective motivates for better work. (16) A retrospective improves team efficiency. (17) A retrospective reveals strengths and weaknesses of the team. (18) A retrospective reveals the problems that occur in the project. (19) A retrospective allows for the development of team members. (20) A retrospective is carried out correctly.

The survey participants chose a decimal value assigned to each answer ranging from 1 (strongly disagree) to 5 (strongly agree). Finally, the respondents were asked for other suggestions or opinions related to a retrospective, which were not included in the questionnaire.

## VI. SURVEY RESULTS

The survey revealed that only 67% of surveyed people working in Scrum projects participate in a retrospective. Thus, only the answers of the respondents who have actually taken part in retrospectives are analysed.

Most people declared that sprints in their projects last for 2 weeks (55%), 3 weeks (30%) or 4 weeks (15%). Regarding the duration of a retrospective, it takes up to 1 hour in 40% of cases, 2 hours in 55% of cases and 3 hours in 5% of cases. During a retrospective, one exercise (75% cases) is performed as a standard, and its goal is to determine the problems that Scrum teams face. It is regrettable to say that only 35% of the respondents prepare for a sprint retrospective.

Figure 6. Average points for 20 questions of the survey

Twenty questions from the third part of the questionnaire make it possible to determine the satisfaction index of a sprint retrospective. For the purpose of this study, satisfaction was measured by assigning points between 1 (strongly disagree) to 5 (strongly agree) as the answers to the questions. The average values are presented in Fig. 6.

The article presents in detail only some of the most surprising answers to the questions. Only 26% of the respondents (Fig. 7) agreed or partially agreed with the assertion that a retrospective leads to many changes in the team's work. At the same time, only 45% (Fig. 8) of them thought that a retrospective motivates them to work better. In addition, only 30% said (Fig. 9) that a retrospective drives the team to action. Even worse, only 20% partially agreed (Fig. 10) that a retrospective leads to the development of the team members. No one was completely convinced of the validity of this statement. When it comes to identifying the problems faced by the participants of the meeting themselves, it was not better, either. Only 40% of the respondents (Fig. 11) made some observations during the meeting. A better situation occurred with sharing ones insights with others - 85% of the respondents (Fig. 12) declared such a desire.

Figure 7. A retrospective introduces many changes to team work

Figure 8. A retrospective motivates for better work

Figure 9. A retrospective drives the team to action

Figure 10. A retrospection enables the development of team members

Figure 11. During a retrospective I have many insights

Figure 12. I want to share my observations during a retrospective

These responses indicate that a retrospective created to give the team the opportunity to develop, motivate and make changes to the process, in most cases does not fulfill its core functions.

Nevertheless, the respondents also noticed a more positive side of a retrospective. They claimed that such meetings verify the team's integration and enable the exchange of experiences between the participants. In addition, a retrospective reveals the problems that have not been noticed during the sprint.

## VII. APPLYING A PERSONA CONCEPT TO RETROSPECTIVE ROLES

An important concept in enterprise architecture modelling is service realized by processes. In the area of service development many solutions are proposed, such as service design thinking or user and customer experience. The question is why not use these solutions to improve agile processes. In the service design a persona is an important concept. The idea of understanding customer segments was proposed by Angus Jenkinson [25] based on creating imagined or fictional characters with certain behaviors and attitudes which represent customer segments or communities. Success of a retrospective depends on the retrospective leader and team members. For that reasons it would be interesting to develop a persona model for the retrospective leader and team members. Fig. 9 presents the persona model expressed in ArchiMate language.

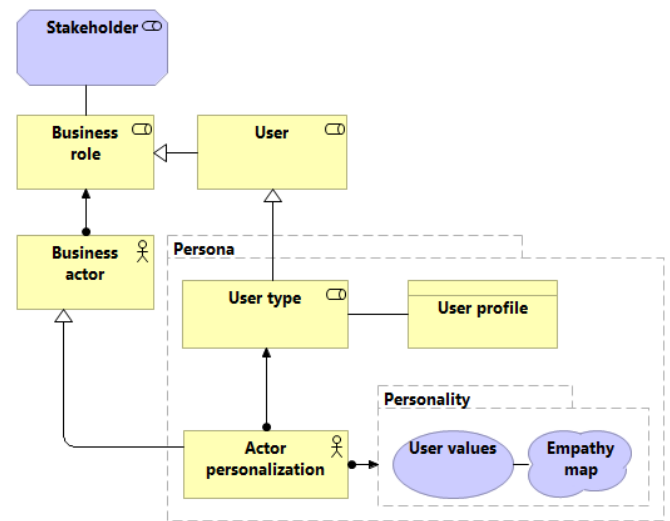

Figure 13. Persona concept

In building a persona model of a team member, at the beginning his profile should be determined, which can be characterized by: experience, job seniority, age, education, family background, and so on. An important issue is to uncover his personality, e.g. motivation, attitude, feelings and the way of thinking. The definition of a persona for a retrospective should be followed by customer journey canvas designed for each persona. An important task while developing a persona and customer journey canvas is to build an empathy map.

The same considerations are valid for the retrospective leader. This role is of great importance for realizing goals of a retrospective. That is why the feelings of the surveyed persons regarding this role seem interesting.

## VIII. SPRINT RETROSPECTIVE LEADER ROLES

Success of a retrospective depends on the retrospective leader and team members. The behavior of the retrospective leader and team members depends on the retrospective phase. A retrospective consists of three phases: preparing for a retrospective, conducting a retrospective, and post-retrospective actions.

**Preparing for a retrospective.** Survey results confirmed that most participants of a retrospective are not prepared for it. The leader should investigate what occurred during the last sprint, exceptional events that took place, the feelings of the team members, the artifacts and the attractors. These should help to outline and understand the problems the team was facing, and, ultimately, to set a retrospective goal. Outlining the purpose of a retrospective makes the team members see the reason why they are going to spend their time attending the meeting. Retrospective duration depends on many factors, including, e.g. the sprint length, the complexity of the project, technologies used, the size of the team, the level of conflict in the team and the issues that arouse controversy. The next step in the preparation of a retrospective is setting up a schedule. The meeting should be typically divided into phases. For each of these phases, special activities must be prepared that allow the group to mobilize to work together. These activities are designed to encourage team members to actively participate in the meeting, increase their creativity and focus on the topic. It is important not to use only one exercise during retrospective meetings, because doing it repeatedly becomes boring and does not promote creative thinking.

**Conducting a retrospective.** The leader should focus on the process and the structure of a retrospective. Adapting to the needs and dynamics of the team should help the team members to reach the goal while staying neutral in a discussion, even if they have their own insights. In addition, the leader, as the person who knows the schedule of a retrospective, has to present each activity before starting it. This will make the team aware of what they can learn from exercises. Every activity should end with a discussion on the obtained effects and conclusions drawn from it. An important task of the leader is to observe the activities of the participants of a retrospective. The leader should draw attention to those who do not participate at all, encouraging them to take part in the discussion and express their opinions, as well as to those who dominate the conversation. During a retrospective, the retrospective leader listens attentively to participants' speeches, trying to capture the signals of the blame or clutter of the team members. Seeing what the conversation is about, the leader should try to change its course. Moreover, it may happen that during a meeting the team loses the sense of time and here emerges another role of the leader connected with managing the time. The leader should give signals so that the meeting proceeds according to the schedule.

**Post-retrospective actions.** The basic principle of a retrospective is - after inspecting - making adaptations in the next sprints. If only a small part of the proposed changes are implemented, the team may become frustrated and not willing to take part in retrospectives in the future.

## IX. SPRINT RETROSPECTIVE IMPROVEMENT CONSIDERATIONS

A retrospective is a part of Scrum, which, unfortunately, is often ignored, depreciated and neglected. As a result, the team cannot obtain desired results from such meetings. But it is assumed that a retrospective influences team development, improves the efficiency of its work and communication

between team members. Without a good retrospective, it is not possible for the team to improve their performance.

Unfortunately, the results of the survey reveal that in most cases retrospectives do not meet the assumptions. A large group of the survey participants failed to notice whether such meetings make proper changes to the team and, in particular, whether they allow them to develop. Does this mean that the belief in the power of a retrospective is only a myth?

In the survey several people noticed certain additional issues during a sprint retrospective. It happened that, despite the improvement resolutions, the team members lacked the consistency in implementing them. In addition, during the meeting itself, the participants often lacked the discipline, which was often the leader's fault.

At the same time, the survey showed that satisfaction with retrospectives was strongly linked with the number of exercises done during meetings and almost did not depend on earlier preparation for them. The more activities were done during the meeting, the more positive effects of the action were noticed by the team members. In addition, a retrospective was better assessed by people who prepared for it.

The analysis of the survey results allowed us to formulate tips helping to fix a retrospective and make it work as expected. One of the most important factors influencing success of a retrospective is the choice of the leader. The leader should be a good observer who can encourage shy people to actively participate in the meeting, while diminishing the behavior of those overactive. In addition, the leader should be a person who knows the schedule of the meeting best and possesses thorough knowledge of how each exercise should be performed during the meeting.

This is directly related to the preparation of a person to lead a retrospective, which consists not only of the preparation of a proper place together with the needed materials, but also of learning about the course of the sprint and the situation in the project, and to determine the purpose of a retrospective. It is also a good habit to divide the meeting into five phases of varying lengths, each with different duration and aim. The direct result of this division is the activity performed during each of the phases aimed at achieving the goal of each phase. Taking these tips into account when preparing for the next retrospective will certainly make the team's attitude to a retrospective meeting more positive and will enable them to notice its positive impact on their work.

Sometimes the reasons why a sprint retrospective does not work well are known, and the time needed for solving problems is much longer than the sprint length. In this case alternative measures should be considered, like e.g. forwarding problems to an issue log system to solve impediments and perform team networking exercises to enhance cooperation.

## X. CONCLUSIONS

Enterprise architecture is a means of improving and understanding activities in a company in a uniform and holistic way. Such an approach may be proposed for agile and classic software products development processes. The presented

enterprise architecture models may be suitable for different stakeholders, because, as shown above, they can model different methodologies with sufficient details and in a way that is understandable to different stakeholders.

Enterprise architecture models are good measures of the improvement of company processes. The main driver of the paper were survey results concerning a sprint retrospective, which showed numerous weaknesses of a retrospective. The main aim was to look at a retrospective from the perspective of enterprise architecture and to find suitable solutions from the company's perspective. The proposed model may be used to compare different approaches. Developing a detailed model of a retrospective will make it possible to assess it from the outside.

The obtained results are a good starting point for developing a more comprehensive and consistent model with sub-models related to project and product management in software houses.

# 4<sup>th</sup> Conference on Multimedia, Interaction, Design and Innovation

**M**IDI Conference provides an interdisciplinary forum for academics, designers and practitioners to discuss the challenges and opportunities for enriching human interaction with digital products and services.

The main focus of MIDI Conference is exploring design methods for creating novel human-system interaction, developing user interfaces and implementing innovations in user-centred development of advanced IT systems and on-line services.

## TOPICS

Topics of interest include (but are not limited to) the following areas:

- interactive multimedia and multimodal interaction design
- novel interaction techniques, voice interfaces, interactive multimedia
- ubiquitous, multimodal, pervasive and mobile interaction, wearable computing
- novel information visualization and presentation techniques, Augmented/Virtual Reality
- design methods for usability, accessibility and outstanding user experience
- prototyping of user interfaces and interactive services
- human-centred design practices, methods and tools, user interface design
- unfolding trends in HCI research and practice, customer experience, Service Design
- advances in user-centred interaction design
- understanding people and interactions: theory, concepts, models and methods
- understanding people and interactions: contextual, ethnographical and field studies
- critique and evolution of methods, processes, theories and tools for human-computer interaction
- novel methodologies for conceptualization, design and evaluation of interactive products and services

**Abstract**—This paper presents an outline of novel approaches and emerging trends related to Human-Computer Interaction (HCI). These trends have been present in the MIDI 2017 conference organized within FedCSIS series. In particular on-line services and mobile applications, often operated by voice-based interfaces and voice-driven assistants, are special areas of interest as to their prospective developments. Also the use of Artificial Intelligence (AI) in user interfaces seems to offer a breakthrough towards more intuitive and error-tolerant interaction needed especially in the most common, mobile context of use.

**Index Terms**—Human-Computer Interaction, Interaction Design, Usability & User Interface, User Experience.

RECENT developments in Information Technology (IT) create new opportunities for creating new user-system interaction techniques. As a result, nowadays we are witnessing a remarkable shift in research and practice of Human-Computer Interaction (HCI).

Traditionally, the domain of HCI has dealt with optimizing user interfaces and developing new interaction styles. Historically, the humans were first placed as trained operators of computer systems dedicated to serving narrowly-defined domains like accounting, manufacturing or process control. With the introduction of Personal Computers (PCs) in the 1980s, the human has become not only a software user, but also an important stakeholder in IT projects. This shift has led to developing User-Centered Design (UCD) approach, very popular in contemporary IT projects. Most recently, availability of wireless networks and handheld devices (especially smartphones) caused that mobile applications and on-line services have become a natural part of everyday life. Ultimately, in IT projects today the human is not only a target user, but also a consumer who decides for instance which payment plan to choose or when to terminate the subscription (often caused by switching to more attractive offer from another vendor).

From a technical viewpoint, developing and launching a mobile app or website is relatively easy, but the competition is usually strong and users have a wide choice of similar solutions on-line. In such conditions the real problem is how to attract attention of potential customers and how to gain

their loyalty. These are the central questions of on-line relationship marketing and on-line branding – areas not present in IT development until very recently.

As a result, currently e-customers often treat IT systems (especially mobile applications and on-line services) as *service solutions*, which help to solve practical problems (like shopping, reservations, navigation etc.) or to improve individual lifestyle (for instance in areas related to fitness, wellbeing, ecology, safety, health, child care etc.). E-customers remain loyal to specific on-line services as long they satisfy their expectations, resulting from everyday context of use (related to specific problem to be solved – what, when and where) as well as from their current lifestyle, or even fashion. E-customers' loyalty to a specific service or app no longer results merely from adequate functionality, decent usability and aesthetic look of an app [11]; now it primarily results from cumulated, constantly positive User Experience (Customer Experience), making a given app or service someone's preferred choice.

Nowadays user interface still remains an essential part of an IT product, but now it is less a technical component, instead more addressing emotional, behavioral, economical, or lifestyle-related needs. However, the contents of recent IT projects has also changed a lot: now the focus is no longer a computer system, but a specific *service* aimed to generate revenues. In addition to the technical part (now often outsourced to subcontractors), today's IT projects often address issues such as on-line relationship marketing strategy, appropriate business model, ethnographical studies, creative design and innovation development. The term "creative projects" is now often related to IT projects, and teamwork creativity (often stimulated by Design Thinking techniques [9, 10]) is expected to produce solutions which will not only attract a customer, but will make him/her loyal to a specific service brand or vendor for a long time.

In the timespan of a recent decade, these trends have changed the role of HCI in IT projects, while new interaction technologies have open new opportunities to deliver on-line services and solutions not even imagined in the past. Also the popularity of IT design paradigms such as SOA (Software Oriented Architecture) or SaaS (Software as a Service), especially attractive among business users, made

IT applications generally perceived *as services*, while ease of use and positive User Experience remain critical requirements enabling their practical use.

As a result of these developments, regarding the current role of interaction design in IT projects we are now facing some novel research problems, for instance:

- developing new methods for providing not only high usability of interactive systems, but also valuable User/Customer Experience over a long time;
- delivering consistency among mobile websites and mobile applications, because users often use several handheld devices to access their favorite on-line services;
- developing effective methods for designing interfaces for small screens, because mobile context of use becomes prevalent for users in everyday life and in business activity;
- rapid development of low-cost Augmented- and Virtual Reality (AR/VR) interfaces soon will change the way how users will be interacting with reality-based objects;
- balancing rapid prototyping techniques, widely used in agile design, with standardization and patterns which enabled easy operation of multiple devices because users were able to utilize previously acquired knowledge and skills;
- fast proliferation of social interfaces, often used in mobile context, changing what used to be Human-Computer-Interaction (HCI) more towards computer-mediated Human-Human Interaction (HHI), with all its benefits but also with quickly emerging serious risks;
- building safety, security and trust, as preconditions of positive User Experience, how they should be developed in design of an IT product/service and how they should be communicated to users/consumers.

These issues – and many others – have been in the focus of MIDI (Multimedia, Interaction, Design and Innovation) Conferences, organized since 2013. Last year's MIDI [2] held for the first time within the FedCSIS series also highlights a number of topics related to a main stream as well as to niche research agendas as follows. User experience issues, accessibility and user interface design were presented by [12][13][14][16][17][18][20][21][23][24] yet different papers put those issues in different context of programming, game design, crowdsourcing or visually impaired people just to name a few. On the other hand some other paper stated questions about affective design, applications for supporting the ongoing therapy or pervasive robot assistants [15][19][22][25].

The MIDI 2017 Conference aims to cover at least some of issues shaping current trends in designing interactions between users/customers and interactive content or services. As usually, also papers included in this MIDI 2017 volume are expected to spark stimulating discussions on the crossroads of multimedia, interaction, design and innovation – as the conference name tells.

Submissions collected in this volume have been divided into following sections, roughly covering:

- Education Systems – interaction design for educational applications [26][27];
- General HCI – various interaction design aspects, from technical to aesthetic ones [28][29][30][31][32][33][34];
- Graphics/Speech – including multimodal user interfaces, present in everyday use, gaming, entertainment or teamwork applications [35][37].

Among latest trends and developments listed above, especially distinct is the advent of digital voice-driven assistants, especially in home and mobile environments. They allow for natural, spoken communication between the user and a computer system, thus providing much more natural interaction style than user interfaces that had been used so far.

As mentioned by many recent references (eg. [3], [4], [5]) one of the latest HCI challenges is the application of Artificial Intelligence (AI), especially voice driven assistants. There are a lot of new advancements here – ranging from enabling technologies up to entire ecosystems of applications. In July 2017 Amazon's Alexa passes 15000 skills (applications defining dialog domains) growing rapidly in one year and its competitors like Google Home or Siri are not far behind. Smart home assistants may control home appliances and are useful in everyday duties. However, preparation of voice interface isn't simple, even with supporting tools [6] and mixed-initiative dialog needs a lot of preparatory work and good knowledge of voice dialog rules. Here HCI specialist may help easing the task of dialog preparation.

We may expect, that definitions and models created for voice interaction with assistants like Alexa or Siri will influence the shape of interaction in a future. Standards for how we interact with voice assistants will emerge in the same way as it happened with web browsing and common icons, forms, and gesture styles used across the app market [7].

Nowadays yet another challenge emerges: as shown also at MIDI conference there are clear trends in computer vision and AI: image classification, scene and object recognition, game play learning, image and video question answering. Visual Dialog is a novel task that requires an AI agent to hold a meaningful dialog with humans in natural language about visual content. Specifically, given an image, a dialog history, and a follow-up question the agent has to answer the question in natural language [8]. This opened new potential applications to support visually impaired users and social human-computer interactions. However, how shape such a dialog is still unclear, but first attempts are already underway.

In comparison to previous editions of MIDI [1, 2] this year, in addition to voice interfaces and speech synthesis, some novel topics have been reflected in submitted contributions, to name a few:

- deep learning for style search engine, which combines state-of-the-art visual object recognition and text queries to find furniture in suitable style and aesthetics,

- rapid VR, graphics, pose and location estimation, which allows for realistic cloth simulation on mobile devices, precise head pose estimation, use of VR in fire safety education, multimodal multi-device ecologies exploration;
- digital heritage, thanatosensitivity, for interaction with digital memorials.

A wide spectrum of other papers presented at the conference indicates how vital is the extended understanding of HCI for the modern IT. MIDI proceedings also address the timely challenges produced by the emergence of mobile computing as the most common interaction paradigm. In many papers interaction design is now considered as an important factor facilitating users' attitude to the interactive product, and shaping its attractiveness. This extended perspective opens an interesting research agenda, for reaching beyond traditional understanding of human-computer interaction, and also for treating interactive systems not only as engineering solutions, but also as services aimed to solve a specific user's problem. We believe that contributions in this area are particularly relevant as making sure that the abundance of data generated by computational artifacts around us used effectively is bound to be crucial in deterring how our lives will look in the near future.

We hope that these proceedings present a good record of the MIDI 2017 conference and will be a valuable resource for researchers in the vibrant interdisciplinary field of interaction design.

**Abstract**—The subject of this paper is to compare two different modality multi-touch interactive surfaces based on both: user experience and results of measurements in order to examine how different properties influence usefulness, in specific, their fitness to act as a "coffee table". Tests were conducted on the Microsoft PixelSense (AKA Surface) and a Samsung touch screen overlay both 40+ inches diagonally. The study covers analysis of obtained measurements and summary of user experience collected over a number of summits and experiments. While tests for both devices returned very similar results, with the overlay more favorable, neither device could truly fit the tested use case due to their inconvenience, form factor and other issues.

## I. INTRODUCTION

Touch enabled devices offer their users a fast and intuitive interface, and those properties skyrocketed the popularity of and demand for such solutions. Traditional control methods of electronic devices — in majority various buttons and switches — have started to become less popular while touch solutions have become cheaper, more accurate and efficient [1]. To best facilitate people with this type of interface, it is crucial to well define human tendencies, perception, behavioral patterns, as well as what constitutes as "common sense", or intuition, while using them [2], [3].

## II. TECHNOLOGY AND METHODS

### A. Technology

There are 3 devices of importance in this paper. The Microsoft PixelSense (AKA. Microsoft Surface, SUR40), Samsung Touch Overlay (both being under tests) and Basler camera (for testing). SUR40 is a touchscreen table with a built in desktop computer. It uses infrared transmitters and sensors mounted underneath the 40" screen itself to complement a more conventional capacitive touchscreen. Such a system can detect many inputs and differ their shapes.

The Samsung Touch overlay is a frame that can be mounted on a 40" TV screen to turn it into a touch screen. The sides of the frame contain built in infrared transmitters and on opposite sides receivers are mounted. This system can detect up to 6 inputs but will not distinguish their shapes.

For testing purposes a Basler ACE Camera ACA2040 180KC was used to measure time between relevant events. The camera itself is capable of capturing 180 frames per second with a resolution of 2046 pixels by 2046 pixels, although in these tests the camera was set to capture only 100 frames per second, due to the screens' 60 hertz refresh rate. The lens that was used for the Basler camera was the Computar M2518-MPW2 with a focal length equal to 16mm, an iris range of F2.0, and a 2/3" format.

### B. Input lag and multi-touch capability test

The test involved a Basler high-speed camera which was used to measure the interval between interaction with the screen and the device's reaction. A Google testing tool called cross touch latency was used. Two test were conducted. First using the click mode of the tool where a time stamp of the moment of the finger breaking contact with the touch area and a time stamp of the reaction (the screen going black) were captured via the high-speed camera. In the second test the reaction to a dragging action was assessed in a similar manner with the scroll mode. In both parts the camera was set to the side of a table looking at it in an angle to adequately distinguish the movement of the testing instrument while still being able to note the reaction of the testing tool.

In multi-touch capability test, the devices' ability to deal with multiple inputs was tested. This was done in three ways. First, using the Microsoft Paint application, which has multi-touch capability out of the box. During the test an increasing number of parallel lines was drawn at the same time. When one of the lines failed to be drawn, the test was considered as failed. The tests were repeated and accuracy changes noted. The second way involved devices such as phones. They were placed on the touch surface in random locations and the device's reaction was noted. The third way was a combination of the first and second, where a few phones were placed on the display and concurrently, parallel lines were drawn. With this, the device's ability to act as a "table" was tested.

Figure 1. Exemplary image to be recreated by the user.

### C. User study protocol

There were  $n=18$  participants. The group consisted mostly of students who attend technical studies. At the beginning, users were introduced to both of the devices on which they were asked to perform 4 prepared tasks. Participants were only told that the devices are controlled by touch. All of them had the same tasks in the same order.

In the first task users were asked to find a weather forecast on the Internet and then shortly report the weather for today and tomorrow. This task made the user use the device in a way that one would use on a daily basis and allowed us to gather their first impressions. Second task required the users to use MS Paint in order to reproduce simple picture of a human, a house and a cat. The third task invited the user into the touch enabled game called "Angry Birds". This task gave users the opportunity to gather opinions about the accuracy or the response time of the touch screen. During the fourth task users had to rewrite first four lines from famous Polish novel. This task allowed user for comparison of speed and accuracy of input during relatively simple task of tapping proper keyboard buttons manifested on the screen via the on-screen keyboard. Picture that was presented to recreate can be viewed as Figure 1.

For each task, the participant was asked to perform it on one device and then again on the other device. After each try, the user would rate, in a scale from one to ten, how comfortable with the device they felt executing specified task. The next two questions asked if the task would have been easier or more comfortable if they had access to a mouse and keyboard, or if they were performing it on a regular smartphone.

## III. RESULTS

Firstly, the input lag test provided information about time between user touching and a reaction visible for the user. During whole test twenty measures were performed from which it can be said that their response times are very close to each other because for the PixelSense it was 146.0 ms (std: 8.6 and median: 145) and for Touch Overlay it was 148.1 ms (std: 11.8 and median: 140).

Secondly, multi-touch capability test were performed for both PixelSense as well as for Touch

Figure 2. Users level of comfort while searching for information.

Overlay devices. For the first test, the PixelSense supported drawing up to 10 lines in Paint. After seven lines a noticeable loss of accuracy was recorded. As Paint only uses 10 touch points, the built-in Surface Shell was used for further testing. Up to 35 touch points were recorded as working before the size of the display made distinguishing any more difficult. Only objects with conductive surfaces could be used to interact with the screen. The screen would often recognize the palm of the hand as a touch point. For the second test, the PixelSense recognized the phones as touch points in the middle of their center of mass fairly well. Some devices, however, would not be recognized by the device, and some would cause glitches when put too close together. For the third test, the phones placed on PixelSense would correctly register as a touch point and would not otherwise interfere from drawing other parallel lines.

Next, Samsung Touch Overlay was tested. For the first test, the overlay supported up to six concurrent lines in Paint. Drawing them too close to each other caused accuracy problems. Items such as pens could be used to interact with the screen. For the second test, the overlay would not recognize the phone as a touch point, unless only a single corner of it was close to the screen at a time. For the third test, a placed phone or other obstruction would prevent any touch near it in a cross formation from registering.

### A. User study

Results from the user study are presented in Fig. 2 - 5. Fig. 2 shows information about level of comfort during first task was presented. Moreover in this task the Touch Overlay got the better ending score because the average level of comfort was at 7.6 (std: 1.8, median: 8) than the PixelSense which got 5.3 (std: 1.4, median: 5).

During second test users were asked to replicate a simple drawing. The average level of comfort on Touch Overlay was at 6.3 (std: 2.0, median: 7) and on the PixelSense at 6.1 (std: 2.1, median: 7).

Additionally in this test users were asked to provide level of satisfaction after performing the drawing test. The results can be found in Figure 4.

Figure 3. Users level of comfort while drawing in paint.

Figure 6. Users level of comfort while typing.

Figure 4. Users level of satisfaction on completing drawing in paint.

The summarized results are as follows. On Touch Overlay average score was at 6.3 (std: 2.5, median: 7) and on PixelSense at 5.0 (std: 2.5, median: 7).

The following test was focused on performance during the game "Angry Birds". Once more users graded their comfort during the test (the results can be seen on Figure 5), the following results were obtained. On the Touch Overlay average level of comfort was at 5.5 (std: 2.3, median: 6) and on PixelSense 5.1 (std: 2.0, median: 5)

Last part involved potential users in typing part of a text. The total results can be viewed in Figure 6. On Touch Overlay average was at 6.2 (std: 1.5, median: 6) and on PixelSense at 6.0 (std: 1.9, median: 6).

#### IV. DISCUSSION

Tests on Input lag for both devices suggest a response time of around 150 milliseconds, while average response time of a human lands between 200 and 250 milliseconds. During user tests the lag did not however raise any complaints. Nonetheless, it is high enough to influence activities requiring

Figure 5. Users level of comfort while playing game (Angry Birds).

quick reaction times and this issue should be further investigated.

Multi-touch capability test was conducted in order to ascertain the viability of use by multiple users or with obstructions in form of phones or cups at the surface. While results indicate over-performance of PixelSense over Touch Overlay in handling objects placed on the surface, many people are already accustomed to using no more than 2 fingers to operate an interface. Hence, the overlay could be used by 3 people at once without issues, and as long as it is clear of any obstructions, could function as a coffee table. The biggest issues with such a configuration may in fact be the form factor of the overlay (no space to place hands) and the small viewing angle of the screen. On the other hand, the PixelSense, with a dedicated area for elbows and a great viewing angle, fails in a practical sense. The infrared touch supplement is extremely sensitive and frequently turns everything from the user's palm to a sleeve into a touch, resulting in less accuracy.

The first task of searching for the weather went well on both devices. Participants generally claimed that working with the Touch Overlay was easier than the PixelSense. Only a few judged the Touch Overlay as less accurate, in part because of the attachment of the device a few millimeters above the screen. Another issue that was brought up was the roughness of the digitizer not being fit for a touch device.

The painting exercise on PixelSense often required to inform participants about the infrared sensor position. After adjusting by moving the arm higher, the task could be completed, but not without comments that such a position is unnatural. The results of the task on both devices were satisfactory for most participants, who also noted that the device is more fit to it than a mouse or a phone. On the other hand users reported video game experience as much less satisfactory. Large number of participants could not reliably make 'hold and drag' motion and felt that whatever they succeed or not is random. During typing task many participants noted that the hand position required to use the touch keyboard was unusual and slowed

them down. Standing up or adjusting the device's angle helped some of them.

Additionally, results from User study was applied to student T test from which it can be stated that the averages of results from both devices are significant different ( $t = 2.496945$ ,  $p < 0.014848$ )

## V. FUTURE WORK

There exists a large swath of work that has to be done in the future to truly find out about themviability of large size touch screen devices in consumer situations. If they are to be installed as coffee tables, for example, a big amount of attention must be paid to the device's ability to deal with multiple users at the same time and to deal with objects placed on it in an intelligent way. However, even the best touch screen means nothing if users do not feel like they are enjoying an experience which is worth the money they spent, or at least one that is meaningfully different from the one they could have simply using a regular computer or smart-phone [4]. Thus, apart from research aimed to improve the hardware, research to find better use cases and create better suited applications is also needed. Also more devices should be tested [5] possibly with more than one person [6].

Also the field of persuasive systems could benefit from incorporating disputed technology [7]. It is interesting if multitouch devices of large screen, when widely available could support specific mundane tasks such as scientific image annotation by ordinary users, as proposed through online crowdsourcing systems recently [8] [9]. In fact there is a need of users of a process tomography domain for constructing a specialized system for presenting and visualising the raw and reconstructed measurement data such as available here [9] [8] [10] [11].

## VI. CONCLUSIONS

This paper shows a comparative study for two can be used with success for educational purposes [12]. modality interactive multitouch surfaces in terms of multi-user use. Both tested devices are clearly fit for the task of becoming a table in the living room, with the Samsung Overlay seemingly being the more convenient choice, yet generally users are less than eager to use these kind of devices because of their inconsistent touch experience. In order for them to be more popular, performance and usability should be improved in order for the users willing to switch from ordinary devices to multi-modal touch interactive surfaces. The devices were not versatile enough, with users quickly becoming disinterested after learning their flaws. Additionally, software support for multiple users is currently low, with

few applications capable of handling more than one person (even two fingers only each). Another thing that prevent both devices from becoming a table is their inherent fragility and reluctance of users to place objects on them. This technology, however, can be used with success for educational purposes [12].

**Abstract** — This research intends to analyze how users that are also HCI designers relate to the interaction with digital memorials linked to graves through QRcodes. To do so, we have carried out an immersive practice in the Consolação Cemetery (São Paulo, Brazil), where that technology is used to tag the graves of famous deceased people and to guide the visitors in the site. Those QR code tags link the graves to an online application for digital memorials called MemoriAll. To address the problem, this paper analyzes the data collected from the surveys answered by the research subjects before and after the immersive practice, along with data from a semiotic inspection of MemoriAll.

### I. INTRODUCTION

IN the last years, cemeteries have undergone several changes, from the architecture of graves (which are now considerably smaller and cheaper) to the reasons why people visit those sites. Besides visitors who want to remember or pay homage to deceased relatives or friends in front of their graves, there is now a growing number of tourists going to cemeteries. They are mainly interested in funerary art or graves of famous people, which help preserving the collective memory of a social group. Some cemeteries are considered landmarks for sightseeing, such as Père-Lachaise, in Paris (France), and La Recoleta, in Buenos Aires (Argentina). Therefore, there is also a growing use of digital technologies in the visits to those places, similar to what happens in museums other cultural sites [28].

Technology-mediated visits to these spaces may permit experiences beyond the immediate interaction with physical objects. With a simple mobile device, a visitor in a cemetery can access information about the deceased or about works of funerary art by means of a QR Code<sup>1</sup>. According to Cann [4], “QR codes transfer the dead from the cemetery to the realm of the living by giving the living a connection to the deceased that can be accessed anywhere.”

In general, QR codes in cemeteries permit the access to digital memorials, where different kinds of data about the deceased (photos, videos, textual information etc.) can be found. This technology creates a connection between the physical place where the deceased’s remains are buried and some virtual representations of what that person had been in life. Some digital memorials on the web permit paying homage to the dead [1] or even performing some religious

rites. They comprise a very specific kind of system, which can be modeled with social network elements [9], but the solutions designers can come up with are still limited by their beliefs and taboos on death [13].

Facing this context, the following questions arise: do these systems meet users’ expectations? How do HCI designers see these systems? This research intends to analyze how users that are also HCI designers relate to the interaction with digital memorials linked to graves through QR codes. To do so, we have carried out an immersive practice in the Consolação Cemetery (São Paulo, Brazil), where that technology is used to tag the graves of famous deceased people and to guide the visitors in the site. Those QR code tags link the graves to an online application for digital memorials called “MemoriAll<sup>2</sup>”. The profiles of the dead in MemoriAll include different data, such as biography, family tree, photos, messages, videos, obituary etc.

The use of digital technologies like QRcodes in Brazilian cemeteries is still very recent, which reinforces the need to carry out studies about them in that country. More generally speaking, many other cultures and countries do not use automated technologies in cemeteries, so there is a gap to develop, innovate and experiment on this area.

In order to address the aforementioned problem, this paper analyzes the data collected from the surveys answered before and after the immersive practice, along with data from a general semiotic analysis of MemoriAll.

### II. METHODOLOGY

To carry out this exploratory field study, we opted for a participant observation [13] to collect data. Considering the characteristics of the immersive practice, its planning and preparation demanded great effort from the researchers.

The immersive practice in the Consolação Cemetery herein described was carried out during the 7<sup>th</sup> edition of the *Workshop on Human-Computer Interaction Aspects in the Social Web*, within the *Brazilian Symposium on Human Factors in Computer Systems*, in São Paulo. The workshop promoted the debate about opportunities and challenges that Social Web poses to the Brazilian community of researchers on HCI regarding digital legacy. Among other activities, the organizers of the workshop proposed the qualitative research herein reported, in order to articulate theoretical discussions and practical activities within the domain of digital legacy.

In the workshop’s morning shift, participants discussed digital legacy and digital memorial issues. In the afternoon,

<sup>1</sup> Quick Response Code, a machine-readable optical tag usually linked to extra information about the object to which it is attached

<sup>2</sup> <http://MemoriAll.com.br/>

those who accepted to participate in the immersive practice followed the 4 researchers to the Consolação Cemetery. 21 workshop participants agreed to be research subjects. They were all informed that they should bring the conference badge and charged cell phones with QR code readers to the cemetery. As this was our first immersive practice in cemeteries, a place that can evoke memories of different kinds of intensities (including very passionate ones), we decided to recruit only HCI experts, which we believed would be more capable of separating private concerns about cemeteries and the experience of using QR code technologies in that setting.

Because the study was intrinsically complex, requiring perceptions and understanding of not only usability and accessibility issues, but also of communicability, emotion and human values, we recruited only HCI experts interested in social applications *as they tend to be sensitive to a wide range of technical and social issues*.

At the entry of the cemetery, the researchers made a brief explanation about the activity, its goals and instruments (the scenario, the survey, the QR code reader etc.). Participants were asked to sign a consent term, whereby they agreed to be research subjects and allowed researchers to publish data from this study. The consent term said that *"The field study is intended to permit that workshop participants have an immersive experience in the context of digital legacy, by carrying out stages of a qualitative research on Social Web, in order to reflect upon issues such as ethics, privacy, digital legacy and human issues"*.

During the visit, users were photographed and recorded while interacting with memorials. They also answered two surveys: one before and the other after the visit. The pre-visit survey contained 7 questions about general data and experience in HCI, 11 questions about religion, 2 questions about representations of death, 7 questions about cemeteries and 2 questions about expectations about the immersive practice. The post-visit survey contained 2 questions about how the users felt after the practice, 10 questions about the *Memoriall* application, 1 question about their cell phones and 2 questions about the immersive practice. To guide the visit to the cemetery, the participants should follow a scenario, which is presented below.

*"You are a tourist sightseeing in São Paulo with your friends. You decided to visit the Consolação Cemetery, which is famous for works of funerary art and for the graves of famous Brazilian people, such as Tarsila do Amaral, Monteiro Lobato, Mário de Andrade and de Santos Marchise. You heard that in this cemetery visitors can use technology to access QR codes on totems and on the graves of famous people.*

*When you got to the cemetery, you checked the printed map available next to the front gate and decided to take a look at the following graves: 1. de Santos Marquise's; 2. Cícero Pompeu de Toledo's; and 3. Mário de Andrade's.*

*Then, you chose the graves you would like to visit, copied their addresses from the map and entered the cemetery.*

*When you turned onto the street where 1. de Santos Marquise's grave is located, you saw a totem with a QR*

*code tag on your right and you decided to explore it. Then, you went to de Santos Marquise's grave, accessed her memorial through the QR code and: 1.1. Observed the possibilities on the webpage of her memorial; 1.2. Read her obituary; and 1.3. Read her messages.*

*Then you moved to 2. Cícero Pompeu de Toledo's grave and accessed his memorial, where you looked for the following information: 2.1. Causa mortis; 2.2. Date of death; 2.3. Why he was famous; 2.4. Messages to him.*

*Then you crossed the cemetery to visit 3. Mário de Andrade's grave, accessed his profile and: 3.1. Read his biography; 3.2. Read the available links; and 3.3. Shared with your friends that you were there.*

*Finally, you walked to the exit of the cemetery, while observing other interesting things you found on the way"*.

The immersive practice ran as proposed in the scenario. Throughout the visit, participants exchanged impressions about the place and the experience of being there in a research activity. The visit took about 3 hours and finished when the participants answered the post-visit survey.

The data from the surveys were tabulated in an Excel spreadsheet following the numbers of the questions in the survey, and graphs were created with the aid of the software program Google Sheets<sup>3</sup>. As there is no information about the population size, the statistical significance of the responses could not be calculated. In this paper, all questions are referred to by using the letter Q and their respective number in the survey. Some multiple-choice questions were correlated in the analysis for promoting deeper results. In the analysis of the open questions, participants were identified by the letter U followed by a number to preserve their anonymousness and to permit the comparison of each respondent's pre-visit and post-visit surveys.

The answers from the surveys were also contrasted with a semiotic analysis of the application *Memoriall* considering the sign categories proposed by Peirce [21] and adopted to describe computer interfaces by de Souza et al. [8] and Lopes et al. [11], among other practitioners of Semiotic Engineering. However, as the main objective of the study was not the reconstruction of the designer's metamessages, we did not follow a specific semiotic method; instead, we read the screens from *Memoriall* scaffolded by the sign categories adopted in Semiotic Engineering to describe computer interfaces.

The software interfaces inspected were the same the participants dealt with when performing the activities suggested in the scenario for the immersive practice.

The qualitative analysis based on the semiotic analysis and on the answers to the surveys permit to identify relevant elements and information in this domain. It is also enriched by quantitative data regarding the impressions participants had during the immersive practice.

### III. RELATED WORKS

In the last years, researches have been carried out on thanatosensitivity, an approach that actively integrates

<sup>3</sup> <https://www.google.com/sheets/about/>

mortality, grieving and death into design and HCI research [17]. In 2011, Massimi et al. [18] defended that HCI studies must address death in a lifespan-oriented approach. According to the authors, there are four main concepts in this area: life, death, the dead and the bereaved; and there are four main research topics on the end of life: materiality, identity, temporality and methods.

Nalini [20] explains that the two main approaches to death are the scientific and the religious one. Technology itself does not promote a new approach. Instead, it is a new transversal lens through which death can be seen.

When it comes to the dead and the bereaved, different technologies have been designed and adapted to allow users to pay homage to the deceased. For instance, Oliveira *et al.* [7] pointed out four different categories of functionalities for Digital Legacy Management Platforms (1. sending previously configured messages; 2. creating online memorials; 3. storing and managing digital legacy; and 4. creating bots/avatars that simulate users' behavior).

Riechers [26], mentioned that websites for digital memorials have been there since 1996, when the platform *Virtual Memorials*<sup>4</sup> was created. Therefore, another relevant system design issue is the development or transformation of social network profiles into digital or online memorials. The concept of digital memorials comes from the idea of memorials in the physical world, where concrete monuments are used to honor the memory of a person or an event. According to Riechers [26], all personal memorials come from a common human need: honoring death, so as to evoke memories of happiness and pain, and to comfort the bereaved. That social practice has now been transposed to web environments, where users can pay homage to the dead by offering them virtual flowers, lighting virtual candles or sending them digital verbal messages. Some systems even allow users to make virtual prayers for the deceased. According to Carroll and Romano [5], online memorials are unique because they transcend space and time. For example, one can take part in a virtual wake or visit a virtual grave in the web, regardless of space and time constraints.

The development of platforms for both the living and the dead leads Brubaker et al. [2] to consider dead users not as a special subgroup of users, but as a case of extreme users, whose particular technological needs require special attention from software. In a research on digital memorials, Lopes, Maciel and Pereira [10] analyzed the systems iHeaven<sup>5</sup> and *Saudade Eterna*<sup>6</sup> in the light of social network characteristics and experiments with users. The authors created some practical recommendations for the design of digital memorial systems [9]. The recommendations and the prototypes are aimed at designers working on solutions in that area, so they can meet users' expectations, protect dead users' reputation, and project multicultural applications.

Funeral companies have also entered the market for memorial services. For example, the *Memorial Necrópole Ecumênica* (Ecumenical Necropolis Memorial, in a free

translation), in São Paulo, Brazil, offers not only the physical cemeterial structure, but also virtual and online services<sup>7</sup>, which offer profiles of deceased people, allow mourners to interact among themselves, post sympathetic messages or participate in funereal rites online.

*Digital Memorial*<sup>8</sup> is described by its owners as an application that “create[s] and implement[s] Digital Memorial solutions to improve family and friends' bereavement processes”. Its services include QR code products and solutions, NFC (Near Field Communication) software and tags, the “Keeping their memory alive” campaign, GPS solutions and giftboxes to express sympathy.

Facebook gives the option to transform a common profile into a digital memorial after a form proving the user's death is filled in. According to Facebook, “*Memorialized accounts are a place for friends and family to gather and share memories after a person has passed away. Memorializing an account also helps keep it secure by preventing anyone from logging into it. If Facebook is made aware that a person has passed away, it's our policy to memorialize the account*”. In Facebook, it is also possible to name a legacy contact for the account<sup>9</sup>, somehow similar to an heir with enough privileges to share a final message on the person's behalf, respond to new friend requests, update your profile picture and cover photo, download everything that was shared on Facebook and so on. Changing dead users' profiles into memorials is innovative, but it considers neither multicultural approaches to death and legacy nor other functionalities a digital memorial can have.

Pereira, Maciel and Leitão [24] have carried out studies on the design of real-world artifacts such as graves, tombstones and physical memorials in order to analyze the diverse messages these objects convey through different semiotic systems. They identified design elements and built speculative and theoretical knowledge on that domain, offering: i) a description of the design space of digital memorials in terms of agents involved and their objectives for interacting with the application; and b) scaffolds for reflecting about the process of designing them.

When it comes to the impact of digital technologies in the experience of visiting physical cemeteries, QR codes on tombstones and smartphone technology have a great impact on the funeral industry in Asia, the UK and the USA [4]. For the author, QR codes are effective in presenting supplementary information within a limited space (which is the case of physical memorials in cemeteries, where QR codes expand not only geographical space, but also life itself). QR codes were created in Asia, where they have been most largely and diversely used in industry and marketing. In Japan, QR codes are used in tombstones to allow the family and friends of the deceased to see photos, videos and information about the dead. It also permits that users click on buttons to offer Buddhist chants or prayers, as well as gifts, such as incenses or food. That shows the service is not anymore restricted to marketing: it entered the realm of

<sup>8</sup> <http://www.digital-memorial.com/> (Last access: Oct 2016)

<sup>9</sup> <https://www.facebook.com/help/1568013990080948?helpref=search&sr=21&query=memorial> (Last access: Oct 2016)

religion. Besides, the Japanese government has put QR codes in the first 500 tombstones of people killed by the Tsunami in March, 2011, so visitors can access governmental messages about what to do in case a tsunami happens. In turn, the Chinese government is stimulating the use of QR codes in deathscapes, as it reduces the huge foot traffic to clean the gravesite and to make offerings to the dead in special dates and religious festivals. Besides, due to the land shortage for the burial of the deceased, Chinese government now buries the dead in individual graves for 7 years, and then moves the remains to mass graves. Internet memorials allow the living to make offerings and honor the dead even after they are no longer in individual graves.

Cann [4] also shows that, whereas in Asian countries the government stimulates the use of QR codes in tombstones and cemeteries for practical reasons, in the UK and in USA that remains mostly a personal choice. Part of that is driven by the fact that, different from China or Japan, most cemeteries in the West are privately run. In the UK and the USA, QR codes have been little used in cemeteries, due to: (i) a lack of awareness of how to use QR codes; (ii) a lack of accessibility, because QR code technology in these countries tends to require multi-step processes; (iii) a more timid use of QR codes in marketing in these countries. However, cemeteries are employing this technology to spur funeral tourism in an inexpensive manner. The author also says that in the UK and the US QR codes are used to give more information about the deceased, through texts, photos or videos, but they are very little employed to allow religious interactions, such as praying or making offerings. In Brazil, this market is even more under-explored.

Also regarding the impact of technology in visiting cemeteries, Van der Linden et al. [27] carried out a research that consisted on having 2 groups of users visiting an old Victorian cemetery in the UK with the mediation of interactive displays and mobile devices (including smartphones, tablets, video links and a shared multi-touch surface). These were placed indoors and outdoors for users to interact with them. The results showed that visitors went beyond reading inscriptions and looking at graves, delving deeper and making connections among data about the dead, but also relating to their own personal histories. They had pleasure in seeing the photos they took integrated into the digital map, in serendipitously discovering new information about famous people buried in the cemetery and also in relating their own family histories to that of people whose tombstone inscriptions they read. One of the main questions raised by the paper is how memories created through the evocative computing approach differ from those arising from visiting a cemetery without technological mediations.

Another perspective for the study of post-mortem digital legacy consists on posthumous interaction, which includes writing messages of mourning, creating profiles or communities about a deceased person, or visiting digital memorials. The concept of posthumous interaction was coined by Maciel and Pereira [15] to refer to “*system interactions with dead users’ data, or to interactions between living users and dead users’ data through digital systems*”. Such interactive patterns must be considered in the

design of digital memorials, so as to allow diverse rapports to death, the dead and their legacy. The domain has also been analyzed under different theoretical and methodological semiotic lenses, such as in [22], [12] and [8].

#### IV. DATA ANALYSIS

In this section, data from our immersive study are analyzed and dis-cussed. First, we present the results from the semiotic analysis of the interfaces from Memoriall. Next, we analyze the data from the pre-visit and post-visit surveys. In the analysis of the data from the surveys, the answers to multiple choice questions where respondents could choose a single option are expressed in percentage values, whereas, when more than one option could be chosen, answers are expressed in absolute values.

##### A. Semiotic analysis

As reported in the methodology section, the semiotic analysis of the application interface followed the same navigation path proposed in the scenario. The three memorials (de Santos Marquise’s, Cícero Pompeu de Toledo’s and Mário de Andrade’s) participants were supposed to visit have the same general structure, as described in this section. They are also mostly composed of static signs, that is, signs that depict the state of the system through non-causal and non-temporal relations [8].

In all profiles, at the top center of the interface, there is the icon for the Memoriall enterprise, which is a stylized tree whose leaves are different shades of grey and have the shape of squares, possibly alluding to QR code tags. The name “Memoriall” is an explicit pun between the noun “memory” and the pronoun “all”, suggesting all people can have digital memorials when they pass away.

As can be seen in Figure 1, there is a box where the deceased’s full name, birth date and death date can be found. Interestingly, in de Santos Marquise’s and Mário de Andrade’s profiles, this box shows both their full civil names (Maria Domitila de Castro e Melo and Mario Raul de Moraes Andrade, respectively) and the names under which they became famous in Brazilian history. The display of pseudonyms or artistic names together with civil names is common in famous people’s tombstones, as reported by Pereira, Maciel and Leitão [23]. However, maybe because of the non-official status of a digital memorial, in de Santos Marquise’s and Mário de Andrade’s profiles their artistic names come first, highlighted by quotation marks.

As to the birth date and the death date, they are both accompanied by metalinguistic signs, which point to other signs in the interface in order to explain or clarify their meanings [8]. In this case, the metalinguistic signs are a five-pointed star and a cross, which are placed at the left of the birth date and the death date, respectively. As discussed by Pereira, Maciel and Leitao [23], the cross is a highly-conventionalized symbol for death in Brazilian culture, where Christianity is by far the predominant religion. On the other hand, stars are not necessarily associated to birth out of the funerary domain, but they are frequently placed beside birth dates in tombstones in Brazil. By scrolling down the interface, one sees another important static sign for digital

memorials: the photo (or portrait) of the dead.

Figure 2 shows six iconic buttons that lead to different areas in the profile: biography, genealogic tree, photos, links, messages, obituary and videos. Some of those icons convey important aspects of the designer's assumptions regarding death. For example, the illustration for the link to the biography section shows a pair of glasses and an open book, which suggests an understanding of someone's biography as something bookish or merely documental, rather than human or living.

Fig. 1 MemoriALL's profile

Fig. 2 MemoriALL's buttons

The illustration for the link to the messages section is also worthy of attention, as it shows a bottled message on a desert beach. Bottled messages are usually associated to communication in situations of despair and loneliness. Besides, bottled messages are unlikely to be answered, like those sent to the dead in a digital memorial.

By scrolling down the interface a bit more, one sees an advertisement for the "Memory and Life" program of the Consolação Cemetery (a social program to attract visitors to cemeteries), a link for the admin area and, at the bottom, a button with the sentence "Send a message to the family".

Throughout the whole navigation path, three buttons are constantly present in the interface. They connect the user to his/her profile in social networks (Facebook, Twitter and Google+) so he/she can share with others where he/she is. By clicking the "obituary" button in de Santos Marquise's memorial, the user is taken to a new page, where, once again, static signs are dominant.

In the top left corner, a "home" button takes the user back to the main page of the memorial. Below, the user reads data divided into the following fields: name, address, neighborhood, zip code, city, state, block and causa mortis. But for the causa mortis, all the other fields are not related to the person honored by that digital memorial. Instead, they simply define the location where her remains are buried (for example, in the "name" field, the information presented is "Consolação Cemetery", not de Santos Marquise's civil name). Evidently, in *Memoriall* the obituary does not play the same role as in real-world institutions, where an obituary is a notice of a person's death usually including a short biographical account. Obituaries in the application mainly serve the purpose of locating the remains of the deceased in

the physical world. Therefore, they can be considered deictic signs [11], similarly to the link to the Google Maps image of the location of the grave (at the bottom of the interface).

By returning to the main page of de Santos Marquise's memorial profile and clicking on the "messages" button, the user is led to a page where there are six messages — four of which were written by the participants of this research during the immersive practice. The date of the sending and the author's name are informed before each message. Interestingly, none of those six messages was addressed to de Santos Marquise. Three of them praise her (as a third person, like in "she was a great woman"), two express sympathy through phrases in Portuguese typically addressed to the deceased's family, and one just says "like it", possibly referring to the application.

Moving on, to find the pieces of information about Cícero Pompeu de Toledo required in the scenario (causa mortis, date of death and why he was famous), a natural choice for the user would be to access the "obituary" and "biography" sections. However, in the "obituary" section, the user only finds the fields name, address, neighborhood, zip code, city, state and block, as well as the link to the Google Maps image of the location of the grave. There is no field for the causa mortis in this obituary, which reinforces the suggestion that in this application the role of an obituary is mainly deictic, defining the location of the deceased's remains in the physical world.

In turn, the "biography section" repeats some of the static signs from the main page of the memorial. But there, below Cícero Pompeu de Toledo's name and photo, the user finds a paragraph (extracted from the Wikipedia) about his achievements as the president of a Brazilian soccer team.

In the "messages" section, the user finds three messages: the first one, with no name or text (just a blank space preceded by the date of the sending); the second one with the chant of the soccer team of which Cícero Pompeu de Toledo was a president; the third one addressing him, with the sentence "rest in peace".

Following the scenario, the user finally gets to Mário de Andrade's memorial. In the "biography" section, the user finds a text extracted from a biographies website, followed by a list of the main books written by him. The fact that exhaustive lists of literary works are not common in biographies suggests that users might interpret the "biography" section in *Memoriall* as an "about the deceased" section, where all sorts of information would fit.

By clicking the "Links" button, the user is led to a page where he/she finds links to external sites with school projects, news and events about Mário de Andrade. Finally, if the user decided to share with his friends in Twitter that he was by Mário de Andrade's grave, he would click the respective button in the interface. That would lead him/her to his/her profile on Twitter, where the following post would be automatically written: "*Memoriall* 0074A — "*Mário de Andrade*" *Mário Raul de Moraes Andrade* <http://Memoriall.com.br/0074A>". That message indicates the number of the *Memoriall* tag, the deceased's artistic name, his civil name, and the URL for his digital memorial. However, the meaning of those pieces of information is very

unlikely to be understood by friends in the social network who had never used the application. The automatic message is the same in case the user decides to share his/her status with his/her friends in Facebook or Google+.

### B. Immersive practice

This section analyzes data from the surveys answered by 21 respondents before and after the immersive practice. The data are analyzed in the following order: demographic data, data about habitual practices in cemeteries, and data about the interaction with the *Memoriall*.

#### Demographic data

In Q1, 52.4% of the participants in the immersive practice answered they are between 20 and 29 years old; 28.6% are between 30 and 39 years old; 9.5% are between 40 and 49 years old; and 9.5% are older than 50. According to their answers to Q2, 71.4% are men and 28.6% are women.

According to the answers to Q3, our sample was composed of people from all Brazilian regions: 42.9% from the South East (5 participants from the state of São Paulo, 3 from Rio de Janeiro, 1 from Minas Gerais); 28.6% from the South (3 participants from Paraná, 2 from Rio Grande do Sul, 1 from Santa Catarina); 9.5% from the North (2 participants from Amazonas); 14.3% from the North East (1 participant from Bahia, 1 from Rio Grande do Norte, 1 from Maranhão); and 4.8% from the Middle West (1 from the state of Mato Grosso).

In relation to their academic/professional profile (question Q4), 3 participants answered they are undergraduate students, 10 are graduate students, 10 are professors and 12 are researchers. It is important to notice that, in this question, respondents were allowed to choose one or more options. None of them claimed to be an industry professional.

The participants have a significant experience in HCI, as shown in their answers to Q5. 33.3% have been in the field for 5 or more years; 4.9%, for about 4 years; 19%, for about 3 years; 23.8%, for about 2 years; and 19%, for 1 year or less. As to the experience in interface evaluation (question p6), 58.2% claim to have carried out evaluations in the past; 31.8% answered they often evaluate interfaces; and only 9.1% had never done it. Such experienced profile is due to the fact that all participants were recruited from an academic conference on HCI.

Q9 asked about participants' religion, an important cultural element in the context of death, cemeteries and memorials. 32.75% answered they are Catholics; 23.8%, Protestants; and 12.5%, Spiritualists. 25% claimed to have no religion, and 4.2% did not answer Q9. In Q8, 57.14% answered they believed in God; 30.10% are atheists and 4.76% are agnostics.

However, in Q10, when asked whether they often attend rituals of their religions, 66.7% answered that they rarely do it; 23.3% never do it; and 9.5% often do it. As to life after death (P11), 57.1% believe it, whereas 42.9% don't.

Q13 asked if the respondents used social networks. The consensual answer was "yes". The most popular social networks among them are Facebook, WhatsApp and Instagram. In Q40, respondents had to answer what

operational systems they had used in their cellphone when visiting the cemetery. 66.67% used Android; 28.57%, iOS; and 4.76%, Windows.

### Data about habitual practices in cemeteries

Q21 asked how often and why respondents went to cemeteries. Allowed to choose more than one option, participants answered that they go to cemeteries (Table 1):

TABLE I: HOW OFTEN RESPONDENTS WENT TO CEMETERIES

Frequently, to pay homage to deceased people	4.8%
Sometimes, to pay homage to deceased people	19.0%
To attend funerals of closely related people	47.6%
To attend funerals of not closely related people	38.1%
In touristic activities	9.5%
Never	9.5%

U16 chose the option "other", and wrote that he goes in "All Souls' Day and death anniversaries". His answer, along with the two most frequently chosen options in Q21 ("to attend funerals of closely related people" and "to attend funerals of not closely related people"), shows that respondents had somehow a relationship to cemeteries ruled by social norms, thus visiting them only in dates when they were expected to according to Brazilian etiquette rules.

The social nature of those visits, rather than a more personal one, is confirmed by the answers to Q22, when respondents were asked whether they visited cemeteries alone or accompanied, and by whom. Allowed to choose more than one option, 19 out of the 21 respondents said they go accompanied by family, and 10 said they go accompanied by friends. Only 4 said they go alone.

In Q23, respondents could choose more than one option regarding how they usually feel upon going to cemeteries. The options "uneasiness" (10 respondents) and "nostalgia" (7 respondents) were the most frequent ones. 3 research subjects chose the option "other" and expressed "sadness", "reflectiveness" and "introspectiveness".

On the other hand, Q30 asked them what they felt after participating in the immersive practice in the Consolação Cemetery. The two most frequent options were "indifference" and "peace". Respondents that chose the option "other" added nouns as "surprise", "experience", "wisdom", "wonder" and "curiosity".

In another research, Lopes et al. [10] carried out an empirical observation of digital memorials in Brazil by investigating if they had characteristics of the social web. Through an interaction test and a survey, they analyzed how users felt when interacting with digital memorials and how they evaluated the functionalities of those applications. By comparing the answers we got about users' feelings after interacting with digital memorials in an immersive practice and the answers [10] got regarding users' feelings after interacting with digital memorials in a controlled environment, one sees that "uneasiness" and "peace" are common answers.

Q24 asked what users normally do when going to cemeteries. The participants could to select more than one

option. Table 2 summarizes what participants answered that they go to cemeteries for.

TABLE II: WHY PARTICIPANTS GO TO CEMETERIES

To enjoy funerary art	47.6%
To pray	19.0%
To look for memories of the deceased	28.6%
To talk to the deceased	14.3%
To leave objects on graves	14.3%
To wander through graves	42.9%
To read information on tombstones	61.9%
Other	9.5%

Two respondents answered “other” and added “to keep graves tidy” and “to photograph funerals”. The most common answers (“to enjoy funerary art” and “to read information on tombstones”) suggest that a great share of the experience of visiting cemeteries consists of semiotic processes, where the reception and interpretation of verbal and non verbal messages play a central role. The interaction with the deceased or with the place is thus greatly mediated by linguistic artifacts, which cannot be dissociated from the role any memorial (digital or physical ones) play.

The 3 respondents who answered in Q24 that they “leave objects on graves” were asked in Q25 what kind objects they leave. Among the eight options (“flowers”, “funeral wreaths”, “candles”, “religious symbols”, “photos”, “notices”, “the deceased’s belongings”, “other”), only 4 were chosen: “flowers” (1 respondent), “funeral wreaths” (1 respondent) and “candles” (2 respondents). Those choices are possibly due to Brazilian culture, where those elements are more frequently used to pay homage to the dead. However, in other countries, as reported by Pereira et al. [23], religious symbols and personal belongings of the deceased are often left on graves. Q26 asked what resources respondents had ever used when visiting cemeteries. Allowed to choose more than one option, respondents answered what they had already used (see Table 3).

TABLE III: RESOURCES USED WHEN VISITING CEMETERIES

Item	Yes	No
Used a map	23.8%	71.4%
Followed a guide	28.6%	66.7%
Used an audioguide	9.5%	85.7%
Read print material about the deceased	4.8%	90.5%
Asked for information at the reception desk	28.6%	66.7%
Looked for information with a web browser	28.6%	66.7%
Used QR Codes	0.0%	95.2%

One of the research subjects chose not to answer that question. The answers from those who answered it show that digital resources are very infrequent in visits to cemeteries, especially QR codes, which nobody chose as an answer. Besides, the answers show that visitors rarely read print material with information about the deceased, which might result different in case the information about the dead were displayed in digital interfaces, as digital memorials do.

### Data about the interaction with memoriall

In the post-visit survey, all participants answered Q35 informing they would like to use *Memoriall* in other visits to cemeteries to learn about the deceased.

Q31 asked how easy to use *Memoriall* is. 80,95% of the respondents said it is easy to use, whereas 19,04% considered it hard. However, when asked in Q32 about the design of the application, only 23,80% of the respondents said they were satisfied with it. By correlating the data from those questions with the answers to Q40 (about the operational system in the respondents’ cell phones), results show that Android users were more likely to find *Memoriall* hard to use, but some iOS users reported dissatisfaction too.

When asked in Q34 about what the exploratory use of *Memoriall* promotes, participants could choose more than one option. Table 4 presents their answers:

TABLE IV: WHAT THE EXPLORARY USE OF MEMORIALL PROMOTES

Curiosity	81.0%
Exploration of the physical space	33.3%
Interaction in the cemetery	81.0%
Interaction with other people	23.8%
Access to the deceased’s memories	52.4%
Other	4.8%

U8, who chose the option “other”, added that the use of the system promotes “limited information”, which suggests dissatisfaction with the system. The fact that the information available in the system is indeed quite limited is confirmed by the semiotic analysis of *Memoriall* we carried out. The only piece of information all memorials presented in full was the location of the grave.

The two other least frequent answers to Q34 (“interaction with other people” and “exploration of the physical space”) show that the experience promoted by the digital memorial was not perceived by most respondents as necessarily social or anchored in a particular physical space. The fact that interaction through a digital memorial with information about deceased people took place *in* a cemetery was considered relevant by respondents, but few felt interacting *with* the cemetery, by exploring its physical space. In our semiotic analysis of the digital memorials we found no photos of the cemetery or the grave. The only image that differs from one memorial to another is the deceased’s photo (or portrait).

In Q41, participants were asked to write freely about the main problems in the system. The fact that the application did not follow responsive design principles, i.e. the fact it did not meet some design principles for mobile applications, was reported by two participants (U14 and U18). Other three participants (U2, U9, U15) said they had problems with the quality of the QR Code. In the development of applications, designers must be careful with different non-functional requirements, which impact on the user’s experience.

As to the “send messages” functionality, U5 answered that “some functions are hidden”, and U7 complained that “it was a messy process to send messages”.

Other problems were also pointed out: unclear menu (U3),

navigation problems (U7, U10, U20), lack of consistency and patterns (U4), unreliability (U8), usability problems (U12, U17), and accessibility problems (U17).

As to visual aspects, U16 considered the interface outdated, U19 said that “some missing elements could make the system more interactive”, and U20 answered that the system lacks “an interface with adequate colors and images”.

The missing or incomplete information was a concern of for five other participants. U1 said there is “missing information; some deceased are not represented in the system; only the famous ones”. This respondent referred to a celebrity’s family’s grave, where different relatives were buried, but the QR code tag on the grave led only to the famous family member’s digital memorial. U17 also said “the information presented in the memorials follows no pattern”. That confirms our semiotic analysis of the obituary and biography sections in de Santos Marquise’s, Cícero Pompeu de Toledo’s and Mário de Andrade’s memorials, which showed different sorts of information.

In Q42, users were asked to write freely and give suggestions to improve the system. The main suggestions include: enhancing usability (U2, U3, U9, U10 and U14), following responsive design principles (U18), a full redesign (U4, U14, U17, U21), showing the cemetery map (U1), improving the quality of the information (U1, U3), filling in the information for all graves (U2, U8, U11 and U16), integration with Wikipedia (U1), a module for approving the messages left by visitors (U1), allowing the deceased’s family to moderate the messages (U5), making it easier to send messages (U5), moving the button “write a message” to the same screen where messages are read (U15), improving the navigation (U7, U12), making the interface more visual (U7), warranting the reliability of information about the deceased (U8), allowing visitors to insert data about the deceased (U16), showing the deceased’s photos (U19), adding links to the interface so as to improve the access to the system (U19), and changing *Memoriall* into a collaborative system (U7).

Q37 asked if the respondents would like to add information to the memorial profiles if *Memoriall* were a collaborative system. 61,90% answered they would add data about the deceased. Q38 asked them to justify their answers. U5 stated that he “would add information only if the deceased were a person he admired”. In turn, U12 and U16 said they would add information about friends or relatives. U1 said “*that possibility* [adding information to profiles] *is interesting for historians*”.

Some respondents also defined what kind of information they would like to add: “information about graves and funerary art” (U14), “related links” (U20), and “the relationship between deceased people buried in the same grave” (U3). According to U10, “the users should be allowed to edit content”. For U9, a more collaborative system would “enrich the memorials with relevant information”. Likewise, U15 showed concern with the quality of information; for him, “there should be an administrator to avoid defamation”. On the other hand, U7 answered the system “*is somehow collaborative, as I [she] was able to send messages to the memorial*”.

In Q39, respondents could choose more than one option to say what they found more interesting in the system. Their answers are summarized in Table 5.

TABLE V: PARTICIPANTS’ PREFERRED ASPECTS OF THE APPLICATION

Finding graves in the cemetery	57.1%
Getting information about the deceased	95.2%
Getting information about the deceased's family	23.8%
Using technology in a cemetery	66.7%
Sharing experience with other people	33.3%

Their answers suggest a good reception of the use of digital technologies in cemeteries and confirm the main role of the application: presenting information about the deceased. As to the kind of information about a dead person to be presented in a cemetery, respondents have different opinions depending on the medium where the data would be available: either a tombstone or a digital memorial.

In the pre-visit survey, Q27 asked what kind of data a tombstone should contain. The five elements most frequently chosen by participants were: full name (20 respondents), birth date (17), death date (17), photo (13) and epitaph (10). Such choices are in accordance with popular tombstone formats in Brazil [23]. Interestingly, no respondent chose the option “religion”, although religious symbols, such as crosses, are commonly found in Brazilian tombstones beside death dates. Our semiotic analysis showed that *Memoriall* uses a cross by default as a symbol for death, which suggests a disregard for different religions and visual representations of death.

Q36, in turn, asked what kind of data about deceased people a digital memorial should contain. The most frequent answers were almost consensual: full name (20 respondents), biographic information (20), birth date (18), death date (18), photos (19) and causa mortis (17). Possibly due to less space constraints, digital memorials are expected by users to show more information about the deceased. In the option “other”, for example, users suggested adding to digital profiles information like the deceased’s “favorite films”, “funny facts”, “likes” and “media articles”. In contrast to the information available in the digital memorials we analyzed in a semiotic perspective, the respondents’ answers show they want more personal information about the deceased, rather than public data like the location of the grave or the obituary. The graph (Figure 3) compares the answers to Q27 and Q36.

Fig. 3 Comparison between Q27 and Q36.

Causa mortis is a delicate subject, though: whereas it interests users, it also affects dead users' privacy requirements, so that a greater care must be taken.

Q20 asked what symbols best represent death. 36% of the respondents chose tombstones; 16% coffins; 12% light; 8% skulls; 8% sky; 8% graves; 4% crosses; 4% black ribbons; 4% the option "other", but did not add a new symbol.

Maciel and Pereira [16] posed the same question in a study with teenagers from the Z generation. The researchers report that the three most frequent answers were "cross", "coffin" and "tombstone". Our sample is too small for generalizations, but the difference between the answers in the study herein described and in that by [16] suggests that visual representations of death change not only when different nationalities are compared, but even when different ages or social classes are at stake. According to Maciel and Pereira [16], discussing symbols that can represent death might provide valuable input for the design of digital memorials, especially when it comes to warranting multicultural representations in graphic interfaces.

From the most frequent answers to Q20, *Memoriall* only presents crosses, in a very small size, beside the deceased's death date. In turn, the application has a tree as its logo, which might suggest a connotation of life and death as part of a natural cycle.

Finally, in Q43, participants were asked to give their opinions about the immersive practice. 95.24% considered it interesting, and only 1 participant (4.76%) was indifferent about it. When asked in Q44 to freely comment about the practice, U8 suggested "there should be a first moment of the experience without smartphones".

#### V.FINAL CONSIDERATIONS

The study presented and discussed in this paper allowed to analyze users' perception — experienced in interaction design — regarding the understanding and use of digital memorials linked to graves via QR Code technology in a cemetery space. More than informing about the satisfaction of these users with the analyzed system and the possible improvements for its redesign, the results offer interesting insights and contributions for the research area.

Because thanatosensitivity applications are a new, different and challenging domain, a user-centered approach for requirements understanding, identification and analysis is essential. Immersive practices, such as the one reported in this paper, allow a situated identification and understanding of requirements supported by ubiquitous computing solutions. This kind of practice tends to produce rich information and allows more in-depth analysis, favoring, for instance, the consideration of cultural facets (e.g., space, arts, materials) of the usage situation as well as patterns of behavior when people use these applications in the wild. Such practices can be combined with specific requirements elicitation techniques (e.g., the Semiotic Analysis) in order to obtain better results.

From the lessons learned from this research, we highlight the need for a careful planning of the entire study. Because

the practice is conducted in the external environment (i.e., in the wild), many factors can trigger interference and influence both the activities and their results, thus requiring a risk identification and management strategy. Furthermore, conducting a pilot test is fundamental to anticipate and avoid possible problems. The study and the methodology presented in this paper may serve as inspiration for other similar studies, contributing to exploratory and in-the-wild thanatosensitivity studies in HCI.

On the one hand, the analysis presented in this paper offers useful insights for digital memory application designers regarding requirements understanding and elicitation. On the other, it draws attention to the need of reflecting on the possible impact of such applications. In this sense, the study of users' perceptions, as well as their practices and customs in cemeterial spaces, favors a better understanding of this domain and a user-focused modeling for these solutions.

One of the problems evidenced by this study was the lack of information in deceased profiles. Because the information is not collaboratively inserted, depending on specific stakeholders to be available (e.g., the family, or the company that manages the software), the lack of information is commonly noticed. Additionally, the information architecture interfered negatively in the navigability and accessibility of information on mobile devices — usability and/or communicability tests could help identifying and fixing such kind of problems. Additionally, the possibility of integrating these systems with other social tools could add value to the memorials, promoting its adoption and usage.

Cemeteries can be a useful space for educational practices. Activities with young people have been held in cemeteries and the use of digital memorials can be very helpful to promote teaching-learning activities. Indeed, users in these scenarios could also collaborate inserting information into these systems, adding value to them.

Related to this research is the concern of professionals and researchers [6][19] with the preservation of cemeteries. For Araujo [6], *"tombs should be considered historical heritage, as well as a source for the past, because they make sense in our daily lives"*. Indeed, in addition to the information about he deceased, as evidenced by the users in this research, the cemetery design and its exploration by people can be studied. For technology-enthusiastic researchers, an interesting market appears in the automation of these spaces, which requires attention to ethical and cultural issues, mainly related to human values. Finally, with the possibilities of cremation and / or guarding the physical body for limited time in certain cemeteries, digital memories can be a possible way of immortalizing the deceased ones.

As future research, there is the possibility of analyzing more sources of data collection, such as photos and audios captured during the practice, as well as a Semiotic Inspection of the tool used. These data can be compared with the analysis of the immersive practice presented in this paper in order to formulate a set of useful guidelines or requirements in this area. Finally, the Web interface for the system, which allows someone to hire company's services, buying a *Tag Memoriall*, and also paying tribute to a deceased (e.g.,

lighting a candle, leaving a message) is another space for future research.

#### ACKNOWLEDGMENTS

The authors of this paper would like to thank the members of the Brazilian HCI community, especially those who attended the 7<sup>th</sup> *Workshop on Human-Computer Interaction Aspects in the Social Web* and engaged in the immersive practice in the Consolação Cemetery herein analyzed. We also thank the Uniselva Foundation for the financial support for attending the event.

**Abstract**—Experiential attributes are a possible way of explaining user's experiences during interaction. Recently presented set of 23 aesthetic categories of interaction was established with a purpose to explain users' aesthetic experiences. This recent work focused on touch devices, such as smartphones and tablets, and concluded with the need to study further the goodness of established categories. The study, reported in this paper, continues to explore the consistency and aesthetic relations of these categories by comparing their goodness in explaining aesthetic perceptions on different devices: a smartphone and a laptop computer. Experimental research design with 2x2 conditions was used. Two of the conditions consisted of completing the same interaction episode on two different devices. The other two conditions consisted of passive watching the screen recordings of previous interactions on the same two devices. In conclusion, the aesthetic categories of interaction were found capable of explaining users perceptions across devices, but further study was suggested.

## I. INTRODUCTION

A RECENT study by Mõttus et al. explored users' aesthetic perceptions during interaction [20]. This study used repertory grid technique (RGT) to elicit total number of 134 personal constructs, which were then sorted into 23 aesthetic categories of interaction (ACI). Quantitative data from RGT allowed to assess inner consistency and aesthetic correlation of established categories. Not all of these categories were proved consistent and neither did all of them show significant aesthetic correlations. Low inner consistency and aesthetic correlation in case of some categories may occur due to a low number of evaluations per category (ranging from 1 to 10) during the RGT study. This study reported numerous overlappings, which were found between experiential attributes, established earlier by other similar studies e.g., [12], [13], [14], [6], [19], and the newly established categories. Recurrence of similar items in various occasions suggests not to reject inconsistent categories but test them again in various context. In conclusion, further studies were proposed with different stimuli, different sample of participants and different situation of use. Following general research questions were posed to find out more about the goodness of aesthetic categories of interaction.

1. How consistently do users perceive aesthetic

categories of interaction?

2. How capable are given categories of explaining users aesthetic perceptions during the interaction?

- Whether the categories are capable of explaining users' aesthetic perceptions?
- Whether the categories are capable of distinguishing aesthetics of interaction and aesthetics of appearance?

Current study deploys the data, collected during a user testing of the Estonian Tourist Information website, <http://visitestonia.com> with two different types of devices, computer and smart phone [9].

## II. RELEVANT WORKS

This study is focused on aesthetics of interaction, defined through the products that feel beautiful in use [1]. The beauty of use is often obscured by the beauty of appearance, a phenomenon that still earns researchers' major attention on field of HCI [17], [24], [15], [18], [25]. However, the beauty of use begins to gain more attention in light of gradual changes towards novel ways of interaction. Daily-use interfaces have become more multimodal when compared to traditional PC setups with mouse, keyboard and monitor. Modern interactions require at least three of our senses (sight, hearing and touch) for perceiving system reactions as well as completing user actions. The extremely popular mobile and tablet devices are accompanied by solutions of distributed interfaces (e.g., public displays, accessible from personal devices), smart home technology (e.g., smart TV, smart car), wearable physiological equipment (e.g., medical health monitors, sports trackers) and more. There has opened much wider scope of user experiences (UX), suggesting a good reason to study the aesthetics of interaction more closely.

### A. Aesthetics of interaction

Aesthetics of interaction was first mentioned in design-related studies and theoretical discussions in the beginning of 2000's. Hallnäs and Redström describe aesthetics of interaction as a phenomenon to be considered in pleasure-oriented design approach called slow technology [2]. The authors of this study believed that certain dynamics, both physical and mental, afford additional perception of pleasure in otherwise pragmatic interactions. Further, Djajadiningrat et

al. introduce the term *beauty of use* while analysing the design cases of tangible interactions [1]. During a discussion about the principles of pleasurable design, Hekkert argues whether our aesthetic experiences are limited only to the pleasure from sensory perception [7]. The discussion continues by narrowing down the notion of beauty to visual perception, as it may better correspond to laypersons' understanding [5]. These thoughts are further developed in Löwgren's five beliefs about aesthetics in interaction design [16]. Three of these beliefs seem to be more relevant for current study. First, genre determines the aesthetic qualities; second, it makes little sense to talk about visual aesthetics as an isolated modality; and third, aesthetic experience is connected with intellectual deliberation as much as with immediate, visceral response. Altogether these works contribute to the understanding of aesthetics in interaction, while also contradicting each other in some aspects. One of such aspects is multimodality of aesthetics. Current study will handle aesthetics as a multimodal experiences, i.e., perceived by all senses, and processed through intellectual deliberation. Multimodality of senses has been addressed by a relatively small number of previous studies in HCI. Those works concern senses of sight, hearing and touch. Aesthetics of sound has been mentioned in connection with sonic system reaction in interaction design by Rocchesso et al. [22]. Aesthetic framework of touch for tactile interactions has been proposed by Shiphorst et al. [23]. This last work refers to Laban effort theory [10] when explaining the aesthetics of gestures and interface dynamics. The design of graceful movements during the interaction is more thoroughly covered in series of works by Hashim et al. [26], [4], [3], [21]. Beauty of dynamics and grace of the movements has become more relevant in context of growing popularity of gesture-based interactive devices.

#### B. Aesthetics Categories of Interaction

A recent study was conducted to understand users aesthetic perceptions during interaction with touch devices, such as smart phones and tablets [20]. This study deployed RGT to elicit aesthetic constructs directly from users. The elicitation process used nine short interaction episodes as stimuli. These episodes were carefully selected to provide possibly diverse UX. Participants were asked to try out stimuli and provide the reasons why these stimuli were either beautiful or ugly. Participants were also instructed to focus on beauty of interactions and avoid the beauty of appearance. All together 21 participants succeeded of eliciting 134 personal constructs. Finally, 23 aesthetic categories of interaction (ACI) (shown in Table I) were established as a result of grouping the personal constructs by similarity. Authors believed the use of lay people in elicitation process could add new aspects to the body of earlier work. The attributes, established in earlier similar studies were elicited using experts e.g., [13], or theories [19] of aesthetics or UX.

#### C. Attributes of UX

The context of previously established experiential attributes of interaction is different across these works. Following list of most distinct examples varies from the visual aesthetics of websites to the UX in industrial design: visual aesthetics of website's graphical layout [19], visually perceived aesthetics of website interactions [12], aesthetic-related features of websites' interactions [14], UX-related features of industrial interaction design [13] and general UX [6]. Yet, many similar items appear across different sets of attributes from different studies in various context. After ACI were established within the context of touch devices (smart phones and tablets), authors found 15 out of 23 categories to be similar to the ones across earlier works: Hassenzahl et al. [6] (*playfulness, fashion, personal relatedness, complexity and predictability*), Lim et al. [14] (*speed, delay, synaesthesia, smooth phrasing and range*) and Lenz et al. [13] (*precision, predictability, controllability, speed, delay, smooth mechanics, force,*

TABLE I.  
AESTHETIC CATEGORIES OF INTERACTION WITH  
CORRESPONDING SEMANTIC DIFFERENTIALS.

	Aesthetic Category of Interaction
1	Arousal: exciting / calm
2	Playfulness: playful / serious
3	Dynamics: dynamic / static
4	Fashion: modern / old fashioned
5	Natural realism: natural / unnatural
6	Precision: precise / imprecise
7	Congruence: appropriate / inappropriate
8	Informativeness: informative / arbitrary
9	Personal relatedness: fits me / doesn't fit me
10	Closure: complete / incomplete
11	Complexity: complex / simple
12	Predictability: predictable / unpredictable
13	Controllability: controlled / uncontrolled
14	Time/Speed: fast / slow
15	Delay: immediate / delayed
16	Synaesthesia: synchronized / unsynchronized
17	Smooth mechanics: continuous / stepwise
18	Smooth phrasing: flowing / dripping
19	Force: powerful / gentle
20	Proximity: close / distant
21	Smooth texture: smooth / rough
22	Range: free / limited
23	Dimensionality: 3D / 2D

*proximity*). Additionally, the category of *dynamics* is found among the aspects of visual aesthetics by Moshagen [19] and *arousal* is similar to fascination by Lavie and Tractinsky [12]. Not all of the discussed attributes are strictly connected to the aesthetics of interaction, however, they all express various users' experiences through the features of design. For example Hassenzahl et al. describe experiential attributes in 4 groups, each related to a certain type of user needs: pragmatic, hedonic stimulation, hedonic identification and attractiveness. Some of the discussed attributes express the goodness of design, for example, symmetrical visual design is generally considered more pleasing [12] and visually complex interfaces are generally perceived less pleasing [19]. Other attributes may well describe the experiences, but do not necessarily express the goodness of design. For example, the attribute stepwise vs fluent [13] can not be explicitly related to either good or bad design. However, specific context may make users to prefer one or another end of the scale. For example users tended to be more pleased with predictable course of interactions in pragmatic situation (like sending an email), while predictable interactions during a situation of game were often felt less pleasurable and rather boring. In such a way, the context of use determines relations between the attributes and the quality of interactions. A sequence of studies by Karapanos et al. focuses on four sources of diversity in UX: individual, product, situation and time [8]. Awareness of these four sources would help to specify the conditions for more or less homogeneous UX. When looking at the analysis of goodness of ACI [20], the diversity of UX was mainly accounted through the product, i.e., an interaction episode on a specific device. Individuals were chosen from lay people and the situation was not accounted, except the purpose of use, as the episodes could have been recognized either pragmatic or leisure-related. Time was determined by the duration of interaction episodes which were considerably short and more or less similar, e.g., tap to select a menu item or slide to scroll the page.

Unlike in elicitation study of ACI, the longer interaction episodes may not be as easy to analyse. Different actions and reactions in sequence may cause various aesthetic perceptions, resulting eventually in experiences that are difficult to attribute to any particular feature of design. Therefore authors sought for a way of describing common elementary interactions. User actions for mobile and tablet devices could be described according to the list of touch efforts in a conceptual framework for understanding the aesthetic qualities of multi-touch and tactile interfaces, proposed by Schiphorst et al. [23] (e.g., tap, hold, glide). System reactions were described in two ways. First as a description of interaction mechanics according to attributes of interactivity by Lim et al. [14] (e.g., slowly, concurrently, instantly), and secondly through the user's pragmatic intentions (e.g., to select menu items, to scroll the view). Authors believe the consideration of elementary descriptions of user actions and system reactions may help to

attribute the aesthetic experience during a longer sequence of interactions.

### III. STUDY

#### A. Method

The study used experimental design with four conditions. The conditions were applied through the stimuli — an interaction episode on tourist information website. Two of the conditions concerned interactive devices, a computer and a smart phone were used to test the completion of the same task. The other two conditions distinguished aesthetics of appearance from aesthetics of interaction: a short video of interface and a hands on interactive task were used on both types of devices. The participants were asked to test all 4 conditions and empirical data were collected immediately after each condition (stimulus).

Answering the research questions required the data about perceived aesthetics of interaction and perceptions on the scales, based on ACI. Corresponding semantic differentials, which were planned to use as scales are listed in the Table I. Two instruments were considered in order to evaluate aesthetics of interaction: the attractiveness facet in AttrakDiff questionnaire [6] and similar facet in User Experience Questionnaire (UEQ) [11]. The items of both questionnaires are listed in Table II. We identified 2 items in each instrument, which do not directly express aesthetic judgement: bad-good, discouraging-motivating and friendly-unfriendly (emphasized in Table II). Five relevant items in AttrakDiff questionnaire

TABLE II.  
COMPARISON OF ATTRACTIVENESS-RELATED ITEMS IN  
ATTRAKDIFF AND UEQ QUESTIONNAIRES.

AttrakDiff	
1	unpleasant / pleasant
2	ugly / attractive
3	disagreeable / likeable
4	rejecting / inviting
5	<b>bad / good</b>
6	repelling / appealing
7	<b>discouraging / motivating</b>
UEQ	
1	annoying / enjoyable
2	<b>good / bad</b>
3	unlikable / pleasing
4	unpleasant / pleasant
5	attractive / unattractive
6	<b>friendly / unfriendly</b>

(vs 4 in UEQ) was considered to afford better description of users' aesthetic judgement, therefore the attractiveness facet of AttrakDiff was used in current study. All data were collected on 7p Likert scales.

### B. Stimuli

Fig.1 and Fig.2 show the website <http://visitestonia.com> view for a computer and smart phone. The website's attractiveness was originally tested for design purposes [9]. Current study used the data from two episodes of interaction (with smart-phone and computer). First, the participant was passive viewer of interactions happening on the screen, followed by hands on interaction episode. The conditions of the experiment were deployed as follows:

- 30-second video, featuring the essential aspects of website usage, played on smart phone.
- 30-second video, featuring the essential aspects of website usage, played on computer screen.
- Episode of hands on usage according to prepared user task on smart phone
- Episode of hands on usage according to prepared user task on computer

The episode of usage had a pragmatic nature and included information search (finding a restaurant), followed by an action of requesting the information (booking a table in a restaurant). Completion of this task represented well available user actions on given website. For a smart phone, the interactions included slide to scroll, flick to scroll and tap to select where system reaction was intended to be immediate and precise in case of slide and tap gestures, and delayed and approximate in case of flick gesture. For computer interactions, only the mouse was used to navigate the site (keyboard was not needed). All interactions on computer were precise and immediate, however, hovering the mouse over interactive objects induced soft and slightly delayed dynamics such as fade in-out, transparency change, zoom and slight pan.

### C. Participants

The participants were recruited with respect to two relevant criteria. First, they needed to have sufficient experience (at least weekly use) in browsing the web on both types of devices, computer and smart phone, and second, they should not have been familiar with the website under testing. The number of participants was chosen to be sufficient for valid results.

### D. Procedure

Participants were invited one by one. They were then briefed about upcoming session, informed consent was agreed and demographic data were collected during 5 minutes after arrival. The session took place in lab conditions. A Windows 10 desktop computer with 24" monitor and iPhone 7 or Nexus 5 smart phones were used in the study. Google Chrome browser for browsing the website on computer, and both smart phones' native browsers were used in order to exclude the influence of

browser differences. A more familiar smart phone was chosen according to user's previous experience. Testing phase under all 4 conditions took maximum 30 minutes in total, including also the completion of questionnaires after each condition.

### E. Analysis

Collected data were normalized for better comparison with other similar studies, e.g., for comparing the variability in UX related psychometric scales. Standard deviation was used to assess the consistency of users' perceptions on all ACI-based scales in four different conditions. Further analysis intended

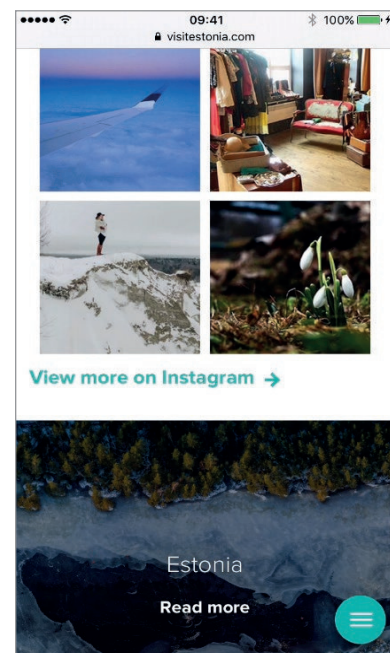

Fig. 1 Screenshot of stimuli on a smartphone

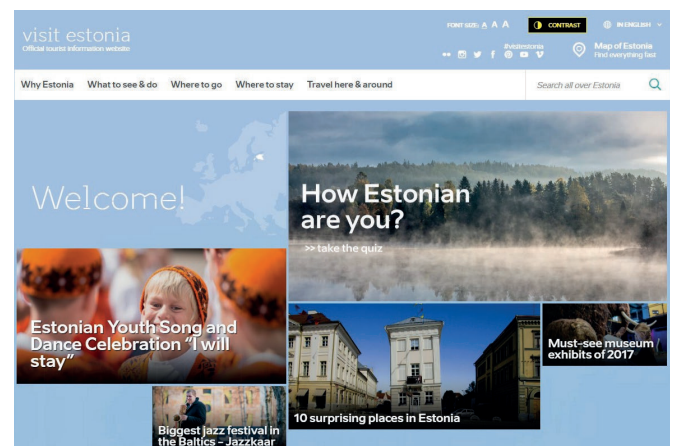

Fig. 2 Screenshot of stimuli on a computer

to reveal whether aesthetic categories are related to perceived aesthetics of interaction. The Pearson correlation coefficients were calculated between attractiveness and the ACI-based scales. We assumed the attractiveness measure of AttrakDiff questionnaire represents users' perception on aesthetics of interaction. This assumption is based on the authors' expert opinion that five (out of 7) items in attractiveness facet concern users' aesthetic judgment. The significance and the value of correlations was expected to express the aesthetic relevance of different ACI's in various context of use.

#### IV. RESULTS AND DISCUSSION

All in all 27 users (11 male) with age ranging from 21 to 59 (average 33.6), participated in an empirical study. The participants first watched 30 second screen videos of the use of <http://visitestonia.com> and then tested the short interaction episodes on the same website using two different devices: desktop computer and smart phone. Completing the interaction episode took 1:49 min in average. The values of attractiveness and ACI were collected after each of the four conditions (two interaction episodes and two screen videos). Table III shows average values and standard deviations of all

measures for all conditions separately and for a total of all conditions.

#### A. Diversity of Perceptions

The standard deviation ( $\sigma$ ), of reported values of attractiveness across the conditions ranges from  $\sigma = 0.14$  to  $\sigma = 0.18$ . The same statistic across the scales of ACI ranges:  $0.14 < \sigma < 0.3$ . The halfway value of latter range was used as a threshold ( $\sigma > 0.22$ ) to indicate the categories where participants' perceptions were more diverse (highlighted in TableIII). Most distinctive examples of such categories were *arousal*, *personal relatedness*, *complexity*, *informativeness*, *range* and *dimensionality*. We were interested whether the categories were perceived more or less homogeneously across different conditions. Count of more diversely perceived categories was used to analyse differences between conditions. As a result,

hands on interactions resulted in more diverse perceptions than watching the videos. At the same time the conditions with interactions (computer and phone) had more or less the same diversity of perceptions. Must also be noted that stimuli were perceived more attractive on computer than on phone in all conditions. Further interest was focused on how differently were ACI perceived during the interactions with computer and phone. Most diverse perceptions were found on *informativeness* on phone ( $\sigma=0.3$ ) while the same category had medium diversity ( $\sigma=0.22$ ) for computer interactions. *Congruence*, in contrast, was perceived more diversely on computer than on phone. Evaluations on *arousal* and *dimensionality* were slightly more diverse on computer while *complexity* was more diversely perceived on phone.

TABLE IV.

AESTHETIC CORRELATIONS OF 23 CATEGORIES IN DIFFERENT CONDITIONS. FIRST WORD OF SEMANTIC DIFFERENTIAL STANDS FOR LOWER END OF SCALE (E.G. EXCITING=0 AND CALM=1). ATTRACTIVENESS SCALE IS POSITIONED UNATTRACTIVE=0, AND ATTRACTIVE=1 (\*  $p < 0.05$ ; \*\*  $p < 0.01$ ).

Dimensionality: 3D / 2D	-0.23	-0.14	-0.22	-0.30

### B. Aesthetic Correlations

Next step of the analysis intended to find out how much ACI are capable of explaining the aesthetics of interaction in current conditions. The correlation analysis was applied to reveal relations between ACI and attractiveness measure. Seventeen out of 23 ACI showed significant correlation with perceived attractiveness in both conditions of hands on interactions. The results are presented in TableIV. Four categories were not found correlated to the perceived attractiveness in any of the conditions. These categories were *arousal*, *playfulness*, *force* and *dimensionality*. Two of these categories (*arousal* and *dimensionality*) were perceived rather diversely (see TableIII), which could explain low correlations in corresponding cases. Must be noted that the category of *range* had high aesthetic correlation despite of higher diversity of perceptions ( $\sigma=0.24...0.25$ ). Low aesthetic correlation of *playfulness* category, however, could be explained with the pragmatic nature of interactions in given stimuli. Two of the categories did not have significant correlation in both conditions of interaction. The category of *dynamics* had significant correlation in interactions with computer, while the category of *delay* had significant correlation only in case of interaction with the phone. Ten of the categories showed significant aesthetic correlations in both conditions of watching the video, which indicates the connection to aesthetics of appearance. According to the significance and value of correlation coefficient, seven of the categories seemed more explicitly related to aesthetics of interaction. These categories are: *dynamics*, *complexity*, *predictability*, *speed/time*, *smooth mechanics*, *smooth texture* and *range*.

## V. CONCLUSION

The study addressed users' aesthetic perceptions during interactions with computer and smartphone. This was a follow-up of previously conducted elicitation study of ACI (previous study). Goal of current study was to explore the goodness of ACI. Previous study concluded with uncertain goodness of 10 categories (*arousal*, *dynamics*, *natural realism*, *informativeness*, *personal relatedness*, *closure*, *controllability*, *speed/time*, *delay* and *force*), suggesting additional research. Previous study also requested for contribution to additional understanding of 6 newly established categories, which were not addressed by prior work (*natural realism*, *congruence*, *informativeness*, *closure*, *smooth texture* and *dimensionality*). The goodness of categories was first assessed via consistency of users' perceptions, expressed by standard deviation. Then the aesthetic relevance, expressed correlation between ACI and attractiveness measure was used to assess the goodness. First we focused on 6 newly established categories. As a result, two out of 6 categories (*natural realism*, *smooth texture*) were considered both consistent and aesthetically relevant. Three categories (*congruence*, *informativeness* and *closure*) were partly consistent, but still aesthetically

relevant; and one category (*dimensionality*) was found inconsistent and aesthetically not relevant in current context. Two other categories, found inconsistent in previous study (*controllability* and *speed/time*) appeared both consistent and aesthetically relevant, but the categories of *force* and *arousal* were found inconsistent and aesthetically not relevant. The categories of *dynamics*, *personal relatedness* and *delay* proved to be aesthetically relevant in some of the tested conditions. Similarly to the initial study, category of *playfulness* was perceived consistently, but did not show aesthetic correlations in any of tested conditions.

Most of the ACI (20 out of 23) proved to be relevant at least in some of given conditions. Authors suggest further study of all 23 ACI using various context. Further study of ACI is expected to have two main interests. One objective is to study the aesthetics in context of non-pragmatic, pleasure-oriented interactions, such as games and interactive art. The other objective is to test ACI in broader selection of different interaction modalities. E. g., motorics of user effort, wider scope of touch and body gestures, interface dynamics, haptics and sound.

Another idea of further study is to explore the use of ACI for informing the design about aesthetically relevant features in interaction. The pattern of diversity of perceptions (similar to the TableIII) could be used to test the design against ACI. I.e., whether the category is distinct in given design. The pattern of aesthetic relevance (similar to the TableIV) could verify how relevant are the categories in a given context. The question to find answer is: how to bind product features to those categories?

# User-Centered Design Case Study: Ribbon Interface Development for Point of Sale Software

Zdzisław Sroczyński  
Institute of Mathematics  
Silesian University of Technology  
23 Kaszubska Str.  
44-100 Gliwice, Poland  
Email: zdzislaw.sroczynski@polsl.pl

**Abstract**—The article is devoted to user-centered design (UCD) applied to the development process of the point of sale software. The influence of UCD methodology on the whole project's progress and its results is described alongside with exemplary user interface designs. In particular, there is a ribbon menu elaborated with the results of the user experience evaluation.

## I. INTRODUCTION

THE software supporting point of sale (POS) operations is a common branch in computer industry. Although there are many solutions on the market, the variable users' requirements and changing law regulations still open the new opportunities to develop dedicated POS applications.

The operations at the retail desk take place frequently through all the working shift, therefore the human-computer interaction (HCI) for the POS software should be optimized to reduce time and guarantee the comfort of usage and reliability during repetitive activities. This reason makes the research in this area especially interesting and worth thorough experiments, regardless of potential organizational difficulties.

## II. STATE OF THE ART

There is a growing interest in human factors in contemporary computing. User experience and human-computer interaction issues are vital parts of almost every software project. Moreover, the agile methodologies focusing at the user are becoming more and more popular, with user-centered design in the lead.

The user interface of popular office applications has evolved for a long time, from terminal mode, keyboard shortcuts, textual menu, dedicated graphical menus until pull-down menus and adaptable toolbars [1], which became a part of modern operating systems. The unified graphical user interface (GUI) improved the user experience especially in terms of learnability. Next GUI improvements introduced sets of standard controls and consistent look-and-feel, especially when it comes to mobile operating systems with touch screens.

Nowadays, the most progressive desktop user interface for the set of options and controls is the ribbon menu, introduced for the first time by Microsoft Corporation in Office 2007 suite. Despite the legal controversies, this kind of interface proved to be efficient and becomes common. It is a good example of

implementation of Fitts's law [2] into computer GUI, giving the comfort of usage even for the people with lesser computer literacy.

There are continuous works on user interface design described in literature [3][4][5][6]. The research in the field of modern ribbon-based user interfaces is widely elaborated in [7][8][9][10][11]. Authors of [12][13] discuss some interesting applications of ribbon menus, while [14] gives a review of sophisticated interfaces of medical devices. Examples for alternative, adaptable interfaces and interactions designed to support disabled persons are given in [15][16][17][18] and [19]. Novel methods of interaction design for multimedia applications and computer games are discussed in [20] and [21].

The ribbon interface was strongly supported while its introduction in the MS Office suite, even with the use of gamification. Therefore Microsoft game "Ribbon Hero" is mentioned by many publications in that field [22][23][24].

The general philosophy behind the User-centered design (UCD) term is involving users in the design process of the computer system. Users' participation level can vary. It can be limited to consulting, observations and testing. On the other hand, the users can be intensively involved throughout every stage of the development as actual partners. UCD clearly suites and complements the other agile methodologies, being probably the most general framework incorporating human-computer interface and user experience factors into the software development process.

User-centered design is the subject of many research projects, from theory [25][26], through formal [27], up to real life examples [28][29]. The topics regarding evaluation of the user experience are covered by [30], [31] and [32].

## III. MOTIVATION AND METHODS

The presented research work is motivated by the author's observations during a real-world development process of the point of sale (POS) software. While the POS applications are quite common, there is a significant specialization in this kind of software, and due to diversity in business operations, the dedicated solutions happen very often. The incorporation of the user-centered design paradigm is natural in this case, as the users' needs can vary strongly.

This case study includes all the development stages of the POS software and presents some valuable insights from the software engineering point of view, because of the long period of monitoring, internal author's involvement in the development team and wide commitment of the actual users. It is worth noting, that the total timespan of the described development cycles is wider than ten years, covers several versions of the IDE tools and includes surveys from several dozen of employees. This way it illustrated the changes in the computer industry and human perception for one of the common software categories.

In the initial stage of the development of POS software, the general assumptions for the project were defined through experts' brainstorming and surveying potential users during face-to-face interviews and panel discussions. The experts – IT development team and customer's management staff – drew conclusions from the review of the out-of-the-box ready POS software. Examined software packages were in general too complex and did not cooperate well with external hardware, especially fiscal printers (popular in Poland model Vento) – there was no option to include salesman identification in the receipt. The other inconvenience forced the operator to close a shift and begin another with every change of person at the desk, which did not fit into manner of work in the customer's retail network, taking too much time. In the end, the stock operations were too complex for the small retail shops, forcing to create shipping and delivery notes, as well as queue priorities (LIFO/FIFO) and variable prices for the articles.

Therefore the need of software targeting small and medium-sized retail companies, with limited financial resources, operating by users with average computer skills was formulated. Issues related to this category of family business often determine applicable technical solutions [33][34].

On the other hand, the potential users – salesmen – formulated the following, comprehensive list of additional requirements and remarks:

- informative, simple graphical interface and set of operations,
- fast processing, especially while scrolling data in the grid, containing a few thousands of articles,
- focus at article search and filtering, taking into account many attributes,
- fast login and switching of users – there may be several salesmen on one shift in the same time,
- easy operations helping to avoid errors, so only one open receipt at the time, all discounts per receipt,
- fast access to the stock level for the article, editable at any time without dedicated shipping/delivery notes,
- possibility to use negative stock levels, to support mid-shift deliveries,
- adaptation to the formal Polish law regulations, fully Polish interface,
- proper, fast and stable communication with fiscal printers,
- convenient reports, fiscal and statistical, giving informative results about the efforts of particular employees,

- barcodes printing on the ordinary printer and self-adhesive paper sheets,
- browser of archive receipts with filtering,
- cash payments and withdrawals support,
- different payment methods: cash, credit/debit card, gift cards.

It is clear, that partially the recommendations from the experts were parallel to the users' remarks.

These to sets of requirements were elaborated by the development team with the usability in mind, taking into account the main attributes of proper user experience, distinguished in [35]: efficiency, satisfaction, learnability, memorizability and faultlessness. Consequently almost all requirements were incorporated in the very first version of the POS software, which had to be prepared in the very short time – about two weeks – due to deadlines set by the customer (small retail network).

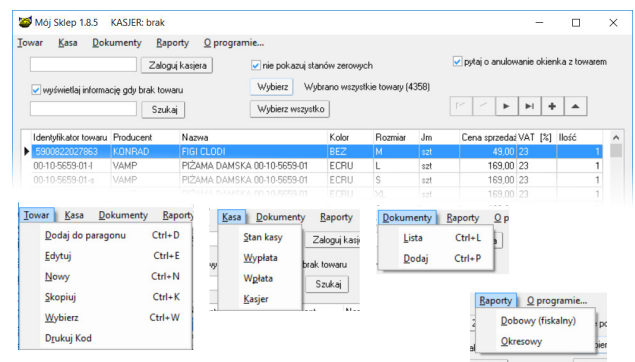

Fig. 1. The user interface of the first version of POS software with classic pull-down menu. Expanded menu options are shown in the subpictures.

The POS software is based on a data grid, overlapping almost the whole screen (see Fig. 1). For the fastest possible operations it was designed as desktop Windows application using local database. This way it matched requirements for low budget (no need for server hardware and software) and allowed easy integration with SDK for the fiscal printers. The development IDE was Embarcadero RAD Studio, generating pure win32 applications, with excellent database connectivity components and known for solid backwards compatibility. This choice profited in the future, when subsequent version of POS software appeared without struggle for adapting changed APIs. Nowadays, thanks to multiplatform capabilities introduced meanwhile to RAD Studio compilers, there is a possibility to port the software to different desktop operating systems: macOS and Linux without great effort, or use it as a base for mobile applications running at Android or iOS [36].

There were three main software versions developed during the further development of the POS application basing on UCD methodology. They are thoroughly elaborated in the following section.

#### IV. APPLICATION DEVELOPMENT CYCLE

The programmers team developed three main versions of the POS application, having of course many subversions with minor improvements. They were developed in subsequent iterations and in general the system was immediately upgraded to the newest version available. The first version had a classic MS Windows pull-down menu and the set of functionality needed to perform sale operations. This version has been used for a long time on rather budget computers with small monitor screens. There was no need to customize font sizes in the data grid and only essential fiscal reports were available.

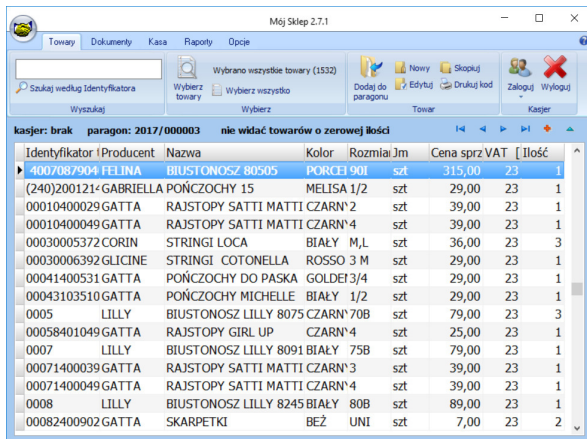

Fig. 2. POS application with a menu mimicking Office 2007 MS Ribbon, after reorganization of options and introduction of icons. More important options acquired bigger icons.

The second main version of the GUI for POS application, shown in Fig. 2, had a MS Ribbon menu (introduced in MS Office 2007) with three colour themes analogous to standard settings in Microsoft Windows (Luna, Obsidian, Silver). This ribbon had skeuomorphic look-and-feel with the characteristic yellow focus. It also mimicked the most confusing behaviour of genuine MS Ribbon: hiding the ribbons after double click on the menu option. In this state the ribbon menu is losing one of the main advantages in comparison to common pull-down menu, as the controls are not visible without extra click needed to unfold the ribbon. The introduction of the ribbon interface was partially inspired by some of the surveyed users, showing interest in a "modern" look of the software. The second reason was the management's need to simplify the software and reduction of the duration and costs of new employee trainings.

The novel ribbon-based menu interface in this version of POS software forced some refactorings in the internal structure of the application. The TAction component was used to put the event handlers in order, making the software somewhat more compatible with MVC (model-view-controller) paradigm. Although this improvement had nothing to do with users' opinions or influence, it significantly helped to support the ribbon menu and modern look-and-feel in the next software version.

Microsoft Corporation decided to force developers to "sign" a special licence for the usage of MS Ribbon control. The

licence concerned not the internals of the software component (actually included in the operating system since Vista version), but the overall graphical design, look-and-feel and user experience. This way independent software vendors were put in rather troublesome conditions, possibly violating Microsoft's licence even when providing their own implementation of the ribbon control. In fact, the ribbon is of course very similar to tabs, and moreover – analogous solutions were available and used in many applications before Office 2007. The only (but important) difference is the consistent GUI proposed and promoted by Microsoft. Consequently, the usage of ribbon interface became less common, than it could be without these controversies. Eventually, to avoid legal issues, the support for the ribbon interface in Embarcadero RAD Studio was ceased, what had an impact on the development of our POS application and its third version.

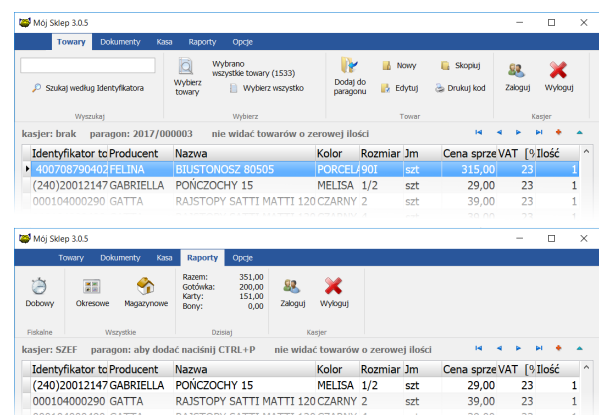

Fig. 3. GUI of the most modern looking version of the POS software, following Office 2016 flat design. Two different ribbon tabs are shown with the exemplary options and info labels.

The third, developed recently version of POS terminal software introduced novel visual appearance based on MS Office 2016 GUI guidelines as a consequence of development according to current trends. This time consulting users suggested to stick to one colour scheme, so the blue one was chosen. In this version for the first time the non-standard component from third-party software vendor was used, as standard RAD Studio development environment does not provide modern looking ribbon components due to licensing problems described above. An introduction of Almediadev BusinessSkinForm suite provided flat Office 2016 ribbon (Fig. 3) and the other controls, but it also required another set of source code refactorings.

These circumstances indicate that legal issues can affect software engineering development process: slow it down or even enforce extra costs.

Here are some other improvements introduced according to users' suggestions and cooperation during the UCD-driven development process:

- direct preview of daily income on the ribbon,
- coloured discount warning,
- simplified user logging – fast selection of the user,
- user logging from every ribbon tab,

- font size customization and other HDPI screen improvements,
- alternate row colours in the grid,
- planned availability for the article – ordering simplification,
- inventory report.

There are somewhat complex improvements in the list, as well as minor visual changes. Anyway, they help the users in more efficient work and suite perfectly to their actual needs.

The ribbon interface was in fact introduced experimentally only at the moment, when the appropriate components in the development IDE became available. Because the users signalled the interest in similar solutions before, there was a positive reception of this novelty. Most of the users pointed out the high visual compatibility with the other modern applications (i.e. Microsoft Office). Some more objective factors are of course worth noting also, as for example better visibility of controls, shorter learning path and better memorizability. The standard ribbon interface is less adaptable than classic pull-down menus, as the ribbon tabs are in general still in the same sequence with exactly the same set of controls. This approach can be inconvenient in very complex, huge and multifunctional applications (which miss the place in the ribbon for enormous count of options). Although, when it comes to properly designed software with well defined functionalities, this method meets users' expectations.

This kind of unification becomes especially valuable, when the user model for the software is variable, because of different professional experience of the users. In this case the fixed GUI is acceptable for power users and simultaneously easy to learn for beginners.

## V. EVALUATION OF THE USER EXPERIENCE

There were 25 users involved into the UCD process: full-time employees, management staff and some interns. The level of commitment clearly differed depending on the particular job position. Computer skills of the users were in general similar, as majority of them knew the basics of Windows operating system and popular Office applications from the school. For two senior employees computerized POS was a complete novelty and they were significantly against it. We observed classic difficulties, as for example tendency to learn exact sequences of keystrokes without monitoring the system response. Sometimes these less experienced users were just ignoring the messages, and moreover – were not even able to remember the general meaning of the messages.

Except these problems at the very beginning of the development of POS system, all the users were successfully using the application, the barcode reader and the fiscal printer. Although not all users were employed for the whole time of the development process, the remarks from them were valuable and useful for the rest of the crew.

The first version of the application had just 5 users working with very budget desktop computers (Pentium II class), next the shops network increased, eventually reaching 20 users. Nowadays, the application is utilized on very wide set of

Fig. 4. POS application during user experience tests at the complete workplace, equipped with credit card terminal, Dell all-in-one computer running Windows 10, barcode scanner and fiscal printer Vento.

computer systems, from common desktop ones, up to modern all-in-one machines with touch screens (as Dell OptiPlex 3030 – see Fig. 4) or laptops (as hybrid Lenovo Flex). Direct connection with fiscal printer forces usage of MS Windows machines, but touch screens are sort of game changer here, because younger salesmen are very familiar with this technology and use it intuitively. This way the user experience gap between classic desktop applications and mobile world narrows.

UCD was involved at every stage of the development, from the first general project, upto the newest ribbon-based application. The main methods of evaluation for the overall user experience were face-to-face surveys and observations of users' behaviour in real world POS installations. This way a very strong relation between development team and final users was built, which is distinctive for agile methodologies. While all these methods were rather informal, the resulting software become a stable and reliable solution supporting POS operations.

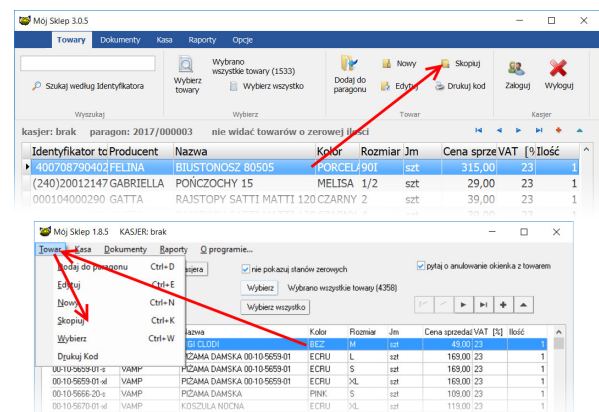

Fig. 5. The advantage of ribbon menu against ordinary pull-down one. For some controls mouse track can be two times shorter and there is only one click needed.

The users of the final product were also surveyed by more formal paper questionnaires. We asked about the overall satisfaction from the usage of the system (Q1), does the ribbon interface have a general advantage against common menu (Q2), is the ribbon interface "Office 2016"-like more readable than "Office 2007" one (Q3), can the actions with ribbon interface be performed faster (Q4), does the ribbon interface help to memorize the recipes for common operations (Q5), is the POS software more comfortable than the others you know (Q6)? All the questions had the scale from 1 (strong disagreement) to 5 (strong agreement).

Fig. 6. Average scores for particular questions from the questionnaire about the latest version of the POS software with ribbon menu.

Average response rate about 4.5 (compare Fig. 6) confirms that UCD approach was the right choice. It helped to develop the software which fits very well to users' preferences. There were some users with a bit more conservative approach, sceptical about the novelties and their opinions proved to be decisive for slightly lower ratings in questions 2 and 3. People accustomed to proven solutions are naturally less inclined to accept and appreciate significant changes. On the other hand, the results for the question about memorizability (Q5) point out, that objective indicators for ribbon menu are much better than superficial opinions about it.

Incremental development process took less resources than classic waterfall model, although the time needed was probably longer. The usage of stable and backwards compatible software toolset seems to be another essential factor in the agile UCD. When the subsequent iterations were taking their time, there was no pressure on extra effort involved with the maintenance of the IDE, compiler and software libraries. Instead of that, the novel possibilities, as for example ribbon interface, appeared and were ready to implement. This way the POS project went from the very basic menu driven application to modern looking one. User experience of the project gained much from that solution without extensive costs.

The initial experiments shown, that in general the ribbon interface optimizes the effort of the user. The reduction of mouse movement and number of clicks is significant, which increases the reliability of actions and helps in faster work (Fig. 5). The extra factor concluded from these experiments is the size of controls and necessity of thorough project for

layout of every ribbon tab, in order to profit from Fitts's law as much as possible.

## VI. CONCLUSIONS

UCD introduced into the development process of the POS software was a key factor of success. It helped to design an interface that users desired, suitable for the necessary activities, but not complicated. This way the quality of user experience increased with every novel version of the software, eventually reaching the modern and effective ribbon menu form.

All three versions of the software profited from the UCD approach, although the scope of the improvements was variable: from the very tiny details to significant rearrangements of the whole user interface. The cooperation between the developers and the users of the system was fluent and agile, as UCD model did not force any artificial restrictions and time frames.

The survey of users' opinions about the software system designed this way leads to interesting conclusions. First, the users profit from easiness and memorizability of the ribbon interface. On the other hand, some users have of course doubts when it comes to fundamental changes in UX.

In general, the evaluation of the satisfaction and experiments regarding some objective characteristics confirmed usefulness of the user-centered design methodology. Further research steps can be focused on statistical analysis of user behaviour with the use of actiontracking [37] and optimization of the controls' placement and sizing.

# Implementation and verification of speech database for unit selection speech synthesis

Krzysztof Szklanny, Sebastian Koszuta

Polish-Japanese Academy of Information Technology, Multimedia Department, Koszykowa 86, Warsaw, Poland

Email: {kszkanny, s7127}@pjwstk.edu.pl

**Abstract**— The main aim of this study was to prepare a new speech database for the purpose of unit selection speech synthesis. The object was to design a database with improved parameters compared with the existing database [1], making use of the theses proved in studies [2]–[4]. The quality of the corpus, a selection of the suitable speaker, and the quality of the speech database are all crucially important for the quality of synthesized speech. The considerably larger text corpora used in the study as well as the broader multiple balancing of the database yielded a greater number of varied acoustic units. For the purpose of the recording, one voice talent was selected from among a group of 30 professional speakers. The next stage involved database segmentation. The resultant database was then verified with a prototype speech synthesizer. The quality of the synthetic speech was compared to that of synthetic speech obtained in other Polish unit selection speech synthesis systems. Consequently, the end result proved to be better than the one obtained in the previous study [4]. The database had been supplemented and extended, significantly enhancing the quality of synthesized speech.

## I. INTRODUCTION

UNIT selection speech synthesis remains an effective and popular method of concatenative synthesis, yielding speech which is closest to natural sounding human speech. The quality of synthesized speech depends on a number of factors. First and foremost, it is essential to create a comprehensive speech database which will form the core of the system. The database should comprise a variety of acoustic units (phonemes, diphones, syllables) produced in a range of different contexts, of different occurrence and length.

The first stage in the creation of speech database is the construction of a balanced corpus. This process involves a selection, from a large text database, of a number of sentences which best meet the input criteria. The larger the database, the more likely it is that the selected sentences will meet the set criteria. However, a larger corpus also means a greater computer processing capacity necessary to synthesize a single sentence. What is crucial is a proper balancing that will ensure an optimal database size while maintaining the right proportion of acoustic units

characteristic of a particular language. The speech corpus is built in a semi-automatic way and then corrected manually. The manual part of the designing process is implemented in restricted domain speech synthesis such as the speaking clock and train departure announcements, and restricted speech recognition systems. The process is automated with the use of tools based on a greedy algorithm [5].

Another important aspect involves a careful selection of the speaker who will record the corpus. The speaker is usually voted on by experts, while an online questionnaire is often used to speed up the selection process. The recordings are made in a recording studio during a number of sessions, each several hours long. Each consecutive session is preceded by a hearing of the previously recorded material in order to establish a consistent volume, tone of voice, way of speaking, etc.

The final stage in the construction of speech database, following the recordings, is the appropriate labeling and segmentation. The segmentation of the database is carried out automatically with the use of statistical models, or heuristic methods, such as neural networks. Such a database should then be verified for the accuracy of the alignment of the defined boundaries of acoustic units.

The aim of this study was to design a new speech database with improved parameters. To this end, theses proved in [2]–[4] were used. The quality of the corpus, the selection of the right speaker and the quality of the database have a considerable influence on the quality of synthesized speech. The completed database was verified in a prototype synthesis engine.

## II. METHODS

### A. Designing the speech database

The database was created with three corpora: no. 1 - a normalized collection of parliamentary speeches, stenographic records from select committee sessions, and extracts from IT e-books of 600MB (equivalent to 5 million sentences); no. 2 - subtitles for three feature films, i.e. Q. Tarantino's 1994 'Pulp Fiction', S. Kubrick's 1987 'Full Metal Jacket' and K. Smith's 1994 'Clerks', containing 4300 utterances; no. 3 - a corpus of 2150 sentences which served as a basis for the creation of the corpus-based speech synthesis [1],[4]. This corpus was based on a 300 MB text file containing, among others, a selection of parliamentary

<sup>1</sup>This work was partially supported by the Research Centre of the Polish-Japanese Academy of Information Technology, supported by the Ministry of Science and Higher Education in Poland

speeches. It underwent multiple balancing (complying with the criteria outlined in section 2.3) and was supplemented with low frequency phonemes. The final corpus includes 1196 different diphones and 11524 triphones [1],[4].

Corpus no. 1 was subdivided into 250 files, each containing 20,000 sentences, of which 16 sub-corpora were randomly selected for further processing. Such a division makes data processing more efficient. In the final stage of the balancing, corpora no. 2 and no. 3 were used to expand the newly designed corpus. Findings presented in [2] indicate that multiple balancing helps to make the corpus more representative, thereby enhancing the quality of speech synthesis.

### B. Phonetic transcription

Phonetic transcription makes it possible to convert orthographic text into phonetic script. This is done by means of a special phonetic alphabet, such as PL-SAMPA [6].

The automatic phonetic transcription was generated with the help of software available as part of the Clarin project [7]. The application operates within a rule-based system. The diphone and triphone transcriptions were generated in Perl.

### C. Multiple balancing

The CorpusCrt program is an implementation of Greedy algorithm [8]. It was used as a balancing tool for sentence selection. Each of the 16 sub-corpora was balanced according to the following criteria:

- Each sentence should contain a minimum of 16 phonemes;
- Each sentence should contain a maximum of 80 phonemes;
- Each phoneme should occur at least 40 times in the entire corpus;
- Each diphone should occur at least 4 times in the entire corpus;
- Each triphone should occur at least 3 times in the entire corpus (due to the large number of possible triphones, this particular criterion could only be met for 400 most frequently used triphones in the Polish language);
- The output corpus should contain 2500 sentences.

TABLE I. PERCENT FREQUENCY DISTRIBUTION OF LOW-FREQUENCY POLISH PHONEMES IN A RANDOMLY SELECTED SUB-CORPUS BEFORE AND AFTER THE INITIAL BALANCING

Phoneme	Before balancing	After balancing
<b>dZ</b>	0.01%	0.02%
<b>z'</b>	0.10%	0.16%
<b>N</b>	0.20%	0.17%
<b>dz</b>	0.31%	0.36%
<b>o~</b>	0.59%	0.77%
<b>dz'</b>	0.76%	0.78%
<b>X</b>	0.79%	0.87%
<b>ts'</b>	0.83%	0.94%
<b>e~</b>	0.78%	1.09%

Table I shows a percent frequency distribution of lowest frequency polish phonemes in a randomly selected sub-corpus before and after the initial balancing.

The aim of the second balancing was to create one corpus that would include the phonetically richest sentences from the 16 already existent sub-corpora. The sub-corpora were first merged into a file of 40,000 utterances which, when balanced, yielded a corpus of 2,500 sentences. The result was a richer coverage of acoustic units in comparison to each of the separate sub-corpora.

### 1) Merging with the corpus assigned for unit-selection speech synthesis

The resultant corpus was then merged with corpus no. 3 and balanced to 2,500 sentences. The number of low-frequency phonemes (DZ, z', N, o~, e~) increased from 148 879 to 149 635.

It was essential that the corpus contained a wide range of prosodic contexts for the different phonetic components. Therefore, it was subsequently supplemented with prosodic features from corpus no. 2. This involved using all the interrogative and exclamatory sentences. The corpus was then balanced to yield two corpora of 50 sentences each. The first one contained interrogative sentences, while the other contained exclamatory sentences. These corpora were then concatenated with the main corpus (without further balancing). Previous findings indicate [2] that it is possible to reduce the size of a corpus. In the final balancing, the corpus was reduced to 2,150 sentences, with the assumption that a corpus must contain a minimum of 15,000 triphones while the number of diphones must remain unchanged. The average length of a sentence in the corpus is that of 63.93, whereas the total number of phonemes is 128,169. The corpus contains 1279 different diphones and 15,087 different triphones. Table II shows data concerning the number of acoustic units depending on the size of a corpus. Fig. 1 shows a percent frequency distribution of phonemes in the final corpus.

TABLE II. NUMBER OF ACOUSTIC UNITS AFTER CORPUS SIZE REDUCTION WHICH SERVED AS A BASIS FOR THE SELECTION OF THE FINAL CORPUS

No. of sentences	2600	2400	2200	2150	2100
No. of diphones	1279	1279	1279	1279	1279
No. of triphones	15869	15615	15218	15078	14979
No. of triphones < 3	8379	8387	8285	8228	8189
No. of diphones < 5	165	184	199	199	203

### D. Speaker selection and recordings

The speaker was selected on the basis of recorded voice samples collected from 30 candidates. Each candidate was a voice talent. The objective was to find a speaker with a strong steady voice. The voice assessment was carried out by eight voice analysis experts, who chose a female voice.

The recordings were conducted in the recording studio of the Polish-Japanese Institute of Information Technology, Warsaw (now Polish-Japanese Academy of Information

Fig.1: Percent frequency distribution of phonemes in the final corpus

Technology), using an Audio-Technica AT2020 microphone with a pop filter. The signal was recorded in the AIFF format with a 48 kHz sampling frequency and a 24 bit resolution, using the audio Focusrite Scarlett 2i4 interface.

The corpus was recorded during 15 two-hour sessions. Each prompt was recorded as a separate file. After each session, the files were exported in the WAV format with file names corresponding to the prompt numbers in the corpus. The recordings were then checked for distortions and external noises as well as mistakes made by the speaker. 480 prompts were re-recorded.

### E. Segmentation

The automatic segmentation was carried out with a program based on the Kaldi project [9]. Kaldi is an open source speech recognition toolkit, written in C++. The segmentation was based on the ‘forced alignment’ technique, which involves matching phoneme boundaries on the basis of a file containing phonetic transcription. First, the program creates an FST graph whose states correspond to the consecutive segmental phonemes of the analyzed phrase. Following that, a sequence of states with set boundaries is assigned for recording, by means of the Viterbi algorithm. The phonetic transcription for the segmentation was performed on the basis of an orthographic transcription using a Polish language dictionary with SAMPA transcriptions. The transcription of foreign words and proper nouns was performed manually [10].

### III. VERIFICATION OF THE SPEECH DATABASE

To examine the quality of the speech database and to verify the quality of the segmentation, a prototype speech synthesizer, written in Java, was used to conduct a series of tests. The program does not contain the NLP module but allows a preliminary evaluation of the quality of the corpus. It facilitates unit selection using three different algorithms: ‘Random’, ‘Forward’ and ‘Viterbi’ (the so-called Viterbi algorithm) [11]. These algorithms are responsible for the way acoustic units are selected from the database. The main criterion that is taken into account in the selection of acoustic units is their direct neighborhood in the database, which reduces the likelihood of the occurrence of artifacts, such as energy discontinuity, which render synthesized

speech artificial. The similarity of  $F_0$  at the boundaries of concatenated units is also taken into account.

The ‘Random’ algorithm randomly selects acoustic units that match the phonetic transcription, without cost function. Its application is the least effective of all the three algorithms.

'Forward' and 'Viterbi' are more advanced algorithms which make it possible to use cost function for the comparison of hypotheses. In unit selection speech synthesis, a hypothesis is a sequence of acoustic units selected from the database which, having been concatenated, produce a phrase that is to be synthesized. The object is to select a sequence that will produce the most natural sounding speech. These two algorithms are similar and yield similar results. The Viterbi algorithm was chosen for the testing process. The searching process is based on the trellis of all the candidates which is formed by the paths between them. The Viterbi algorithm searches the trellis from left to right, calculating partial costs, which is the sum total of the sequences of the cost function. The optimum path with the lowest cost is then chosen.

The prototype synthesizer utilizes MLF files (with diphone boundaries in the corpus), WAV sound files (with recorded prompts), and files containing data about  $F_0$  for each of the prompts. The text to be synthesized is provided in the form of a phonetic transcription.

## IV. RESULTS

A Mean Opinion Score (MOS) test was designed to check the quality of the synthesizer. MOS is a subjective measure for audio and video quality evaluation. In the test, subjects are administered audio or video samples, after which they give their subjective opinion using the following five-point scale: 1 – bad, 2 – poor, 3 – fair, 4 – good, 5 – excellent. The MOS is expressed as the arithmetic mean of all the collected ratings. MOS is also recommended as a method for evaluating the quality of synthesized speech [12]. To assess the quality of the voice a special website with an online questionnaire was designed, which served as an anonymous tool for evaluating speech samples on the five-point scale. The test involved 14 individuals who were familiar with issues related to speech synthesis, phonetics of the Polish language and phonetic transcription, and who were also well-informed about natural language processing. The test was divided into three parts. The first five recorded sentences were used to judge the quality of lector voice; the samples were then used to generate another five resynthesized sentences; the third part of the test involved sentences synthesized in the prototype speech synthesizer. Long, phonetically rich sentences were selected to this end. The first part of the test received the average score of 4.3, which indicates that the speaker's voice was rated high by the experts. The speaker's voice rating reflects the respondents' opinion concerning the potential effectiveness of the future synthesizer. It is the maximum score that the best synthesizer could receive. Resynthesis of sentences

inevitably involves a decrease in their quality. In the test, the quality of the synthesis received an average opinion score of 3.41, which is a good result. The third part of the test received an opinion score of 2.07.

## V. DISCUSSION

It would be worthwhile to compare the obtained results with the commercial and non-commercial systems functioning in Poland, taking into account the evaluation of the quality of the entire system and not merely the speech database.

The first Polish system for unit selection speech synthesis was BOSS, which was created as part of a collaborative research project between Adam Mickiewicz University, Poznan and IKP (Institut für Kommunikationsforschung und Phonetik) in Bonn [13]-[15]. The speech database consists of approximately 115 minutes of audio material read by a professional speaker, recorded during several sessions and supervised by an expert phonetician. The database is subdivided into six parts. The first part consists of phrases with most frequent consonant structures, where 258 consonant clusters of various types are used. The second part consists of all Polish diphones realised in 92 grammatically correct but semantically nonsense phrases. The third part consists of 664 phrases with CVC triphones (consonant-vowel-consonant, in non-sonorant voiced context and with various intonation patterns). The fourth part consists of 985 phrases, each made up of 6 to 14 syllables. The fifth part consists of 1109 sentences made up of 6000 most frequent vocabulary items. The sixth part consists of 15-minute long prose passages and newspaper articles [16]. The database was implemented in the Bonn Speech Synthesis System. A three-part MOS test was conducted for the designed system: the first part involved common utterances – 25 sentences and phrases created especially for the purpose, mostly using the top high frequency vocabulary items from a large vocabulary newspaper frequency list, and conversational utterances; the second part comprised 25 typical Polish conversational phrases, dialogue phrases, short expressions and natural utterances; the third part comprised a reference set, i.e. 24 original recordings of the speaker reading short utterances. The speaker's voice received an opinion score of 4.6, whereas the speech synthesis system received a score of 3.39. Further experiments, which involved manual correction of the speech database while focusing on duration weighting, increased the MOS opinion score to 3.62 [17] for the speech synthesis system. The quality of synthesized speech based on automatically segmented database received an overall score of 2.44. This result covers re-synthesized sentences from the corpus, sentences with high frequency vocabulary items and words that are 'difficult' for the synthesizer, i.e. phonetically rich items.

However, the quality rating for difficult sentences, i.e. sentences similar to those used for testing the original database, was 1.70, which then rose to 1.71 following a

manual correction of the segmentation. Unfortunately, the publication [17],[18] does not present the tested sentences, which could be used to evaluate the quality of the database.

IVONA, a commercial system for unit selection speech synthesis, was created by IVOSOFTWARE (now Amazon). In the Blizzard Challenge 2006, the system received the following opinion scores: 4.66 for the speaker, and 3.69 for the quality of synthesis with an ATR database [19],[20]. In 2007, the scores were 4.70 and 3.90 respectively, using the same database. In the 2009 Blizzard Challenge, IVONA received 4.90 for the speaker and 4.00 for the quality of the synthesis, with an EH1 database [21]. The presented data concerns speech synthesis for the English language. However, no publication presenting MOS results for the Polish language is available.

Tests were also conducted for the original synthetic speech system that was developed in the Festival meta system [22]. These were carried out following work on a speech synthesizer [4]. 28 experts were involved in the tests, and the average MOS result for the speaker's voice was 4.60. The experts assessed the quality of the resynthesis at 3.79, which is a good result. Sentence synthesis with the best cost function, optimized with an evolutionary algorithm, received an opinion score of 2.71, the worst cost function 1.97, and the default cost function 2.19. These results are worse than those obtained for the other speech synthesis systems. However, it must be noted that the basic problem stemmed from the construction of a database recorded by a non-professional speaker. The utterances exhibited considerable  $F_0$  fluctuations, which in turn affected the right selection of appropriate acoustic units. Despite this, the synthesis in the complete speech synthesizer with a default cost function received a score similar to that of a new database that was tested in the prototype synthesizer (2.11 vs. 2.07), even though the segmentation quality did not undergo manual correction. Compared with the BOSS system, this result is better for phonetically rich sentences.

When comparing the opinion scores of recorded samples and resynthesized samples, one can notice a significant discrepancy (0.88). This may indicate errors in the functioning of the prototype synthesizer and/or an incorrect phonetic transcription used in the selection of acoustic units for speech synthesis. Other reasons may include the presence of elements of acoustic units which appear in synthesized sentences as a result of automatic segmentation. This problem can be eliminated by manual correction. One of the methods is described in [23]. This kind of correction, as well as improvements made to the prototype speech synthesizer, will ensure a higher opinion score. Criteria applied in previous studies [23] will still be used in order to detect durational outliers. These include phonemes of abnormal duration, zero crossing errors, plosive phonemes and other distortions.

The construction of the new speech database made it possible to eliminate the errors which the author encountered when designing the previous database. These involved the quality of the speaker's voice, including the

excessively fast speech delivery, and considerable  $F_0$  fluctuations in sentences. What was also eliminated was the errors that occurred at the corpus building stage. The corpus was extended to include utterances from everyday speech, which should improve the quality of synthesized sentences in this area.

## VI. CONCLUSIONS

When designing the speech database, the author drew on the experience gained during the implementation of the unit selection speech synthesis. The corpus was supplemented and extended, and the recordings were made by a professional speaker selected by means of tests, which is crucial for the quality of synthetically generated speech. The database created for previous studies was recorded by a semi-professional speaker.

Despite the fact that manual segmentation correction was not performed, the results obtained in a MOS test were similar to those of a manually corrected database (2.07 vs. 2.18), and its opinion score for phonetically rich sentences was higher than that for the BOSS database (2.07 vs. 1.70).

What it means is that the elimination of other errors during the implementation of the new speech synthesis system will make it possible to achieve a higher quality of synthesized speech, comparable to that of the BOSS and IVONA synthetic speech systems. The next stage of the research will be to incorporate the database into the existent multimodal speech synthesis. We also plan to verify and place the database in compliance with the ECESS standards and to arrange for the database to be validated by an independent institution, such as ELDA [24].

## ACKNOWLEDGMENT

The author would like to thank Danijel Koržinek for his help with the implementation of the prototype speech synthesizer and Prof. Krzysztof Marasek for his help in finding professional speaker.

# Creating an Interactive and Storytelling Educational Physics App for Mobile Devices

Krzysztof Szklanny, Łukasz Homoncik, Marcin Wichrowski, Alicja Wiczorkowska  
Polish-Japanese Academy of Information Technology, Koszykowa 86, Warsaw, Poland  
Email: {kszklnny, lukasz.homoncik, mati}@pjwstk.edu.pl, alicja@poljap.edu.pl

**Abstract**—Ubiquitous mobile technology makes m-learning a popular method of education. Our goal was to use education and entertainment (edutainment) for teaching physics on mobile devices, as the technology is available for most of the students. A game was designed, as an interactive and storytelling educational physics app based on user experience and edutainment guidelines. The testers in usability tests considered the game useful; they also suggested improvements. Learning through play can be broadly applied to teach physics, educational apps can be created, and supplement education.

## I. INTRODUCTION

**M**-LEARNING is a teaching technique that requires the use of portable devices (mobile phones, smartphones, PDAs, tablets) [1]; it may take place outside of school [2]. It is distance learning based on mobile phones, smartphones, PDAs and tablets with wireless Internet, with communication replaced with various communication technologies.

“Edutainment” (education and entertainment) is applied in m-learning. It encourages the user to learn through games and interaction, and evokes emotions, so it is easier to remember the content. Entertainment is (9P): Perennial, Pervasive, Popular, Personal, Pleasurable, Persuasive, Passionate, Profitable, and Practical [3]. Learning in the 21<sup>st</sup> century is: Learner-centered, Media-driven, Personalized, Transfer-by-Design, Visibility Relevant, Data-Reach, Adaptable, Interdependent, and Diverse (9 features) [4].

The effectiveness of edutainment has been proven [5], [6]; it gives the opportunity to interact, for example in a game.

Edutainment has spread with the development of mobile devices (more common now than desktops). Smartphones sales increase by 70-80% per year [7]. Since 2013 more smartphones than feature phones are sold, and 50% of people own a mobile phone. Various apps increased the capabilities of smartphones, especially with Internet access. The number of Internet surfers exceeds 3.6 billion [8].

Our app *Apollo* is a form of edutainment. It combines a game and a multimedia presentation, using the methodology proposed by the authors, including interaction, storytelling and a 3D (3-dimensional) visualization. It presents physics concepts, including satellite motions, geostationary orbit and gravitational acceleration [9]. Our goal was to visualize the

phenomena of physics and present them in an entertaining way. Physics is a difficult class; teachers indicate that young people lose the ability to imagine abstract concepts, and have difficulties in understanding the physics laws. There are not many physics apps available on the market.

The app was prepared in Polish, for junior high school students, who spend a lot of time on their smartphones. We researched on market penetration with smartphones, and checked which operating system is most popular. The usability tests of the app are presented in this paper.

## II. MOBILE MARKET ANALYSIS

### A. World

More than 1.2 billion smartphones were sold worldwide in 2014[10], and over 1.4 billion in 2016. Currently, 4.6 billion mobile devices are registered, and there will be more active devices than people [11]. In 2016, mobile web usage overtook desktop [12]. 80% of internet users own a smartphone [13]. The interest in edutainment also grows.

The most popular brand of mobile devices is Samsung [14], with Android as the most popular operating system [7]. Young people 18-30, often referred to as ‘Generation Y’, mostly use Apple or Samsung devices [15]. They live with phones in their hands. 60% permanently participate in the life of social networks, and browse news. 70% cannot imagine their lives without mobile apps and use 1-9 apps every day. This brings an opportunity for m-learning, and we decided to create the app for Android-based smartphones.

### B. Predictions for the Future

Customizing websites for mobile devices will become increasingly important. Mobile devices are equipped with gyroscopes, GPS, multi-touch technology, accelerometers and cameras, which increases their potential for edutainment.

By 2020 mobile devices with the latest technologies available today will cost \$10 [16]. Paper will be replaced by mobile devices [17]; a digital notebook that allows displaying content is currently sold for \$100 [18].

Mobile devices are becoming thinner, of credit card size, and flexible [19]. It will be possible to adjust mobile devices to any shape [20]; they are already produced as bracelets. The devices will be multisensory, allowing for detection and emission of smells. Mobile device sensors that monitor heartrate are already available. We will be able to monitor

This work was partially supported by the Research Centre of the Polish-Japanese Academy of Information Technology, supported by the Ministry of Science and Higher Education in Poland

the body state in real time, with high-speed wireless access to the cloud computing. Monitoring tools, wearable devices, mobile User Experience (UX) design, and location sensing are already the most significant mobile technologies [21]. Works on better batteries are also performed.

The research on mobile devices continues. Toyota's *Windows to World* based on AR (Augmented Reality) turns the car window into an interactive multi-touch screen, which can also be used as a drawing tool that references real world objects; work is underway on future cars that communicate with each other. The University of Washington is working on transparent AR contact lenses powered by solar energy.

#### C. Poland

The number of mobile app users keeps growing; 44% of mobile phone users owned a smartphone in 2014, but 1/3 of them do not buy apps from app stores [22]. They use phones for Internet browsing (mostly to use social media), watch video, play mobile games, as localizers, and for banking. But, 74% of 15-19 year-old teens own a smartphone [23].

Daily Internet usage rate in Poland in 2016 was 90% in the age group 16-24 [10], with the average Internet speed 14 Mbps for download and 4.9 Mbps for upload [24].

#### D. Mobile apps market

Google Play has 2.8 million apps for Android, App Store has 2 million apps for iOS. Every month 100,000 apps are introduced. In 2014, 179 billion apps were downloaded. 11% of smartphone and tablet users have educational apps installed [15]. Entertainment apps are most often downloaded. In Poland, most common are instant messaging and social networking apps, games, radio and navigation.

### III. PHYSICS APPS FOR SMARTPHONES

14 apps are listed at [25]; 6 are marked with 4 (out of 5) stars: *VMS–Velocity and Acceleration Animation*, *Newtonium–Physics Simulator*, *Bridge Constructor Playground*, *Thomas Edison*, *Tory Odyssey: Motion Commotion*, and *Physics One Gravity*.

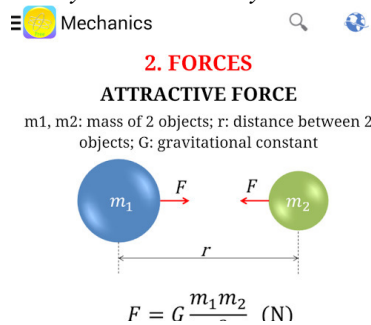

Figure 1. Physics Formulas Free app (screen from Google Play)

At Google Play, there are several hundred apps for physics, with several dozen for learning, mostly in English:

- *Physics Formulas Free*, rated 4.5 (out of 5) stars, with more than 500,000 downloads,
- *Complete Physics*, rated 4.1, over 500,000 downloads,
- *Learn Physics*, rated 4 stars, over 500,000 downloads,
- *PhyWiz-Physics Solver*, 4.6, over 100,000 downloads,
- *Physics Notes*, rated 4.2 stars, over 100,000 downloads.

Figure 2. Complete Physics app (screen from Google Play)

*Physics Formulas Free* (Figure 1) is for calculating physics problems; it allows adding user-defined formulas. *Complete Physics* (Figure 2) has tutorials, questions, and a quiz. *Learn Physics* (Figure 3) has tutorials, formulas calculator and quizzes. *PhyWiz – Physics Solver* helps doing physics homework; it solves physics questions. *Physics Notes* has tutorials, step by step instructions, and allows learning in a deep and intuitive way. It is praised [25], but criticized: “I would like to see (...) testing features and instant-feedback in order to really put the theory into practice. (...) it would be great if students could add their own notes (...) it will enhance the revision.”

Figure 3. Learn Physics app (screen from Google Play)

#### A. Physics Apps in Polish

There are few apps for learning physics in Polish, not offering entertainment. *Fizyka na 5!* (Figure 4), rated 4.1, with over 1,000,000 downloads is a crib with formulas. *Fizyka–Słownik*, rated 4.4, 50,000-100,000 downloads, is a physics dictionary, with quizzes. *Fizyka – kalkulator*, rated 4.3, 10,000-50,000 downloads, calculates physical formulas.

Figure 4 Fizyka na 5! app (screen from Google Play)

### IV. APOLLO APP

Based on the analysis of physics apps, mobile devices market, and operating systems, we prepared an edutainment physics app for Android. We used our experience in implementing an educational platform with elements of puzzle learning [26]. The app, *Apollo* (Figure 5) is a RPG

(role playing game), with storytelling and 3D world [9] in the *first person perspective* - rendered from the player's viewpoint.

#### A. Storytelling

In interactive storytelling, the user can control the course of events in an app. It can be applied to physics education [27], [28], but there are no such games on the Polish market.

The narrative of the *Apollo* app is based on space travel. The spaceship *Apollo* experiences propulsion breakdown and loses contact with Earth. The computer must be fixed, and to do this, it is necessary to contact Earth. The pilot must help in determining the parameters necessary to send the message, and the computer gives the user a physics task to solve, and shows an explanatory video presentation.

#### B. Interactive 3D World

The most common engine for creating games is Unity 3D [29]; also Unreal Engine [30] is popular. We used Unity 4.5. Unity works with Direct 3D (for Windows), and OpenGL ES for Android. It offers options for real time rendering, and detects the best hardware settings of a device on which the app is initialized, and automatically adjusts the settings. Functionality tests were carried out in Unity 3D Remote; simulating the game on the target device.

Figure 5 Start screen of the *Apollo* app

#### C. User Interface and Interaction

The app should be easy to use for junior high school students, so we followed UX guidelines [6]. The game is controlled through gestures, 2 virtual joysticks displayed on the screen, and a touch-activated interface of high usability. Our app is engaging, and uses simple communication.

The user of the *Apollo* app moves in a space station (Figure 6) using virtual joysticks in the lower corners of the screen. Consequent steps encourage the user to learn. The user explores the spaceship, to find hints and educational materials on the guidance computers. The interaction is through touching or approaching an interactive object (Figure 7), which have charts with formulas (Figure 8), movies, etc.

#### D. Implementation

The app is for Android 2.3.1 or higher, GPU supporting OpenGL ES 2.0 or higher, Internet, and 1 GB of RAM.

The planet and spaceship were modelled in 3ds Max [31]. Animation was rendered using V-Ray 2.0, and 3D objects exported to FBX format. Textures, texts and graphics (1024 x1024) were made in Adobe Photoshop [32], and normal maps in Quixel Suite [33]. 25 colliders with an active trigger function were designed to activate sliding doors animations, move consoles, and to activate video clips and sounds.

Figure 6 The interior of the space ship in *Apollo*, with lights shown

Figure 7 Interactive element in *Apollo*: the screen

Figure 8 A chart with physical formulas in *Apollo*

We used speech synthesis [34] to get the voice of the computer. Adobe Audition [32] was used to edit audio files. Intro was created in Adobe After Effects [32].

### V. USABILITY TESTS OF *APOLLO*

The usability tests were performed using Samsung Galaxy Tab 4 (10" screen), to observe how the users navigate the game environment and accomplish simple tasks in their first contact with the app. We also wanted to study the users' first impression of educational storytelling on a mobile device.

11 IT students (Information technology, college seniors from Poland, age: 22-46, M=29.9, SD=7.6) took part in the experiments; 5 participants is sufficient in such tests [35]. All testers used tablets and smartphones before. Each student owned a smartphone and 8 of them also a tablet. All except 1 person had already used educational apps:

- 7 persons used educational applications on laptops,
- 6 used educational apps on smartphones,
- 5 used educational applications on desktop computers,
- 4 used educational apps on tablets,
- 1 used educational games on Nintendo DS console.

Prior experience of the students included: foreign language learning (7 persons), programming language learning (2 persons), and geography and anatomy learning (one person each). 1 person never used educational apps.

#### A. Test Procedure

Each test had a form of an individual session, guided by a moderator, observing the user performing the tasks:

1. Start the app on the tablet.
2. Start navigating a character in the game environment.
3. Leave a room and go to the bridge deck of the space ship.
4. Find the captain's console; listen to the computer's orders.
5. Find the navigation console with further instructions.
6. Find the science room and see an educational video.

Next, the testers completed an online survey, to assess the usability, interaction and audio-visual aspects of the app, and prior experience in using mobile devices in education.

## VI. RESULTS OF USABILITY TESTS

### 1. To what extent the app was easy to use?

A majority of users (Figure 9) evaluated the app as easy to use ( $M=3.8$ ,  $SD=0.6$ ;  $M$  – mean value,  $SD$  – standard deviation).

Figure 9 Ease of use of the Apollo app

### 2. To what extent it was easy to navigate the character?

The users evaluated it as convenient ( $M=3.6$ ,  $SD=0.9$ , Figure 10). Some users had difficulties to navigate the characters at the beginning. They were unable to find controllers, shown as semi-transparent ellipses in the corners (Figure 11).

Figure 10 Convenience of navigating the character in the app

### 3. To what extent the graphical elements of the interface were clear and understandable?

They were mostly evaluated as understandable and very understandable (Figure 12,  $M=3.8$ ,  $SD=1.1$ ). The users tested if it was easy to find infographics, recognize them as navigation elements, and follow. Some users missed lettering on the doors, and readability of information screens was low in some cases because of poorly selected colours and fonts.

Figure 11 Controllers in Apollo (in the lower corners)

Figure 12 Understandability of the graphical elements of the interface

### 4. Was the size of buttons appropriate?

All users considered it appropriate ( $M=3.0$ ,  $SD=0.0$ ).

### 5. Was the size of fonts and graphics large enough to maintain their readability?

Opinions (Figure 13) were mainly moderate and very good ( $M=3.6$ ,  $SD=1.2$ ). Some users did not notice letterings on the door, and readability of information screens was also low in some cases because of poorly selected colours and font. Therefore, colours and fonts should be improved.

Figure 13 Size of fonts and graphics in the app

### 6. Evaluation of scoring

Most users evaluated scoring and sound quality as good and very good, but some as moderate or bad ( $M=3.8$ ,  $SD=1.2$ , Figure 14). The users mainly complained about the bothersome voice of the synthesizer, reading the commands.

Figure 14 Evaluation of scoring in the app

### 7. Aesthetic value of the app

Diverse opinions were shown ( $M=3.6$ ,  $SD=1.1$ , Figure 15). Probably more sophisticated design is needed.

Figure 15 Aesthetic value of the app

### 8. General evaluation of the app for tablets

Most users evaluated the app for tablets as moderate or good to be used on tablets ( $M=3.5$ ,  $SD=0.8$ , Figure 16).

Figure 16 General evaluation of the app for tablets

### 9. How do you evaluate the usefulness of similar educational apps for learning with tablets?

Most users evaluated it as useful, but some might had a bad experience ( $M=3.7$ ,  $SD=1.5$ , Figure 17).

Figure 17 Usefulness of similar educational apps for learning with tablets

### 10. What screen size would you recommend for convenient use of such apps on mobile devices?

Most users preferred 10" screens for similar apps (Figure 18).

#### 11. What screen orientation do you prefer when using the app with a smartphone/tablet?

The testers preferred horizontal orientation when using the app with a tablet, and vertical with a smartphone (Figure 19).

#### 12. What caused problems?

The main problem was learning to control the character, with the lack of noticeable controllers. The readability of information screens, texts on the floor and doors was low, Polish diacritics were missing, font sizes too small, and bold font unnecessary. The contrast between font colours and the background was insufficient. The text in the intro was too long, and displayed too quickly. It was not clear, which elements are interactive, and how to interact (approach or touch the element). Some testers had problems with door opening, or starting video. One person reported low level of graphics and non-intuitive introduction.

#### 13. What did you like best in the app?

The users liked the clear arrangement of rooms, game environment, and setting the scientific issues in the space.

Figure 18 Screen size for similar apps (multiple choice question)

Figure 19 Screen orientation preferred o a smartphone or a tablet

#### 14. What should be improved in the app for tablets?

The testers suggested more animations, decreasing the character's inertia, levelling of the camera view at eye level, and decreasing the transparency of the controllers. They also asked for bigger fonts, Polish diacritics, and different colours to improve contrast. Other suggestions:

- Adding an option to choose subtitles, or the narrator,
- Adding the button for skipping video material,
- Adding icons representing interactive elements,
- Better explanation of the goal of the game,
- Adjusting the scientific level to the target group.

#### 15. What was missing in the app?

The users suggested to add interactive tasks, control the character perspective through a gyroscope (rotate the device) or gestures on touchscreens, and mark interactive spots.

#### 16. Other remarks

The users asked for more interaction to enliven the game; the tasks should be more complex and engaging. The speech synthesizer (computer's voice) should be abandoned.

### VII. SUMMARY

We designed an edutainment app for learning physics on mobile devices, as young people commonly use them. The results of the usability tests of *Apollo* show that although some elements could be improved, the methodology applied to create it was properly selected.

# What Looks Good with my Sofa: Multimodal Search Engine for Interior Design

Ivona Tautkute<sup>1,3</sup>, Aleksandra Możejko<sup>3</sup>, Wojciech Stokowiec<sup>1,3</sup>,  
Tomasz Trzciński<sup>2,3</sup>, Łukasz Brocki<sup>1</sup> and Krzysztof Marasek<sup>1</sup>

**Abstract**—In this paper, we propose a multi-modal search engine for interior design that combines visual and textual queries. The goal of our engine is to retrieve interior objects, *e.g.* furniture or wall clocks, that share visual and aesthetic similarities with the query. Our search engine allows the user to take a photo of a room and retrieve with a high recall a list of items identical or visually similar to those present in the photo. Additionally, it allows to return other items that aesthetically and stylistically fit well together. To achieve this goal, our system blends the results obtained using textual and visual modalities. Thanks to this blending strategy, we increase the average style similarity score of the retrieved items by 11%. Our work is implemented as a Web-based application and it is planned to be opened to the public.

## I. INTRODUCTION

Recent advancements in the development of efficient and effective deep learning methods that rely on multi-layer neural networks have lead to impressive results obtained for many computer vision applications, such as object detection or object classification [1], [2]. Nevertheless, a set of challenges regarding image understanding is still to be solved, for instance training a model which is able not only to detect an object, *e.g.* sofa or chair, in the picture, but based on this detection suggest a table or wallpaper to match their style. This is exactly the topic of this work and the applications of such system are numerous, including but not limited to interior design augmented reality applications or e-commerce recommendation engines.

Although several methods for finding visually similar objects exist [3], [4], they rather focus on the similarities related to the appearance of the objects, not their style or context. On the other hand, recently proposed textual representation called *word2vec* [5] that is used in many text-based search engines is trained mainly using contextual information present in the training corpus. This approach allows to map words describing objects that often appear together, *e.g.* *chair* and *table*, to spaces where their representations are closer to each other than, *e.g.* *table* and *bath tub*. Therefore, one can imagine using *word2vec* representation for finding interior design items that correspond to the same style, as they would often appear together. Nevertheless, textual search often falls short when applied to interior design applications, as the variety of stylistic and aesthetic descriptions, such as *Scandinavian style* or *minimalistic design*, is only known

by a limited number of professional interior designers, and remains cryptic for target users of those applications.

In this paper, we address the above mentioned shortcomings of visual or textual search when applied to interior design by combining the best of both worlds. More precisely, we propose a multi-modal approach to interior design search, dubbed Style Search Engine, which retrieves a list of visually similar objects enhanced with textual input from the user. Fig. 1 shows a high-level overview of our proposed Style Search Engine. The first building block of our engine combines state-of-the-art object detection algorithm YOLO 9000 [6] with visual search engine based on the outputs of deep neural network. The second block allows to further specify search criteria with text and it uses this textual input for context-aware retrieval of stylistically similar objects. At final stage, our method blends the visual and textual search results using similarity score in their respective feature spaces. This leads to 11% performance improvement in terms of style similarity of the retrieved objects.

To summarize, the contributions of this work are threefold:

- Firstly, we propose a multi-modal search framework that combines object detection, visual search and textual query to return a set of results that are visually and stylistically similar.
- Secondly, we propose a new blending method for search models (image and text) that increases the quality of the results.
- Thirdly, we implement our Style Search Engine as a working Web application with the aim of opening it to the public.

The remainder of this paper is organized in the following manner. We begin with a brief overview of the related work and then describe our Style Search Engine along with their building blocks. In Sec. IV, we introduce the datasets that is then used in Sec. V for experiments and validation of our method. We present our Web-based application of Style Search Engine in Sec. VI and in Sec. VII we conclude the paper.

## II. RELATED WORK

In this section, we first give an overview of the visual search methods proposed in the literature. We then discuss several approaches used in the context of textual search. Finally, we present works related to defining similarity in the context of aesthetics and style, as it directly pertains to the results obtained using our proposed method.

<sup>2</sup>Warsaw University of Technology, Warsaw, Poland

<sup>3</sup>Tooploox, Warsaw, Poland.

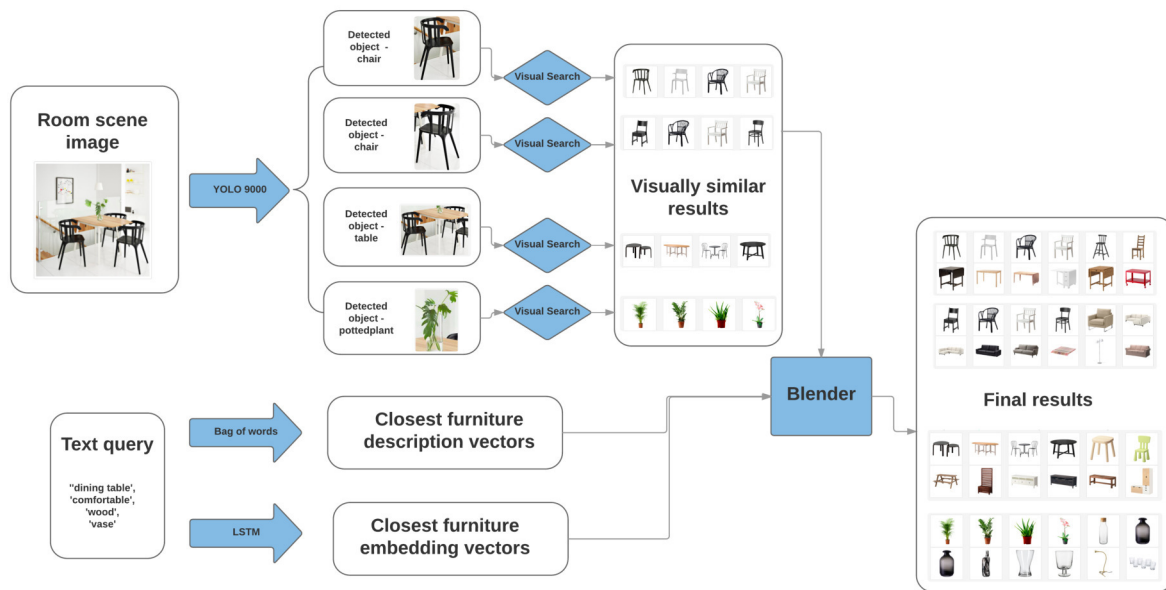

Fig. 1. High-level overview of our proposed Style Search Engine. The visual search block of our engine uses state-of-the-art object detection algorithm YOLO 9000 [6] and the outputs of deep neural network. The textual block allows to further specify search criteria with text and increases the contextual importance of the retrieved results. Finally, by blending the visual and textual search results using similarity score in their respective feature spaces, our method significantly improves the stylistic and aesthetic similarity of the retrieved items.

#### A. Visual search

Traditionally, image-based search methods drew their inspiration from textual retrieval systems [3]. By using  $k$ -means clustering method in the space of local feature descriptors, such as SIFT [7], they are able to mimic textual word entities with the so-called *visual words*. Once the mapping from image salient keypoints to visually representative *words* was established, typical textual retrieval methods, such as Bag-of-Words [8] could be used. Video Google [9] was one of the first visual search engines that relied on this concept. Several extensions of this concept were proposed, *e.g.* spatial verification [4] that checks for geometrical correctness of initial query and eliminates the results that are not geometrically plausible. Other descriptor pooling methods were also proposed, *e.g.* Fisher Vectors [10] or VLAD [11].

Successful applications of deep learning techniques in other computer vision applications have motivated researchers to apply those methods also to visual search. Although preliminary results did not seem promising due to lack of robustness to cropping, scaling and image clutter [12], later works proved potential of those methods in the domain of image-based retrieval. For instance, by incorporation of R-MAC technique [13] image representation based on the outputs of convolutional neural networks could be computed in a fixed layout of spatial regions. Many other deep architectures were also proposed, such as siamese networks, and proved successful when applied to content-based image retrieval [14].

Nevertheless, all of the above mentioned methods suffer from an important drawback, namely they do not take into

account the contextual and stylistic similarity of the retrieved objects, which yields their application to the problem of interior design items retrieval infeasible.

#### B. Textual Search

First methods proposed to address textual information retrieval have been based on token counts, *e.g.* Bag-of-Words [8] or *TF-IDF* [15]. Despite being conceptually simple and adequate to small-scale search problems, the scalability of those methods is very limited. This is due to the fact that the representation size grows with the indexed *corpus* size and, in turn, causes problems with less frequent tokens. Additionally, when using such representations long sequences (documents) tend to have similar token distributions which results in lower discriminative power of the representation and lower retrieval precision. One way to avoid those problems is to apply a SVD decomposition of the token co-occurrence matrix and, hence, reduce the dimensionality of a representation vector [16], [17]. This, however, does not address another problem commonly occurring in token-based representations, namely the fact that they are insensitive to any sequence (token) permutation. Moreover, it is not straightforward to obtain a good representation of single tokens using above mentioned methods.

To handle those shortcomings, a new type of representation called *word2vec* has been proposed by Mikolov *et. al* [5]. The proposed instances of *word2vec*, namely continuous Bag of Words (CBOW) and Skip-Grams, allow the token representation to be learned based on its local context. To grasp also the global context of the token, later extension of *word2vec* called GLoVe [18] has been introduced. GLoVe

takes advantage of information both from local context and the global co-occurrence matrix, therefore providing a powerful and discriminative representation of textual data.

### C. Stylistic Similarity

Comparing the style similarity of two objects or scenes is one of the challenges that has to be answered when training a machine learning model for interior design retrieval application. This problem is far from being solved mainly due to the lack of a clear metric defining how to measure style similarity. Various approaches have been proposed for defining style similarity metric. Some of them focus on evaluating similarity between shapes based on their structures [19], [20] and measuring the differences between scales and orientations of bounding boxes. Other approach propose structure-transcending style similarity measure that accounts for element similarity, element saliency and prevalence [21]. In this work, we follow [22], and define style as *a distinctive manner which permits the grouping of works into related categories*. Nevertheless, instead of using hand-crafted features and predefined styles, we take data-driven probabilistic approach to determine stylistic similarity measure that we define in Sec. V-B.

## III. STYLE SEARCH ENGINE

In this section, we present the pipeline of our multi-modal Style Search Engine. As an input, it takes two types of query information: an image of an interior, *e.g.* a picture of a dining room, and a textual query used to specify search criteria, *e.g.* *cozy and fluffy*. Then, an object detection algorithm is run on the uploaded picture to detect objects of classes of interest such as chairs, tables or sofas. Once the objects are detected, their regions of interest are extracted as picture patches and submitted to visual search method. Simultaneously, the engine retrieves the results for a textual query. With all visual and textual matches retrieved, our *blending algorithm* ranks them depending on the similarity in the respective features spaces and serves the resulting list of stylistically and aesthetically similar objects. Fig. 1 shows a high-level overview of our Style Search Engine. Below, we describe each part of the engine in more details.

### A. Visual search

Instead of using an entire image of the interior as a query, our search engine applies an object detection algorithm as a pre-processing step of. This way, not only can we retrieve the results with higher precision, as we search only within a limited space of same-class pictures, but we do not need to know the object category beforehand. This is in contrast to other visual search engines proposed in the literature [14], [23], where the object category is known at test time or inferred from textual tags provided by human labeling.

As our object detection method, we use the state-of-the-art detection model YOLO 9000 [6]. It is based on DarkNet-19 model [24], [6] with 19 convolutional layers and 5 max-pooling levels. YOLO 9000 is able to detect multiple furniture classes along with their bounding boxes.

The bounding boxes are then used to generate Regions of Interest (ROIs) in the pictures and visual search is performed on the extracted ROIs.

In a set of initial experiments, we optimized the parameters of YOLO 9000 detection algorithm, mainly focusing on the detection confidence threshold. We set this threshold to 0.1, although in case of overlapping bounding boxes returned by the model, we take the one with the highest confidence score.

Once the ROIs are extracted, we compute their representation using the outputs of pre-trained deep neural networks. More precisely, we use the outputs of fully connected layers of neural networks pre-trained on ImageNet dataset [2]. We then normalize the extracted vectors of outputs, so that their  $L_2$  norm is equal to 1 and search for similar images within the dataset using this representation. To determine the neural network architecture providing the best performance, we conducted several experiments described in details in Sec. V-A.

### B. Text query search

To extend the functionality of our Style Search Engine, we implement a text query search that allows to further specify the search criteria. This part of our engine is particularly useful when trying to search for interior items that represent abstract concepts, such as *minimalism* or *Scandinavian style*.

In order to perform such a search, we need to find the mapping from textual information to vector representation of the interior item. The resulting representation should live in a multi-dimensional space, where stylistically similar objects reside close to each other. We formulate this problem in the following manner. Let us first define  $\mathbf{f} \in \mathbb{R}^n$  to be a vector representation of an item stored in the database and  $(t_1, t_2, \dots, t_i) = \mathbf{t} \in \mathcal{T}$  be a variable length sequence that represents a textual query. We are interested in finding a mapping  $m : \mathcal{T} \rightarrow \mathbb{R}^n$  from the space of queries to the vector space of interior items, such that  $dist(m(\mathbf{t}), \mathbf{f})$  is small, when  $\mathbf{f}$  are relevant to the query  $\mathbf{t}$ . Having found such a mapping, we can perform search by returning  $k$ -nearest neighbors of transformed query in interior item space using cosine similarity as a distance measure.

To obtain the above defined space embedding, we use a state-of-the-art Continuous Bag-of-Words (CBOW) model that belongs to word2vec model family [5]. We use the descriptions of various household parts, such as living rooms or kitchens, to infer the contextual information about interior items. Such descriptions are available as part of the IKEA dataset which we describe in details in Sec. IV. It is worth noticing that our embedding is trained without relying on any linguistic knowledge since the only information that the model sees during training is whether given objects appeared in the same room.

In order to optimize hyper-parameters of CBOW for furniture embedding, we run a set of initial experiments on the validation dataset and use cluster analysis of the embedding results. We select the parameters that minimize intra-cluster distances at the same maximizing inter-cluster distance. Fig. 2 shows the obtained feature embeddings using

Fig. 2. t-SNE visualization of interior items' embedding. Distinctive classes of objects, *e.g.* those that appear in bathroom or baby room, are clustered around the same region of the space.

t-SNE dimensionality reduction algorithm [25]. One can see that some classes of objects, *e.g.* those that appear in bathroom or baby room, are clustered around the same region of the space.

After obtaining the furniture embedding, we need a model to find an appropriate mapping  $m : \mathcal{T} \rightarrow \mathbb{R}^n$  from query space to the space of furniture embeddings.

To this end, we train a Long Short-Term Memory (LSTM) deep neural network architecture that has been successfully applied in several other natural language processing applications such as language modeling [26], machine translation [27] or on-line content popularity prediction [28].

We formulate the question of finding  $m : \mathcal{T} \rightarrow \mathbb{R}^n$  as a regression problem. To be more explicit, let  $\mathbf{t} = (t_1, t_2, \dots, t_i) \in \mathcal{T}$  be a furniture description from IKEA Dataset and  $\mathbf{f} \in \mathbb{R}^n$  denote its furniture embedding. We train our model to minimize the MSE between the predicted item embedding based on its description  $\hat{\mathbf{f}} = \text{LSTM}(\mathbf{t})$  and the ground-truth furniture embedding  $\mathbf{f}$ .

Due to the fact, that vocabulary of IKEA Dataset products description is rather limited and may possibly not contain words from user-generated queries, we initialized the LSTM's query embedding layer with word embeddings trained on dump of English Wikipedia with CBOW model. Additionally, to avoid overfitting, we froze the query embedding layer during training.

#### IV. DATASET

In order to evaluate our proposed Style Search Engine, we collected a dataset of interior items along with their textual description and the context in which they appear. Although several datasets for standard visual search methods exist, *e.g.* Oxford 5K [4] or Paris 6K [29], we could not use them in our work, as our multi-modal approach requires additional type of information to be evaluated. More precisely, our dataset that can be used in the context of multi-modal interior design search engine should fulfill the following conditions:

- It should contain both images of individual objects as well as room scene images with those objects present.

- It should have a ground truth defining which objects are present in a given room scene photo.
- It should also have a textual description for each room scene image.

To our knowledge, no such dataset is publicly available. Hence, we collected our own dataset by recursively scrapping the website of one of the most popular interior design distributor - IKEA<sup>1</sup>. We were able to download 298 room photos with their description and 2193 individual product photos with their textual descriptions. A sample image of the room scene and interior item along with their description can be seen in Fig. 3. We have also grouped together some of the most frequent object classes (*e.g.* chair, table, sofa) for more detailed analysis. In addition, we also divided room scene photos into 10 categories based on the room class (kitchen, living room, bedroom, children room, office). This kind of classification can be useful, *e.g.* for qualitative analysis of embedding results, as shown in Fig. 2. We plan to release our IKEA dataset to the public.

#### V. EXPERIMENTS

In this section, we present the results of the experiments conducted using our Style Search Engine to evaluate its performance with respect to the baseline methods. We first show how incorporating object detection algorithm and deep neural network architectures within our visual search engine improves the search accuracy. We then present our method for blending the results of multi-modal search and prove that using this approach we can increase the system performance by 11%.

##### A. Visual Search with Object Detection and Neural Networks

In this experiment, we analyze the results of our visual search when using various neural network architectures combined with YOLO 9000 object detection algorithm. The goal of this experiment is to select the right configuration of deep neural network used as the descriptor extractor for our interior design images, as well as to quantify the improvement obtained when adding a pre-processing step of object detection. To that end, we evaluate two neural network architectures that were successfully applied to object recognition task on ImageNet dataset: ResNet [30] and VGG[31]. We use VGG network with  $3 \times 3$  convolutional filters in two configurations, with 16 and 19 weight layers. We analyze the outputs of the first (*fc6*) and the second fully connected layer (*fc7*) of the VGG network. For ResNet, we take the average pooling layer. In all experiments, we use normalized outputs of the networks pre-trained on ImageNet dataset and we compute the similarity measure with Euclidean distance. The networks were implemented using Keras [32] with Theano backend for deep feature extraction.

**Baseline:** As our baseline, we take the conventional Bag-of-Visual-Words search engine [9]. It is based on the SIFT feature extraction algorithm [7]. We extract the descriptors and cluster them using *k*-means clustering [3] into  $k = 1000$

<sup>1</sup><https://ikea.com/>

Room images:	Object images:	Description:
		You sit comfortably thanks to the armrests.
		There's a natural and living feeling of wood, as knots and other marks remain on the surface.
		This lamp gives a pleasant light for dining and spreads a good directed light across your dining or bar table.
		Extendable, so it can be pulled out as your child grows.
		You can adjust the height of the clothes rail and shelves as your child grows.
		Made of plastic which makes it easy to carry and move for children.

Fig. 3. Example entries from IKEA dataset contain room images, object images and their respective text descriptions.

*visual words*. We use SIFT implementation available in OpenCV for Python [33] with contrast threshold set to 0.05, edge threshold to 11 and  $L_2$  norm.

**Evaluation metric:** To measure the performance of our system, we use Hit@ $k$  metric [34]. We define it in the following manner. Let  $\mathcal{F}$  denote a set of all possible interior items available in the dataset. We define a room  $\mathcal{R} \in \mathfrak{R}$  as a set that contains elements  $f \in \mathcal{F}$ . Hit@ $k$  is therefore defined as the fraction of retrieved items that contain at least one of the ground truth objects in the top  $k$  predictions. More formally, if  $rank_{f,\mathcal{R}}$  is the rank of furniture  $f$  in the room  $\mathcal{R}$  (the highest scoring furniture having rank 1) and  $G_{\mathcal{R}}$  is the set of ground-truth objects for  $\mathcal{R}$ , then Hit@ $k$  is defined as:

$$\frac{1}{|\mathfrak{R}|} \sum_{\mathcal{R} \in \mathfrak{R}} \vee_{f \in G_{\mathcal{R}}} \mathbb{I}(rank_{f,\mathcal{R}} \leq k), \quad (1)$$

where  $\vee$  is logical OR operator.

**Results:** Tab. I displays the results obtained for this experiment. Adding object detection algorithm as a pre-processing step significantly increases the number of correctly retrieved results across all evaluated configurations. We have illustrated the results for Hit@6 as we retrieved visually similar objects for six distinct object classes - chair, table, sofa, bed, wall clock and pottedplant. For Hit@6 the performance gains reach up to 175% (in the case of ResNet) and 238% (for VGG-19 with fc7). Feature extraction with ResNet and object detection pre-processing yields the highest

Fig. 4. Quantitative evaluation of various feature extraction methods combined with object detection algorithm YOLO 9000. We use recall as an evaluation metric that shows whether or not a single item present in the room picture was returned by the search engine. The recall is plotted as a function of the number of returned items  $k$ .

Hit@ $k$  score, retrieving correct results for almost half of all queries. To further analyze the performances of the proposed methods, in Fig. 4 we also plot recall curves for two sample object classes. Again, ResNet combined with object detection step remains the best performing configuration. One can also notice that all methods based on deep network architectures significantly outperform baseline BoVW method.

### B. Results blending

In order to use the full potential of our multi-modal interior design search engine, we introduce a blending method to

TABLE I

RESULTS FOR CONTENT BASED IMAGE RETRIEVAL EXPERIMENT FOR DIFFERENT MODELS AND ALL OBJECT CLASSES. CONFIGURATION OF RESNET NEURAL NETWORK WITH YOLO 9000 OBJECT DETECTION AS A PRE-PROCESSING STEP SIGNIFICANTLY OUTPERFORMS BOTH THE BASELINE BoVW MODEL AND OTHER DEEP NEURAL NETWORK ARCHITECTURES.

Model	Layer	Hit@6	
		whole image	with object detection
BoVW	N/A	0.066	0.26
VGG-16	fc6	0.126	0.392
	fc7	0.153	0.314
VGG-19	fc6	0.141	0.43
	fc7	0.136	0.445
ResNet	avg pool	0.167	<b>0.458</b>

combine the retrieval results of visual and textual search engines and present them to the user. To that end, we use *feature similarity blending* approach. More precisely, the search engine returns an initial set of results for each modality, extracts visual features (normalized outputs of pre-trained deep neural network) and then re-ranks them using the distance from the query to the item in visual features' space for each modality independently (visual search results do not need to be re-ranked). A set of closest items is returned as a final result.

**Simple blending:** As an alternative method for blending the results, we blend  $k$  best results from each modality and return them as a final result.

**Evaluation metric:** As mentioned in Sec. II-C, defining a similarity metric that allows to quantify the stylistic similarity between interior design objects is a challenging task and an active area of research. In this work, we propose the following similarity measure that is inspired by [22] and based on a probabilistic data-driven approach. Similarly to Hit@ $k$  metric, let us first define  $\mathcal{F}$  as a set of all possible interior items available in our dataset and a room  $\mathcal{R} \in \mathcal{R}$  as a set containing elements  $f \in \mathcal{F}$ . Our proposed similarity metric between two items  $f_1, f_2 \in \mathcal{F}$  that determines if they fit well together can be computed as:

$$C(f_1, f_2) = |\{\mathcal{R} : f_1 \in \mathcal{R} \wedge f_2 \in \mathcal{R}\}|. \quad (2)$$

We defined the style similarity as:

$$s(f_1, f_2) = \frac{C(f_1, f_2)}{\max_{f_i, f_j \in \mathcal{F}} C(f_i, f_j)}. \quad (3)$$

In fact, it is the fraction of the number of rooms, in which both  $f_1$  and  $f_2$  appear and total number of rooms in which any of those items co-occur. This metric can be interpreted as empirical probability for two objects  $f_1$  and  $f_2$  to appear in the same room.

**Results:** Tab. II shows the results of the blending methods in terms of mean value of our similarity metric. *Text query*

= *object class name* means that detected object class, *i.e.* the one with the highest detection confidence, was used as a text query.

Vanilla visual search without text query achieves an average value of 0.2295 where similarity is calculated over visually similar results to the query object, all belonging to the same object class. For text search average similarity was slightly lower - 0.2243.

When analyzing the results of the evaluated blending approaches, both of them have a score that is higher than the ones obtained for vanilla visual and text search. Our proposed blending method outperforms both the visual search and simple blending, yielding an improvement of 11% and 4% respectively. It is worth noticing that simply adding a name of detected object class as a text query improves the search results already. Providing additional information such as color or style (*e.g. white* or *decorative*) yields further performance improvement.

## VI. WEB APPLICATION

To enable dissemination of our work, we implemented a Web-based application of our Style Search Engine. The application allows the user either to choose the query image from a pre-defined set of room images or to upload his/her own image. The application was implemented using Python Flask<sup>2</sup> - a lightweight server library. It is currently available for restricted use only<sup>3</sup> and we plan to open it to the public, once it passes the initial tests with trial users. Fig. 5 shows a set of screenshots from the working Web application with Style Search Engine.

## VII. CONCLUSIONS

In this paper, we proposed a multi-modal search engine for interior design applications dubbed Style Search Engine. By combining textual and visual information, it can successfully and with high recall retrieve stylistically similar images from a dataset of interior items. Thanks to the object detection pre-processing step, the results of our visual search component improved by over 200%. Using feature similarity blending approach to combine the results of visual and textual search engines, we increased the overall similarity score of the retrieved results by 11%. We also implemented working prototype of a Web application that uses our Style Search Engine.

In our future research, we plan to explore various approaches towards common latent space mapping that could allow to map both textual and visual queries to a common space and perform similarity search there.

**Abstract**—The realistic simulation of cloths is nowadays a key to produce good-quality, authentic graphical visualizations of various cloth, such as characters garment elements, flags or curtains. This can be computationally expensive, more and more as number of particles, which cloth is divided into, increases. The solution to this matter was to use GPU (Graphic Processing Unit) and perform all calculations on this device. On PC platform, this technique proved to be much faster than the standard CPU approach. The main purpose of this work is to check whether this solution could also be introduced on the mobile devices. In this paper, we developed fast vertex optimization methods for dynamic cloth in mobile GPU units. Additionally we develop a user interface which providing new ways of user interaction with a cloth dynamics simulation on mobile devices.

## I. INTRODUCTION

NAVIGATION, 3D models and interactive performance has significant role in computer games and other interactive graphics applications [1]. Cloth dynamics simulations are an important visual cue for creating believably objects in virtual environments. The beginnings of cloth simulation in computer graphics appeared the end of the 80's [2]. First methods employs finite differential equations for the behavior of non-rigid curves, surfaces, and solids as a function of time for elastically deformable models (Lagrange equations of motion). The next significant step was the work of Baraff and Witkin [3]. They presents fast system for enforcing constraints on individual cloth particles with an implicit integration method. Since this time many methods extends the implicit time integration of Baraff and Witkin. Eberhardt et al. [4] propose the solution of the differential equation for particle systems to be computed both correctly and very quickly. They use an IMEX method (Implicit-Explicit) to simulate draping textiles.

Parks and Forsyth [5] propose the improved Runge-Kutta method. Improvement bring some advantages for cloth simulation. Different class of methods use precomputed data. Feng et al. [6] propose hybrid method for real-time cloth animation. They use relationship between cloth deformations at two resolutions. Data transformation is trained using rotation

invariant quantities extracted from the cloth models, and is independent of the simulation technique chosen for the lower resolution model with fast collision detection. Algorithm was implemented on programmable graphics hardware to achieve an overall real-time. Hahn et al. [7] propose low-dimensional linear subspace clothing simulation using adaptive bases. This was a combination of machine learning with a dynamically updated subspace basis. This approach is not fast enough for real-time applications because requires close-fitting clothing rigged to a skeleton and a set of training simulations for learning step. Gillette et al. [8] propose framework that does not require training data or a reference shape. They use a two-pass method. First pass is segmentation technique to extract spatially and temporally reliable surface motion patterns. Second pass is the detection of motion patterns to compute adaptive reference shape and a stretch tensor to dynamically generate new wrinkle geometry on the coarse cloth mesh by taking advantage of the GPU tessellation unit. There are many methods that aim for faster cloth simulation. Most of presented algorithms is suitable for the current generation of consoles and PC graphics cards [9]. Popular multi-model framework SOFA for interactive physical simulation for researchers and developers is dedicated to PC platform [10].

The main purpose of this work is to check whether this solution could also be introduced on the mobile devices. Most of them nowadays also have their own specialized GPU chips. General Purpose GPU Computing is mentioned, along with GPU framework and a comparison between it and a CPU is made, in the matter of architecture and performance. Presented implementation on mobile devices has mid-range GPU can perform very well, producing smooth animation of cloth's dense mesh, but not without a few important limitations. These include less useful API functions and shorter work time on battery as a result of intensive computations and tendency to overheating.

Fig. 1. Diagram of the mass model on the spring. The colors indicate all the springs involved in the vertex position calculation

## II. SIMULATION METHODS

The most popular approaches for the simulation of Real-time Cloth Animation systems in computer graphics take into account discretize the cloth by a polygonal mesh. This approaches to simulating dynamic objects based on the use of forces. We can distinguish two methods of simulating these forces for the cloth simulation: “Spring Force Formulas” [11] and “Position Based Dynamics” [12].

### A. Spring Force Formula

Real-time cloth simulation for games typically uses a mass and spring system on a coarse mesh [11]. These mass and spring systems form a series of differential equations that are typically integrated using a stable integration method [13].

Real-time cloth simulation is rendered by graphical API, as a polygonal mesh with grid of vertices in 3D space. For simulations, each of these vertices had a mass and was subjected by force formulas for the displacement. In order to preserve the shape and the mesh behavior, the vertices are connected in rectangular grid, and then connected each vertex to neighboring vertex with springs. Springs has specific coefficients of elasticity and damping (Fig. 1).

There are three types of springs that appear in the presented model (Fig 1.)

- Structural springs (red) - they are used to maintain the general shape of the cloth.
- Springs for folds of the cloth (green) - they are located along the diagonal edges of the grid.
- Springs responsible for flexibility of the cloth (blue) - they protect against excessive stretching. They do not connect neighboring vertices, but follow the neighbor in the same direction.

Each type of spring can be described by other coefficients of elasticity and vibration damping, which allows to simulation of specific behavior. Figure 2 shows that the forces affect for each point of mass.

Fig. 2. Forces for a single vertex

The forces can be classified as internal and external. Gravity and collision forces are examples of external forces. Examples of internal forces are elastic forces in deformable objects or viscosity and pressure forces in fluids. To determine its value, the Hooke's Law is used to define the force of the spring and its direction and return are proportional to the pitch of the spring, ie the difference in distance between its present length and its resting length. Each vertex ( $i$ ) is connected to its neighbor with 12 springs:

$$\mathbf{F}_{se} = - \sum_{j=0}^{j<12} k_s (|\mathbf{x}_i - \mathbf{x}_j| - l_{(i,j)}) \cdot \frac{\mathbf{x}_i - \mathbf{x}_j}{|\mathbf{x}_i - \mathbf{x}_j|}, \quad (1)$$

where  $k_s$  - elasticity coefficient  $\mathbf{x}_i$  and  $\mathbf{x}_j$  - Position of vertices connected by one spring  $l_{(i,j)}$  - The distance between these points at relaxation vector.

Also the force of elastic vibration damping has been introduced to minimize unnecessary unrealistic vibration and risk of out of control simulation:

$$\mathbf{F}_s = \sum_{j=0}^{j<12} -k_s (|\mathbf{x}_i - \mathbf{x}_j| - l_{(i,j)}) \cdot \frac{\mathbf{x}_i - \mathbf{x}_j}{|\mathbf{x}_i - \mathbf{x}_j|} + k_d \left( \frac{|\mathbf{x}_i - \mathbf{x}_j| \cdot |\mathbf{v}_i - \mathbf{v}_j|}{l_{(i,j)}} \right) \quad (2)$$

where  $k_d$  - vibration damping factor

These mass and spring systems form a series of differential equations that are typically integrated using a stable Verlet integration method, this method stores the velocity implicitly as the difference between the current and the last position:

$$\mathbf{x}(t + \delta t) = 2\mathbf{x}(t) - \mathbf{x}(t - \delta t) + \mathbf{a}(t)\delta t^2, \quad (3)$$

where  $\mathbf{x}(t + \delta t)$ ,  $\mathbf{x}(t)$ ,  $\mathbf{x}(t - \delta t)$  - indicate the position of the vertex in the next, current, and previous simulation step.  $\mathbf{a}(t)$  - acceleration. This solution imposes an implicit calculation of the current vertex speed. This makes it necessary to provide not only the current position of each mass point, but also the location of the previous one. This increases the memory cost of the simulation to other integration techniques, but provides very fast calculations and stable results.

### B. Position Based Dynamics

The model based on the position and the mass model on the spring have a common part - it is the calculation of shifts caused by gravitational forces and air resistance by the Verlet integration. The shifts resulting from the external forces are

Fig. 3. Diagram of operation of the limiters between two points of mass

called predicted shifts. Each vertex of the grid is described, apart from mass, position and velocity, also by the so-called limiters set. Each of them is defined by a certain function  $C_j : R^{3n_j} \rightarrow R$  Set of indices  $\{i_1, \dots, i_{n_j}\}, i_k \in [1, \dots, N]$  i- stiffness parameter,  $k \in [0 \dots 1]$ . The limiter may be of the type of equality, which means that its limitation is fulfilled when  $C_j(x_{i_1}, \dots, x_{i_{n_j}}) = 0$ . It can also be the type of unevenness, with the condition  $C_j(x_{i_1}, \dots, x_{i_{n_j}}) \geq 0$ . In this case only the first type stops will be considered. The key element of course is the function  $C_j$ , which defines how the predicted position will be improved, where this improvement depends - that is, the behavior of the cloth.

The basic type of limiter is the stretch limiter. It is defines the overall shape and proper behavior of the cloth. Its function is:

$$C(\mathbf{p}_1, \mathbf{p}_2) = |\mathbf{p}_1 - \mathbf{p}_2| - d . \quad (4)$$

where  $\mathbf{p}_1$  and  $\mathbf{p}_2$  are the positions of the considered vertices, and  $d$  - the initial distance between them.

Li et al [14] propose function solution  $C_j(x_{i_1}, \dots, x_{i_{n_j}})$ :

$$s = \frac{C_j(\mathbf{p}_{i_1}, \dots, \mathbf{p}_{i_{n_j}})}{\sum_j w_j |\nabla_{\mathbf{p}_j} C_j(\mathbf{p}_{i_1}, \dots, \mathbf{p}_{i_{n_j}})|^2} , \quad (5)$$

where:

$$\delta \mathbf{p}_i = -s w_i \nabla_{\mathbf{p}_i} C_j(\mathbf{p}_{i_1}, \dots, \mathbf{p}_{i_{n_j}}) . \quad (6)$$

where  $w_i$  - inverse mass of vertex. This two simulation methods, it should be noted that each of them has its pros and cons. The greatest advantage of the spring mass model is its ease of simplicity and ease of implementation. It is easy to imagine a cloth as a collection of vertices connected by elastic springs, whose elastic forces are calculated using the simple laws of physics. Certainly the biggest advantage of a position-based model is the performance advantage. It results from the lack of need to use numerical integration. The cloth behavior is not determined by the set of resilient forces, and the limiters immediately modify the position. This allows for significant computational savings. In case of a spring mass model, these calculations can not be avoided for each of the springs. For more accurate results, more complex integration methods should be used. This leads to a decrease in productivity.

### C. Improved Position-Based Method

Considering that the displacement is directly proportional to weight, it is easy to consider that - if the mass of the particle is infinite, the offset will be equal to zero. When function  $C_j(x_{i_1}, \dots, x_{i_{n_j}})$  will be replaced by  $C(p_1, p_2 = |p_1 - p_2| - d)$ , we can get the following stretch limiter:

$$\delta \mathbf{p}_1 = -\frac{w_1}{w_1 + w_2} (|\mathbf{p}_1 - \mathbf{p}_2| - d) \frac{\mathbf{p}_1 - \mathbf{p}_2}{|\mathbf{p}_1 - \mathbf{p}_2|} , \quad (7)$$

$$\delta \mathbf{p}_2 = \frac{w_2}{w_1 + w_2} (|\mathbf{p}_1 - \mathbf{p}_2| - d) \frac{\mathbf{p}_1 - \mathbf{p}_2}{|\mathbf{p}_1 - \mathbf{p}_2|} . \quad (8)$$

As with the spring mass model, the 'force' of the limiter depends on the difference between the current distance between the mass points and the resting distance. The coefficient of elasticity is like the stiffness parameter multiplied by offset (result from the projection). For  $k$  equal 0, the delimiter will not be taken into account at all. For  $k$  equal 1 the point never changes its initial position.

In the presented method there were delimiter of bending. This method uses other collision detections. Most of the methods are based on a baseline approach where stretchers are used, taking into account only vertices located in the neighborhood of a given point. Experiments have shown that the effect similar to the use of bending delimiters can be achieved by increasing the set of considered vertices by one more position from the mesh. This is not the exact like method of bending deflection, where we adjust the angle between the triangles, but still gives the correct visual effect with better performance. The presented solution include bounding spheres and AABB in the case of external collision and the bounding spheres in the internal collision.

### III. A CPU-GPU FOR REAL-TIME CLOTHING ANIMATION

Optimizing graphics performance for GPU vs. CPU are quite different. The CPU has too many vertices to process. Rendering is not a problem on the GPU or the CPU, there may be an issue for physics of cloth (dynamic forces). It is quite important to get a good performance on mobile GPUs. Mobile GPUs are less powerful like low-end PC GPUs. CPU commonly has 4 to 8 fast, flexible cores, GPU's has massive parallelism (Fig. 4). This highly parallel architecture is the reason that a GPU can quickly process large number of data (dynamic cloth simulation).

Development of such experiments requires "Application of Experimental Test". Setting goals and objectives for experiment accomplishes key objectives. First task, is presentation of two models of textile simulation. It is important to compare them in terms of performance, stability and visual effect.

Performance is understood as the time for calculate one step of simulation. The application informs the user about it by displaying the relevant information in a textual form. As for the next two factors, it is best to evaluate the cloth visually simulation - visualization. For this purpose, the program draws it in 3D space. The key issue here is the interaction with other 3D objects. The purpose of this paper is also to compare

Fig. 4. Typical CPU's architecture vs. a typical GPU's architecture (source <http://blog.goldenhelix.com/>)

the speed of simulation calculations of real-time cloth models simulation on CPUs and GPUs, and to examine the difference in GPU performance of the mobile device and the GPU of the PC. For the first case, at each step, the appropriate GPU assignments should be assigned to the vertices of the vertices that contain the pre-generated data needed for the simulation. Then set graphics library to the computation program mode, set all homogeneous variables, bound buffers homogeneous, and run the transform join. Case for the CPU is much simpler as all data and arrays have already been initialized in the process described in the previous section and simulation can start immediately. The situation is complicated when using multithreading. In this method, four working threads were broken up, because the device has four physical processing units. The division algorithm is simple - the number of vertices is complemented by the number divisible by 4 and divides it into four equal ranges, with the first three being considered, and the last one being equal to the number of other vertices. Mutexes and thread counters have been used for synchronization. Work threads manage the main thread. Each of the former is slumbered into the mutex until the simulator function is called. Then they wake up and start calculating. After they have finished raising the counter and waiting for the next mutex. The main thread at this time waits until the counter reaches the required value and unlocks the next calculation step.

The process was divided into three separate stages. The first step is to calculate the movement of the cloth according to the accepted simulation model. The second step is solving collisions and applying cloth movement resulting from user interaction. The third stage is the conversion of normal vectors. After the first two steps, the input and output data identifiers are exchanged. For both implementations on the CPU, after completing the processing step, you still need to submit new position and vector data for normal vertices to the GPU, so that they can be drawn.

All possible data that does not need to be recalculated at each step is calculated during the initialization of the simulator, and the results are simply passed to the corresponding

functions during the program run. This is perfect for the GPU programming methodology. This solution minimizing the number of conditional statements and avoiding unnecessary calculations that are repeatedly performed. Each vertex will be assigned a list of identifiers and multipliers that are 1 when the neighbor exists or 0 if it is not, and in this case the calculated force or displacement does not take part in further processing. That also eliminates the need for conditional commands, which further improves performance. Each vertex has the following attributes:

- position (16 Bytes),
- texture coordinate (8 Bytes),
- normal vector (16 Bytes),
- color (16 Bytes),
- centrobaric coordinate (16 Bytes),
- index (4 Bytes).

Simulation of clothes requires the definition of a large number of parameters. Initially they are initialized on the CPU side. Some of them may be different for each vertex, so they are passed to the GPU in the form of array attribute values.

#### IV. USER INTERFACE FOR INTERACTION WITH A CLOTH DYNAMICS SIMULATION ON MOBILE DEVICES

Very important for real-time visualization is the ability to interact by the user with cloth by Graphical User Interface (GUI). User can easily to work with software and collect data for the test results. The program can draw two-dimensional GUI elements in the screen space, such as text dynamic fields, real-time animation and buttons. User input requires different handling in a mobile application like addition to the on-screen input methods. The application design assumes that the user must be able to reposition, rotate and zoom the camera, reset the simulation and modify its parameters, change the object display mode and interact with the cloth in two ways. The first way is to move the object to collide with the clothes. The second way is to move the clothes with finger movements. It is also required to inform the user about the speed at which the simulation is running and what parameters it currently has and what type it is (Fig. 5).

There are two ways for interaction with a cloth by the user. By moving an object (sphere or cuboid) with which it collides, or by means of a touch screen. In the first case, the effects are applied when solving external collisions. For the second method, special calculations need to be made to know which vertices need to be further shifted to which direction and to what extent.

The only input data are two two-dimensional vectors, called "touch vectors". One specifies the place on the screen where user touched the screen, and the second is the direction in which users finger moves. They were expressed in screen space. In order to make a vertex translation, important is a vector position in that space. It is obtained by multiplying it successively by world matrices, view matrix and projection matrix, and dividing the result by component  $w$ . In this way, a vertex vector with components is obtained in the range  $< -1, 1 >$ , same as the touch vector. Next, using the Gaussian

Fig. 5. Interactive Graphical User Interface and results of the simulation in real-time

formula, the  $c$  coefficient is calculated to determine how far the translation will take place. It is directly proportional to the distance of the vertex position from the touch point:

$$c = Ae^{\frac{(\mathbf{p}_t \cdot \mathbf{p}_i - \mathbf{p}_i \cdot \mathbf{p}_i)^2 + (\mathbf{p}_t \cdot \mathbf{p}_i - \mathbf{p}_i \cdot \mathbf{p}_i)^2}{2\sigma}}, \quad (9)$$

where  $A$  and  $\sigma$  are top-defined constants and they are respectively 200 and 300, while  $\mathbf{p}_t$  are the position of the touch,  $\mathbf{p}_i$  of the vertex.

Once it have moved, it have to express them back in the model coordinates. This is multiplied by the inverse of the projection, view, and world matrix. At the end, it simply added offset vector to current position.

## V. RESULTS

The execution time is understood as the time it takes to process one full step of a clothes simulation. Expressed in milliseconds. This is the most important benchmark because it tells how much computing takes on the hardware, how large a percentage of the total engine work is and, if the simulator is fluid.

The effect for execution time has number of processed data, like density of the cloth mesh, and the selected implementation. These relationships are presented in tables and graphs, separately for each method and implementation. It was assumed that:

- 1)  $C$  - number of all vertices.
- 2) MS-GPU-A - Spring mass model, GPU implementation, Android platform.
- 3) PB-GPU-A - Item based model, GPU implementation, Android platform.
- 4) MS-GPU-W - Spring mass model, GPU implementation, Windows platform.
- 5) PB-GPU-W - Item based model, GPU implementation, Windows platform.
- 6) MS-CPU-A - Weight model on the spring, CPU implementation, Android platform.

Fig. 6. Graph of time dependence on the number of vertices.

- 7) PB-CPU-A - Position based model, CPU implementation, Android platform.
- 8) MS-CPUx4-A - Spring mass model, CPU implementation (4 working threads), Android platform.
- 9) PB-CPUx4-A - Position based model, CPU implementation (4 working threads), Android platform.

The graph shows a great performance advantage of methods implemented on the GPU. In the case of Android, the calculation time is almost constant regardless of the number of vertices of the cloth. Minor fluctuations are mainly due to measurement error (in the order of several ms). A slight increase in processing time at the final test phase may not result from the same computational overhead as with the increasing temperature of the device and the consequent gradual decrease in performance by the operating system. The inability to obtain a calculation time of less than 12-15ms is probably due to the fact that vertical synchronization is enforced by the implementation of transformational feedback in the Adreno graphics card driver. As it might expect, the GPU version on the PC platform is much more efficient. In this case, the difference is almost 300 times. Interestingly, the vertical sync problem does not occur here, although the processing time also remains constant.

The implementation of the CPU is a separate issue. It can be seen that the processing time increases linearly with the number of vertices and very quickly reaches values for nice image. Only for the low density of the grid has the advantage over the GPU, due to the problem mentioned above. It can also be seen that a decrease in performance for implementation with 4 threads of work is about twice less than in the case of a sequential approach.

For GPUs, no significant difference in performance was made between simulation methods, although on a CPU, the position model achieved for large numbers of vertices was slightly better than its rivals. The second most important problem of the simulation is its instability, understood as

Fig. 7. Diagram of vibration dependence from stiffness coefficient.

the tendency for the cloth to fall into uncontrolled vibration, which in turn can lead to an "explosion". Even if this does not happen, continuous movements of the system result in unrealistic visual effects. This phenomenon is therefore very undesirable and often forces you to restart the simulator. One of the peaks in the middle of the cloth was selected for testing, and its vibration at rest was examined, i.e. the mean difference between the present and the previous position at each simulation step. Measurements were made for different stiffness coefficients, and then presented this relationship in the form of tables and graphs. Two methods were used for each method, including different masses, gravitational forces, attenuation coefficients, and mesh density. The state of rest is defined as the state in which the cloth has fallen freely from horizontal to vertical, suspended at two points, and ceased to move. It is worth recalling that for a position-based model the stiffness parameter ( $s$ ) was scaled accordingly to fit within the required range  $[0, 1]$ , and carried the same effect as its equivalent in the spring mass model. The test platform is a mobile version of the application, with an implementation on the GPU.

The main difference between spring and position-based mass models is that in the first case, for the first attempt, the lowest oscillation was recorded from the beginning, but it is growing rapidly with the increase of the stiffness parameter, at its highest value, leading to the "explosion" of the simulation. As for the second approach, large oscillations can be observed practically regardless of the flexibility of the cloth, suggesting that mesh compaction also has a significant impact on vibration. They were present for practically the entire time of the simulation. Still moving small distortions are very detrimental to visual reception and in any practical application would be unacceptable. Tests have shown that position-based models are exceptionally stable - oscillations are sometimes slightly larger than rivals, but in both trials they remained steady, regardless of the increase in the stiffness parameter or the number of vertices. The second test showed,

however, that for a little elasticity and a dense mesh, the cloth begins to fall into uncontrolled collisions with itself. It is so rigid that, with the proper alignment of the masses, lead to the "hovering on itself" and the immobilization in the air, in fact ignoring the force of gravity. Strong waving occurred mainly in the red rectangle, and the middle area of the sample was left at rest. The last criterion is simply the degree to which the behavior and appearance of the simulated cloth reflects reality. This identifier is completely subjective, but one can clearly see the direct proportional relationship between quality and mesh density. A small number of vertices physically does not allow for the generation of realistic wrinkles or folds, so characteristic elements of cloth animation. For each simulation model, screenshots showing the "visual effect" dependence will be presented on the various parameters and in particular on the grid density. The test platform is the mobile version of the application. Similarities, however, end when they compare the parameters used to achieve similar effects - they are completely different. Undoubtedly, a positioning model generates a stiffer cloth than its rival. Sometimes this results in the above errors. The velocity of the cloth itself is also important - it should fall off and react to interactions with moving objects as quickly as in reality. In spite of their anomalies and the difficulty of obtaining a suitably flexible model, the denser spring mass method gives better visual results. On the other hand, the position-based approach is much easier to adjust flexibility and greater stability, but there may be problems with setting the appropriate animation speed. Fixed the  $\delta t$  parameter sent to the simulator. In both methods, it is easier to select the parameters for the desired behavior, with fewer nodes having a mesh.

In the case of a small number of edges, inaccurate collision detection between cloth and cuboid can be observed. This is not a rule, as the problem also occurs for denser nets. Here, however, there is also a lack of friction force implementation, which causes the tops to slide over the straight walls of the object, stretching the cloth and creating larger holes in the breakthrough. For the surrounding sphere, due to its uneven shape, the problem of breakage is not present. Exceptions are fast-moving objects that can simply jump through the cloth, in one step of calculations, in front of her, and then in the next. A continuous collision detection method, more complex mathematically but eliminating such phenomena, should be used.

## VI. DISCUSSIONS

A test application was created, one of its main purposes being the visualisation of two selected simulation methods – mass-spring and position-based model. It was equally important to show cloth's collisions between other objects in scene and itself. The user is allowed to set various parameters that influence the simulation, such as the aforementioned method type, mesh density and dimensions or elasticity coefficient. He can also impact the movement of the cloth, swiping his finger along the device's touch screen, which is something unique to the mobile platform. To fully measure every important factor

of the simulation, its three implementations were created – one using GPU for computing and the other two using GPU, in sequential and multi-threaded approach. To have a comparison between mobile and PC platform, a PC version of the application was created, both similar and sharing as much code with each other as possible. Both methods bring similar results, with a very small victory of the positioning model in CPU implementations. It was not possible to accurately examine differences in GPUs as the volume of homogeneous buffers did not allow the cloth to produce so many vertexes that performance time increased beyond 20 ms. Given the similar level of complexity of the code itself, it should be assumed that it would also be small. During testing, it was noted that a significant portion of the computation time was occupied by a fragment of the algorithm responsible for solving the collision. This may be due to the fact of using conditional statements in code executed on the GPU. More objects in the scene would certainly be associated with a deeper optimization of the issue, for example by limiting the number of potential entities that may come into contact with the cloth at the CPU level.

Both simulation models are characterized by a certain parameter-dependent instability, but it is much higher in the case of the spring mass model. The fact is that the composition of the formula on which the force acting on the vertex is calculated is the component responsible for vibration damping, and the user can adjust its coefficient. This method is characterized by an increase in net oscillation with an increase in the coefficient of elasticity. They have the form of small but fast vibrations on the entire surface of the fabric. With the turn for large numbers of edges, it takes a lot of rigidity to maintain the right shape, which further increases the problem. Large oscillations seem to keep them constant, but with any sudden change of position of vertices, such as in collisions, they can lead to a rapid 'burst' of simulation, which in practice is unacceptable. In the case of the position-based model, also the relationship between the increase in mesh density and its rigidity was observed, and loss of stability. The vibrations here are much slower and have a delicate, uncontrolled ripple, which is much less noticeable to the user. A big plus is the absence of an "explosion" effect, regardless of the parameters set. This effect was achieved through a kind of implementation trick - the position of the vertex transmitted to the calculator function of the limiter is updated only in the context of adjacent neighbors. The disadvantage of the position-based model in the present implementation is the tendency to fabric block itself on high elasticity.

Both methods of cloth simulation generate the desired visual effect, ie realistic folds and wrinkles of the fabric and its characteristic positioning on the object. Their quality is minimal for the position-based model. There are no minor vibrations there and more responsive to changes in stiffness coefficient. It should be noted that for example, for games in many cases there is no need for detailed mapping of fabric details, these can be obtained using normal maps. The two discussed methods have a faithful reproduction of this aspect even for a small number of edges. With the turn, when considering dense

grids, there is a problem with the speed of animation. A high number of vertices requires a sufficiently high stiffness factor, this slows down fabric shifting, especially in a position-based model. The solution could be a more accurate matching of coefficients or an increase in the  $\delta t$  parameter, unchanged in simulation. Improvements to the situation can also be achieved by setting other stiffness parameters for each of the groups of springs or stops (ie parallel to the edge of the fabric, lying diagonally and such as the first, but located one position further). The collision detection method has proved to be a major disadvantage in the visual effects issue. It does not satisfactorily resolve internal collisions, and external collision errors are often encountered, eg when the fabric falls on the cuboid. To fix the problem, a different technique would have to be implemented. However, it would definitely entail the loss in performance and the most demanding computational component of the simulation.

The tests clearly indicate the winner of this performance comparison. GPUs are many times faster than CPUs when calculating issues that can be processed in parallel, and that is exactly what the problem is. Spreading the cloth overheads to individual GPUs is an intuitive and efficient solution despite the redundancy. Regardless of the amount of data, the recorded speed of performance turns out to be the same, which can not be said for CPU implementations, where it decreases linearly. Split into working threads increases it twice, which a little improves the situation, but in the case of detailed fabrics and so the performance is too low. With the turn on the GPU, there was a limitation by the transformational feedback of the rendered frames in one second to the value that matched the refresh of the screen. This is a defect that does not allow full evaluation of the performance and in some cases blocks the full speed of the application. The problem might be solving a change of test equipment to another, or using another GPGPU computation API.

All this does not change the fact that CPU implementation also has its uses and advantages. It is necessary to use it if device does not support OpenGL ES 3.0 or any specialized API such as OpenCL. OpenGL ES is a flavor of the OpenGL specification intended for embedded devices. It may be that it would have a performance advantage when the test platform had a very low-level GPU. It can also be used with certainty when the data set is only a very small number of vertexes, or if you have decided to do animation only in 2D space. It should also be noted that fabric simulation is much easier to implement on the CPU, as it does not require a deeper knowledge of the graphical API or GPGPU, and the creation of fairly complex buffering, homogeneous variables, programs, and transformational feedback.

The performance of mobile devices in this issue will be many times lower than that of PCs. Creation of two versions of the application, one on the Android platform, the other on the Windows platform, confirmed this assumption. The speed difference is about 300 times, the problem with the number of rendered frames per second disappears in the PC add-on. As far as how a GPU smartphone can seamlessly animate a very

dense mesh fabric that is sufficient to reproduce most details, this platform is harnessing a number of significant issues.

The first is the repeated lack of textured buffers on the part of the device, which limits the maximum possible quality. Cloth simulation heavily utilizes hardware capabilities, leading to overheating of the device. This leads to performance degradation by the operating system, which, in turn, results in significantly longer processing times and has had an impact on test results.

It is proved that the cloth simulation can be implemented on mobile devices and the mid-range GPU can perform very well, producing smooth animation of fabric's dense mesh, but not without a few important limitations. These include less useful API functions and shorter work time on battery as a result of intensive computations and tendency to overheating.

## VII. CONCLUSIONS AND FUTURE WORK

This paper presented a technique for efficient fabric simulation in the real-time on a mobile device. The experience has shown that mobile devices can be used for real-time simulation of cloth animation with fast vertex optimization methods in mobile GPU units.

Tests have shown that while the GPUs of mobile devices are slightly slower than PC's ones, the relationship between processing speed on CPU and GPU remains similar. The GPU in both cases is significantly faster than the CPU built into the same machine.

Although technical aspects of User Interface have been created, they still require UX testing and further development.

**Abstract**—Head pose estimation from camera images is a computational problem that may influence many sociological, cognitive, interaction and marketing researches. It is especially crucial in the process of visual gaze estimation which accuracy depends not only on eye region analysis, but head inferring as well. Presented method exploits a 3d head model for a user head pose estimation as it outperforms, in the context of performance, popular appearance based approaches and assures efficient face head pose analysis. The novelty of the presented approach lies in a default head model refinement according to the selected facial features localisation. The new method not only achieves very high precision (about  $4^\circ$ ), but iteratively improves the reference head model. The results of the head pose inferring experiments were verified with professional Vicon motion tracking system and head model refinement accuracy was verified with high precision Artec structural light scanner.

## I. INTRODUCTION

**O**RIENTATION and movement of human head allow not only to interpret person intentions, but become a part of nonverbal communication as well. It might be exploited in sociological children behaviour monitoring [4], [5], distant computer interface control [6], [31], crowdsourcing systems [7], [8] or in cognitive computation researches [9], [29]. Though very intuitively and naturally accomplished by humans, the problem of head pose estimation is still a challenging problem for current computer systems.

From the computer vision point of view head pose estimation is a process of evaluating head position and orientation from digital images. Eye tracking process which the authors studied in previous researches [1], definitely requires inferring head position and orientation as it considerably affects gaze tracking precision. Moreover psychological investigations show that both head pose and eye direction are strongly correlated and influence person's gaze prediction [2]. In such context (gaze controlled interaction) head pose tracking can be considered relatively to the view direction of the camera rather than global coordinating system.

Current state of art methods [3], [23], targeting at RGB camera image head pose inferring, claim to achieve head orientation angular precision of about  $5^\circ$  for individual axes: pitch, yaw, roll. Proposed head 3d model based solution can not only obtain comparable estimation precision, but also reveals high performance due to robust head image to model

assignment - aligned just with a few face predominant key features. The method can start without prior knowledge of user head dimensions and iteratively, during the process of alignment, refines considerably default head model parameters.

## II. HEAD POSE ESTIMATION METHODS

Geometrical based approaches to head pose estimation rely on cues such as deviations of the head from bilateral symmetry [10]. They consider both a head shape and a configuration of local features to estimate its pose. Features search-space can be effectively reduced by using knowledge of human face structure. The key aspect seems to be a proper selection and in-face localisation of the face fiducial points.

Horprasert et al. [13] proposed selection of 5 feature points (outer eyes and outer mouth corners and tip of the nose) for reconstruction of head pose. Authors suggested geometrical analysis of vectors connecting feature points: face normal vector rotation and feature points spanned vectors affine projection. Gee et al. [12] and Wang et al. [17] analysed eyes' crossing line and mouth vertically crossing line interrelation. They provided an approach where head pose expectation maximisation was obtained due to eyes and mouth lines perspective convergence analysis. More recently Baltrusaitis et al. [23] considered conditional local neural fields (CLNF) [24] for face features detection and applied their orthographic projection on the camera image plane. Subsequently PnP problem solution was used for an appropriate head pose estimation. Though authors claim that their method head inferring precision varies between  $2.8^\circ$  -  $6^\circ$  (depending on a tested dataset) 3d head model, obtained in the reprojection stage, was not verified for its precision. There are also auxiliary sensors considered for supporting camera view head pose estimation. Morency et al. [25] suggested additional inertial and magnetic sensor drift reduction and Funes et al. [30] used depth data for head orientation analysis.

The geometric methods are fast and simple however their difficulty lies in detecting the features with high precision and accuracy. The process might be even more challenging when features become outlying or missing. The most frequent approaches for in-image face detection, relies on active appearance model (AAM) [28] or active shape model (ASM) [27]. Competitive local approaches, constrained local model (CLM)

TABLE I  
INITIAL HEAD SELLION RELATED COORDINATES OF AN AVERAGE  
ANTHROPOMETRIC HEAD MODEL FEATURE POINTS

Point name	X[mm]	Y[mm]	Z[mm]
Sellion	0	0	0
Right eye	65,5	-5	20
Left eye	-65,5	-5	20
Right ear	77,5	-6	100
Right ear	-77,5	-6	100
Nose	0	-48	-21
Stomion	0	-75	-10
Menton	0	-133	-0

[18] and constrained local neural fields (CLNF) [24], claim to obtain higher precision of landmark detection, especially in strictly constrained, restricted environment (inconvenient light, partial face occlusion). Highly efficient local analysis may also base on gradient templates [29].

Face feature points, retrieved within face analysis, can be subsequently structured in a face or head reference model. 3d model is used for optimizing temporal face features spatial positioning and face image features alignment. For example Kazemi et al. [14] suggested regression trees for one millisecond face alignment. The head model can be reconstructed basing on real head of the user [11] or it can be constructed basing on default average anthropological measures.

On contrary to previous approaches, presented solution coherently refines 3d model while head pose estimation and uses it directly for better head inferring. Elaborated method preserves and in some scenarios outperforms, state-of-the-art methods accuracy.

### III. METHOD

Presented method consists of two main steps: head pose estimation and head model refinement. The head model consists of 8 points: sellion, eyes outer corners, ears, top of the nose, stomion (center of mouth) and menton. Points locations are presented in image 1.

At the beginning, the average anthropometric head model was retrieved. This head model corresponds to the head shape of averaged male adult and was based on anthropometric data collection [20], [21]. The initial values of points coordinates (sellion related) are presented in the table I.

#### A. Head pose estimation

Head pose estimation stage is divided into 2 substeps: localizing facial landmarks (points corresponding to the 8 selected head model points) and head pose calculation.

Facial landmarks detection method should work in real time and reliably calculate landmarks positions, even in difficult lighting conditions. In our tests, we decided to use the method described in [14] (implemented in [15]), however it is possible to replace it with other methods satisfying mentioned

requirements. We decided to use this method, because it performs well even in poor lighting conditions and can deal with long hair, glasses and different skin colors as well. Additionally it provide more precise results than other currently used methods, such as Supervised Descent Method [32] or Face Alignment by Explicit Shape Regression [33]. The method can retrieve up to 68 face fiducial points from which several facial landmarks should be selected. Though 8 specific points (fig. 1) were selected some substitutions are possible (for example - eyes inner corners instead of outer corners), as well as it might be necessary to change the number and coordinates of the initial points.

Once the facial landmarks are detected, it's possible to calculate algebraically the head position and rotation. We decided to use classic solution of PnP problem - iterative method based on Levenberg-Marquardt optimization. This method is implemented in OpenCV library. Obviously, the calculated pose is not perfect. The most important reasons of pose inaccuracies are: not accurate head model (initial head model was based on averaged anthropometric values) and facial landmarks detection imprecision. First problem is handled during head model refinement step and second problem is addressed in the next substep.

All, currently available, facial landmarks localization methods produce some errors. Usually it's not a real problem, since subpixel accuracy is not required in most use-cases. It is important to note, that usually most of the detected points, are localized with high accuracy and only some points contains errors big enough to produce meaningful inaccuracies in head rotation and translation estimation process. Due to this fact, we decided to use easy method to improve accuracy of our system. After initial head pose calculation, we calculate head model points reprojections. Next, for each point, the reprojection error (distance between detected and reprojected points) is calculated. After that, we repeat calculation of rotation and translation, using all points except the point with the biggest error. The calculated values are final head rotation and translation values. The rationale of this decision is that the removed point most likely contains the biggest localization error and generally makes it much harder (or even impossible) to find good PnP solution. Obviously the removed point, can be perfectly fine, but in this situation it's possible to calculate descent solution from only 7 (instead of 8) points. It's quite easy to note, that this approach is a bit similar to RANSAC method [16]. RANSAC method solves PnP problem multiple times for different random points selected from all 8 points, which makes it robust in precision, but relatively slow (because it tests all 8 possibilities, assuming only 1 outlier). Our method solves PnP problem only twice, which makes it much faster than RANSAC approach. Since we already know which point burdens solving PnP problem, we can achieve optimal solution without testing all other possibilities. In contrast to RANSAC, our method is not based on randomness, which makes testing, evaluating and debugging much easier.

The overall algorithm of head pose estimation, for single frame, is presented in 1.

**Algorithm 1** Head pose estimation algorithm

**Require:** *head\_model* - model of head (eight 3D points -  $P_i$ , where  $i = 1, 2, \dots, 8$ ), at the beginning it's initial head model from table I, after each head pose refinement points are adjusted;

- 1: Detect and assign facial landmarks:  
 $landmarks\ L_i \leftarrow detected\ face\ landmarks$
- 2: Get rotation ( $R$ ) and translation ( $t$ ), solving PnP problem using *landmarks* as projected points and *head\_model* as 3D points:  
 $R, t = solvePnP(landmarks - L_i, head\_model - P_i)$ ;
- 3: Calculate reprojection  $L'_i$  of each point  $P_i$  of *head\_model*:  
 $L'_i \leftarrow K[R|t]P_i$   
{ $K$  - camera intrinsic (focal length and principal point) parameters matrix,  $P_i$  - 3D point of the head model}
- 4: Calculate error of each reprojection (using *landmarks*):  
 $e \leftarrow distance(L'_i, L_i)$   
{ $(L'_i, L_i)$  - corresponding landmarks for  $i = 1, 2, \dots, 8$ }
- 5: Find which point  $P_k$ , where  $k \in (1, 2, \dots, 8)$  produces the biggest reprojection error  $e$ , where  $L'_k$  - corresponding facial landmark point  
 $head\_model' \leftarrow all\ points\ from\ head\_model\ except\ P_k$   
 $landmarks' \leftarrow all\ points\ from\ landmarks\ except\ L'_k$
- 6: Solve PnP using *landmarks'* and *head\_model'*  $R', t' = solvePnP(landmarks', head\_model')$ ;
- 7:  $R', t'$  - final result of algorithm

**B. Head model refinement**

As already mentioned, inaccurate head model is one of the most important reasons of head pose inferring. Of course using model from digital 3D scanner is not available in most of cases, therefore we had to find another solution. Analysing results of facial landmarks detection and reprojected head model points it was easy to note that detected landmarks  $L_i$  are much more accurate than reprojected points  $L'_i$ . Discrepancies were presented in image 1, especially big differences between left eye corner points and mouth center should be noted. Based on that fact we decided to create method which adjust and refine head model points according to the results of facial landmarks detection (i.e. minimize reprojection error). A classic approach for such problem is bundle adjustment method [19], which optimizes both - camera poses and points positions. However, this method tends to be too slow for real time applications and can be replaced with our much simpler approach. Additionally in our method, we can easily use information from facial landmarks detector.

This part of our method is executed only in every  $n$ -th (usually 175) frame. The algorithm operates on all frames since last head model refinement.

The result of algorithm 2 (even after single iteration) retrieves more precise face model. This face model was afterwards used in the head pose estimation stage, which results in overall higher accuracy. The biggest refinement takes place in first and second iteration of algorithm. For next iterations,

Fig. 1. Detected facial landmarks  $L_i$  (blue circles), reprojected head model points  $L'_i$  (yellow circles)

**Algorithm 2** Head model refinement algorithm

- 1:  $v\_array \leftarrow array\ of\ 8\ zero\ vectors(0, 0, 0)$
- 2: **for** each frame since last *head\_model* refinement iteration **do**
- 3:   **for** each facial landmark  $L_i$  **do**
- 4:      $l \leftarrow line\ through\ camera\ (point(0, 0, 0))$   
and detected landmark  $L_i$ ; {line should be in parametric form -  $P = P_0 + t\vec{v}$ }
- 5:      $R \leftarrow rotation\ calculated\ for\ this\ frame$ ;
- 6:      $t \leftarrow translation\ calculated\ for\ this\ frame$ ;
- 7:     Create  $[R|t]$  3x4 transformation matrix, calculate its pseudo inverse transform and apply it to line  $l$
- 8:      $P_i \leftarrow head\ model\ point\ (corresponding\ to\ processed\ facial\ landmark\ point\ L_i)$
- 9:      $P'_i \leftarrow P_i\ projection\ on\ line\ l$  {Note that  $P'_i$  is the nearest point from  $P_i$  that is on line  $l$ }
- 10:      $\vec{w} \leftarrow P'_i - P_i$  { $\vec{w}$  is the correction vector - if it would be added to  $P_i$  the resulting point would give perfect reprojection (for this frame)}
- 11:      $v\_array[i] \leftarrow v\_array[i] + \vec{w}$
- 12:   **end for**
- 13: **end for**
- 14:  $N \leftarrow number\ of\ frames\ used\ in\ head\ model\ refinement$
- 15: **for** each *head\_model* point  $\{P_i\}$  **do**
- 16:    $hp = head\_model\_points[i]$
- 17:    $hp = hp + v\_array[i]/N$
- 18:    $head\_model\_points[i] = hp$
- 19: **end for**

the changes are much smaller, therefore recommended number of iterations is 3 to 5.

The resultant model was also interesting on its own - for example it can be part of face reconstruction or recognition system, that's why we decided to check the accuracy of head model refinement. For this purpose we compared results with ground truth data from 3d digital scanner 2.

Fig. 2. Digital scan of author's head, acquired using Artec Eva [22] scanner

Fig. 3. Images from recorded movies. Note motion tracking system markers on the head. On (4) we can see markers used to synchronisation. In the background - 2 IR cameras used by motion tracking system.

#### IV. EXPERIMENTS RESULTS

The verification of the method accuracy was performed with a professional ground truth data. Head movements of user were recorded simultaneously by camera assigned to the laptop monitor and by professional Vicon passive tracking system. Tests were performed and recorded with standard webcam camera of 640x480 resolution. The precision of the reference Vicon tracking system is very well known and reach 0.5 mm within large (several cubic meters) tracking volume. Both data streams, video camera and head movement tracking system were synchronised. Tests were performed in changing lighting conditions (strong light from one side, blinking light in different colors, etc.). The distance between subject was in range 30-100cm, simulating average laptop usage. An example frames from movies are shown in image 3.

The results of head pose estimation and head model refinement algorithm are presented separately in two independent subsections. In both cases the results are dependent on frequency of head model refinement and maximum number of allowed refinements.

##### A. Results of head pose estimation

Results of head pose estimation were compared with ground truth data from reference Vicon motion tracking system. In the table II we can find the influence of different parameters on average head rotation angle differences. It can be noticed

TABLE II  
RESULTS OF HEAD POSE ESTIMATION ERRORS.  $x, y, z$  AXES REPRESENT RESPECTIVELY PITCH, YAW, ROLL HEAD ROTATIONS;

Head model	Remove with biggest reprojection error	Frames between refinements	X[°]	Y[°]	Z[°]	avg[°]
Initial model	no	-	6,07	5,69	2,45	4,74
	yes	-	4,94	6,05	2,91	4,64
Initial model refinements	yes	100	6,46	5,25	5,23	5,65
	yes	175	2,87	5,37	2,53	3,59
	no	175	4,14	4,95	2,43	3,84
	yes	250	3,40	5,47	2,53	3,80
	no	250	4,44	5,10	2,51	4,02
	yes	500	4,76	5,46	2,52	4,25

that only selected results have been provided (for discrete set of configuration parameters). The best achieved configuration considered removing the most erroneous head model point with refinement for every 175-th frame. Then the average head orientation error was 3.59 degrees but individual axes reached an error of about 2.5 degree ( $Z$  axis representing *roll* head rotation). The average frames per second value during performing tests was 13.66, which in our opinion is enough for real-time applications.

##### B. Results of head model refinement

Table III presents exemplary results of head refinement process. Provided parameters were obtained for the least head orientation error described in previous section. The results were obtained with exclusion of the point with the biggest reprojection error, with assignment of number of frames between refinements to 175 and maximum number of refinements set to 5. The overall head model correction reaches only about 10% and is mainly affected by the noise of ears imprecise positioning. This is most likely caused, by the imperfection of tested facial landmarks detection method, especially when ears feature points are not visible. Assuming exclusion of ears feature points, from the head model, its considerable improvement can be presumed.

#### V. CONCLUSIONS

Performed experiments revealed unquestionable high average accuracy of head pose estimation. Average orientation error oscillates around 4° what situates presented method at a comparable position with the state-of-the-art approaches. Consecutively corresponding 3d head model robust refinement was performed but still a considerable space for further improvements in this field are noticeable. The refinement process assures much faster, than corresponding bundle adjustment process, face image alignment and resulting head pose interactive (real-time - average FPS 13.66) estimation.

The best results were obtained for relatively seldom refinement (every 175-th frame) and the worst head model point exclusion appeared to improve the final estimation results. According to conducted experiments further exclusion of the worst points, in subsequent iterations, can improve the results

TABLE III  
RESULTS OF HEAD MODEL REFINEMENT

Point	Error of initial model[mm]				Error of refined model[mm]			
	x	y	z	sum	x	y	z	sum
Sellion	0	0	0	0	0	0	0	0
Right eye	-19,62	-0,04	2,76	22,43	0,56	-2,33	0,29	3,18
Left eye	17,01	0,93	4,39	22,35	0,51	-0,35	5,51	6,38
Right ear	8,99	26,34	12,16	47,50	16,19	25,30	12,64	54,14
Right ear	-12,60	27,96	6,43	47,00	-22,58	26,02	11,93	60,55
Nose	-3,20	27,86	30,00	61,07	-0,65	13,19	35,62	49,48
Stomion	-1,97	3,22	3,68	8,88	-2,10	-3,01	6,07	11,19
Menton	-1,17	-0,93	22,16	24,28	-0,45	3,18	25,16	28,81
Sum	-	-	-	233,52	-	-	-	213,75

only within one or two further steps - if the points misalignment is relatively big. If not, further *bad points* removal results in perceivable worse general method precision.

The proposed head model refinement corrects the average head orientation error by about 20% - for considered method coefficients average head orientation error decreased from  $4.64^\circ$  to  $3.59^\circ$ .

Further perspectives of the method improvements encompass: filtering components of the refinement vectors specified in the algorithm 2, introducing certain anthropometric constraints of the head model modifications as not to allow extensive model degeneration while refinement (in this context symmetry of the face might be considered for further face feature points stabilization and for head model refinement stabilization as well) and calculating head position using information about facial features detection uncertainty (for example - usually ears are detected with bigger error than nose or eyes).

**Abstract**—Fire safety education is essential to every student on campus. Fire safety knowledge learning and operational practice are both important. There is evidence that the virtual reality (VR) based educational method can be a novel and effective approach to learning and practice. However, the existing VR-based system for fire safety education has some shortcomings such as lack of interactivity and high equipment complexity, resulting in low practicability. In order to improve the effect of fire safety education on campus, this paper establishes the model and architecture of fire safety education system based on VR technology. The framework and various elements of fire safety education system are designed and implemented according to the combination of relevant fire safety education theory and VR technology. Finally the prototype version of fire safety education system based on VR technology is built on the HTC VIVE helmet equipment. Through the usability test and comparative analysis of the application experiment, the experiment results prove the feasibility and effectiveness of the proposed approach.

## I. INTRODUCTION

THE fire is a major disaster that threatens human safety. Due to lack of safety knowledge, improper emergency measures and so on, the campus is prone to fire. The colleges and universities must attach great importance to fire safety education. Each student must learn and master the fire safety knowledge and necessary skills to prevent the fire and handle properly in the event of fire [1]. This is of great significance for maintaining the campus order and the safety of students.

Fire safety education emphasizes the close combination of knowledge learning and operational practice. It is important to choose the appropriate teaching method [2], which will directly affect the teaching effect.

The traditional teaching methods are mainly textbook teaching or multimedia presentation. Both of these methods have the shortcomings of poor interaction and lack of practical exercise. Fire drills can effectively help students become familiar with firefighting equipment and learn extinguishing and self-protection skills [3]. However, due to the constraints of material, manpower and money, fire drills cannot be carried out frequently, which may lead to the decline in students' fire safety ability.

With the emergence of virtual reality (VR) technology, it is widely used in game development, virtual training [4], and introduced into the field of education [5]. VR technology can provide a realistic virtual environment, allowing students to have the flow feeling with multi-sensory experience [6]. VR technology has also been introduced into the fire safety education. Bhagat [7] designs a cost-effective 3D VR system for military live fire training. Xu [8] establishes a VR-based fire training simulator with smoke assessment capability. On the whole, current research and applications are mainly focused on firefighting programs and evacuation plans. Especially, there are still some shortcomings in the VR-based fire safety education system. They are not in-depth integration with educational theory. The lack of interactivity and high equipment complexity also lead to the low practicability [9]. They cannot make full use in the practical fire safety education and teaching process.

Therefore, in order to improve the effect of fire safety education on campus, this paper establishes the design model and architecture of fire safety education system based on VR technology. The framework and various elements of fire safety education system are designed and implemented according to the combination of relevant educational theory and VR technology. Finally, VR-based fire safety education system is built on HTC VIVE helmet equipment. The system is applied to fire safety education, to help students learn fire safety knowledge and improve fire safety skills.

## II. SYSTEM DESIGN

The design of fire safety education system fully integrates the relevant educational theory with VR technology, and follows the five design concepts. Thus, the system model and architecture are established.

### A. Relevant Educational Theory

#### 1) Constructivism Learning Theory

Constructivism theory advocates situational teaching. The student's knowledge is obtained through the construction of meaning in certain learning environments, with the aid of the necessary information and interaction. VR technology can create a virtual fire safety education environment similar to the actual situation. It provides students with the situational

This work was supported by the Research Funds of CCNU from the Colleges' Basic Research and Operation of MOE (No. CCNU17QN0002).

experience to learn the fire safety teaching content and to carry out fire safety interactive operation, which is conducive to students' construction of knowledge.

#### 2) Flow Theory

The flow theory describes the phenomenon that students are fully immersed in the current environment and enter the flow state, concentrating their attention on learning content and achieving good learning outcomes. VR technology can provide students with a more realistic situational experience. Students will be easy to enter the flow state. They are fully concerned about the fire safety learning content and get more profound operation experience that will deepen the cognition and understanding of fire safety.

#### 3) Gamification Learning

The gamification emphasizes the combination of learning content and gamified elements. The core of gamification is interest and reward mechanism. Through the scientific and attractive reward mechanism, students will have a continuous learning motivation. VR-based fire safety education system is presented in the form of gamification. With the interesting reward mechanism, students improve the participation and learning interest, and get more efficient learning outcomes.

#### 4) Transfer of Learning

Transfer of learning provides a theoretical basis for the acquired skills transfer between virtual environment and real environment. The firefighting devices in the VR environment are mapped to the equipment in real world. Through virtual interaction with firefighting devices, students can learn fire safety skills and obtain the operational experience that can be transferred to the real activities. Through experiments, the effectiveness of learning transfer can be verified.

### B. Design Concept

#### 1) Instructional Design

Fire safety teaching content is divided into two categories, fire safety knowledge and operational practice. Fire safety knowledge contains fire alarm, fire protection, fire hazards and so on. The operational practice includes firefighting, fire escape, etc. According to constructivism theory, the teaching content is presented in a variety of different virtual situations. Students can explore and interact in the virtual environment, so as to construct their own knowledge system.

#### 2) Authentic Design

The authenticity of the virtual situations can help students construct knowledge, enter the flow state, and get a profound learning experience. In order to ensure the authenticity of the VR scene, the object modeling design is the key. The 3ds Max is used to design and implement a set of models such as fire extinguishers, hydrants and so on. Then these models will be imported into Unity platform with further editing and rendering, to make the VR scene more realistic and vivid.

#### 3) Interactive Design

The system interface is designed based on the principle of unconscious, making the interaction in line with the natural behavior of students. The operation of the system is designed

based on the concept of natural human-computer interaction to facilitate the natural interaction between students and VR scenes. Students enter the flow state, explore and interact with a variety of fire safety situations. Interactive feedback is provided to help correcting errors and constructing cognition. The necessary instructions will be pre-set so that students can understand the basic situation.

#### 4) Interesting Design

Related researches show that the gamification can not only increase student's interest, but also increase the learning effect. Visual effects and music melodies can create a variety of atmosphere, resulting in emotional resonance to stimulate student interest. Challenging reward strategies are also very helpful. The formulation of reward strategy needs to consider three aspects: principle, timing and form. Only the proper rewards can inspire students' interest. Through the usability test, it can get feedback for further improvement.

### C. System Architecture

The architecture of VR-based fire safety education system includes user module, scene teaching module, test module, database module and I/O Module.

1) The user module is used to register and modify the user's basic information.

2) The scene teaching module is the core of the system. A series of virtual campus scenes are constructed to show fire safety knowledge and operational practice. Students can roam in the virtual campus, free access to different virtual scenes for interactive experience, so as to learn knowledge and master fire safety skills.

3) The test module is mainly used for students to carry out fire safety knowledge assessment, in order to check the effect of learning. The test content is consistent with the fire safety knowledge in the scene teaching module.

4) The database module is used to store students' usage records and data information, mainly including test scores, time cost and so on. SQLite is used as the database engine.

5) The I/O Module describes the way of interacting with the system, including the interactive mode based on helmet display and wireless controller (HTC VIVE), as well as the traditional I/O modes (keyboard, mouse and monitor).

## III. SYSTEM IMPLEMENTATION

### A. Scene Implementation

Using 3ds Max software, and Unity development platform, the virtual fire safety education environment similar to the actual situation is implemented to demonstrate the teaching contents, including fire safety knowledge and operational practice. A series of virtual campus scenes are constructed, including classrooms, dormitories and so on. Students can roam in the virtual campus, voluntarily enter different virtual scenes to explore and interact, so as to learn and construct their own knowledge system.

#### 1) Knowledge Learning

Fire safety knowledge includes fire type, fire hazard, fire alarm, fire prevention and so on. The teaching content is set in various places on the virtual campus scene. A series of fire safety signs and equipment will appear on the roaming route. When students point to them, the corresponding knowledge will be presented with voice, video and other forms. When students roam into several dedicated classrooms, they will carry out the collective learning of fire safety knowledge, in the form of multimedia presentation and knowledge quiz. Students handle the controller to answer, as shown in Fig. 1.

Fig. 1 The view of fire safety knowledge learning

## 2) Operational Practice

The realistic and vivid fire safety scenes are implemented and presented in front of students, enabling them to enter the flow state, get a profound experience and learn the fire safety operation skills that can be transferred to the real activities.

When students roam into certain specific scenes, they will trigger the corresponding fire drill tasks, including searching for fire points, fire extinguishing simulation, safe evacuation, etc. Students need to do the proper operation in virtual scenes, complete the fire practice task and get the reward.

One of the cases is to put out an office fire. The paper in the trash bin is ignited by a cigarette butt. The flame appears and continues to grow, accompanied by the burning sound. Following the prompts, the student need to pick up the fire extinguisher on the ground, operate it in accordance with the correct steps, and extinguish the fire, as shown in Fig. 2. After the task is completed, the office staff will come in, express gratitude and give bonus points. The accumulated points can be used to open more scenes.

Fig. 2 The view of using fire extinguisher to put out a fire

Using VR scenes for virtual fire drills can overcome some limitations of traditional fire drills. More students can get the profound experience, and grasp the use of fire equipment. Subsequent experiments will verify the effect of transferring the skills acquired by virtual fire drills to the real activities.

## B. Interaction Implementation

The interaction between students and the system is mainly based on HTC VIVE hardware platform. The kit consists of a helmet, two wireless controllers and two base stations for positioning. The VIVE controller is equipped with dual-stage trigger, 24 sensors, and has realistic haptic feedback. The base stations use Room-Scale positioning technology to track the exact locations of the helmet and controller with low latency and high accuracy. Wireless controllers in each hand combined with precise positioning and tracking mean that students can freely explore and interact with virtual objects, characters and environments, with the most natural behavior such as move forward, back off, squat, head rotation, grab and release and so on, as shown in Fig. 3.

Fig. 3 The view of using HTC VIVE helmet equipment

In the scene shown in Fig. 2, the system track the exact location of the student's hand to determine if it touches the fire extinguisher. The student presses the trigger button on the controller to grab the fire extinguisher. When close to the trash bin, the student presses again to push down the handle of the fire extinguisher and carry out firefighting action. The controllers generate haptic feedback synchronously. Several hand actions are shown in Fig. 4.

Fig. 4 Hand actions of operating the fire extinguisher

In addition, the necessary guidance and feedback will be provided to make better use of the system and help students correct the error. For example, two yellow footprints and subtitles are set to prompt student to enter the operating area. When the student enters, the color will turn green. When the student is in the wrong direction, the hand tip will appear to guide the student to turn around.

#### IV. EXPERIMENT AND ANALYSIS

##### A. Usability Test

The prototype version of fire safety education system has been built and tested. The user feedback is gathered in time to understand the user's comments and suggestions on the system. The usability and effect of the system is analyzed in order to verify that the desired goals have been achieved.

Eight potential users are recruited as testers. They are free to explore in the virtual campus and complete all the learning tasks. Through interviews, the feedback of interface design, ease of operation and process rationality are consulted. The usability test results show that most of them have high degree of satisfaction with the system. They indicate that the system has the characteristics of accessibility, good memorability and high learning efficiency, without fatal errors. Compared to traditional desktop-based interactions (using keyboard and mouse to control virtual devices), the HTC VIVE controllers combined with precise tracking feature can provide better experience, especially in the session of virtual fire drills.

The usability test results are of great help in optimizing the system, and those users feel inconvenient have been further improved. Thus the final solution has been formed.

##### B. Application Effect Analysis

Participants in the experiment are randomly recruited on campus, and then 60 students are selected, with the same age, background, and motivation. Through a pre-test volume, they are divided into three groups with the same level, according to the test results. Each group has 10 males and 10 females. The first group is the experimental group, using the VR system based on HTC VIVE. The second group is the control group, using the VR system based on traditional desktop computer. The third group is also the control group, and students use the textbook to learn fire safety knowledge.

Fig. 5 Mean and variance results of the three groups

Each group uses their own method to learn the fire safety knowledge for 60 minutes, and take 3 rounds of learning process. After that, the three groups are tested within the specified time. The test consists of two parts. The first part is the knowledge quiz, developed by the fire safety knowledge

manual issued by government, with full score of 80 points. The second part is operational practice, such as how to use fire extinguishers properly, with full score of 20 points. The judgment is conducted by experienced fire safety teachers. The test results are shown in Fig. 5.

For the first part of the knowledge quiz, the scores of the first and second group are significantly higher than the third group. This shows that the use of VR technology can better improve the effect of fire safety knowledge learning than the textbook teaching. For the second part of the practice, the result of first group is significantly higher than the other two groups. It indicates that students can master more fire safety skills using VR system based on HTC VIVE than traditional system. The experience gained in the virtual environment can be well transferred to actual activities. Overall the VR-based fire safety education system can effectively improve the fire safety learning effect.

#### V. CONCLUSION

Fire safety education is very important to every student on campus. The fire safety education system based on virtual reality technology established in the paper has enriched the teaching form of fire safety education on campus, which can effectively help students learn fire safety knowledge, master fire safety skills and improve fire safety education effect.

With the development of modern educational theory and virtual reality technology, it is still necessary to carry out more relevant research in this field.

# The 37<sup>th</sup> IEEE Software Engineering Workshop

**T**HE IEEE Software Engineering Workshop (SEW) is the oldest Software Engineering event in the world, dating back to 1969, and with the last 36<sup>th</sup> workshop organized in Gdansk, Poland, 11-14 September 2016.

The workshop was originally run as the NASA Software Engineering Workshop and focused on software engineering issues relevant to NASA and the space industry. After the 25th edition, it became the NASA/IEEE Software Engineering Workshop and expanded its remit to address many more areas of software engineering with emphasis on practical issues, industrial experience and case studies in addition to traditional technical papers. Since its 31st edition, it has been sponsored by IEEE and has continued to broaden its areas of interest.

## TOPICS

The workshop aims to bring together all those with an interest in software engineering. Traditionally, the workshop attracts industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practice. The workshop provides a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

Topics of interest include, but are not limited to:

- Experiments and experience reports
- Software quality assurance and Metrics
- Formal methods and formal approaches to software development
- Software engineering processes and process improvement
- Agile and Lean Methods
- Requirements engineering
- Software architectures
- Real-time Software Engineering
- Software maintenance, reuse, and legacy systems
- Agent-based software systems
- Self-managing systems
- New approaches to software engineering (e.g., search based software engineering)
- Software engineering issues Cyber-physical systems
- Software Engineering for social media

**Abstract—** Based on a systematic review of empirical studies about software components selection and usability techniques applied to a functional prototype, this article maps the functional and non-functional requirements of a components sharing network that aims to accelerate JavaScript software development. Results point out that integrating the development environment to a component search mechanism with automated filters, ordered by quality criteria, and allow code snippets rank and improvements submission on a version control system are the path to accelerate the development and motivate IT students and professionals to participate in this network.

## I. INTRODUCTION

SINCE the 90th, known as the Dot-com bubble, many has changed regarding user experience on the web. In October 2014, W3C has released the fifth revision of HTML5, essential technology for multiple platforms [1]. As web scope increases, targeting almost every device, a plethora of frameworks and components have been released to simplify development on this platform. Bower (bower.io), a package manager created to store frameworks, libraries, assets, and utilities for HTML, CSS and JavaScript development has more than 60,000 packages on its database (data collected on January, 2017). Building systems through third party components reuse has being recognized as a crucial success factor in software industry, but only a few companies formalize their selection processes and employ any method to document their decisions [2].

Usually, API documentation is insufficient to assist programmers while coding. A survey [3] shows that the crowd can significantly enhance an existing API documentation, and indicates there is a strong association between API coverage on Stack Overflow and its usage in real software systems. Relevance data extracted from crowd participation can help narrowing down component options and preventing the YAFS syndrome [4], when developers tend to create new frameworks instead of using frameworks with the same features, because they could not afford evaluating a large number of options.

This paper aims to join the analysis of empirical studies and human-computer interaction techniques for eliciting functional and non-functional requirements of a components sharing network and understand how IT students and

professionals could benefit from this approach and get motivated to participate in this network.

The following sections present the whole survey process that contemplates the analysis of papers on empirical methods and current industry practice for components selection, the creation of a prototype to elicit the possible requirements of this network, usage observation and focus group with 26 IT students, and a heuristic assessment on the prototype conducted by 3 specialists.

## II. BACKGROUND

In the academic context, [21] evaluates quality, validation and performance of 7 JavaScript web frameworks. On quality perspective, they analyzed size, complexity and maintainability using JSMeter (jsmeter.info), Cloc (cloc.sourceforge.net) and Understand (scitools.com). On validation perspective, critical and high severity errors were analyzed with Yasca (sourceforge.net/projects/yasca) and JSLint (javascriptlint.com) tools. Lastly, on performance perspective, SlickSpeed (github.com/kamicane/slickspeed) was used in 7 different browsers and 4 operational systems. As detected in [22], there is lack of studies to help professionals to select best JavaScript framework by its purpose and functionalities, as specific concerns on JavaScript frameworks are not addressed in more generic component selection methods.

In [21] they present important criteria that are missing in most academic studies, extracted from a questionnaire applied to 4 front-end developers: adequacy of the documentation to user needs, how many people contribute and use the code, and how fast it is for the component to bring value to user's application. All criteria listed vary according to user / project constraints. Besides these studies [21] and [22] approaches same language, another proximity between this study and [21] is the intention of reusing existing OSS tools to provide metrics on JavaScript code.

This study is focused on code snippets and components, and the other 2 are more focused on frameworks. The demand for organizational tools for JavaScript development is perceived by software community and has being addressed by package managers like Bower and scaffolding tools like

Yeoman (yeoman.io). Developers heavily use these tools, but still they keep continuously seeking new tools that will make them deliver faster and with a better quality. In this sense, there is room for new tools that addresses problems still not solved, e.g. how to classify JavaScript packages by the feature(s) they provide [22].

In this study, the agile requirements engineering process with prototypes is applied [20]: initial requirements are elicited, prototype is built / updated, submitted to end user revision, and prototype is refactored for next iteration. Prototypes increase motivation for requirements gathering and force users to discuss about requirements in less subjective terms [20]. Based on [5], a key question was defined: what are the empirical studies recently published related to the selection or evaluation of open-source (known as OSS) or commercial-off-the-shelf (known as COTS) components? Table I shows the search string generated.

TABLE I.  
INDUSTRY PRACTICE THROUGH EMPIRICAL STUDIES

Libraries	Articles	Search string
IEEEExplore	59	(("empirical study") AND ("Open Source Software" OR "Off-The-Shelf") AND ("Software evaluation" OR "Software selection" OR "Component selection" OR "Component evaluation"))
ACM DL	24	
Science Direct	30	
Springer Link	16	
topics: title and abstract; language: English; when: 2005 to Jan. 2017; discipline: Computer Science; types: articles, conferences & chapters		
[Author] Objective		focus   target   tool   participants
[6] map reasons COTS or OSS are used in Norway, Italy & Germany		COTS, OSS   decision makers   questionnaires   127 companies
[7] understand how researches can contribute to practice in Norway		OSS   developers   questionnaires   16 software companies
[8] identify the principles of software packages selection		COTS   decision makers   interviews   39 people
[9] investigate COTS selection practice in Jordan companies		COTS   decision makers   questionnaires   10 companies
[10] understand components selection practice and emphasize underestimated topics in academy		COTS, OSS   developers   interviews   23 people / 20 software companies
[11] challenges on OSS component selection, licensing and maintenance on Chinese software companies		OSS   decision makers   questionnaires   43 companies
[12] Examine state-of-practice in OTS component-based development		COTS, OSS   decision makers   questionnaires   127 companies
Industry Practice Characteristics [found in:]		
ad-hoc and situational; generic selection methods not applied [7][9][10]		
rely on developer team's previous experiences [7][9][10][11][12]		
selection process, criteria and decisions are not registered [9][7]		
search engine (google) is the source for new components; repositories rarely used [7][10][11][12]		
market is continuously monitored [7][10][9]		
selection happens in early development phases [10]		
selection can happen in any phase, based on project context & flexibility [12]		
evidences of real component usage matters on decision [10]		
comply to functional requirements and project constraints [7][10][11]		
future support assurance matters on decision [6][10][9]		
bring less effort and take less time to apply matters on decision [6]		
licensing terms matters on decision [11]		

To filter these papers, the following criteria was defined: remove duplicated surveys, in-progress studies and outdated survey versions; and select papers approaching industry

practice in component selection through an empirical study; or academic methods or criteria for component selection. This filter reduced the list to 46 articles, 38 focused on academic methods or criteria, which will not be cover on this article. Table I shows the remaining 7 articles that approaches industry practice through an empirical study.

In a research on component selection practices with architects and researchers that perform this activity, [23] concluded that 4 criteria are fundamental for component assessment: features, non-functional attributes, architecture compatibility and business considerations. Evaluation process is an iterative process interleaved with requirements engineering. Based on the analysis of the selected articles, focusing on their main conclusions from interviews and questionnaires, the key characteristics of the Industry practice on selection is summarized in Table I. These characteristics should be considered in a component selection process more connected to the industry practice.

### III. PROTOTYPE, FOCUS GROUP AND HEURISTIC RESULTS

The main purpose of this prototype was to showcase a variety of possible features available on a components sharing network. The prototype focus was on user interface, a proposed taxonomy and selection criteria. The prototype was not linked to an IDE (Integrated Development Environment), but hosted in a web server. The prototype is the artifact that allows specialists and users to provide very early feedback on **requirement** elicitation, data **taxonomy** and terminologies, relevant selection **criteria**, possible **integrations** to bring value to the solution and detailed **use cases** that could address real problems.

The prototype was designed to be a repository of component bootstraps. Every component would contain a package with dependent files (scripts/resources/styles) and a code snippet that could be easily applied in user's code. These packages would be classified by feature and accessible through a search engine. The first criteria supported would be performance comparison through test cases evaluation and users rating. In search page, user can filter a feature by name and navigate to a list of components that implements this feature, referred in the prototype as techniques. Sample data was extracted manually from blogs, books and framework's documentation. Test cases were created for every feature, and a benchmark tool (benchmarkjs.com) was used to run them. For component rates, mocked data was used; the assumption is that when the final tool were delivered, users will start rating the components they use. After component selections, users would be able to generate an online documentation of their selections and packages with dependencies and snippets, named receipts. A simple reputation system was simulated, where users would earn points by adding snippets, ranking or generating receipts.

Two sessions were conducted with 26 IT students in computer labs of FEI University Center in São Bernardo do Campo, São Paulo, Brazil. Programmers composed the majority of the group: 73% of the group works with IT, 92%

read and write in English, 38% code some days every week and 31% code on a daily basis; 69% informed that are familiar to JavaScript language and CSS, and 92% are familiar to HTML. Activities contemplated a questionnaire to map group expertise level, user observation, where pairs had to complete a list of tasks while being observed, a post questionnaire and a focus group to discuss post questionnaire answers. Post questionnaire topics were: how people should use this tool (Q1); if they agree a code snippets database would play a crucial role in component selection (Q2); if they recognize any differential between this tool and other tools available in the market (Q3); and if the recognition simulation is seen as relevant (Q4). Researcher role was to moderate discussion and not influence group [14].

On Q1, group agreed users would use this tool to rank the best snippets and receipts (88%), and when tool had more access, use it to extract component development patterns (85%), find solutions recognized by development community (81%) and share them in Question and Answer (Q&A) sites (81%). Group agreed the receipts concept was not clear so they would not use it. On Q2, group agreed code snippets available on the web influence JavaScript, HTML and CSS development (85%). 96% agree code snippets that work are the information source that most helps when adopting a framework, confirming [10] results. The second main information source is technical blogs (85%) followed by Q&A sites (81%).

On Q3, groups disagreed. First group agree this tool has potential, but it should be integrated with existing tools like GitHub (github.com). The other group argued they would only use this tool if it could compete with tools like Stack Overflow in performance and search engine quality. On Q4, recognition mechanisms are considered positive by 69% of the group, but group pointed out its relevance depends on how it prevents people from cheating.

Heuristic evaluation was conducted by 3 specialist during three days. Specialists recommended organization, quality, communication and integration changes.

Table II shows the fundamentals of a Component Sharing Network based on the software engineering dimensions: Requirements, Integrations, Taxonomy, Criteria and Use Cases. This list integrates data from academic background, user observation and heuristic evaluation.

#### IV. CONCLUSION

This research aims to go beyond a new rational method for component selection, aggregating info on how this activity is done, a fundamental step to design a successful tool with this purpose [7] [10]. There are only a few studies focusing on gathering Industry feedback, which is one of the purposes of this study, and bring more evidences of real component selection practice. On internal and external validity [18], the 26 participants and 3 heuristic specialists formed a heterogeneous group of people directly or indirectly involved in software development, only 35% of them with a more active role in development community, in observation to 90-

TABLE II.  
FUNDAMENTALS OF A COMPONENT SHARING NETWORK

<b>Structure Requirements:</b> invest on search engine; User area should list project's snippets, components & versions; Component and snippet's rank should be per criteria; Search should be contextualized by project metadata; Component comparison should be by criteria (adherence, performance), not code; Components already used in user's project should have precedence in search results; IDE results should be ordered by best option based on project metadata; allow users to add test cases to an existing snippet; tool should support storing private data for companies; allow running performance reports for the entire project
<b>Quality Requirements:</b> pay special attention to search engine and package dependency resolver performance; performance analysis should be done in background; tool should deduplicate code; recognition system should stimulate user interaction and avoid cheating; a tag system should be used to classify snippets; avoid anonymous user to submit content to the tool; moderation of abusive content; free text restrictions should be applied; moderation program should be established, with moderators chosen by their reputation on the network
<b>Communication Requirements:</b> clearly inform languages available and supported; tool features should be well documented; content should be in English; allow user to change criteria used to select a component in a given context;
<b>GitHub Integration:</b> create repositories, branches, forks, pull requests
<b>Atom, VS Code and Cloud9 Integration:</b> code pre-analysis to speed up contextualized snippets suggestion; search snippets per feature & component (best option and list); resolve component dependencies on selection; allow rating inside IDE
<b>GitHub and Package Managers Integration:</b> extract component reputation data
<b>Google Integration:</b> define search engine optimization strategy
<b>Bower Integration:</b> resolve components dependencies of code snippets
<b>JsMeter, Cloc, Understand, Benchmark.js, Jslint and SlickSpeed Integration:</b> use to run component evaluation metrics
<b>Taxonomy:</b> features, techniques (code snippets), components; package dependencies instead of receipts
<b>Criteria:</b> performance; constraints adherence (components/frameworks in use, architecture); code complexity (lines of code, cyclomatic complexity, maintainability index); vulnerability and conformance (critical and severity errors in component)
<b>Use Cases:</b> choose a list of components that matches a list of features before starting a new project; find a list of components that matches a specific feature and user project metadata; infer project constraints from code analysis to generate search metadata; find a list of components that matches your project metadata; find the fastest component for a feature disregarding project metadata; apply code snippet to an existing project and resolve dependencies automatically; find most popular components;

9-1 rule of [15] for online communities. We strictly followed rules described in [17] and [14] for conducting user observation and focus groups. Interaction between researcher and users were as low as possible, they had no previous contact with the prototype and questionnaires before the session and answered questions individually at the same time. Sessions were recorded, transcript and analyzed. During focus group, researcher read the questions, clarified that an agreement of the group was expected for every question, helped on doubts and controlled time available for each discussion.

Heuristic specialists had previous experience in heuristic evaluation and strictly followed Nielsen heuristics and severity ratings [18] [19]. They did not participate at the user observation and focus group sessions.

This study do not attempt to make universal generalizations, it is concerned with characterizing and

aligning its own solution to the practice under the context of this study [16]. As evidenced in [10], evidence of real usage are the source of information that most help in the adoption of a JavaScript, CSS or HTML component, and this was proven to influence the result of this type of software.

Two perspectives were identified in component selection process, one when user is studying component options for his new project, more open to new options and the second one when user is in the middle of a project and needs a technical solution for a specific problem, looking for compatible components. This tool should address both use cases, supporting project bootstrap with best components available under initial project constraints, and suggesting the best component to solve technical problems or missing features in an existing code. The main differential identified on prototype was the capacity to run performance tests and rate snippets.

Performance and usability problems on the prototype disturbed user perception, but most participants think that, over time, when integrated to a version system and IDE, this tool can be used to map component patterns. The reward mechanism showed moderated relevance, which can be consequence of the limited usage period. Participants down voted the receipts feature. A more practical approach would be to rely on an existing package management tool. Users did not report major problems navigating in features, techniques and criteria, which suggests that the taxonomy defined was considered natural.

The results of this study are a stimulus to early user involvement on software projects, a key resource on the design phase, and the use of prototypes to help increasing the capacity to share the envision of features and requirements. Future studies will focus on applying the fundamentals gathered in this study to create a new prototype that will be validated for a longer time (some months). The focus will be on IDE integration and code analysis with metadata generation to provide contextualized search results.

#### ACKNOWLEDGMENT

Special thanks to professor Gordana Manic, PhD. that conducted the initial research and providing important information. We thank FAPESP (São Paulo Research Foundation) for financial support.

**Abstract**—Nowadays enterprise software solutions must deal with ever-growing complexity and a multitude of business processes. The mainstream system design decomposes the system into small reusable services. While these services isolate certain system logic and address efficient elasticity towards growing user demands, there are multiple issues related to such a design, such as limitations to deal with restated information, information reuse or the ability to address cross-cutting concerns across multiple services. This paper highlights limitations of service-oriented architecture and proposes an alternative decomposition through aspect-driven service-oriented architecture. Such architecture involves adaptive, context-aware services preserving simple maintenance while addressing information reuse and crosscuts across services. The paper provides a formal description of the proposed architecture as well as a demonstration through a case study, showing approach properties and benefits.

## I. INTRODUCTION

CONTEMPORARY Enterprise Information Systems (EISs) grow in both scale and complexity. Functional requirements are becoming more advanced because they require context-awareness. Considering various aspects of a business domain within current execution context, i.e., within time, user's privileges, and state of the system. Non-functional requirements often include scalability and distribution, handle and serve a large amount of requests or process large volumes of data [1].

Having this mind, conventional systems have to deal with several aspects of a business domain. Besides complex domain models [2], there are access policies and business rules that need to be implemented to properly secure and maintain data.

For illustration, consider a basic e-shop system as an example of conventional EIS. There are *users* representing both customers and employees with various access roles and responsibilities. Next, there are *products* with description and photo gallery, organized into categories, and connected to the *store* to manage delivery and stock. Finally, the system maintains *orders*, their state, changes in time, billing, and state of delivery. Obviously, even this simple and reduced example is quite complex. The business model is tangled and there are a few stateful objects implying conditional business rules and access policy. Finally, there exist 3rd party services for *billing*, *shipping*, and *emailing*. For the sake of simplicity, we do not consider sales introducing time-based conditions combined with the stock.

One common way to implement these systems is to use conventional technologies that head towards monolith appli-

cations with poor scalability and maintenance. This results from difficult domain decomposition and high information repetition due to significant concerns tangling [3]. Alternatively and more likely, to deliver a highly scalable and distributed system, there exists Service-Oriented Architecture (SOA) [1], [4], [5] decomposing a system into many smaller services following Single Responsibility Principle [6]. However, while this decomposition increases scalability and throughput, its maintenance gets more difficult as the services are more encapsulated, self-standing, isolated, and possibly written in different programming languages, which significantly reduces a possibility of information reuse and forces manual repetition instead.

In this paper, we discuss system decomposition into services, and highlight limitation of the overall architecture. Next, we propose an enhancement of SOA through adaptive context-aware services preserving simple maintenance and keeping minimal information restatement.

This paper is structured as follows. In Section II, we discuss SOA more deeply and in Section III highlight its limitations and opened challenges. In Section IV, we present Aspect-Oriented Design Approach efficiently dealing with business rules repetition and transformation, and we generalize and modify this approach to fit SOA environment and present the design in Section V. We show a case study in Section VI and in Section VII we elaborate and briefly evaluate the alternative existing approaches. We conclude the paper in Section VIII.

## II. CONVENTIONAL DESIGN

Complexity and wide use of EISs emphasize their robustness and scalability. The common approach in SOA to design a large distributed system suggests decomposition of the application logic into small encapsulated standalone units called *services* responsible for and encapsulating a part of the business domain [4]. For example, in the e-shop system, one service is responsible for the user management, while the other for the product management. These services are then composed together to deliver more complex functionality. An example of such a *composite service* [7] is the orders management. It depends on both users and products plus adds additional features.

**Definition.** A *service* is a reusable, cohesive, managed, deployable, and independent process interacting via messages. [7] [8]

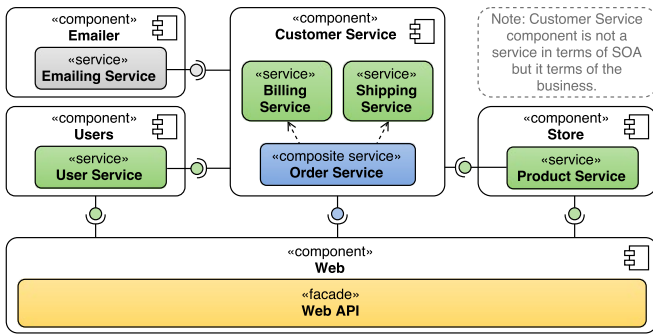

Fig. 1: E-shop design in conventional SOA

**Definition.** A composite service accesses and combines information and functions from existing service providers. [7]

SOA suggests a system infrastructure following the structure of the real business [4]. In consequence, when the e-shop has departments responsible for the store (products and stock) and customer service (orders), then these are also components [1], [7] in the system. The internal design of these components may differ based on their implementation. Properly implemented SOA emphasizes scalability and testability because it significantly reduces the complexity of services comparing to monolith applications [8]. On the other hand, it significantly reduces and complicates information reuse and enforces manual repetition instead, which easily leads to inconsistencies [3] and error-prone and expensive maintenance.

**Definition.** SOA is set of design principles organizing software components (services) around business capabilities and connects them through standard interfaces and messaging protocols. Each component is self-contained, black box for consumers, and exposes only its interface [7], [9].

Having the e-shop example from the previous section, Figure 1 presents the system architecture applying conventional SOA, more specifically Microservices<sup>1</sup> pattern. The *User*, *Store*, and *Customer service* components represent departments of the business with a *Web* service as a composite service implementing a user interface. The services interact through a RESTful protocol<sup>2</sup> [11]. We use this example as a reference later in this paper.

### III. CHALLENGES IN SERVICE-ORIENTED ARCHITECTURE

Decomposition of a system into these small units delivers much simpler design, evolution, and maintenance of both units and the system itself. Furthermore, the communication through a neutral environment such as HTTP protocol makes the services independent of a particular technology. That enables us

<sup>1</sup>There exist attempts to deprecate SOA due to poor implementation and many failed projects in past. However, the approach itself is general and there are more evolved specializations such as Microservices pattern [9].

<sup>2</sup>Microservices pattern suggests a use of a simple connection and smart endpoints [9], but we could also use more complex alternatives such as catalogs, service locators, and Enterprise Service Bus [5], [10]. It would be major overhead in this example plus conventional approaches highlight choreography over orchestration [8].

to develop each service in a different programming language and to use different frameworks. Next, the natural decomposition by the business structure clearly defines responsibilities of components, which supports agile programming [1], multi-team development, and rapid delivery. Unfortunately, there still remain some challenges we face. Among others, we address the following issues in this paper.

#### A. Composition of Business Rules

First, while decomposition brings clear design, the composition requires reuse of information from services it depends on. For example, *Order* composite service needs to know the model structure and the business rules of the underlying services *User* and *Product* to be able to validate incoming orders or even additionally transform and expose the rules to web API, e.g., for client-side validation necessary for a user-friendly user interface. However, distributed environment and possibly different technologies basically prevent the simple sharing. The model description can be exposed through API schema<sup>3</sup>, but reuse of business rules is very difficult even in monolithic applications [3], [14].

#### B. Business Domain Configuration

Business domain configuration is a special case of service composition. In an existing system, multiple services often need to share some configuration, for example, a VAT percentage or business hours definition. While the VAT computation could be extracted to a single specialized microservice, a specialized service determining whether now are business hours or not seems to be unnecessary overhead. Instead, shared simple configuration would be the much easier solution. Unfortunately, either we configure each service separately and have difficult maintenance due to information restatement, or we basically hit a special case of service composition; this is similar the reuse of business rules of a basic service configuring the domain. Neither way it is efficient and easily maintainable using conventional technologies.

#### C. Business Rules Maintenance

Having the business logic distributed into many self-standing services carries besides benefits also difficult evolution. When a change request occurs, we must manually update each affected service. The effort might be too high to make a small change such as an adjustment of business rules due to changes in the business domain. Unfortunately, there is no way to share the rules or update them in a batch.

#### D. Business Documentation Extraction

Finally, the overall system can get quite complex especially when the system is large or grows. Acquisition of current business documentation covering the services, their operations, model, and applied business rules is very challenging and often requires a lot of manual efforts. Extraction of this information from distributed systems is very limited.

<sup>3</sup>We may use SOAP with WSDL [12] or RESTful services optionally with controversial WADL [13].

In this paper, we present a novel adjusted aspect-driven design approach to fit SOA and distributed systems. The approach focuses on simplification of development and maintenance through the elimination of manual information repetition. Instead, it automates transformation, reuse, and re-statement of business rules, which enables us to provide an alternative and efficient solution to these challenges.

#### IV. ASPECT-DRIVEN DESIGN APPROACH

As we demonstrated in the previous sections, there are concerns in EISs, which are hard to effectively capture within SOA, e.g. business rules composition and maintenance. We call them *cross-cutting concerns* because they affect other concerns throughout the system. For instance, multiple services are affected by the underlying data model, or they are subject to a global business rule. By using conventional approach, these concerns usually get tangled into the underlying code in multiple points, making it hard to develop and maintain.

**Definition.** A *cross-cutting concern*, or *aspect*, is a system property which affects other system components by cross-cutting their functionality. [15]

Aspect-Driven Design Approach (ADDA) utilizes principles of Aspect-Oriented Programming [15] (AOP) to tackle problems introduced by cross-cutting concerns in monolithic EISs. It reduces information restatement through extraction of tangled concerns and their isolation in the single focal point [3]. The concerns are then automatically distributed throughout the system by aspect weavers at runtime. This leads to more efficient development and maintenance of such system, as well as it reduces the risk of human error, compared to manually repeated and tangled concerns. Furthermore, the concern distribution can be carried out across different platforms [16]. This helps us to use various technologies for individual modules while preserving the single point of truth.

ADDA uses Domain-Specific Languages (DSLs) rather than General Programming Languages to capture the cross-cutting concerns. DSLs are more efficient in describing domain-specific logic, as they are tailored for that particular domain while relaxing stress on generality. This reduces development efforts and enables domain experts to directly participate in the system development [17].

In ADDA, EIS is perceived as a multi-dimensional space [3], with the concerns as individual axes and the states of the system as points in such a space. The state of the system is determined by its current *execution context* and *business context* [18], e.g., a locale of the user, a business operation, and the current time. Based on the information from the current context, respective concerns are dynamically weaved together at runtime.

**Definition.** The *Execution context* is a complex information structure including information about the current Application context, User context, and operation parameters. [18]

**Definition.** The *Application context of EIS* is a set of global variables and their values at the current point in time. [18]

**Definition.** The *User context of EIS* is a set of information about the current user of the system. [18]

**Definition.** The *Business context* is a set of preconditions and post-conditions defined by a business operation. [18]

As we have established, ADDA simplifies separation of cross-cutting concerns through their description in DSLs and automated transformation and distribution from the single point of truth. Therefore, it reduces maintenance efforts through reduction of manual information restatement. However, this comes with a significant cost of initial investment, as the weavers and DSLs need to be implemented first. They are not project-specific and can be reused, though.

#### V. ASPECT-DRIVEN SERVICE-ORIENTED ARCHITECTURE

In SOA, composite services face to the challenge of limited inspection of business contexts, i.e., limited reuse of business rules declared by services they depend on. It results from difficult information extraction. In this chapter, we introduce modified service design to ease information inspection and exposition. That enables us to define all the information in the single point of truth and then automatically transform, reuse, and distribute it at runtime. Next, with runtime composition, we are able to consider current execution context and thus make the services context-aware. In order to apply AOP-based principles, we identify the cross-cutting concerns, i.e., the aspects, and formalize the challenge in terms of AOP.

**Note.** In this section, we demonstrate the concept on the e-shop system example described in Section II.

##### A. Formalization

First, we identify the *aspects* in the system:

- (i) *Business context* of a business operation defines *business rules* and *business domain configuration*. Operations of composite services often reference business contexts, or their subsets, from services they depend on. Consider the Order Service. For example, order creation validates the input also by the rules specified by the user creation operation in the User service. It also references business domain configuration of the Billing service, e.g., VAT percentage to properly compute the price.
- (ii) *Model structure*, or more specifically the structure of the model in the protocol, has to be always considered on both sides of the communication to serialize and deserialize the data. This aspect is usable for verification that both communicating services expect the same protocol structure and there are no inconsistencies.

Second, the *advice* represents the functionality to weave in:

- (a) *Business context preconditions* advice is a set of rules to meet before a business operation is executed, e.g., the user is logged in and has the required privileges.
- (b) *Business context post-conditions* are rules applied after a business operation is executed, e.g., data filtering based on the logged user's privileges or expected results.
- (c) *Business domain configuration* is part of the application context represented by a map of business domain-related

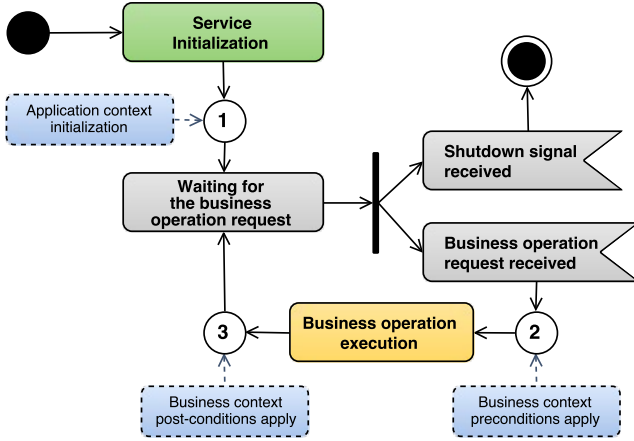

Fig. 2: Service life-cycle and application of the advice

variables used within a service, i.e., during rules evaluation or business logic execution, e.g., the VAT percentage.

- (d) *Model structure* advice contains information about the public business objects defined within each service, i.e., a name of the objects and name and type of each field.

Third, we identify the *join points*, i.e., the points, where advice is applied. Those are denoted in Figure 2:

- ① First join point triggers during *service initialization* when the service establishes its application context.
- ② *Before the execution* of a business operation, it validates preconditions of the addressed business context.
- ③ *After the execution* of a business operation, it applies post-conditions of the business context.

Finally, the *aspect weaving* combines all the advice into proper join points with the respect to current execution context. It is conducted by platform-specific *aspect weavers*, included within each individual service.

### B. Architecture

We modify the conventional layered architecture of a service [19] to accommodate the needs of runtime aspect weaving, as displayed in Figure 3. Each service separates the concerns and stores them in registries. This helps to decompose the system into smaller units with a single responsibility. On the other hand, it prevents simple reuse of such information as they are in platform-agnostic form outside the execution point. We apply ADDA to overcome this limitation.

First, the *business contexts* defined by operations of a service, e.g., access policies and order validation rules, are stored in platform-independent DSL in a *Business Context Registry*. Second, the *business domain configuration*, e.g., VAT percentage or business hours definition, is represented by a map of variable names and their values. Those are stored in a *Domain Configuration Registry*. Third, the *Model Structure Repository* maintains the metadata of the structure of its public model. Finally, in order to distribute the information among services, each service must expose its registers through a Meta API. Then other services access this API and retrieve the information they need.

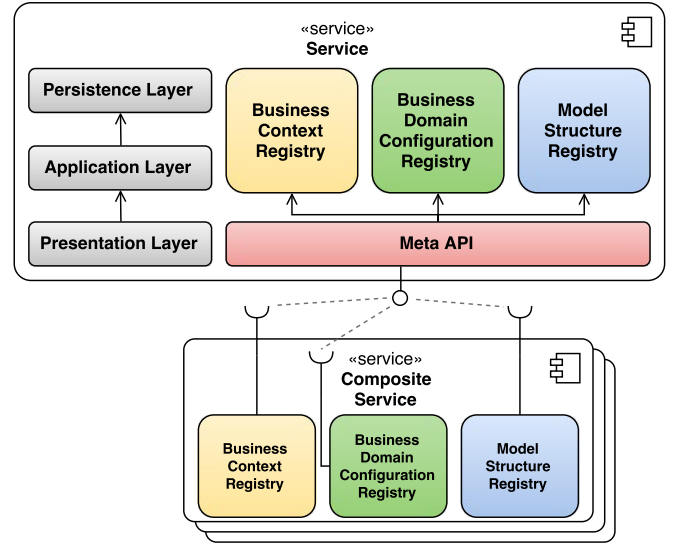

Fig. 3: Service architecture using ADDA for SOA

### C. Service initialization

When a service starts, it initializes its application context including environmental variables and all business contexts. In an environment with shared business contexts, the service must fetch addressed contexts and business domain configuration from services it depends on. For example, the Order Service requires business contexts and domain configuration defined by the Billing, Shipping, Product, and User services.

First, the Order Service discovers all the other services so that it can contact them. This could be achieved in different ways, depending on particular SOA implementation. For example, we can use Service catalogs or Enterprise Service Bus. For the sake of simplicity, we will not discuss this problem, because it is not relevant to the ADDA approach.

Second, the Order Service downloads the business domain configuration from its dependencies. As we have established, the domain configuration is a set of environment variables, so the service merges them into its application context straight away and exposes them in the registry.

Third, the Order Service downloads the business contexts from its dependencies. Then, it compiles them with its own business contexts. Finally, it inserts them into the application context in the platform-specific format, and into the registry in the platform-independent format.

Finally, it extracts the public model structure metadata and stores them within the Model Structure Registry. Then, it verifies the structure of the communication protocol comparing its own metadata to the metadata of the dependencies.

### D. Business operation execution

Once the service is initialized and running, it expects requests to execute business operations. For each business operation, there is a business context defining the preconditions and post-conditions.

First, when the execution of a business operation is requested, the aspect weavers intercept the request and check the current business context and validate the applicable pre-conditions of business rules with the execution context. For example, they verify the user is logged in. If the validation fails, the business operation execution is prevented, and the service returns an error message.

Second, when the execution of the business operation finishes, the aspect weavers intercept the response and apply the corresponding post-conditions to restrict the returned data. For example, they drop a link into the application backend when the user is not an administrator.

#### E. Summary

Application of ADDA into SOA achieves information reuse while keeps the concerns of each service separated. It maintains the business contexts and business domain configuration in platform-independent format within the individual services and exposes them to other services via API. This allows *easier composition of services*, where one service executes business operations of other services. The service it is able to apply up-to-date restrictions defined by the other services on its input.

This approach reduces overall development and maintenance efforts in the long run. We achieve this through reduction of manual information restatement and separation and reuse of the cross-cutting concerns, i.e., the business rules, the business domain configuration and the model structure. Having them in the single point of truth reduces the size of the codebase, as well as lowers the risk of human error because the restated information does not have to be synchronized manually, which is a highly error-prone activity.

On the other hand, this approach introduces significant initial overhead. It requires implementation of the aspect weavers and registers for each platform. However, these can be reused across services built on the same platform, and also across different projects.

### VI. CASE STUDY

In order to evaluate ADDA for SOA and receive a preliminary feedback, we conduct a case study and elaborate how we tackled the challenges discussed in Section III. Consider the e-shop system example introduced in Section II. There are six individual services, which provide different functionality. First, there is the *Users service*, which maintains both customers and employees, and their profiles and privileges. Second, there is the *Store service*, which deals with storage supplies. Third, the *Emailing service* sends e-mails to both customers and employees. Finally, the component *Customer service*, which includes the composite *Order service* maintaining orders, the *Billing service* providing API to the 3rd party billing services, and the *Shipping service* providing a facade to the 3rd party shipping services.

Consider the services are implemented using different technologies, due to the fact that there are multiple teams working on the system. Each team has different a experience and fulfills different non-functional requirements through the solution

stack. The *Billing*, *Store*, and *Emailing* services are implemented in Java, because of its reliability and performance. The *Customer* and *Order* services are implemented using Python, because it provides the best libraries for data analysis, and the company needs to analyze the orders to support business decisions. The *Shipping* service is written in server-side JavaScript, because it deals with various third-party APIs and JavaScript provides the most libraries for such tasks.

#### A. Business rules centralization

First, we implemented the *Business Context Registers* for each platform to persists business contexts and expose them through API. We also tailored a DSL similar to JBoss Drools<sup>4</sup>, which a powerful DSL for rule-based systems. We implemented the language in JetBrains MPS<sup>5</sup>, which is a tool designed for tailoring custom DSLs. It also provides a parser and a compiler into customizable output. This enabled us to define, store, and distribute business rules in platform-independent format.

Second, we implemented DSL compilers, which merge local and remote<sup>6</sup> business rules and translate them from the platform-independent format into platform-specific executable languages. Moreover, we implemented aspect weavers, which intercept the business operations and apply the business rules advice.

The composite Order service is now able to apply transitive business rules of the User, Billing, and Shipping services without their manual restatement.

#### B. Configuration centralization

As we stated earlier, the business domain configuration is a special case of service composition. We solved this problem similarly as the business rules centralization. We implemented the *Business Configuration Registers* for each platform. These registers store the configuration variables in a name-value dictionary and provide access to them through API. Then, we also added aspect weavers, which download and merge the business domain configuration from dependencies.

Alternatively, having more powerful DSL, we might declare the configuration as a part of the root business context, i.e., the parent context to all other contexts. Then, we could drop the Business Domain Configuration Registry and all related weavers as the configuration would be included in the Business Context Registry as another context. However, for simplicity, we maintain the configuration separately.

#### C. Documentation extraction

ADDA approach already provides a mechanism to extract an up-to-date business documentation of a monolithic system [20]. As all the services follow ADDA, we can also extract their documentation. Since each service exposes its metadata through public API, we implemented advanced documentation

<sup>4</sup><https://www.drools.org/>

<sup>5</sup><https://www.jetbrains.com/mps/>

<sup>6</sup>The business rules definitions are downloaded from Business Contexts Registers of services this service depends on.

generator discovering all services in the system and fetching their metadata. Then, similarly to pure ADDA, we combine the information together to identify the services, their operations and business contexts, their dependencies, and the structure of their public model, i.e., the structure of business objects. The generator implementation follows the suggestion for pure ADDA documentation generator, only it loops over all services and identifies their dependencies.

Having this documentation generator opens new possibilities. First, we can produce the result as HTML to overview the system and archive it or give it to the architects. We can also give it to domain experts to review and validate the flow and business rules. Having the overview of the entire SOA system significantly simplifies their work. Finally, we can produce the documentation in a formal language and then reason over it. For example, we can verify the feasibility of all contexts or find contradictions, which may result from the automated composition of business contexts.

#### D. Summary

We described the implementation of ADDA concept into SOA to reduce information restatement and simplify development of the system. Furthermore, ADDA for SOA opens new ways to use the extracted and exposed information, e.g., for automated business documentation extraction and its validation and verification. Unfortunately, the efficient implementation requires that all services in SOA follow ADDA for SOA concept. Otherwise, the concern reuse is significantly limited. Next, the concept implementation relies on complex tools as a DSL for business context description and platform-specific aspect weavers, which introduces a significant initial overhead. In consequence, migrating an existing system to ADDA for SOA concept seems to be highly challenging.

### VII. RELATED WORK

SOA is one of existing architectural solutions for large applications with difficult maintenance, performance issues, and multiple development teams. Deployment, composition, and maintenance of services belong among the most significant issues. In this paper, we propose a novel approach addressing composition and maintenance difficulties, and this section elaborates them in the context of existing work.

#### A. The architecture

Nowadays, SOA itself is considered outdated and replaced by a novel and more evolved approaches. Microservices pattern is the leading architecture replacing SOA [9]. However, this architecture preserves existing SOA principles and adds additional constraints addressing deployment and maintenance issues. For example, it emphasizes simple services and rapid delivery. Next, it suggests the use of multiple agile teams and service communication through an independent, usually HTTP-based, protocol such as REST and SOAP. Finally, it stresses decentralization through choreography [8], [21]. Contrary, plain SOA often uses orchestration, e.g., Enterprise Service Bus, which brings centralization.

Nevertheless, the basic principles persist and this work applies to them. The proposal expects distributed environment, independent standalone services, and communication through the network. Development workflow, service deployment or actual composition of services are orthogonal to the approach.

#### B. Service composition

There are two basic approaches to the service composition. First, the services are orchestrated in a network with a director validating and forwarding messages, or the services know their dependencies and somehow they look up them themselves [8]. While the first more centric approach is known as an *orchestration*, the other is known as a *choreography*. None of these actually apply to the proposed approach. Whether the services are discovered through a service registry such as Universal Description, Discovery, and Integration (UDDI) catalog, their addresses are hard-coded in services, or the configuration is provided by a central component is not significant [22]. The proposed ADDA for SOA approach assumes the existence of the dependencies but does not deal with the implementation of a discovery process.

Novel approaches to service composition often use Artificial Intelligence (AI) due to increasing number of existing services and their complexity [10]. There are these automated composition approaches as manually maintaining and evaluation the services is difficult and exacting. The proposed techniques use AI to optimize deployment of the services into a cloud to utilize the performance, to compose services together, to find the best implementation of the dependency etc. All these are performed based on the conducted analyses by an AI.

Each composition service has to consider at least a subset of the business rules declared by services it depends on, but unfortunately, none of these composition approaches efficiently supports the composition of business rules. There exist too many implementations of service description, discovery, and meta-data extraction techniques that it is nearly impossible to gather and reuse this information. Thus, in this work, we propose the approach focusing on reuse of business rules, which does not interfere with existing service composition approaches.

#### C. Business rules representation and composition

The major part of this paper deals with extraction, reuse, and composition of business rules within composite services. Inspection of dependencies and extraction of business rules requires suitable and inspectable representation of the rules.

Model-Driven Architecture (MDA) belongs among both major research and industrial approaches to SOA design. It describes the business domain in multiple models on different levels of abstraction to avoid manual information restatement and enable information reuse. The more specific models are generated from the more abstract models using transformation and forward engineering techniques. In the end, the service source code is produced [23]. Unfortunately, this technique suffers from the lack of support of backward transformation, i.e., when the more specific model is modified, we are

unable to propagate these modifications into more abstract models. Then regeneration of this model overwrites these modifications. In addition, MDA for SOA usually uses special languages with the better focus on services, service providers, etc., and lacks the support of business rules [24]. Unfortunately, the business rules with their cross-cutting nature are difficult to encapsulate in object-oriented techniques such as MDA [25]. Although there are options such as OCL to extend the models, but they are still unable to encapsulate and reuse repeated rules, they restate them manually instead [18].

Similar intentions as ours are discussed in [26]. The authors claim that business rules are often a subject of change, while implementation of services and SOA structure changes less frequently. Thus, then separation of concerns, more particularly business rules, leads to maintainable implementation. They propose a Business Process Execution Language (BPEL) [27] extension separating the business rules from services and declaring them using DSLs. As business rules are more about declaration what to do than how to do it, they introduce several new central meta-services dealing with business declaration, transformation, and business process interception to trigger actions. These services run rule-based engines to deliver high-performance rules evaluation. While this approach surely simplifies the maintenance, it has significant limitations. First, BPEL is designed for a centric orchestration, while recent research and best practices suggest decentralization through a choreography. Then, having DSLs simplifies maintenance comparing to hard-coding the rules into source code, but their further inspection and transformation is still difficult as there are multiple different languages. Finally, as the rules are part of the orchestration description in BPEL, then when they change, the whole orchestration must be updated. Contrary, our approach is more restrictive about used DSL, but it is agnostic to used composition method. Furthermore, when a single service changes, only the services depending on it are notified by a push event and then are internally reloaded.

The alternative approach focuses on identification of business contexts and reuse of business rules from dependencies [28]. The authors propose a framework for the construction of composite services. For each dependency service, they describe its API including business operations, their preconditions and post-conditions, which is a business context in terms of this paper. Then, using their framework, they produce a composite service considering the contexts of the dependencies. While the intentions are similar, this paper proposes more generic approach. Instead of the manual description of each dependency, it reuses their contexts through inspection of automatically exposed meta-data, which it does through separation of concerns using AOP.

#### D. Documentation extraction

Maintaining up-to-date business documentation of existing SOA is very challenging. SOA is vast living system and with many performed changes, the documentation gets quickly obsolete. Acquiring then up-to-date documentation is barely

possible, we must fall back to reverse engineering methods. Extracting the business documentation, i.e., the list of services, their operations with business contexts and a structure of communication protocol from SOA is basically like extracting it from a monolithic application plus dependencies.

Reverse engineering of monolithic applications is well discussed. For example, we may apply phrasal pattern matching on the source code to extract the rules [29] or construct a call-graph and look for branching [30]. Either way, we must identify the execution context, i.e., variables and their origin used in extracted expressions. Generation of such documentation is challenging and the result may be inaccurate depending on the technology and code conventions. Importance but the difficulty of business rules extraction from legacy information systems is discussed in [31]. The authors propose a semi-automated technique to extract the rules, but as it is obvious, such a documentation would require significant efforts, be inaccurate, and might not be up to date.

The difficulty of business rules encapsulation and subsequent automated extraction lies in their characteristic. As they are considered throughout the whole system, they cross-cut multiple layers, components, and often technologies. Unfortunately, commonly used Object-oriented programming fails in the encapsulation of such cross-cutting behavior [15], and tends to their manual tangling and duplication in a code base. Their separation is very difficult [25] due to the necessity to apply them in various places and technologies [3]. However, there exists an efficient documentation extraction technique for applications using ADDA to separate business rules [20]. Having business contexts described in DSLs and available for transformation, we are able to read this meta-data to construct the documentation. This technique applies to this paper. As we propose, each service uses some implementation of ADDA and exposes this meta-data through public API. Then, we are able to browse the SOA and fetch all meta-data to construct the documentation of the overall system.

## VIII. CONCLUSION

There exist many open challenges in SOA. For example domain decomposition, service discovery, composition, deployment, and evolution, or inter-team communication. In this paper, we focused on the separation of concerns and their reuse among composite services. We proposed a novel aspect-based approach ADDA for SOA. It introduces several new components into a conventional service architecture. They maintain separated concerns such as business contexts describing preconditions and post-conditions of business operations, business domain configuration, and the structure of the public model in the platform-independent format. These isolated concerns are exposed via API to other services. That enables them to fetch this metadata, transform them and combine with their own business contexts and configuration. The model structure is used for the verification of the communication protocol. Besides the simplification of service composition, we show the simplicity of generation of up-to-date business

documentation listing the services, their operations, preconditions, post-conditions, and the structure of the communication protocol, which often reflects the structure of business objects.

ADDA for SOA delivers significant maintenance improvement, codebase reduction, and context-awareness to services. It isolates business rules into the single point of truth in DSL and weaves the rules together at runtime with the respect to the current execution context. Use of DSL enables the involvement of domain experts into development. Automated distribution and restatement of business rules remove the need for manual synchronization of all places, which reduces maintenance efforts and lowers the risk of human error.

On the other hand, ADDA itself introduces significant overhead, as it requires design and implementation of the DSL, and platform-specific application-independent aspect weavers. In SOA, there are multiple programming languages and platforms involved, which increases the number of required aspect weavers. Development of the technological stack requires major efforts. Furthermore, all services in SOA have to follow ADDA for SOA concept, otherwise, no automated concerns composition and reuse can happen. Moreover, separation of concerns slightly reduces cohesion and thus maintaining the business rules apart of the related code is more demanding.

There is still work to do in future. Besides the need for the production-ready implementation, we will focus on delivery of larger evaluation of development efforts comparing ADDA for SOA to pure SOA or some its alternative. Finally, we will focus on design and formalization complex but easy to use DSL for business rules in SOA. There is the need for many features such as inheritance, rules modifiers, and declaration of constants. Use of ADDA for SOA also opens new possibilities. For example, having all metadata exposed via API, we are able to maintain business rules for all services from a single place, e.g., a maintenance application. We might visualize the relations, modify the rules, and then let the services update themselves and reload the configuration.

**Abstract**—Mutation testing of object-oriented programs differs from that of standard (traditional) mutation operators in accordance to the number of generated mutants and ability of tests to kill mutants. Therefore, outcomes of cost reduction analysis cannot be directly transferred from a standard mutation to an object-oriented one. Mutant sampling is one of reduction methods of the number of generated and tested mutants. We proposed different mutant sampling criteria based on equivalence partitioning in respect to object-oriented program features. The criteria were experimentally evaluated for object-oriented and standard mutation operators applied in C# programs. We compared results using a quality metric, which combines mutation score accuracy with mutation cost factors. In result, class random sampling and operator random sampling are recommended for OO and standard mutation testing, accordingly. With a reasonable decline of result accuracy, the mutant sampling technique is easily applicable in comparison to other cost reduction techniques.

## I. INTRODUCTION

FAULT detection ability of a test suite can be measured with assistance of mutation analysis [1]. After seeding a fault into a program, its mutated variant - a *mutant* is run against tests. If any test detects a changed behavior of the mutant, it is called to be *killed* by the test suite. Capability of a test suite to reveal faults introduced through mutations is expressed by a *mutation score* (MS). It is calculated as a ratio between the number of killed mutants and the number of all non-equivalent mutants. A mutant is said to be *equivalent* with the original program if its behavior is identical and none test case can kill it.

Faults injected automatically into a program are specified with so-called *mutation operators*. Standard (traditional) operators introduce simple changes in typical expressions of general purpose languages. According to experiments with thousands of mutants on several C# programs [2], standard mutation operators are not sufficient in dealing with flows in object-oriented program structures. Such flows can be served by OO and other specialized mutation operators.

The major drawback of the mutation method is its high cost because of executing many mutants against many tests. There are many approaches trying to lower the mutation cost that are based on decreasing a number of considered mutants [1], [3], such as mutant sampling, selective mutation, higher order mutation, mutant clustering, etc. However, due to different characteristic of object-oriented mutation, their benefits could be not necessarily as promising as for standard mutation operators. For example, mutation score accuracy for mutation operator selection was worse about few to 10% for OO operators in comparison to standard ones [4].

Therefore, we undertake research on cost reduction techniques with OO operators applied to C# programs, including mutant sampling. In mutant sampling, test runs are performed on a random subset of mutants [5]. The subset includes  $R\%$  of all mutants, where  $R$  is a parameter of the method (*sampling degree*). In the opposite to other mutant selection approaches [6], none of mutation operators is discarded. Apart from this simple sampling method, we proposed and experimentally investigated five other sampling criteria based on an equivalence partitioning according to OO program structure. The sampling results were evaluated using a quality metric [4] that approximates a tradeoff between the mutation score accuracy and the mutation cost in terms of mutant number and test number. A unified investigation process was used, which helps to compare results of different programs and different cost reduction methods, as mutant selection [4] and mutation clustering [7]. The main contributions of the paper are:

- proposal and evaluation of different sampling criteria,
- comparison of sampling in regard to OO and standard mutation operators,
- quality analysis of mutant sampling results based on the quality metric that concerns an impact of a number of mutants and a number of tests,

- preformation of comprehensive experiments on mutant sampling with C# programs.

This paper is organized as follows: the next Section describes mutant sampling methodology. Section III presents details about an experimental set-up and results of the experiments carried out. The final sections present related work and conclusions.

## II. MUTANT SAMPLING

In this section, we present methodology on which experiments were based: different criteria of mutant sampling, a flow of the investigation process, and how results are evaluated with a quality metric.

### A. Mutant Sampling Criteria

Mutant sampling was proposed by Acree [8] and Budd [9]. In a simple mutant sampling approach, a subset of mutants is randomly chosen from a defined set of mutants [5]. It will be referred as the first sampling criterion.

While taking into account a structure of an object-oriented program, different sampling criteria can also be proposed. The idea behind these sampling criteria is to divide a set of all mutants into disjoint partitions, i.e. equivalence classes. Then, random selection refers not to the whole mutant set, as in the fully random sampling, but some mutants are selected from each partition. In this way, each partition is represented in a reduced set of mutants. The criteria differ in the way such partitions are constituted. This general idea is analogous to the equivalence partitioning-based testing [10], in which selection of tests from different partitions assures a test coverage for all partitions. In this paper, the following sampling criteria have been investigated ( $R$  denotes a *sampling degree*):

1. *fully random* -  $R\%$  of mutants is randomly chosen from the set of all mutants,
2. *class random* - random selection of mutants is equally distributed for all classes, i.e. for each class  $R\%$  of its mutants is chosen,
3. *file random* - random selection of mutants is equally distributed for all files of the source code, for each file  $R\%$  of its mutants is chosen,
4. *method random* - random selection of mutants is equally distributed for all methods of the source code, for each method  $R\%$  of its mutants is chosen,
5. *mutation operator random* - random selection of mutants is equally distributed for all mutation operators, i.e. for each operator  $R\%$  of mutants generated by this operator are randomly chosen,
6. *namespace random* - random selection of mutants is equally distributed for all namespaces of the source code, for each namespace  $R\%$  of its mutants is chosen.

It should be stressed that the fifth criterion, *mutation operator random*, is not equivalent to the selective mutation [6]. In the mutant sampling according to this criterion, we

use subsets of mutants generated by each considered mutation operator; whereas in the selective mutation all mutants generated by specified operators are used and mutants of remaining operators are discarded.

### B. Investigation Process

The experiment under concern investigates influence of the sampling criteria and their parameter, i.e. an amount of percentage of chosen mutants, on mutation results.

A prerequisite of the investigation process is generation of all first order mutants for a given program using a considered set of mutation operators. This set of all mutants will be denoted as  $M_{All}$ . Afterwards, all mutants are run against all tests from a given pool ( $T_{All}$ ). Mutation results are referred as positions in a mutant execution matrix, where a pair  $\langle \text{mutant } m, \text{test } t \rangle$  evaluates to an outcome whether the mutant  $m$  was killed by the test  $t$  or not.

After having tested all mutants with all tests, we can determine a reference mutation score (a ratio of killed mutants to nonequivalent). This measure called here *original mutation score*  $MS_{orig} = MS(M_{All}, T_{All})$  is calculated using the mutant execution matrix. The value of  $MS_{orig}$  is treated as the most accurate  $MS$  of the process but obtained in the most costly way - using many mutants and tests.

### C. Minimal Test Sets

A research question is whether mutant sets reduced by sampling are efficient in assessing the quality of all tests. Therefore, using a concept of minimal test sets we refer results of reduced sets to those of all possible mutants. Minimal test sets have the same ability of killing mutants and its notion can be explained in the following way.

Let assume that  $M_X$  is a subset of all considered mutants  $M_X \subseteq M_{All}$  that satisfies the following condition: if all tests from a given test pool  $T_{All}$  are used, this subset determines the maximal mutation score  $MS_{Xmax} = MS(M_X, T_{All})$ . However, it could be possible to obtain the same mutation score using a smaller number of tests than  $|T_{All}|$  (where  $|S|$  states for the cardinality of set  $S$ ). A subset of all tests  $T_j \subseteq T_{All}$  is a *minimal test set* in accordance to  $M_X$  if evaluation of mutation results of tests from this set gives the maximum mutation score  $MS_{Xmax} = MS(M_X, T_j)$ . Moreover, this test set includes the minimal number of tests, i.e. none of its tests could be omitted. In further steps of the process, we investigate if such minimal test sets are able to kill mutants from the whole mutant set  $M_{All}$ .

In general, many different minimal test sets for  $M_X$  can exist giving the same mutation score. All minimal test sets can be effectively generated using the prime implicant of a monotonous Boolean function [11].

### D. Process Steps

After a mutant execution matrix has been evaluated, results for different sampling criteria and different sampling

degree  $R$  are calculated. The following steps are executed for a given pair of parameters (*criterion*,  $R$ ):

C1) Based on a given sampling criterion and a selected sampling degree  $R$ , a subset of all mutants is determined:  $M_{C1} \subseteq M_{All}$ . This subset includes all mutants (if  $R=100\%$ ) or a proper subset (for a lower sampling degree).

Then, we can calculate the mutation score that would be obtained running mutants from this subset against all tests from the considered test pool:  $MS_{C1max} = MS(M_{C1}, T_{All})$ . This mutation score will be called the *maximum mutation score* for the set  $M_{C1}$ .

C2) According to the maximum mutation score for the set  $M_{C1}$  we create a collection  $L$  that includes minimal subsets of tests sufficient to obtain  $MS_{C1max}$ . The collection contains all minimal test sets determined by  $M_{C1}$  or a limited number of such tests. A maximal cardinality of the collection - *TestSetLimit* is an experiment parameter.

C3) Mutation scores are calculated for each minimal test set comprised in collection  $L$  and the set of all mutants  $M_{All}$ :  $MS_{C3j} = MS(M_{All}, T_j)$ , where  $T_j \in L, j=1..|L|$ .

C4) An average mutation score is determined taking into account mutation results of all components of  $L$  calculated in the previous step. We also compute an average number of tests over all minimal test sets included in  $L$ .

D) The steps C1)-C4) are repeated many times with the same sampling parameters in order to get different random statistics. Using average values obtained in consecutive steps C4), the final average mutation score  $MS_{avg}$  and the average test number  $NT_{avg}$  are calculated over the number of sampling repetition runs.

Finally, the whole process is recalculated for other values of sampling parameter  $R$  and other sampling criteria.

All average values mentioned in the process description are calculated as an arithmetic average.

It should be noted that the process described in this section requires generating and running all mutants against all tests from a given test suite. However, the process is for research purposes. In a practical mutant sampling, only a subset of mutants is run against tests. Furthermore, not all mutants have to be generated. It is possible to generate a randomly selected subset of mutants according to a given sampling criterion. Moreover, this facility can be easily incorporated into existing mutation tools.

#### E. Metric-Based Quality Evaluation

Comparison of different approaches to cost reduction of mutation testing should take into account a tradeoff between benefits and possible shortcoming of a method. Benefits can relate to a lower number of mutants that have to be generated and run in tests. Another advantage could be a reduced number of tests used in test runs of mutants. However, application of cost reduction methods can cause decline of mutation score adequacy in comparison to the one obtained using all mutants and more tests. Therefore,

we proposed a quality metric [4] that can be adjusted for balancing these factors in study on cost reduction.

The metric depends on three components (Eq. 1). Each component is a normalized variable multiplied by a weight coefficient. The whole metric is a normalized sum of the components. Assuming a given sampling criterion, values of variables and the whole metric are normalized over their data set calculated for all values of a sampling parameter  $R$ .

$$EQ(W_{MS}, W_T, W_M) = I(W_{MS} * I(S_{MS}) + W_T * I(Z_T) + W_M * I(Z_M)) \quad (1)$$

The weight coefficients  $W_{MS}$ ,  $W_T$ ,  $W_M$  determine an impact of particular variables into the quality measure. The sum of coefficients must be equal to 1. A normalization function is denoted by  $I()$ . Three variables approximate the following measures:

- $S_{MS}$  - a loss of mutation score adequacy in an experiment,
- $Z_T$  - a cost decrease due to a reduced number of tests required for killing mutants in an experiment,
- $Z_M$  - a cost decrease due to a reduced number of mutants considered in an experiment.

The variables in mutant sampling experiments were calculated according to the following formulae (Eq. 2).

$$S_{MS} = MS_{avg} / MS_{orig} \quad (2)$$

$$Z_T = \begin{cases} 1 - (NT_{avg} / |T_{All}|) & \text{if } NT_{avg} > 0 \\ 0 & \text{otherwise} \end{cases}$$

$$Z_M = \begin{cases} 1 - (|M_{C1}| / |M_{All}|) & \text{if } |M_{C1}| > 0 \\ 0 & \text{otherwise} \end{cases}$$

Where symbols  $MS_{avg}$ ,  $MS_{orig}$ ,  $NT_{avg}$ ,  $T_{All}$ ,  $M_{C1}$  and  $M_{All}$  have the same meaning as in the process description.

While examining quality results with respect to different sampling criteria and different sampling degree  $R$ , we are looking for a “good randomization mode”. The idea behind this notion is selection of promising sampling criteria and values of  $R$  towards generalization of results. For a given sampling criterion, we can analyze the quality metric as a function of a parameter  $R$  and observe maxima of the function. A good randomization mode should meet two following requirements:

*Unambiguous maximum* - we would like to avoid two situations: first - when increase in the number of randomly selected mutants (increase in  $R$ ) gives the quality measure of the same high value (close to 1), and second - when there are several local maxima. The first situation would imply that taking more mutants we do not benefit in the mutation testing process. The second case corresponds to an ambiguous situation, where a quality measure does not monotonously depend on a sampling degree.

*Repeatability* - the maximum should be independent of a program. It means that quality metric  $EQ$  calculated for a given sampling criterion should reach its maximum within the similar range of parameter  $R$  for each project.

### III. RESULTS AND DISCUSSION

In this section we describe the experimental set-up and discuss outcomes of our mutant sampling experiments.

#### A. Experimental Set-up

Experiments were conducted on the following open-source C# programs corresponding to different software engineering tools:

1. Enterprise Logging.
2. Castle (modules Castle.Core, Castle.DynamicProxy2, CastleMicroCernel and Castle.Windsor).
3. Mono Gendarme.

The programs were companioned with unit tests. The tests were partially originated from the source projects and partially developed in order to improve code coverage. The basic complexity measures of the programs, the number of code lines and the number of classes and interfaces, as well as obtained coverage results are summarized in Table I.

The experiments were conducted using the CREAM tool (CREA<sup>T</sup>or of Mutants) devoted to mutation testing of C# programs [12],[13]. Apart from the support of the typical mutation testing process, the third version of the tool facilitates experiments on cost reduction methods [4]. The tool is extended with a wizard that assists in performing experiments on mutation operator selection, mutant sampling and mutation clustering. Having created all mutants and performed all test runs, the mutation results are evaluated according to a given investigation process. Then the quality metrics are calculated and analyzed.

The experiments have been performed and their results evaluated under to the following assumptions:

- *Mutation operators* - in experiments first-order mutants were created with use of all object-oriented (18) and all standard (8) mutation operators implemented in CREAM v.3, including all standard mutation operators proposed to be selective [6].

- *Covered mutants* - only mutants covered by tests were taken into account in evaluation of the mutation score. CREAM has an option to generate only covered mutants if required. We checked that none of uncovered mutant of these programs was killed by any tests from  $T_{All}$ .
- *Independent analysis for mutation operator categories* - evaluation of experiment results was performed independently for object-oriented and standard mutation operators. In the OO analysis, the set  $M_{All}$  corresponds to all mutants of a given program generated with all OO operators. In the latter case, all standard mutation operators are considered.
- *Sampling criteria* - experiment results were evaluated independently for six sampling criteria (Sec. II.A).
- *Sampling parameter* - for every sampling criterion, parameter  $R$  was equal to 5%, 10%, 15%, ..., 100% in consecutive experiments.
- *TestSetLimit* - the number of minimal test sets considered in each collection  $L$  was bounded by 15 sets (see step C2 in Sec. II.B).
- *Sampling repetition number* - for a given program, a selected sampling criterion and a given sampling parameter  $R$ , each sampling was repeated 10 times (compare point D in Sec. II.B).
- *Quality metric coefficients* - quality metric was calculated with weight coefficients  $W_{MS}$ ,  $W_T$ ,  $W_M$  equal to 0.6, 0.2, 0.2, if not stated elsewhere. These values are interpreted in the following way: mutation score accuracy amounts to 60% in the quality metric whereas the number of mutants and the number of tests amounts per 20% each (Sec. II.C).
- *Normalization* - metric variables  $S_{MS}$ ,  $Z_T$ ,  $Z_M$ , and the whole quality metric were normalized over the data set calculated for each sampling parameter value, i.e. 5%, 10%, 15%, ...100%.

During a preliminary step, all mutants were generated and run with all tests. The basic outcome of the mutation testing of the subjects is given in Table II. Mutants that were not killed might be equivalent, i.e. not to be killable by any tests, although CREAM tries to prevent from generating equivalent mutants. After manual examination some mutants were determined being equivalent. The last column shows the original mutation score  $MS_{orig}$  (i.e. covered mutants not recognized as equivalent divided by killed mutants). Those values were used as a reference in evaluation of mutant sampling.

#### A. Evaluation of Mutant Sampling Results

Evaluation of results stored in the mutant execution matrix was performed according to the investigation process presented in Sec. II.B. Experiment results are given in three tables (Table III, Table IV, Table V) for each considered project, accordingly. They present average mutation scores obtained for different sampling criteria and different values of the parameter. A mutation score was computed as

TABLE I.  
PROGRAM METRICS

No	LOC		Classes & Interfaces		Line coverage [%]
	with tests	without tests	with tests	without tests	
1	87552	57885	991	587	82

Sum	193276	124865	2622	1251	

TABLE II.  
MUTATION RESULTS

No, operator type	Generated covered mutants	Killed mutants	Equivalent mutants	Mutation score (MS <sub>orig</sub> ) [%]
1 OO	1341	558	438	61.8
1 Stand.	1683	1151	60	70.9
2 OO	1208	701	143	65.8
2 Stand.	2379	1611	60	69.6
3 OO	998	478	143	55.9
2 Stand	4153	3009	79	73.9

percentage of killed mutants versus all generated mutants  $M_{All}$ . Mutants were killed using minimal sets of test cases determined for randomly selected subset of mutants. The mutation scores given in the tables are average values calculated over all random runs  $M_{Savg}$  (p. D in Sec. II.B). Due to brevity reasons, only results for selected  $R$  values are shown in the tables.

Analyzing the mutation results in dependence of the random sampling degree  $R$ , we can observe that even a small decline in number of mutants ( $R=95\%$ ) resulted in the lowering of the mutation score. However, when numbers of selected mutants are considerably high, deviation of the mutation score from the original value is quite small.

We calculated quality metric  $EQ$ , which took into account not only the mutation score but also two remaining quality factors (number of mutants and number of tests). In general, values of the quality metric are small for the low number of selected mutants (low  $R$ ) because the mutation score is inaccurate. On the other hand, the quality is also not maximal (lower than 0.99) for the highest  $R$ , as in this case the number of mutants is the biggest. The tradeoff

between the quality factors is represented by the maxima of the quality results.

Quality metric flow in dependence of increase in the sampling parameter  $R$  is presented in the Appendix. The results of object-oriented mutation operators are shown in Fig.1-Fig. 6, and of standard operators in Fig. 7 - Fig. 12. For each kind of mutation operators, six diagrams are shown, which correspond to different sampling criteria. Three lines in any diagram represent different subject programs. In respect to the sampling parameter, the diagrams cover subsets of results, i.e. parameter  $R$  varies from 20% to 75% for OO operators, and from 15% to 60% in case of standard operators. The selected scopes of the parameter give a chance to observe maxima of the quality metric and consequently interpret the results.

Based on the idea of “a good randomization mode” introduced in Sec. II.C, we specify its requirements in a quantitative way:

*Unambiguous maximum* - we discard situations when  $EQ$  is of the same high value ( $>0.9975$ ) for the increase in  $R$  or there are several local maxima for  $EQ$  above 0.99.

**Repeatability** - Maximum of quality metric EQ (equal 1) calculated for a given sampling criterion should be similar for each project, i.e. the appropriate value of parameter  $R$  should be the same or differ only  $\pm 5\%$  of mutants.

Taking into account the above requirements, we analyzed the results independently for the object-oriented and standard mutation operators.

For OO operators, selection of mutants in a *fully random* way (1) or according to *namespace* (6) does not meet both requirements. The first requirement is also not fulfilled for the *file random* (2) and *mutation operator random* (5) criteria. Only the remaining two criteria, *class random* and

100	65.8	69.6	65.8	69.6	65.8	69.6	65.8	69.6	65.8	69.6	65.8	69.6

*method random* (3,4), meet both requirements of the “good” mode. Comparing these two criteria we have found that the *class random* criterion gave better results. For all projects, its quality value was maximal for the same lower sampling degree  $R=40\%$ . In case of *method random* the maximal  $EQ$  were calculated for higher number of mutants:  $R=50-55\%$  for different projects.

It appears that using mutant sampling as a cost reduction method of OO mutation testing, we should select 40% of mutants that could be generated for each class.

Examining the results for standard mutation (Fig. 7 - Fig. 12) we can observe that sampling criteria of *fully random* and *namespace random* do not meet both “good sampling” requirements, similarly as for OO operators. In addition, both criteria are also not fulfilled by the *method random* criterion. In case of *class random* the first requirement is not met.

Two criteria, namely *file random* and *mutation operator random*, gave results consistent with the requirements. However, the maximum of the quality metric was in the range of 35-40% selected mutants for the *file random* criterion, whereas about 30-35% for the *mutation operator random*. The second case required less mutants, therefore, the most beneficial results for standard operators could be obtained while sampling mutants according to *mutation operator* criterion with the sampling degree  $R=30-35\%$ .

Reduced number of mutants and tests indicates at the lower complexity of mutation testing. In order to compare effective benefits we measured real times of mutant generation and test execution. In Table VI, we compare times of all mutants and times of sampling with parameter  $R=35\%$  and *class random* criterion for OO mutation or  $R=30\%$  and *operator random* in case of standard mutation

operators, accordingly. Significant reduction in these times can be observed.

With respect to the average results for all investigated programs, it appears that sampling about 40% of mutants for each class for OO operators took 32% of time to generate the mutants. Mutation score was declined in 15% in reference to all mutants and all tests (85% of  $MS_{orig}$ ). It is possible to use only about 10% of tests to obtain this mutation score.

Mutant sampling gives better results for standard mutation operators than for OO. While sampling of 30% of mutants for each operator, the mutation score was equal to 93% of the original one. Mutant generation time declined in 70%. It would be possible to use only 15% of tests to obtain this result.

#### B. Threats to validity

The experiments were conducted on widely used, complex open-source programs, with 3-5 thousands of mutants per each. However, the conclusion validity can be limited by the small number of subjects. Moreover, only programs in C# were mutated. No detailed results are given for other OO languages, as Java or C++, although we could expect similar trends due to analogy in mutation operators.

The original tests associated with programs had insufficient code coverage; therefore, additional tests were developed. The code coverage did not reach 100% even with all tests. In experiments, only mutants covered by tests were taken into account. The calculation of MS can also be influenced by equivalent mutants, although the most of them was identified before the result evaluation.

The presented results depend on the coefficients  $W_{MS}$ ,  $W_T$ ,  $W_M$  of the quality metric. Therefore, the experiment

outcomes were recalculated for another set of weight coefficients. According to a new set (0.8, 0.1, 0.1), mutation score is a more dominant factor in the metric in comparison to the case discussed above. We obtained results that have corresponded to this interpretation. The quality measures were the best for the same sampling criteria as chosen above but for the higher sampling degree. The percent of sampled mutants was equal to 90-100% for OO operators and 60-70% for standard ones. For these coefficients benefits of lower number of mutants or tests are very small, especially for object-oriented operators.

Another factor that influenced the construct validity was the sampling parameter ( $R$ ). The experiments covered the whole scope of the parameter value (from 5% to 100%) with a small difference (per 5%). All calculations were also repeated ten times for different random sampling.

#### IV. RELATED WORK

There are different methods to reduce a cost of mutation testing. Many of them focus on reduction of mutant number, including mutant sampling [1][3].

Experimental evaluation on mutant sampling with 22 standard mutation operators in Mothra resulted in mutation score drop in 16% assuming 10% of mutants were fully randomly sampled [5]. Our results were different, as in the quality metric we took into account not only a drop in the mutation score but also efficiency factors. However, if we compare  $MS$  only, the results for standard operators applied for C# programs are for the first random criterion very similar, i.e.  $R=10\%$  gives 15% decline of a mutation score. With the same sampling degree but for OO operators  $MS$  decrease is substantially bigger - about 37%.

Other experiments have compared mutant sampling approaches to selective mutation of standard operators applied in C programs. Empirical results reported by [14]

point at the preference of selective mutation over the fully random one. The opposite is claimed in [15], in which two sampling modes were considered: fully random - called here one-round random, and two-round random (first a mutation operator is selected than a mutant within this operator). The results showed that random sampling methods can be as effective as those based on operator selection, but are more stable and predictable. The results of this comparison cannot be simply applied to OO operators. It is known that standard operators can generate much more mutants and many of them can be surplus, but there are less tests killing such mutants or the tests are not adequate to kill OO mutants [4], [16].

An approach that would be an alternative to selective mutation and mutant sampling was also discussed in [17], but it was only illustrated by simulation results. Moreover, assumptions behind the idea were more suitable to standard mutation operators than object-oriented.

Mutant sampling method was also beneficially applied in VHDL description [18]. The sampling criterion was similar to the mutation operator sampling, but the percentage of selected mutants was independently established for each operator.

Sun [19] explored mutant reduction based on a program structure and different strategies of path analysis. Experiments on C programs showed that the best strategies were more effective than the random selection technique preserving a sufficiently high mutation score. However, some other strategies did not outperform random approach.

All discussed above results were devoted to standard mutation operators.

Before the experiments with CREAM were conducted, to the best of our knowledge, no results of OO sampling were performed, and no cost reduction on mutation of C# programs was investigated. Experiments following the

similar process were developed for selective mutation and mutant clustering of C# programs [4], [7].

Experiments on mutant sampling on 8 Java classes were conducted by Bluemke [22]. Fully random sampling with the sampling degree ranged from 60% to 10% were examined. Randomly sampling 60% or 50% of mutants in Java programs gave significant reduction in the cost of testing with acceptable mutation score and code coverage decline. This result has been averaged on all kinds of mutation operators. No quality measures were considered.

Java program were also a target of experiments reported by Ma [23]. The weak mutation technique, in which intermediate program results are taken into account, was combined with mutant clustering, in which a mutant is selected among a group of mutants of similar behavior. Only selected mutants were completely executed to obtain the strong mutation results. The number of mutants was significantly reduced. However, the experiments were limited to simple programs and only several standard mutation operators. Hence, no data about object oriented mutation were given.

Object oriented mutation operators for C++ has been recently investigated in experiments reported by Delgado-Perez [24]. They considered also random selection of operators, but not mutant sampling.

Our study differs also from those of other authors in application of the quality metric that takes into account not only a drop in mutation score but also efficiency measures - numbers of mutants and numbers of tests. The metric applied in experiments was proposed in [4], and used also in other experiments reported in [7].

Other metrics to mutation testing quality were discussed by Ester-Botaro in [25]. Some of them were an extension of a effectiveness metric previously proposed by one of the authors. They discuss quality of mutant and operators in order to omit those of a low quality. However, these metrics do not evaluate a cost of a mutation testing process.

Another approach has been recently investigated in [26], where mutation adequacy score was estimated taking into

account several object-oriented metrics, which capture the structural complexity of a program.

## V. CONCLUSION

The empirical study presented in this paper confirms the tendency that OO mutation operators undergo different characteristics than standard operators and therefore may require slightly different methods of cost reduction.

Moreover, the benefits of the methods previously studied for standard operators are lower in case of OO ones, probably due to a lower number of generated and unnecessary mutants.

Using the sampling approach, we can achieve some lowering the number of mutants and tests but also obtaining a relative decrease in mutation score accuracy. For the selected tradeoff, the mutation score was about 93% of that obtained with all mutants and all tests using standard operators, and about 85% for object oriented ones.

Comparison of mutant sampling of C# programs with other "do fewer" methods, such as selective mutation [4] and mutant clustering [7], does not support one definite leading method. The number of mutants and tests was lower for mutant sampling than for selective mutation and similar to those of clustering. On the other hand, the mutation accuracy was lower than in those methods. However, all differences are about few percent and could also be treated as a measurements' deviation. Moreover, sampling methods are superior because of their stability and simple implementation. Mutant clustering is computationally expensive, whereas selective mutation, especially in respect to object-oriented operators, is not so decisive and can depend on a program [4], [16].

The lessons learned is that instead of fully random sampling we would recommend to use different sampling criteria: *class random* for object-oriented operators and *mutation operator random* for standard ones. Both criteria can be easily implemented and both were the best for different tunings of the impact factors in the quality metric.

The percentage of selected mutants depends on the preferred tradeoff between mutation score decline and the efficiency measures (number of mutants and number of tests). For the ratio 6:2:2 of these three components the suggested sampling degree is about 40% for object oriented operators and 30-35% for standard ones.

It should be noted, that in practice, the number of mutants could be not the most important cost factor. Overall time of mutation testing is also strongly influenced by the number of tests to be performed. Therefore, comparing a process quality we should take into account different factors, as in the quality metric applied in the paper.

Concerning C# programs, improvement in mutation testing efficiency is provided by code mutation at level of the Common Intermediate Language of .NET. Another tool

TABLE VI.  
BENEFITS OF MUTANT GENERATION TIME AND TEST EXECUTION TIME  
FOR MUTANT SAMPLING

R [%]	Time of mutant generation (including compilation) [h:min:sec]		Time of test execution [h:min:sec]	
	All	Sampling	All	Sampling
1 OO	06:26:11	01:48:39	06:32:37	00:09:09

**Abstract**—Similar documents arise in software and business domains. Examples are user guides for different versions of a software product, contracts between vendors and clients, or legal documents. The usual practice is to capture common document formats and contents in templates that must be manually customized to a new context – often a slow, tedious, and error-prone process. We propose a method based on a proven approach developed for software reuse that simplifies and automates routine tasks involved in creating and updating families of similar documents. Our Document Management Environment (DME) provides functions to create templates capable of higher levels of document contents reuse than templates supported by word processors such as MS Word. DME allows users to designate any arbitrary document part as a template’s variation point that can be customized to produce a specific document. DME automates document production by syncing inter-dependent customizations occurring at different variation points. The paper describes two “proof of concept” implementations of DME as Word add-in: The first one uses Content Control mechanism and is specific to MS Word. The second one is based on ART (Adaptive Reuse Technique), a general text manipulation method and tool, and can be used to manage similar documents in any editor that provides an access to the internal representation of documents.

**Keywords:** Documentation, Reuse, Productivity, Document Generation, Templates

### I. INTRODUCTION

Document Management Environment (DME) facilitates and automates reuse of documents written in WORD. DME is useful in Software Product Line (SPL) engineering [1], where we manage a family of similar software products from a common set of reusable SPL core assets such as SPL architecture shared by products, source code components, documentation, test cases, etc. SPL core assets help developers build a custom product. They play the role of templates that are reused after suitable adaptations to derive custom products. All the SPL members are similar, but each one also differs from others in client-specific features. The impact of features shows as many changes that must be applied throughout the product code and documentation.

Creation and evolution of documentation for SPL members involves much repetitive work. Developers can benefit from reuse of software documentation just as much as they benefit from reuse of other SPL assets. For example, User Guides for different SPL members are similar, but also different. The

differences in User Guide versions reflect product-specific variant features implemented into some custom products, but absent from others. With understanding of commonalities and differences among User Guide versions, we can design documentation templates from which to derive custom User Guides for specific products.

Document versions typically share common structure with possible variations such as optional sections. Various document fragments may recur in variant forms in many places, within and across documents. The usual practice is to capture similarities in templates that must be copied and manually customized to create new document versions. Templates of word processors such as MS Word support reuse of text “as is”. However, in reality, templates must be extensively adapted to form a new document version by changing, adding or deleting text fragments. Such adaptation is weakly supported by templates of word processors known to the authors, which often hinders documentation management, making it a slow, tedious, and error-prone process.

Our proposed approach to managing families of similar documents overcomes this limitation, providing means for flexible and semi-automated adaptation of document templates. DME automates routine tasks involved in creating and updating similar documents. The goal is to boost document management productivity.

The challenge of managing a document family is to understand what’s common and what’s different among document versions. The differences between any two documents (irrespective of the degree of their similarity) can be trivially expressed as a sequence of text addition/deletion operations that applied to one document produce the other one. However, such a simple-minded perspective on document differences poorly addresses human-cognitive aspects of document management. In the course of empirical studies, we identified seven basic document variation types that collectively provided a basis for building powerful document templates that are easy to grasp and could be adapted in flexible ways to form document versions (Section IV). DME provides seven text manipulation operations that handle these basic document variation types such as parameter instantiation throughout the documents, selecting text from a list of options, inserting or deleting text at designated points in documents, or repeatedly generating custom text according to a specified template. DME automatically propagates custom changes across templates in

the process of creating new document versions or in updating existing ones. Our intention was to minimize the need for manual customizations of templates, hoping to reduce effort involved in managing documents.

Given popularity of MS Word, we decided that our “proof of concept” implementation of DME would help users manage families of MS Word documents. DME extends the concept of MS Word templates and styles, to provide better controls over reuse of document structure, contents and formatting. We implemented DME user interface as an MS Word add-in.

We considered two different strategies for manipulating the internal representation of MS Word documents. The first strategy used the Content Control API. This solution was straightforward, however it was specific to Microsoft technology. In the second solution, we demonstrated how the seven basic operations could be implemented in any editor providing access to its internal textual representation of documents. For that we applied a general-purpose mechanism of ART (Adaptive Reuse Technique, <http://art-processor.org/>) that we developed and used as a variability management technique for software reuse. We demonstrated how the seven document variation types could be expressed in ART and illustrated document management with an example.

We believe our proposed solution to document management will be particularly useful in any software or business domain that involves large volumes of related documents, with many

repetition patterns, and detailed variations propagating across documents in complex ways. DME complements capabilities of commercially available document generation systems.

In Section II, we set our assumptions regarding the document management process and explain the role of DME in that process. We introduce a working example in Section III. We discuss basic document variation types in Section IV. In Section V, we present users’ perspective of DME implemented as a Word Add-in, and in Section VI we comment on implementation of DME. Section VII illustrates salient features of a general-purpose text manipulation method and tool ART. Discussion of future work, related work and conclusions end the paper.

## II. APPROACH AT A GLANCE

The lifecycle of DME-supported documentation processing fits into the usual SPL lifecycle, with two major phases, namely *Domain Engineering* and *Product Development* (Figure 1). *Document Architect* (or Senior Clerk) analyzes similarities and differences among subject documents (e.g., User Guides for some products), and uses DME to create a template based on text that recurs in documents in variant forms. Templates are richly parameterized, to let our tool manage document variability and reuse at coarse- and fine-granularity levels.

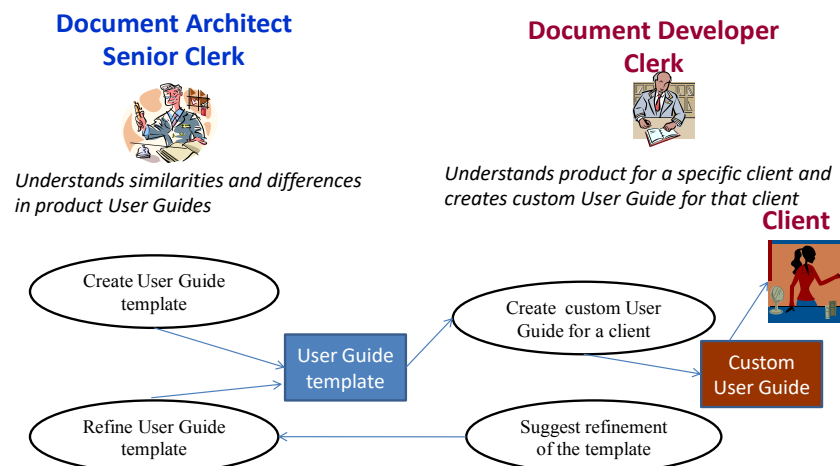

Figure 1. Managing User Guides with DME

To create a template for User Guides, we start with a User Guide for a typical product. We designate various document fragments – words, sentences, paragraphs, sections – as *variation points* that can differ from the sample document. We can also control each variation point’s characteristics, such as its format and repeatability. DME converts this annotated document into a User Guide template that we then use to generate User Guides for other – similar but also different – document variants. All variation points in a DME template are formally inter-linked which allows DME to propagate customizations within and across documents.

*Document Developer* uses DME to customize templates and generate custom documents from them. DME propagates custom changes across documents, streamlining and automating customizations (adaptive reuse) of document variant parts. Customizations defined for one User Guide can be easily reused in creating other User Guides.

## III. A WORKING EXAMPLE

Project Collaboration Environment (PCE) is a web portal supporting software development teams in project planning and

execution. PCE facilitates sharing of project information within and across teams. In particular, PCE allows users to create and maintain records of domain entities such as projects, staff, tasks and relationships among them (e.g., tasks assigned to staff).

Suppose we developed a PCE for the mass market. There will be many PCE versions in use. All such PCEs will be similar but will also differ one from another depending on the team size, development style, and other project- and team-specific details.

A User Guide for PCE describes how to Create, Edit, Delete Staff, Project, or Task records. User Guide contains Staff-Section, Project-Section, Task-Section and in each section

descriptions of relevant operations (Figure 2). The actual lists of domain entities (Staff, Project, or Task), their respective operations and the details of operation description may differ across PCEs, and those differences must be reflected in User Guides.

In the same way as PCE portals form a family of similar but also different portals (that might be supported in reuse-based way using a Software Product Line approach), PCE User Guides form a family of similar, but also different documents that could benefit much from reuse.

### PCE for Agile Development: User Guide

Project Collaboration Environment is an integrated environment that supports project teams in software development. PCE stores staff, project data, facilitates project progress monitoring, communication in the team, etc.  
The following sections provide detail description of operations for domain entities supported by PCE.

#### Staff Section

This section describes operations to manage Staff information in a Project Collaboration Environment. A Staff profile contains the following information:

Name: Full name of Staff

...

##### Create a new Staff

Create operation allows users to add new staff data to PCE. Once added, this new information can be manipulated by using Edit, Delete or Display operations.

##### Edit Staff information

Edit operation allows users to edit staff data. Once edited, this new information can be manipulated again by using Edit, Delete or Display operations.

##### Delete Staff record

..

##### Display Staff information

..

Sort Staff

..

Print an individual Staff

## IV. DOCUMENT VARIATION TYPES

We analyzed families of similar documents such as User Guides to understand how we could capture their commonalities and differences in an intuitive way, leading to templates that would be both powerful in terms of reuse and easy to grasp for users. Differences among documents look ad hoc at first, but after analysis and conceptualization we decided that the following seven basic document Variation Types would help us achieve the goal:

*Comment:* Below, a ‘fragment’ means any arbitrarily selected segment of contiguous text in a document such as word, sentence, paragraph, section, or any part of them.

VT 1. *Parametric variations:* A parameter has the same values within a given document, but may have different values across document versions. Examples: date, section name, syntactic variations: for example spelling (English or US), whether or not

we put “,” before “and”, etc. Parameters become placeholders in document templates.

VT 2. *Selection variation:* This kind of a difference among documents happens when at a specific point each document version should include one or more pre-defined fragments (options). Such variation point is represented by a selection construct in a template that allows the required options to be selectively included into document versions.

VT 3. *Extra fragment:* It is a fragment that appears in only small number of documents. An extra fragment may recur in many places in each of such documents. Such fragments must be also parameterized, as each of its occurrences may differ from other occurrences (in the same or in different document versions). Extra fragments do not become an integral part of templates, instead, they are included into documents when they are needed.

VT 4. *“Almost common” fragment*: It is a fragment that is a part of most (but not all) of the document versions. An “almost common” fragment may recur in many places in each of such documents. “Almost common” fragments must be parameterized. Unlike “extra” fragments that need be included on demand in small number of documents, “almost common” fragments become template defaults, simplifying template customizations. As extra and “almost common” fragments require different treatment during document management, they are distinguished as separate Variation Types.

VT 5. *Repeated section*: A section that recurs a number of times in a given document. Such section may recur different number of times in different documents. Repeated sections must be also parameterized.

VT 6. *Formatting variations*: A fragment that can be formatted using different font type or color in different documents.

VT 7. *Linked documents*: Large documents can be decomposed to parts that are stored in separate files. A link can be placed in a template to show how documents should be composed together. Document composition rules may be different for each document being generated from a template.

Each variation point in a DME template (i.e., a point at which a template can be customized) corresponds to one of the above document Variation Types.

## V. HOW DME WORKS

DME provides seven text manipulation operations corresponding to seven basic Variation Types. In DME interface implemented as an MS Word add-in, these seven operations are accessed via menu buttons shown under “Document Management Environment” toolbar (from “Parameter” to “Link” in Figure 3).

Figure 3. DME menu extending MS Word toolbar

During template creation, these buttons allow a Document Architect to create templates. The same buttons are used by Document Developer to create custom documents from templates.

### A. Creating a User Guide template

As a Document Architect (Figure 1), we must first comprehend variability in a document family such as User Guides, i.e., identify common and variant document parts. Common parts become “frozen” in a template, while variant parts become *variation points* at which template can be customized.

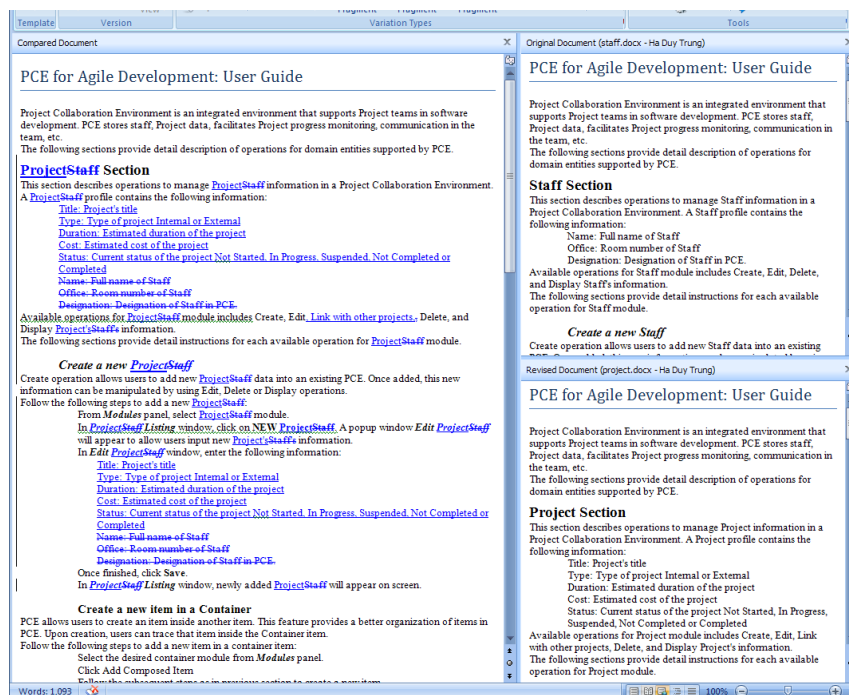

Figure 4. Staff and Project sections compared

The best is to start building a template from a “typical” User Guide, i.e., the one that is “most similar” to other User Guides. Such a User Guide already contains much of the common text that can be reused among User Guides, and also a considerable

number of variant texts. The right choice of a User Guide simplifies template creation.

Terms “typical” and “most similar” are not easy to formalize, and our current approach to identifying a typical document is

rather informal (we hint at better approaches to identifying typical documents and creating templates in Section VIII on Future Work): We run MS Word's *Compare* function on existing User Guides. Differences highlighted by MS Word are candidates for variation points in a template. Of course, we should add more variation points to accommodate variant text found in yet other sections and in User Guides for yet other PCEs. Figure 4 shows common (normal font) and variant (shaded font) parts in Staff and Project sections.

Suppose we observe that sections for Staff, Project, and Task are similar to each other. We could choose to create a Section-Template first. The advantage of creating Section-Template is that Sections recur (and therefore Section-Template can be reused) within a User Guide for one PCE, as well as across User Guides for different PCEs.

At each variation point in a template we define a default value which DME uses when generating custom documents unless the

user overrides the default values. DME function "Toggle View" toggles views between variation point names and their default values. Figure 5 shows a Section-Template with variation points highlighted by DME in different colors.

To convert Staff Section into a Section-Template, we position cursor on fragments highlighted by MS Word as different and click on suitable DME button to turn variant text into a template parameter – a variation point at which template can be customized. For example, we turn 'Staff' into parameter sectionName (VT1), and then qualify other document variant fragments as selection (VT2), extra fragment (VT3) or almost common fragment (VT4). Each of the above actions creates a variation point that DME highlights in different color, depending on its type. DME propagates variation points across a document using Find-Replace buttons.

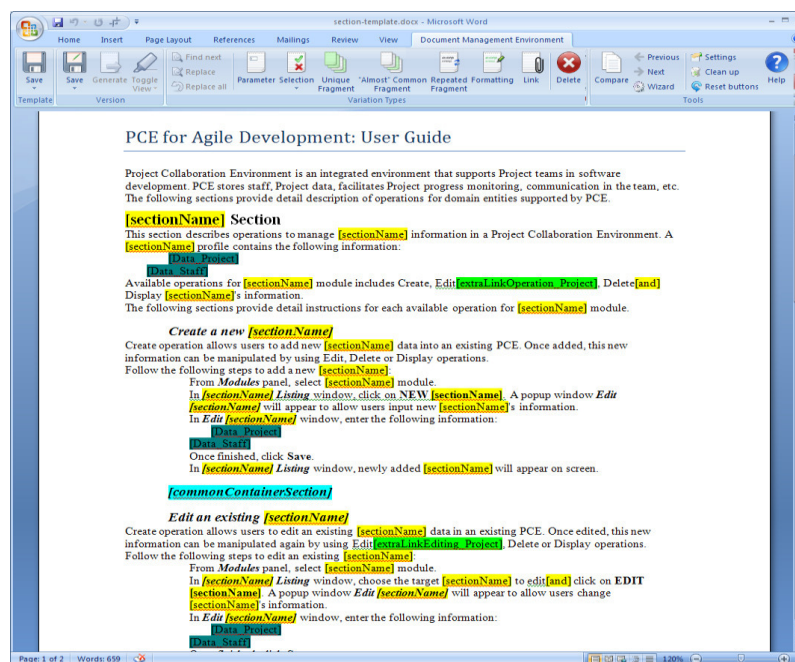

Figure 5. Section-Template created with DME

### B. Creating new User Guides from templates

A Document Developer can customize templates to create User Guides. This is done by overriding default values at template variation points. Whenever this happens, DME automatically propagates new values to all the other relevant variation points in the current template and all templates linked to it. DME rules for propagating values across documents are carefully designed to maximize template reuse and to simplify template customization. DME function "Toggle View" toggles between template view (showing variation point names) and custom document view.

Still, template customization can be tedious. Sometimes, it may be better to start with an existing User Guide that is most

similar to the one we want to create. We can now ask DME to show this document in a template view. This will show all the variation points in the document, with values assigned to them during document creation. We can accept values that suit us (no action required for that), and override the remaining values.

### C. Extra DME features

Document fragments that recur many times should be reusable, after suitable customizations. Domain Engineer should place such reusable fragments in separate templates for inclusion with 'Link' DME button and function. DME traverses all templates linked together to compose a custom document during document generation. Any customizations are propagated to linked templates, making it possible to

consistently instantiate templates in many different ways, depending on the context.

The ability to Link templates and to propagate customizations via links during document generation is critical for scaling the DME approach. Often, many inter-related documents (e.g., a User Guide and Technical Manual) need be customized in sync one with another. Similar document fragments may spread through such documents, even though each document may be derived from different master templates. Common fragments can then be customized and included in variant forms in these documents via ‘Link’ connection.

We presented DME as an interactive tool in which Document Developer enters customizations via DME user interface. However, it is also possible to import customization data from a file, database or from other tools that understand document variability.

## VI. COMMENTS ON TWO IMPLEMENTATIONS OF A TEXT MANIPULATION MECHANISM IN DME

A key question now is how to implement text manipulation operations corresponding to seven Variation Types described in Section IV. We implemented DME’s internal text manipulation mechanism in two ways, using MS Word Content Control API, and a general-purpose variability management method and tool ART (Adaptive Reuse Technique, <http://art-processor.org/>).

Since *Microsoft Office 2007*, Microsoft introduced XML-based file format *Office OpenXML* for MS Office documents. Developers can programmatically manipulate documents via APIs, and enhance MS Word with new functions (Word add-ins). Content Control API released by Microsoft provided a convenient set of operations for text manipulation for our purpose. Content Control API allowed us to treat document fragments as objects, and associate tags and other meta-data with them. Content Control was giving us good control over variation points in an MS Word document. Protecting the text contained at variation points from accidental changes was not a problem either. For better performance, we implemented Document Variability Management (DVM) engine in C#, using

Visual Studio Tools for Office 4.0. DVM engine provided us with text manipulation primitives sufficient for implementing DME functions. It took five person-months to develop DME as an MS Word add-in. This effort also included brainstorming and formalizing DME requirements.

The reason why we considered yet another method to handle text manipulation operations in DME was to demonstrate that our proposed approach to document management could be applied in any text editor that allows users to access its internal textual representation of a document under editing. ART is a general-purpose variability management technique that works with any information represented in textual form. Document parts are instrumented with ART commands to form highly parameterized, adaptable templates. Each of the seven Variation Types discussed in the last section could be handled with proper combination of ART commands (the reader will find details in Section VII.A). This was not surprising as ART was designed to handle much more complex variability situations.

We kept ART commands in comments embedded at designated variation points in a document. Using OpenXML API, we could extract the document text and pass it to ART Processor for executing commands. The actual variability processing with ART was completely hidden from DME users. It took six person-months to develop DME prototype in ART. This effort included the time to learn ART.

We concluded that both MS Word Content Control and ART were viable strategies for text manipulation required in reuse-based document management.

## VII. MANAGING DOCUMENT VARIABILITY IN ART

Here are general rules: ART templates contain document text parameterized with ART commands. ART Processor reads templates, and outputs custom documents. ART commands are interpreted, while text is emitted to the output as is. The processing sequence is defined by ART commands. Required customizations related to the seven Variation Types are defined in the specification file called SPC which is also a start point for processing.

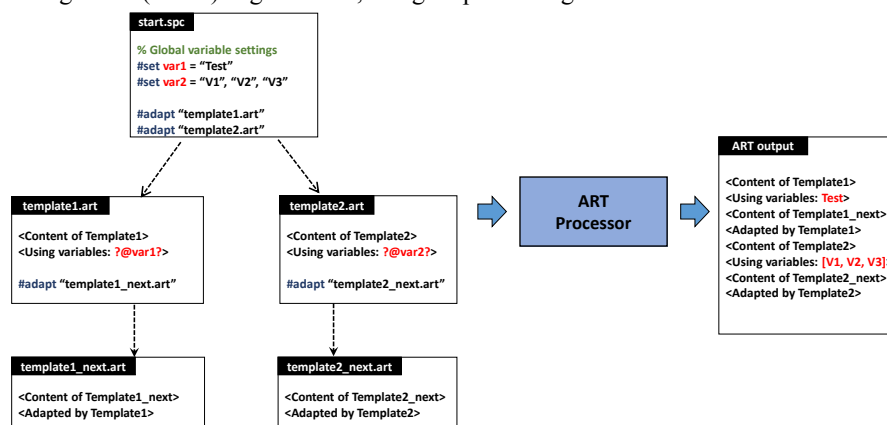

Figure 6. Processing of ART templates

ART commands in SPC, and in each subsequently processed ART template, are processed in the sequence in which they appear. When ART Processor encounters **#adapt** *f2* command in template file *f1*, it suspends processing of file *f1* and starts processing file *f2*. Once processing of file *f2* is completed, ART Processor resumes processing of file *f1* just after **#adapt** command. In that way the processing ends when the Processor reaches the end of the SPC.

Figure 6 illustrates the sequence of processing ART template files. On the right-hand-side side of the figure we see the output emitted by ART Processor after processing the files starting from SPC file and moving along the **#adapt** links.

Variables can be assigned values with **#set** command, and **?@name?** retrieves their value. Values of the variables propagate to the adapted files.

#### A. Document Variation Types in ART

In this section, we describe how we can express in ART the seven Variation Types discussed in Section IV.

#### VT 1. Parametric variations

ART variables handle parametric document variations. Command **#set** **SectionName** = "Staff" defines variable **SectionName** and initializes it to "Staff". **?@SectionName?** refers to the value of that variable. ART Processor emits variable value to the output file (Figure 7).

```
#set SectionName = "Staff"
...
?@SectionName? Section
<Section template text>
```

Figure 7. Sample ART template tempSection.art

Typically, variables are set in SPC and ART Processor propagates their values down to all adapted files. Suppose there is a command **#set** **SectionName** = "Project" in SPC that adapts tempSection.art. Then, ART Processor would emit text "Project Section". Otherwise, should there be no **#set** **SectionName** = ... command in SPC, ART Processor would emit text "Staff Section", as a default value. This way of handling variable values propagation allows ART Processor to emit document variants from the same templates. This is also illustrated in Figure 6.

#### VT 2. Selection

ART command **#select** - **#option** works in a similar way as switch statements in programming languages. **#select** lets us select one of the many variant parts that should be included at a designated point in a document.

```
#select SectionName
  #option "Staff"
  <Extra section(s) for Staff>
  #endoption
  #option "Customer"
  <Extra section(s) for Customer>
  #endoption
#endselect
```

In the above example, if the value of **SectionName** is "Staff", ART Processor emits the content of the first **#option** to the output document; otherwise if the value of **SectionName** is "Customer", ART Processor emits the content of the second **#option**.

#### VT 3. Extra Fragments

Extra fragments are managed by ART commands **#insert** into **#break**. ART Processor emits to the output document fragments or sections contained in **#insert** at points designated by matching **#break** in templates. Matching is done by names associated with **#insert** and **#break**. There are three variations of **#insert** that append, prepend or replace the content marked with matching **#break**.

SPC Staff file:

```
#set SectionName = "Staff"
#adapt: "sectionTemplate.art"
  #insert: "additional_content"
  <Staff extra fragment content>
#endinsert
#endadapt
```

sectionTemplate.art file

```
<template content>
#break "additional_content"
```

In the above example, ART Processor emits extra fragment for Staff when processing **#break** "additional\_content", ignoring any text contained in **#break**.

#### VT 4. "Almost common" fragment

Text in **#break** is a default output in case there is no matching **#insert** for a given **#break**. So "almost common" fragments are conveniently handled by making them **#break**'s defaults. In cases when the "almost common" fragment should be omitted (or replaced by other fragment), we place a suitable **#insert** matching the **#break** in SPC.

#### VT 5. Repeated section

ART command **#while** iterates over its body a predefined number of times emitting output accordingly.

```
#set SectionName = Staff,Project,Task
#while SectionName
  #adapt "PCE_UserGuide.art"
#endwhile
```

SectionName is a multi-value variable, and **#while** iterates over its values adapting template PCE\_UserGuide.art each time in different way.

#### VT 6. Formatting variations

We can use ART variables or selection to handle formatting variations.

#### VT 7. Linked Document

If we wish to split large documents into parts, then we use command **#adapt** to compose the whole document from its parts.

In creating of ART templates, we could address any conceivable differences among documents with a single operation such as **#select** or **#insert**. The reason why we have

seven DME operations is to let the user intuitively think about document differences in terms of the seven Variation Types and map them to DME operations. Also, from our experience with using ART we know that by skillful use of these seven operations ART templates are much simpler than if we tried to address all the document Variation Types with a smaller number of operations.

### B. User Guide Template

Document Architect creates templates using DME interface, for which she does not need to know ART or internal representation of Word documents. Document Architect's view of a template is shown in Figure 5. Figure 8 shows an internal

representation of a template and SPC to create the *Staff User Guide* (Figure 4). Our templates and SPC are written in Rich Text Format (RTF) parameterized with ART commands. Consequently, ART Processor also emits RTF documents. The choice of the format is irrelevant to our ability to parameterize document with ART commands. However, RTF makes text manipulation easy, as the whole document including formatting is defined as a text file.

Document Developers define the required customizations via DME interface, from which DME generates an SPC. The internal representation in RTF instrumented with ART is not easy to read, but it is hidden from users, generated and manipulated by DME user interface operations.

SPC:

```
#set SectionName = "Staff"
#adapt "PCE_UserGuide.art"
```

PCE\_UserGuide.art:

```
{\rtf1\ansi\deff0 \fs20 {\fonttbl {\f0 Times New Roman;}}
{\pard\sbl20\sa240 \qc \fs40 PCE for Agile Development: User Guide \par}
Project Collaboration Environment is an integrated environment that
supports Project teams in software development...
#select SectionName
    #option "Staff"
        #adapt: "sectionTemplate.art"
        #set extraLinkOperation = ""
        #insert "data"
Name: Full name of Staff\line
Office: Room number of Staff\line
...
        #endinsert
    #endadapt
    #endoption
    #option "Project"
        #adapt: "sectionTemplate.art"
        #set extraLinkOperation = ", Link with other projects"
        #insert "data"
Title: Project's title\line
Type: Type of project Internal or External\line
...
        #endinsert
        #insert "extra_actions"
        #adapt "Project_extra_actions.art"
        #endinsert
    #endadapt
    #endoption
#endselect
```

sectionTemplate.art:

```
This section describes operations to manage ?@SectionName? Information
in a Project Collaboration Environment.\line
A ?@SectionName? profile contains the following information:\par}
#break "data"\par}
Available operations for ?@SectionName? module includes Create,
Edit?@extraLinkOperation?, Delete,
and Display ?@SectionName?'s information.\line
The following sections provide detail instructions for each available
operation for ?@SectionName? module
Create a new ?@SectionName?
```

Figure 8. RTF document output from ART code

## VIII. FUTURE WORK

The approach to managing families of similar documents presented in this paper, as well as DME are a proof of concept. We applied DME to a small number of documents. We also did usability tests to evaluate if the approach can be easily communicated to others, and if the DME's user interface was simple and intuitive. We received mostly encouraging feedback from the evaluation. Some comments allowed us to refine the DME's user interface.

Still, much work needs to be done before DME becomes a production quality tool (in terms of usability and reliability) that can be applied in real situations. Some issues, such as more intelligent user interface, may considerably improve usability of DME, but require further research, as we explain below.

Our current DME prototype implements functions related to all document Variation Types except VT6 – repeated section. We are clear about internal mechanism to manage reuse of repeated sections, but still unclear about how to let DME users specify and then instantiate repeated sections in an easy way.

DME described in the last section communicates with users in terms of variant document parts such as sentences or paragraphs. Such DME can provide effective assistance in managing documents in hands of technical staff, but it is too low level for non-technical staff.

DME usability can be enhanced by allowing a Document Architect to model document variability and map it to template variation points. Feature diagrams [3] commonly used in Software Product Line [1] research and practice might be used to model document variability. Feature diagrams explicate common and variant features in an intuitive, hierarchical form that can be comprehended by non-technical staff. Document Architect can create feature diagrams for a given document family based on understanding of commonalities and differences in subject documents. When creating a custom document, Document Developer would select required variant features from the feature diagram, and DME would automatically inject relevant customizations to a template. This can eliminate (or at least substantially reduce) the need for manual customizations.

Even higher-level of interaction can be achieved by letting DME users work on documents in terms of concepts of their application domain. Domain-specific languages and their generators can be implemented using Visual Studio's DSL Toolkit. Both feature diagram-based and domain-specific mode of communication between users and DME will be more intuitive than the mode of communication described in the previous section. DME enhanced with the above features will provide higher levels of automation for document management, and will be easy to use for non-technical staff.

Here is summary of functions that we plan to implement to further enhance usability of DME:

1) DME will display a summary of customizations that occurred at specific variation points in custom documents created so far.

2) Query-based analysis will allow users to selectively retrieve information from a customization history repository.

3) DME will have a flexible rights-control system to allow/disallow different classes or users to perform certain actions. User rights will be applied to control which parts are read-only.

4) DME will accept customization data from external sources such as databases, spreadsheets, data files, requirement management databases (such as DOORS), or already mentioned feature diagrams.

5) Assistance will be provided for analysis of similarities/differences in existing document variants. If many documents already exist, identification of document variability may become difficult just using MS Word's *Compare* function (described in Section A). Document analysis tool can compute editing distance similarity metrics to help Document Architects understand document variability, build a feature model, and identify a "typical" document, suitable for template creation. This will help Document Architect to create templates.

6) DME will support Variation Point Documentation (VPD). VPD will allow users to enter/read meta-data of variation points. VPD will contain information such as variation point name, description, possible values, suggested customizations, etc. User customization rights will be contained in VPD.

## IX. RELATED WORK

The presented approach has been inspired by research on software reuse. In Software Product Line (SPL) engineering [1], we manage a family of similar software products (e.g., financial products) from a common set of reusable software artifacts such as architecture shared by systems, source code components, documentation, test cases, etc. All SPL products are similar, but each one also differs from others in client-specific features. The impact of client-specific features shows as many changes that must be applied through code and documentation - a repetitive, time-consuming and error-prone process if done manually. Methods have been proposed to manage variability in software to address this problem, increasing productivity via software reuse, one of which is ART.

DME can be viewed as a template engine, a tool that generates custom output from templates and a data model. Templates represent the textual contents in parameterized form, while data model defines parameter settings. In DME, parameter settings can be either imported or the user can define them in the interactive session, via DME user interface. DME is unique in fine-granular level of customizations, and in providing template engine capability for MS Word.

Publishing tools such as Adobe FrameMaker™, DocBook™ and DITA™ generate documents and facilitate reuse of document fragments. However, these tools do not support customizations of reused fragments which is a key feature of DME approach.

Generation of documentation for Software Product Lines is addressed in [4][5][6][7]. Research tools [4][7] extend

DocBook with document variability management, while commercial tools [5][6] generate custom documents from variability models. pure:variants [6] allows one to include/exclude optional sections in MS Word documents based on selected features. DME supports optionality and yet other six document variation types (Section IV), and provides interactive means to manage document variability as well as importing of customization data.

Commercial tools implement various approaches to document generation. Many tools provide general means for document design; Q-Pulse stores document versions, provides facilities to track changes, but does not instantiate and propagate specific customizations of document templates; we do; Intelldox generates documents based on selected rules; Corticon focuses on management of companies' business rules/decisions as enterprise assets, and document generation in the context of supported business processes; Wizilegal supports end-user document creation via Web service; MS Word templates can be used to generate documents according to inputs from a database, Excel, XML or other data sources (data-driven document generation). The general goal of these tools is the same as ours – to improve productivity of some aspects of document management. However, the specific goals and capabilities of these tools differ from ours mainly in the granularity and the nature of document variability that is addressed. We have not identified a document management tool on the market that focuses on managing client-specific detailed differences among multiple document versions, which is the strength of our approach. We believe our approach complements rather than competes with existing documentation tools.

## X. CONCLUSIONS

We presented a method and tool called DME for managing families of similar documents. Implemented as an MS Word add-in, DME extends the concept of MS Word templates to achieve documentation reuse with automated propagation of custom changes during custom document generation. DME supports template creation and instantiation (document generation), automated propagation of customizations across documents and ease of adoption due to seamless integration of DME into the usual document processing model (Figure 1) and MS Word. We presented two implementation strategies for handling text manipulation: The first one uses Content Control API and is specific to MS Word technology, and the second one applied general-purpose text manipulation method and tool ART.

We believe the ideas and technical approach to document management described in this paper could find applications in both software and non-software domains, where information reuse based on clear understanding of commonalities and differences among artifacts is important.

Presented here DME is a proof of concept. In future work, we will apply DME in real world projects, validate basic assumptions, and build domain-specific interfaces to enhance DME's usability.

## ACKNOWLEDGEMENT

Authors thank Mr. Paul Bassett, the inventor of Frame Technology™ and a co-founder of Netron, Inc, for his generous contributions to our projects on ART and XVCL, his suggestion to work on the DME project, and insightful comments on this paper.

This study was supported by a grant S/WI/2/2013 from Bialystok University of Technology and founded from the resources for research by Ministry of Science and Higher Education.

**Abstract**—The component-based software development enables to construct applications from reusable components providing particular functionalities and simplifies application evolution. To ensure the correct functioning of a given component-based application and its preservation across evolution steps, it is necessary to test not only the functional properties of the individual components but also the correctness of their mutual interactions and cooperation. This is complicated by the fact that third-party components often come without source code and/or documentation of functional and interaction properties. In this paper, we describe an approach for performing rigorous semi-automated testing of software components with unavailable source code. Utilizing an automated analysis of the component interfaces, scenarios invoking methods with generated parameter values are created. When they are performed on a stable application version and their runtime effects (component interactions) are recorded, the resulting scenarios with recorded effects can be used for accurate regression testing of newly installed versions of selected components. Our experiences with a prototype implementation show that the approach has acceptable demands on manual work and computational resources.

## I. INTRODUCTION

THE component-based software development is an important part of contemporary software engineering. It is based on the utilization of isolated reusable parts of the software (called *software components*), which mutually provide and require services (i.e., functionalities) using public interfaces. A component can be utilized in multiple applications and, at the same time, an application can be constructed from components created by different developers [1]. This reinforces the necessity for testing.

The functionality of an individual component should be tested primarily by its developer. However, it is also necessary to test the functionality of the entire component-based application where the correct cooperation of the components is no less important. The situation is complicated by the fact that many components exist in several versions.

The versions of a single component can differ by the internal behavior (different computations), by external behavior (different interactions with other components), or by the interface (different provided and required services). Theoretically, the change of internal behavior of a component should not affect the behavior of the entire application. Nevertheless, in reality, the change can introduce an unwanted error into the new version, add or remove side effects of some method invocations, prolong computation, which can cause a time-out to expire, and so on. When installing a new version of a component to a functional component-based application, adequate regression testing is, therefore, desirable even when there are no apparent external changes of the component.

The usually performed manual testing is a lengthy and costly process and its automation is desirable wherever possible. In this paper, we describe an approach for semi-automated regression testing of software components whose source code is not available (e.g., third party components). The approach is suited for checking whether a newly installed version of a component exhibits the same behavior within a component-based application as its old version. The approach uses static analysis of the component implementations and employs methods of aspect-oriented programming and stochastic testing to record runtime behavior of the application with the old and new version of a component. The comparison of both recordings can then reveal possible different behaviors and thus support debugging on the architectural level.

The description of the approach along with its validation on two case studies is the main contribution of this paper. Its structure is as follows. The following section provides an overview of the basic notions and Section III discusses related work in component analysis and testing. Section IV covers the details of the proposed approach. Section V presents its validation including an analysis of performance implications, and Section VI summarizes the contribution and future work.

## II. SOFTWARE COMPONENTS

In component-based software development, the applications are sets of individual software components.

### A. Basic Notions

A software component is a black-box entity, which provides services to other components via its well-defined interfaces and may require services of other components in order to function. The inner state of a component is not observable from the outside. So, the components are expected to mutually interact solely using their interfaces. A component should be reusable (i.e., it can be used in multiple applications) and, at the same time, a component-based application can be constructed from components created by different providers. These features are common to the majority of software components regardless of the component model [1].

A component model prescribes the behavior, interactions, and features of its software components and is implemented by (usually several) component frameworks. The experimental implementation of the interface-based component testing approach described in this paper has been created for the OSGi component model. OSGi [2] is a dynamic component model for the Java programming language. It is currently widespread in both industrial and academic spheres making it a good choice for experimentation. There are several commonly used implementations of the OSGi component model (i.e., OSGi frameworks), for example Equinox [3] or Felix.

In OSGi, the components are referred to as *bundles*. Each bundle has the form of a single Java `.jar` file with additional information related to the OSGi component model (e.g., name of the bundle, version of the bundle, lists of provided/required packages, etc.) [2]. Each bundle can provide one or more services represented by standard Java interfaces. Together, the classes in exported packages and the provided services form the accessible interface of the OSGi components.

The dynamic nature of the OSGi means that the bundles can be installed, started, stopped, and uninstalled without the necessity to restart the OSGi framework [4]. For this purpose, the OSGi framework runtime provides standard methods [2] for the exploration of the bundle's context (i.e., environment) and the control of its life cycle.

### B. Testing of Software Components

Testing of individual software components is similar to testing of ordinary monolithic software applications. However, the extra problems, which can be caused by the third party composition, need to be considered.

Generally, the testing methods can be divided according to the available knowledge of the tested software [5]. If its source code is known, it can be (and usually is) used for the preparation of the testing, leading to the *white-box testing*. If their source code is unknown or not considered in test

preparation (the *black-box testing*), other resources can be used for test preparation such as descriptions of the expected software behavior, the definition of its user and application interfaces, and so on [6]. The source code is often unavailable when we want to utilize a third party component in our component-based application and we want to test it first (both individually and as a part of our application).

Regardless the type of the testing, its principle lies in subjecting the tested component(s) to a set of stimuli and observing the congruence of their reactions with the expected ones [7]. In most real situations, it is not feasible to test the responses to all possible stimuli. Instead, a subset of all possible stimuli is used. In that case, it is important to ensure that the stimuli of the subset represent well the complete set of stimuli and various methods for the subset creation are used in practice [5].

An important criterion of the testing is its *coverage*, i.e. the amount of implementation code exercised by the tests. In the case of black-box component testing, coverage can be measured by the different invocations of individual operations on both provided and required sides of the component interface, considering also the actual parameter values. An important constraint is that it must be possible to achieve good coverage using the chosen subset of stimuli in a reasonable time [6].

The test design is usually described in so-called *scenarios* containing the stimuli and (optionally) the expected effects. Considering the testing of software components with unknown source code (i.e., black-box testing), each stimulus corresponds to an invocation of a service method provided by the tested component. The effects can be for example the return of a value or an invocation of an (outgoing) operation through the required side of component's interface.

When the scenario is executed, manually or in an automated way, the actual effects are compared to the expected ones to establish whether the component complies with the behavior specified by the scenario. Automated testing allows the scenarios to be executed repeatedly, which is important for the regression testing verifying whether new versions of components exhibit the same – or equivalent – behavior as the previous version(s). This aspect is important with respect to the highly flexible composition of components by third parties where the component provider cannot foresee the ultimate configuration of the component-based applications.

## III. RELATED WORK

The approach for the semi-automated testing of software components with unknown source code is related to several existing approaches, which are described below.

### A. Behavioral-Diagram-based Scenarios Generation

Many approaches to testing scenarios generation are based on behavioral diagrams of UML (e.g., activity diagrams, sequence diagrams, state machine diagrams, etc.) [8]. The

approaches described below are not intended for utilization with software components, because such examples are rare.

The activity diagrams are used for example in [6] for object-oriented applications. There, these diagrams representing concurrent activities (corresponding to method invocations) in an application are exhaustively explored. The scenarios are generated during the exploration. Because the exploration of all possible flows in the diagrams is infeasible for large applications, there are some constraints based on the application domain. These constraints are used to discard illegal or irrelevant scenarios [6].

The activity diagrams are also used in [8] where they are generated from multiple UML use case diagrams. Their purpose is to express the concurrency of the use cases. The exploration of the created activity diagrams is again used for the generation of the testing scenarios. The approach is intended for object-oriented applications [8].

#### *B. Natural-Language-based Scenarios Generation*

The generation of the testing scenarios from a specification in natural language is an appealing approach. Nevertheless, this approach is still difficult to implement because of the poor understandability, ambiguity, incompleteness, and inconsistency of natural language [9]. To overcome these difficulties, a set of restrictions is commonly used.

A restricted form of natural language is used for descriptions of the use cases in [10]. From them, a control-flow-based state machine is created for each use case. These state machines are then combined into a single global system level state machine. The testing scenarios are then created by this state machine exploration [10].

A similar approach was considered in our previous research focused on the simulation-based testing of software components based on the descriptions of use cases written in natural language (see Section III.E). These descriptions are transformed into an overall behavioral automaton (OBA) using the FOAM tool [11]. Using the OBA, the testing scenarios can be generated. The restrictions of the approach lie in the descriptions of uses cases, which must conform to the rules described in [12], and in the necessity to manually enrich the descriptions of use cases with the annotations describing the flow of the program and its temporal dependencies, as well as connections between the actions in use cases and the corresponding method invocations [13].

#### *C. Interface-Probing-based Scenarios Generation*

Interface probing is an approach, which utilizes the public interface of a software component (or another piece of software with a defined interface) for the examination of its behavior. This approach does not require the source code or any knowledge of the internal working of the software component. So, it is convenient for the black-box testing. Its basic idea is used in our approach as well (see Section IV).

Using the interface probing, the interface of the component – the services of the component and their

methods – is identified first. Then, the input values for the methods are generated and the methods are invoked using them. The outputs of the methods are then observed [14], [15]. For this purpose, the tested component can be wrapped in an enclosing object controlling the input and output data flows [16].

A disadvantage of this approach is the necessity to generate the input values. This can be done randomly, systematically, or manually. In any case, it is possible that input values will be omitted, which are in fact important for examination of the behavior of the tested component [14]. The programmer therefore needs to instruct the generator on suitable value ranges, using a set of the test design methods [5] and based on other descriptions (e.g., Javadoc) of the component if available.

#### *D. Static Byte Code Analysis*

The static byte code analysis is an example of checking of the applications constructed from software components of various developers for type inconsistencies. These inconsistencies can arise even in statically-typed languages (e.g., Java), considering the component-based application. Because each component is compiled separately, the mutual dependencies of the components are not considered by the compiler [17].

A solution of this issue proposed in [17] is the byte code analysis. It consists of three steps – the discovery of component dependencies, the matching of component dependencies, and the consistency verification. All the information necessary for all steps is extracted from the byte code. During the analysis, a graph representing the dependencies of the components is created. The graph is then traversed and the particular dependencies are checked for the type compatibility.

Although this approach represents a reliable method for the static determination of the compatibility of software components of a single component-based application, it cannot detect problems, which are not type-related. For example, if a method returns `null` instead of an expected instance, the problem will not be detected [17].

#### *E. Simulation Testing*

The basic idea of the approach described further in this paper (see Section IV) was already utilized for the simulation testing of software components during our previous research [18]. This approach was based on the testing of real software components in a simulated environment. The testing was based on a discrete-event simulation when the individual events corresponded to the invocations of the particular methods of the tested component. Simulated and intermediate components were used to observe and record the behavior of the tested component [18].

The issues of this approach were the discrepancies of the tested software components running in a real time and the simulation running in a discrete time and the necessity to

create the simulation and intermediate components [18]. Hence, the discrete simulation was abandoned and the entire process was significantly simplified. The result is the approach described further in this paper (see Section IV).

#### IV. INTERFACE-BASED COMPONENT TESTING

As was mentioned above, the main theme of this paper is an approach for the black-box regression testing of software components in a component-based application – the interface-based component testing. During the regression testing, we are determining whether the application with the old and the new version of a component exhibits the same behavior.

In this section, we describe its idea, the model of application it uses, and the particularities of a prototype implementation. The overall process works as follows. It starts with the analysis of the interfaces, services, and methods of software components of a component-based application. Based on this analysis, the sets of invocations of the particular methods are generated and then performed. The consequences of each invocation are observed and recorded. The result is a testing scenario with actions and their consequences. The scenario can be then used to check whether a newly installed version of a component in a component-based application exhibits the same behavior as its old version.

The details of the key parts of this process are discussed below, including experimental implementation aspects.

##### A. The Invocations-Consequences Data Structure

Usually, our method assumes that the entire component-based application is subject to the testing, because the components inside a single application interact with each other and these interactions are important to uncover the behavior of the components. This is the main difference from the interface probing method (see Section III.C) where each component is tested alone.

The service methods need to be determined for all the components of the tested application. This can be in general done by any method, which is able to recover complete method signature information. The components, their services, and their methods are explored and their identifiers are inserted into a tree data structure (see Fig. 1a).

An initial set of invocations for each of the methods thus determined is generated and added to the tree data structure. A set of test data values for each parameter of the method has to be provided in conjunction; each invocation is created as a unique permutation of the values of all parameters of the method.

In the current implementation of the approach (see Section IV.C), we use fully automatic generation of parameter values with a rather straightforward approach to cover the main test cases. The generated values depend on the parameter types. For primitive types, several representative and border values are generated. For general objects, only `null` value is used.

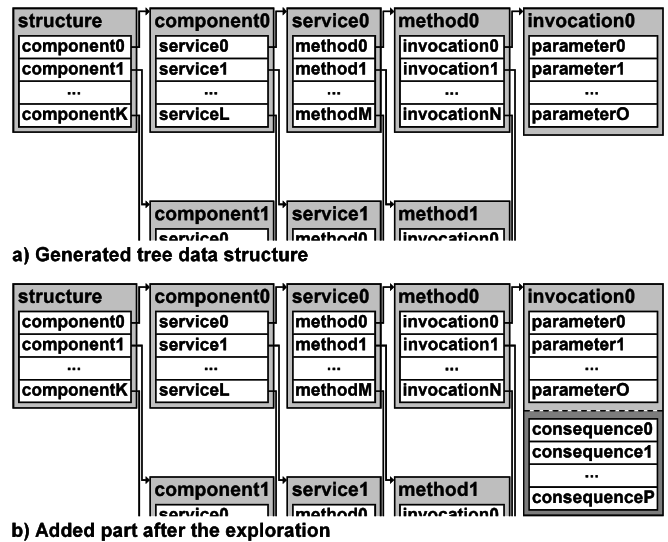

Fig. 1 The tree data structure

Additionally, when the user knows, which parameter values are critical for the tested component application, he or she can select any method, set the required parameter values and thus create and add a new invocation. The user can also restrict the set of generated values, where appropriate.

In principle, it would not be necessary to use all methods for the initial invocation set to achieve good coverage. Since the source code is unknown however, the (side) effects of the methods execution are unknown as well. Hence, with the utilization of all methods, the probability of better exploration of the behavior of the components is higher than if some methods were excluded.

Once the initial invocations are added to the tree data structure, they are performed (i.e., the application is executed in a testing mode) and their consequences (effects) are observed and recorded. The consequences of a method invocation are: the return of a value, a raised exception, a value change in the “out” parameters of the method, a subsequent invocation of a service method of another (depended on) component, and a change of the inner state of the component. The change of the inner state of the component is different from the others consequences, because it is not easily observable. Hence, it is not considered by our method.

There can be more than one consequence per an invocation of a method. All consequences are recorded and inserted into the tree data structure (under the invocation, which caused them), but only if they are not already present. Each invocation consequence record incorporates its type and further data depending on this type (e.g., the return value, the instance of an exception, etc.).

The subsequent (outgoing) invocations are the most important consequences. Each subsequent invocation is described by the method it is invoking and the unique permutation of its parameter values. When a subsequent invocation of a method is performed such that has not yet been observed, it is recorded along with its parameter values.

This invocation is then added to the generated and already recorded invocations in the tree data structure. These invocations are valuable, because their parameter values are genuine, created by the internal logic of the component, which invoked the method. They can for example contain instances of objects, which would be difficult to generate automatically. Again, this is a substantial difference from the interface probing method (see Section III.C).

The disadvantage of recording the subsequent invocations in this way is that we cannot be entirely sure what their actual cause was. As the components under tests are black box, we cannot create their full behavioral model and determine the causal relation between the method invocations. For example, if a component uses active threads, it can perform invocations on other components independently on the incoming invocations performed on its service methods. The invocations performed by such (internal) threads can still be intercepted and added to the tree data structure. Even though there is no causal relation between them and the incoming invocation, which preceded them chronologically, a false cause-effect relation is still recorded in the tree data structure. This may cause false alarms during the comparison of the tree data structures (see Section IV.B), because the corresponding invocation-consequence pairs may not occur in further application executions. The mitigation of this problem can be repeating the invocation and further analysis; it is a part of our future work.

In order to maximally exploit the subsequent invocations during the testing, the invocation-driven exploration of the tree data structure repeats several times. The subsequent invocations generated in  $n$ th exploration can be performed in the  $(n + 1)$ th run and its consequences observed. When no new consequences are generated, the exploration ends.

In the final tree structure, all invocations and consequences contain the number representing the iteration, in which they were inserted (starting with 1). The initial generated invocations or provided by the user prior to the exploration of the structure are numbered 0. The filled tree data structure is therefore enriched by the invocation consequences (see Fig. 1b) and by the invocations extracted from the subsequent invocations. This structure can be then saved to a file as a testing scenario.

### B. Testing Application Evolution: Comparison of Tree Data Structures

The stored tree data structure is useful when a new version of a component is installed to the component-based application. In this case, it can be tested whether the application with the new version of the component exhibits the same behavior as the old version (regression testing). For this purpose, the entire process described in Section IV.A is performed for the application with the new version of the component. The result is again the filled tree data structure.

The original tree data structure (corresponding to the behavior of the application with the old version of the

component) is then loaded from the file and the structures are compared. The comparison is performed on each level of the two tree data structures, which use the same set of initial invocations, starting from the component level.

If a component is only in one tree data structure, this difference is reported and the services of this component are not considered further. For each pair of corresponding components, their services are compared by their names. If a service is only in one tree data structure, this difference is reported and the methods of this service are not considered further. For each pair of corresponding services, their methods are compared by their signatures. If a method is only in one data structure, this difference is reported and the invocations of this method are not considered further. Analogically, this continues down to the invocation consequences level (see Fig. 2 for examples).

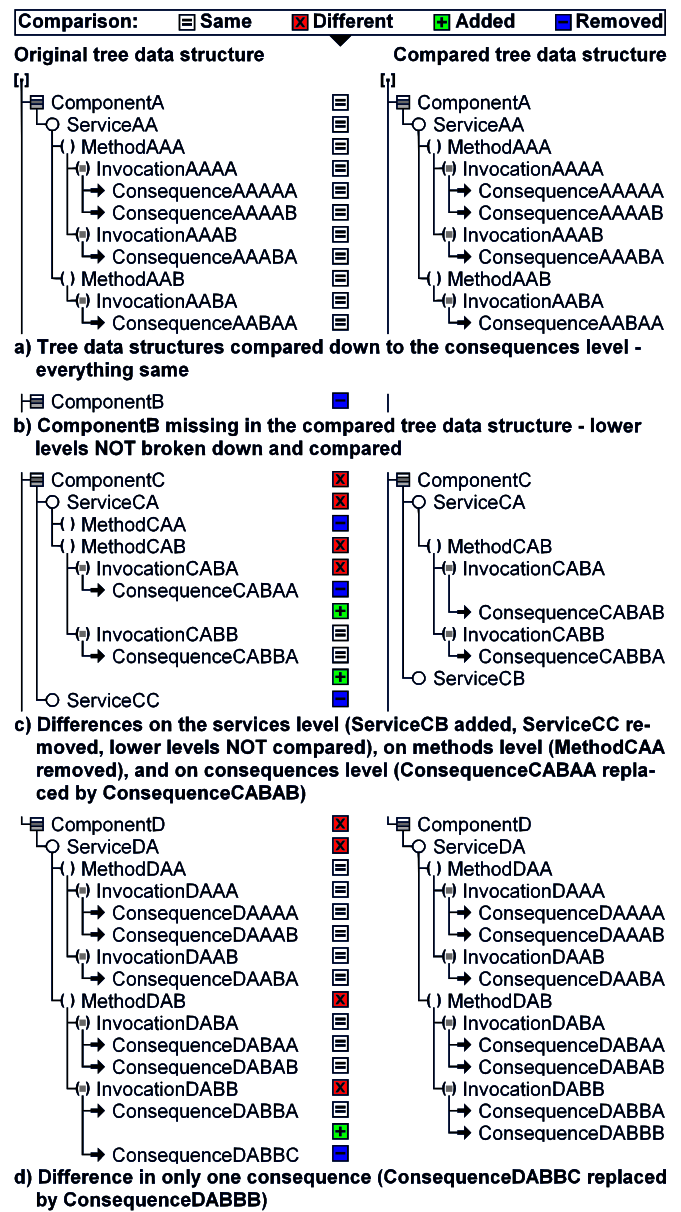

Fig. 2 Comparison of two tree data structures

The differences are expected to occur mainly in the invocations and invocation consequences levels of the tree data structure. Such a difference means that the tested component-based application with the new version of the component exhibits a different behavior. A difference on the methods level or on the services level implies the change in the public interface of the component. Our method is of course capable to detect these changes, but they can be detected also by the other means such as advanced methods of static analysis (e.g., see [17]). However, discovering differences in the invocations and consequences level by the static verification is difficult. Since these differences can mean significant problems in the tested application, the described interface-based component testing add significant value to the functional verification process.

### C. Experimental Implementation and Its Discussion

The approach has been implemented for the Java programming language and the OSGi component model; however, the main ideas behind it can be used for other component models and programming languages as well. The implementation is a part of our Interface Analysis Tool (InAnT), which has the form of a single component (OSGi bundle) and is expected to be installed in the same OSGi framework as the tested component-based application.

The interface-based testing begins when the InAnT component and the components of the tested application are started. The tool searches for all available components and their registered services using standard methods of the OSGi framework for this purpose. A proxy is then automatically created and assigned to each registered service of the components. This is achieved using standard OSGi hooks [2]. Each future invocation of a method of a service is subsequently mediated by the corresponding proxy, which records the invocation and executes it on the corresponding component using Java reflection. This way, all method invocations performed within the tested component-based application can be detected and traced.

The proxies are similar to but much simpler than the intermediate components used in simulation testing (see Section III.E and [18]). There is a single generic proxy implementation whose sole purpose is to record method invocations and, for each registered service, there is one proxy instance. The intermediate components, on the other hand, incorporate functionalities related to the running of the components in a simulated environment [18]. Moreover, each service has an intermediate component designed specifically for it.

There can be more than one independent component-based application deployed in one OSGi framework. So, the user is encouraged to select the components of the application intended for the testing. It is possible to select only some components of the application, but the testing is then likely to be incomplete. Once the components for the testing are selected, the methods of their services are

determined using Java reflection (since the services correspond to standard Java interfaces – see Section II.A)

Since the framework services do not guarantee that the components are discovered in the same order across different framework runs, the components are sorted by bundle symbolic name in the tree data structure. Similarly, particular services of each component and particular methods of each service are sorted as well. This way, it is ensured that the initial set of invocations is always executed in exactly the same order. This is the necessary condition for the correct comparison of two tree data structures.

The automatic generation of the invocations and their parameter values is deterministic and repeatable. Therefore, it does not negatively influence the comparison. However, when the user adds invocations manually or restricts the range of the parameter values of the automatically generated invocations, it is vital that he or she uses the same settings (including the order of manually added invocations).

As it was described in Section IV.A, the parameter values generated by our implementation depend on the parameter types. For the number types, a set of representative values is generated. These values include the maximal and minimal possible values, 0, -1, 1, and several negative and positive values with a constant step. The size of the step can be selected by the user and can significantly influence the number of values and consequently the number of generated invocations. For the `boolean` type, both possible values are generated. For the `char` type, several single-byte values (corresponding to letters, digits, punctuation, and non-printable characters) and several double-byte values are generated. For `enum` types, all possible values including the `null` value are generated. For the `String` class, the `null` value and the empty string are generated. For the wrapping classes of the primitive types (e.g., `Integer` for `int` or `Character` for `char`), the same values as for the primitive data types and `null` value are generated. For the remaining classes, only the `null` value is generated.

The invocations of the tree data structure are then performed as described in Section IV.A. Their consequences are observed directly (the return of a value, a raised exception, a value change in parameters of the method) or indirectly by the proxies (a subsequent invocation).

The filled tree data structure can be then stored to a specific XML file. The XML format was chosen because of its hierarchical nature and legibility for humans, which is useful during the development. The stored filled tree data structure can be compared to another stored filled tree data structure or to filled tree data structure created in the memory. The comparison is performed as described in Section IV.B.

## V. VALIDATION AND RESULTS

The described interface-based component testing approach was validated by two sets of tests. The first one

was focused on the dependency of the number of generated invocations on the number of methods and the number of their parameters; this is described in Section V.B. The second set of tests was focused on the testing the ability of the approach to discover the different behavior of the tested application when a new version of a component was installed (see Section V.C).

#### A. Environment and Application Used for Testing

All tests were performed on a single desktop computer with quad-core Intel i7-4770 CPU at 3.40 GHz, 16 GB of RAM, and 1TB HDD. The software environment consisted of the operating system Windows 7 SP1 (64 bit), Java 1.6 (32 bit), and the Equinox OSGi framework.

A component-based application of our own design was used for the first set of tests. We chose not to use a 3rd party application to facilitate the analysis and manipulation of the test application source code (e.g., add and remove methods and their parameters, change the behavior of the methods, etc.) in order to test various features of the approach. The test application is a simple tool for mathematical calculations and processing of strings. It consists of five components (see Fig. 3). The *Utilities* component represents the interface of the entire application. The methods of its service perform high-level operations. The *Text* component provides a service for the processing of strings and utilizes the *Calculator* component for mathematical operations. The *Calculator* component provides a service for mathematical operations including geometrical transformations. For this purpose, it utilizes the *Geometry* component. The *Logger* component logs the running of the *Utilities* component.

For the second set of tests, the test application was used as well, but, additionally, we used the well known CoCoME (Common Component Modeling Example – see [19]) application to demonstrate that our interface-based component testing approach is able to work with a real world application. The implementation, which was used for the testing, was developed internally in our group.

#### B. Dependency on Number of Methods and Parameters

From the description of the generation of the invocations for the methods in the tree data structure (see Section IV.C), it is obvious that the number of generated invocations grows very rapidly. We expected that it grows linearly with the total number of methods and exponentially with the number of parameters of each single method. In order to verify the assumption, a set of tests was performed.

First, the dependency of the number of generated invocations on the number of parameters of a single method

Fig. 3 The component-based application used for the testing

was investigated. The *Utilities* component was used for this purpose. All its methods were removed and a testing method was added. The method had between one and ten parameters, either all *int* parameters or all *String* parameters. When the number of parameters was changed, the component was recompiled and the invocations were generated for it.

The results are depicted in Fig. 4a. As expected, the dependency on the number of parameters is exponential (note the logarithmic scale of the y-axis). It can be also observed that the increase in the number of generated invocations is far steeper for the *int* parameters than for the *String* parameters. In fact, an out of memory exception occurred for more than 6 *int* parameters. This difference is caused by the number of generated values used for each parameter (9 for *int*, and only 2 for *String* – see Section IV.C). So, the user should limit the range of the generated values wherever he or she is able (e.g., based on the documentation of the component). Although these results seem to negatively affect the usability of our approach, it should be noted that methods with more than 6 parameters are quite rare. Moreover, it is possible not to use all existing combinations of parameters, but use the common t-way approach (discussed for example in [20]) instead.

Second, the dependency of the number of generated invocations on the number of methods with 5 parameters within one component was investigated. The parameters were *String*, *Object*, *Object*, *int*, and *double*. The number of parameters was chosen as a higher than average number in common applications. Similarly, the parameter types were chosen to represent common methods. Again, the *Utilities* component was used for testing and the tests were performed in the same way. The results are depicted in Fig. 4b. As expected, the dependency on the number of methods is linear (note the linear scale on the y-axis). This means that the number of methods per component does not significantly affect the usability of our approach.

Third, the dependency of the number of generated invocations on the number of components each with 10 methods (with total of 26 parameters of various types) was investigated. All the components of the test application (see Section V.A) were used for this purpose. The results are depicted in Fig. 4c. Again, the dependency on the number of components is linear and thus the number of components does not significantly affect the usability of our approach.

The absolute number of generated invocations is highly dependent on the tested application. The purpose of the described set of tests was merely to investigate the dependency of the generated invocations count on the number of method parameters, the number of methods, and the number of components. It was shown that the major problem is the high number of method parameters. This can be mitigated by a more advanced generation of parameter values and the usage of the t-way approach, which is a part of our future work.

Fig. 4 Dependencies of the number of generated invocations

### C. Functioning of the Entire Approach

In order to demonstrate the functioning of the entire interface-based component testing on an example, the second set of tests was performed using the same test application and the CoCoME application. The purpose of the tests was to demonstrate the ability of the approach to uncover changes in the component behavior.

First, the testing method was performed on the test application. The numbers of methods and the total numbers of parameters per component are summarized in Table I. The user did not provide any initial invocations nor placed any restrictions on the invocation generation. The result of the method – the filled tree data structure – was stored to a file. Then, three changes were separately performed to the Calculator component. For each change, the testing was performed again. The resulting filled tree data structure was

then compared to the tree data structure created earlier for the original component. The differences are summarized in Table II. The first change (#1) was one added method (with 4 parameters) to the Calculator component. Second change (#2) was that one method of this component ceased to throw an exception when invoked with the null value. The third change (#3) was that one method of this component started to return null instead of an instance.

The first change caused only one difference on the methods level. Of course, the filled tree data structure with the added method incorporates its invocations (and their consequences) as well (see column #1 in Table II). However, this is not counted as a difference, since the comparison does not explore lower levels of branches of the filled tree data structures when a difference is discovered on the higher levels. The second change caused numerous differences on the invocations and consequences levels (see column #2 in Table II), because the changed behavior of the method (i.e., not throwing an exception when invoked with the null value) influenced other methods as well. The third change caused numerous differences on the consequences level only (see column #3 in Table II).

Second, the testing method was performed on the CoCoME application. The numbers of methods and parameters of the utilized components of the CoCoME application are summarized in Table III. Again, the user did not provide any initial invocations nor placed any restrictions on the invocation generation. The testing was performed the same way as with the test application (see above). Three changes were separately performed to the Data component. The differences are summarized in Table IV. The first change (#1) was one added method (with 1 parameter) to the Data component. Second change (#2) was that one method of this component ceased to throw an exception when invoked with the null value. The third change (#3) was that one method of this component started to return null instead of an instance.

The first change caused only one difference on the methods level. The second change caused several differences on the consequences levels (see column #2 in Table IV), but not on the invocations level like the similar change in the test application (see Table II). The reason is that in the CoCoME application, the second change did not affect other methods. The third change caused only one difference on the consequences level (see column #3 in Table IV).

It should be also noted that there are no subsequent invocations in Table IV. This does not mean that the components do not utilize services of the other components. The reason is that, in the CoCoME application (unlike the test application), the majority of the inter-component interactions are performed using OSGi Events, which are currently not intercepted by the interface-based component testing implementation. Despite this setback, the approach did uncover all introduced differences.

TABLE I. NUMBER OF METHODS AND PARAMETERS OF THE COMPONENTS OF THE TEST APPLICATION

Component	Number of methods	Total number of parameters
Geometry	3	4
Calculator	16	21
Logger	5	3
Text	7	10
Utilities	4	8

TABLE II. DIFFERENCES OF THE FILLED TREE DATA STRUCTURES OF THE TEST APPLICATION

Structure	Original	#1	#2	#3
Explorations	3	3	3	3
Generated invocations	895	917	895	895
Subsequent invocations	747	769	569	725
Exceptions	10	10	9	10
Return values	910	933	890	910
Parameters changes	0	0	0	0
Differences (methods)	N/A	1	0	0
Differences (invocations)	N/A	0	21	0
Differences (consequences)	N/A	0	202	22

TABLE III. NUMBERS OF METHODS AND PARAMETERS OF THE COMPONENTS OF THE CoCoME APPLICATION

Component	Number of methods	Total number of parameters
Coordinator	1	1
Data	16	25
Dispatcher	2	6
Reporting	3	3
Store	12	8
Bank	2	3
CardReaderController	3	3
CashBoxController	7	7
CashDeskApplication	10	10
CashDeskGUIController	10	10
LightDisplayController	2	2
ScannerController	1	1

TABLE IV. DIFFERENCES OF THE FILLED TREE DATA STRUCTURES OF THE CoCoME APPLICATION

Structure	Original	#1	#2	#3
Explorations	2	2	2	2
Generated invocations	297	299	297	297
Subsequent invocations	0	0	0	0
Exceptions	224	224	213	224
Return values	1	3	12	1
Parameters changes	0	0	0	0
Differences (methods)	N/A	1	0	0
Differences (invocations)	N/A	0	0	0
Differences (consequences)	N/A	0	11	1

The second set of tests successfully demonstrated that the interface-based testing was able to uncover all three introduced differences in both component-based applications. The thorough testing of the method including a significantly higher number of components and third party applications is a part of our future work.

## VI. CONCLUSION

In this paper, we described an approach to component testing automation, with scenario generation and augmentation based on a static interface analysis and runtime logging. The approach can be used for detecting the differences in the behavior of various versions of a software component inside a given component-based application.

The feasibility and effectiveness of the approach, as well as its limitations, were demonstrated using two sets of tests, which were performed using a prototype test generation implementation. Although the extent of generated data (parameter value combinations) grows prohibitively fast in the fairly rare case of methods with many parameters, the number of tested components does not significantly affect the usability of our approach.

For future work, enhancing the formal models, on which the approach is based, could improve coverage while reducing test set size. Further, considering the effects of threading together with exploring the possibility of recording all occurrences of the invocation consequences, not only the first one, should improve test quality through better information about the behavior of the components. We will also explore the behavior of our method when there are two or more new versions of components in the tested application and focus on the situations when a subset of highly dependent components is changed for new versions in the component application.

The priority of our future research is however the improved generation of parameter values for method invocations. We are working on creating an automatic generator that will provide the complex testing data, such as objects or object collections with all attributes set to values fulfilling expected criteria. This requires a method for describing the limits for the object attributes and also a tool that will be able to analyze object structure, including references to other objects and create automatically the necessary testing data<sup>1</sup>. Furthermore, along with attribute description, analysis of program control flow can be used in order to create tests that will provide sufficient coverage of tested application.

# 4<sup>th</sup> Doctoral Symposium on Recent Advances in Information Technology

**T**HE aim of this meeting is to provide a platform for exchange of ideas between early-stage researchers, in Computer Science and Information Systems, PhD students in particular. Furthermore, the symposium will provide all participants an opportunity to get feedback on their studies from experienced members of the IT research community invited to chair all DS-RAIT thematic sessions. Therefore, submission of research proposals with limited preliminary results is strongly encouraged.

Besides receiving specific advice for their contributions all participants will be invited to attend plenary lectures on conducting high-quality research studies, excellence in scientific writing and issues related to intellectual property in IT research. Authors of the two most outstanding submissions will have a possibility to present their papers in a form of short plenary lecture.

**Abstract**—In the article a new optimization approach for thermal processes modeling has been presented. In the designed method, the considered process is monitored by a measurement system with a thermal camera. Then, a spatio-temporal dynamics is discretized and transformed into a large-scale optimization problem with differential-algebraic constraints. To preserve the process dynamics in the assumed range, variability constraints have been imposed. Finally, a new interior-point optimization algorithm has been designed to solve the optimization problem with the variability constraints. The applicability of the new approach has been investigated experimentally.

**Index Terms**—variability constraints, DAE systems, nonlinear optimization, thermal processes, thermal camera,

## I. INTRODUCTION

OPTIMIZATION and control of thermal processes is a complex issue, which has a large impact on various branches of industry. Therefore, a general solution procedure is consisted on the following steps:

- 1) Thermal camera-based measurement system to perform observations of the considered surface [15].
- 2) The obtained measurements represent the spatio-temporal dynamics of the process. Therefore, it is needed to design an appropriate model of the considered process [17].
- 3) A direct transcription method enables us to apply a large-scale nonlinear optimization algorithms to solve a model optimization problem.

The complexity of the considered issue motivates a recently progress in the optimization of many real-life technological processes. In the work [18] a three-dimensional numerical model using enthalpy technique to describe the solidification of phase change material has been developed. Therefore, the effect of geometrical parameters on the thermal performance of latent heat thermal energy storage system has been studied. Finally, the optimum system geometry could be identified. Mei and Xia [14] designed a multi-input-multi-output (MIMO) model predictive control (MPC) for a direct expansion air conditioning system to improve an indoor thermal comfort, as well as air quality. Moreover, the energy consumption has been minimized. The considered direct expansion air conditioning system has been described by nonlinear algebraic equations. The designed procedure has been verified by obtained simulation results. In the article [11] a heat management

in optimization of highly exothermic reactions during gas-phase olefin polymerization in fluidized bed reactors has been discussed. Moreover, a high speed infrared (IR) camera and a visual camera have been coupled to present the hydrodynamic and thermal behavior of a pseudo-2D fluidized bed. The applied infrared/visual camera technique generated detailed information on the thermal behavior of the bed and enabled to optimize a combined computational fluid dynamics and discrete element model. Mariani et al. [12] considered a gas-solid cyclone separator used in a complex cement production plant. The objective of the study was aimed at optimization of the performance evaluation, as well as the cyclone separator in terms of particle separation and heat transfer efficiencies. The losses of the pressure were treated as the additional technological constraints. Bhaduri et al. [2] reported results from process optimization experiments aimed at investigating the influence of laser fluence and pulse overlap parameters on resulting workpiece surface roughness following laser polishing of planar 3D printed stainless steel (SS316L) specimens. The optimized laser polishing technology was implemented for serial finishing of structured 3D printed mesoscale SS316L components. Finally, Uribe-Soto et al. [19] presented recent approaches to significantly reduce or avoid CO<sub>2</sub> emissions by a designed process optimization procedure.

A detailed analysis of the thermal processes is possible by efficient numerical optimization algorithms. Among the commonly known nonlinear optimization algorithms, the family of internal point methods is of a significant importance. Recently, an interior-point trust-funnel algorithm for solving large-scale nonlinear optimization problems has been presented in [5]. The designed method achieves global convergence guarantees by combining a trust-region methodology with a funnel mechanism. Moreover, it has a capability to solve problems with equality, as well as inequality constraints. An efficient primal-dual interior-point algorithm using a new non-monotone line search filter method was presented in [20]. The designed non-monotone line search technique has been introduced to lead to relaxed step acceptance conditions and improved convergence performance. Klintberg and Gros [10] designed an interior point method with an inexact factorization technique for optimal control of systems described by Differential-Algebraic Equations (DAEs). A class of convex optimization problems,

where both the objective function and the constraints have a continuous dependence on time, have been considered in [9]. The designed method utilized a time-varying constraint slack and a prediction-correction structure that relies on time derivatives of functions and constraints and Newton steps in the spatial domain. Zorkaltsev [21] discussed a family of interior point algorithms for linear programming problems. In these algorithms, entering the feasible solution region of the original problem has been considered as an optimization process of a new extended problem. To obtain a solution of a large-scale optimization problem with a considerable time, Cao et al. [4] proposed an augmented Lagrangian interior-point approach for general NLP problems that solves in parallel on a Graphics Processing Unit (GPU).

The presented literature research indicates, that thermal process modeling with thermal camera-based approach, as well as with an application of a nonlinear optimization methods, is nowadays under intensive investigations. Therefore, the article is aimed at presentation of a general procedure, which enables us to optimize the temperature distribution model. The new issues introduced into optimization task are the technological constraints imposed on a temperature variability. The designed procedure is independent on a considered process and is consisted on measurement system, as well as an interior point optimization procedure.

This work is constructed as follows. In Section 2 the problem was introduced. The main parts of the measurement system, as well as data structures were presented. Moreover, the main solution idea was proposed. In Section 3 the temperature distribution control problem was transformed into a large-scale nonlinear optimization problem. The variability of the state trajectories are treated as additional decision variables. Finally, the new interior-point optimization algorithm for solving dynamic optimization tasks with variability constraints was designed in Section 4. In Section 5 the presented considerations were practically illustrated. The article was concluded in Section 6.

## II. THE PROBLEM STATEMENT

The task considered in this work is to find such parameters of the surface temperature distribution model  $\tilde{T}(x, y, \mathbf{v}_p, t)$ , that for a given time interval

$$t \in [t_0 \quad t_F] \quad (1)$$

the results obtained by the model simulations are appropriate to the given measurements

$$\min_{\mathbf{v}_p} \int_{t_0}^{t_f} \int_{x_{\min}}^{x_{\max}} \int_{y_{\min}}^{y_{\max}} (T^*(x, y, t) - \tilde{T}(x, y, \mathbf{v}_p, t))^2 dy dx dt \quad (2)$$

or

$$\min_{\mathbf{v}_p} \int_t \int \int_S (T^*(x, y, t) - \tilde{T}(x, y, \mathbf{v}_p, t))^2 dS dt \quad (3)$$

where  $S = [x_{\min} \quad x_{\max}] \times [y_{\min} \quad y_{\max}]$  denotes a range of the considered surface, an observation time range  $t \in [t_0 \quad t_F]$ ,  $T^*(x, y, t)$  denotes a wanted temperature distribution on the

surface at time interval  $t \in [t_0 \quad t_F]$ ,  $\tilde{T}(x, y, \mathbf{v}_p, t)$  is the model of the temperature distribution for a given vector parameters  $\mathbf{v}_p \in \mathcal{R}^{n_{\mathbf{v}_p}}$ .

As one can observe, the process is characterized by the spatio-temporal dynamics. Therefore, the value of measured temperature is dependent on the time, as well as on the values of geometrical coordinates. To reduce the number of independent variables, the spatial discretization approach was applied. This step enables us to divide the considered surface into an assumed number of cells. Therefore, each cell can be characterized by the values of geometrical coordinates.

*Assumption 2.1:* The considered surface  $S$  can be partitioned into a given number of homogeneous cells

$$c_{x,y} = [x - \Delta x \quad x + \Delta x] \times [y - \Delta y \quad y + \Delta y]. \quad (4)$$

Therefore, each cell  $c_{x,y}$  can be described by a function dependent only on the time  $t$

$$c_{x,y} \equiv c_{x,y}(t). \quad (5)$$

This approach was presented on the Figure 1. The size of each cell is dependent on a discretization level. The reasonable size of the cell should be equal or bigger than size of a pixel. In the measurement system the thermal imaging camera FLIR A615 was used. The specification of the used hardware was presented in the Table I.

Fig. 1. An example of a thermal process.

Because each cell can be described by an exactly one-independent-variable function, therefore a wide class of possible model functions can be indicated. One of the most general family of such functions are the index-1 differential-algebraic models

$$c_{x,y}(t) = \begin{cases} \dot{z}_{x,y,d}(t) &= F_{x,y}(z_{x,y,d}(t), z_{x,y,a}(t), \mathbf{v}_p, t) \\ 0 &= G_{x,y}(z_{x,y,d}(t), z_{x,y,a}(t), \mathbf{v}_p, t) \end{cases} \quad (6)$$

TABLE I  
THE THERMAL IMAGING CAMERA FLIR A615 SPECIFICATION.

Image frequency	50 Hz
Focal Plane Array (FPA)/ Spectral range	Uncooled microbolometer / 7.5-14 $\mu\text{m}$
IR resolution	640 $\times$ 480 pixels
Detector time constant	8 ms
Object temperature range	-20 to +150°C +100 to 650°C +300 to +2000°C

where  $z_{x,y,d}(t) \in \mathcal{R}^{n_{z_{x,y,d}}}$  denotes a differential state variable of the cell  $c_{x,y}$ ,  $z_{x,y,a}(t) \in \mathcal{R}^{n_{z_{x,y,a}}}$  is an algebraic state variable of the cell  $c_{x,y}$ ,  $\mathbf{v}_p \in \mathcal{R}^{n_{\mathbf{v}_p}}$  denotes a vector of the model parameters. Moreover, two vector-valued functions are considered

$$F_{x,y} : \mathcal{R}^{n_{z_{x,y,d}}} \times \mathcal{R}^{n_{z_{x,y,a}}} \times \mathcal{R}^{n_{\mathbf{v}_p}} \times \mathcal{R} \rightarrow \mathcal{R}^{n_{z_{x,y,d}}} \quad (7)$$

$$G_{x,y} : \mathcal{R}^{n_{z_{x,y,d}}} \times \mathcal{R}^{n_{z_{x,y,a}}} \times \mathcal{R}^{n_{\mathbf{v}_p}} \times \mathcal{R} \rightarrow \mathcal{R}^{n_{z_{x,y,a}}} \quad (8)$$

The presented approach enables us to describe each cell  $c_{x,y}$  of the surface by a vector of descriptor variables  $\mathbf{z}_{x,y}(t)$

$$c_{x,y}(t) = \begin{cases} \dot{z}_{x,y,d}(t) &= F_{x,y}(\mathbf{z}_{x,y}(t), \mathbf{v}_p, t) \\ 0 &= G_{x,y}(\mathbf{z}_{x,y}(t), \mathbf{v}_p, t) \end{cases} \quad (9)$$

where

$$\mathbf{z}_{x,y}(t) = \begin{bmatrix} z_{x,y,d}(t) \\ z_{x,y,a}(t) \end{bmatrix}. \quad (10)$$

In the numerical simulations of the differential-algebraic systems in the form (6), the index of the system is of a great importance. In general, the algebraic part of the systems (6) can be differentiated according to the independent variable  $t$

$$\begin{aligned} \dot{z}_d(t) &= F(z_d, z_a, \mathbf{v}_p, t) \\ 0 &= G(z_d, z_a, \mathbf{v}_p, t) \end{aligned} \quad (11)$$

and as result the following form can be obtained

$$\begin{aligned} \dot{z}_d(t) &= F(z_d, z_a, \mathbf{v}_p, t) \\ \frac{\partial G}{\partial z_d} \dot{z}_d + \frac{\partial G}{\partial z_a} \dot{z}_a &= -G(z_d, z_a, \mathbf{v}_p, t) \end{aligned} \quad (12)$$

*Definition 2.1:* A differential-algebraic system (6) has an index one, if it can be rewritten as an ODE after exactly one differentiation.

*Definition 2.2:* A system of ordinary differential equations (ODEs) has an index zero.

To solve an index-one DAE system a vector of consistent initial conditions need to be known.

*Definition 2.3:* For the system (6) with the vector of the consistent initial conditions

$$\mathbf{z}_{x,y}(t_0) = \begin{bmatrix} z_{x,y,d}(t_0) \\ z_{x,y,a}(t_0) \end{bmatrix} \quad (13)$$

the equation

$$0 = G_{x,y}(z_{x,y,d}(t_0), z_{x,y,a}(t_0), \mathbf{v}_p, t_0) \quad (14)$$

is fulfilled.

Application of these equations to model thermal phenomena has the following advantages

- the algebraic equations typically describe conservation laws or explicit equality constraints,
- it may be difficult or impossible to reformulate the model as an ODE when nonlinearities are present,
- the implicit models do not require the modeling simplifications often necessary to get an ODE;
- it is easier to vary design parameters in an implicit model,
- the variables keep their original physical interpretation [3].

In some practical applications an additional type of constraints need to be considered - the variability constraints. Especially, in such technological processes like a metal annealing or control of airplane, the observed changes cannot happen too fast, as well as too slow [1]. The variability constraints are imposed on the left-hand side of the ordinary differential equations and take the following form

$$\dot{z}_d(t) < c_{var}(t), \quad (15)$$

where  $z_d(t)$  denotes the differential state variables and  $c_{var}(t)$  represents the constraint function. The function  $c_{var}(t)$  can take any appropriate form. In the literature the variability constraints have been formally introduced in [6]. Till now the variability constraints have been treated informally using the right-hand side of the ODEs model

$$F(z_d, z_a, \mathbf{v}_p, t) < c_{var}(t). \quad (16)$$

The representation (16) introduces all difficulties connected with the considered nonlinear differential model into a nonlinear optimization task.

The surface is consisted on the assumed number of cells  $c_{x,y}(t)$ . The temperature of each cell can be modeled by the system of continuous differential-algebraic equations (eq. 6). Moreover, to simulate the cell behavior, the consisted initial conditions need to be known, eqs. (13)-(14). The constraints, which represents the initial conditions, have a pointwise nature. Finally, the model optimization problem can be extended by the explicitly imposed variability constraints eq. (15). The presented methodology results in the nonlinear optimization task with the piecewise-continuous constraints. Therefore, the

presented method is aimed at minimization of the objective function (2) subject to the presented constraints.

### III. THE OPTIMIZATION PROCEDURE

The structure of the nonlinear optimization task, as well as an optimization procedure, is dependent on the discretization of the considered model-optimization problem. The new optimization-based procedure takes a form of a five step procedure.

- 1) The process duration time

$$t \in [t_0 \quad t_F] \quad (17)$$

is divided into given number  $N$  subintervals. The length of each subinterval is equal  $\Delta t$  and the duration of each interval is equal or larger than a measurements frequency

$$\Delta t \geq \delta t, \quad (18)$$

where  $\delta t$  is the measurements frequency. Therefore, the following relation can be observed

$$t_0 < t_1 < t_2 < \dots < t_{N-1} < t_F, \quad (19)$$

where

$$t_n = t_0 + n \cdot \Delta t \quad (20)$$

with  $n = 0, 1, \dots, N$ .

- 2) The model discretization can be executed according to the obtained subintervals. The cell  $c_{x,y}(t)$  can be represented by a series of submodels  $c_{x,y}^n(t^n)$ ,  $n = 0, 1, \dots, N$ , where

$$\begin{aligned} z_{x,y,d}^n(t^n) &= F_{x,y}^n(z_{x,y,d}^n(t^n), z_{x,y,a}^n(t^n), \mathbf{v}_p, t^n) \\ 0 &= G_{x,y}^n(z_{x,y,d}^n(t^n), z_{x,y,a}^n(t^n), \mathbf{v}_p, t^n) \end{aligned} \quad (21)$$

and

$$t^n = [t_0^n \quad t_F^n] \quad (22)$$

- 3) The obtained measurements  $m_{x,y}(t)$  represent the state of each cell  $c_{x,y}$  at the time  $t$ . Moreover, in practical applications the process can be influenced by additional parameters. This remark indicates, that an external vector-valued control function  $u(t)$  can be also under considerations.
- 4) Model parameters optimization. At this stage the unknown model parameters need to be identified. The identification can be treated as a model parameters optimization according to the obtained measurements

$$\min_{\mathbf{v}_p} \sum_{i=1}^{n_x} \sum_{j=1}^{n_y} \sum_{n=1}^N (c_{i,j}(t^n) - m_{j,j}(t^n))^2. \quad (23)$$

subject to the piecewise-continuous differential-algebraic constraints. In some cases, the chosen cells can be characterized by the different properties.

Therefore, the extended vector of the model parameters need to be defined

$$\mathbf{V} = \begin{bmatrix} \mathbf{v}_{p^{1,1}} \\ \vdots \\ \mathbf{v}_{p^{1,n_y}} \\ \mathbf{v}_{p^{2,1}} \\ \vdots \\ \mathbf{v}_{p^{2,n_y}} \\ \vdots \\ \mathbf{v}_{p^{n_x,1}} \\ \vdots \\ \mathbf{v}_{p^{n_x,n_y}} \end{bmatrix}, \quad (24)$$

where in  $\mathbf{v}_{p^{a,b}}$ :  $a = 1, \dots, n_x$  and  $b = 1, \dots, n_y$ .

- 5) The aim of the optimization algorithm is to find such values of the surface temperature distribution model  $\mathbf{V}$ , which could result in a desired state of the observed process. The presented discretization procedure enables us to obtain the discrete form of the differential-algebraic model constraints and pointwise constraints representing the initial conditions. Finally, all the obtained constraints with the unknown consistent initial conditions can be represented in a short form of the nonlinear optimization problem

$$\min_{\mathbf{V}} \sum_{i=1}^{n_x} \sum_{j=1}^{n_y} \sum_{n=1}^N (c_{i,j}(t^n) - m_{j,j}(t^n))^2 = \min_{\mathbf{V}} f(\mathbf{V}) \quad (25)$$

subject to

$$c_E(\mathbf{V}) = 0 \quad (26)$$

$$c_I(\mathbf{V}) - s = 0 \quad (27)$$

$$s \geq 0. \quad (28)$$

The KKT conditions for the nonlinear optimization task in the form (25)-(28) can be presented as

$$\begin{aligned} \nabla f(\mathbf{V}) - A_E^T(\mathbf{V})\lambda_E - A_I\lambda_I &= 0 \\ S\lambda_I - \mu e &= 0 \\ c_E(\mathbf{V}) &= 0 \\ c_I(\mathbf{V}) - s &= 0 \\ s &\geq 0 \\ \lambda_I &\geq 0 \end{aligned} \quad (29)$$

where  $A_E(\mathbf{V})$  and  $A_I(\mathbf{V})$  are the Jacobian matrices of the functions  $c_E$  and  $c_I$ , respectively. Moreover,  $\lambda_E$  and  $\lambda_I$  are their Lagrange multipliers.  $S$  is the diagonal matrix with diagonal entries given by the vector  $s$ , and let  $e = (1, 1, \dots, 1)^T$  [16]. To solve the KKT system,

the interior-point optimization algorithm implemented in *fmincon* procedure [13] was used.

In the next section the results of the performed experiment, as well as the numerical computations, were presented.

#### IV. THE EXPERIMENTAL RESULTS

The experiment has been performed with a metal key, which was a part of an electrical circuit. The voltage was equal to 22 V. The key is an asymmetrical object and built from different layers. Each layer is characterized by another properties. The measurement interval was equal to 30 sec. The obtained results were presented on the Fig. 2-6.

There are two cells, which have been modeled by the proposed methodology. The applied model for each of the cells Sp1 and Sp2, had the general structure

$$\dot{z}(t) = \mathbf{v}_{p,1}z(t) + \mathbf{v}_{p,2}u. \quad (30)$$

In order to preserve the too fast changes of the object temperature, it was assumed that

$$-10 \leq \dot{z}(t) \leq 10 \quad [^{\circ}\text{C}/\text{sec}] \quad (31)$$

Finally, the optimized model parameters of the assumed model function are as follows

$$\dot{T}_{Sp1}(t) = -42.0085 \cdot T_{Sp1}(t) + 48.1760 \cdot 22 \quad (32)$$

and

$$\dot{T}_{Sp2}(t) = -38.9154 \cdot T_{Sp2}(t) + 73.5950 \cdot 22. \quad (33)$$

The obtained results indicate two important questions, which are open for the future research:

- 1) The number of possible cells is really huge. The important question is, how to use efficient parallelization methods to applied the presented methodology in a real-life optimization algorithms? [7]
- 2) In order to minimize the number of the obtained models, new cells aggregation procedures should be designed [8].

Fig. 2. The state of the object at the beginning of the process.

Fig. 3. The state of the object after 30 sec.

Fig. 4. The state of the object after 60 sec.

#### V. CONCLUSION

In the article a general optimization-based method for thermal processes modeling has been presented. The discussed methodology base on the spatio-temporal discretization of the measured process. To solve the obtained nonlinear optimization problem, the interior-point optimization algorithm was applied. The obtained results suggest two direction of the future work

- How to make the needed simulations in parallel in order to minimize a computation time?
- How to aggregate the spaces characterized by the similar properties in order to minimize the number of considered cell models?

**Abstract**—Analysis of electrocardiogram and heart rate provides useful information about health condition of a patient. The North Sea Bicycle Race is an annual competition in Norway. Examination of ECG recordings collected from participants of this race may allow defining and evaluating the relationship between physical endurance exercises and heart electrophysiology. Parameters reflecting potentially alarming deviations in the latter are to be identified in this study. This paper presents results of a time-domain analysis of ECG data collected in 2014, implementing K-Means clustering. A double stage analysis strategy, aimed at producing hierarchical clusters, is proposed. The first phase allows rough separation of data. Second stage reveals internal structure of the majority clusters. In both steps, discrepancies driving the separation could stem from three sources. The clusters were defined predominantly by combinations of features: heartbeat signals correlation, P-wave shape, and RR intervals; none of the features alone was discriminative for all the clusters.

## I. INTRODUCTION

THE North Sea Bicycle Race (Nordsjørittet) is an international competition organized annually in Rogaland, western Norway, between cities: Egersund and Sandness. It is open to a wide spectrum of competitors, from amateurs to professionals. In 2014, ECG data were collected from over a thousand participants on three days: the day of the race, the day before and after, as part of the North Sea Race Endurance Study (NEEDED). Continuation of this project with extended set of recorded data is planned for years 2017-2019.

Analysis of electrocardiogram (ECG) is a valuable tool in monitoring and diagnosis of patients for various cardiac conditions. The procedure of automatic ECG signal analysis can be performed in time or frequency domain and is usually divided into two steps: feature extraction and classifier designation [1]. There are various methods for feature extraction discussed in the literature. The aspects of Principal Component Analysis (PCA) related to ECG signal processing are discussed in [2], application of customized wavelet transform (WT) in ECG discriminant analysis is described in [3], while the use of Hilbert transform for feature extraction from ECG signal was examined in [4]. Comparison of support vector machine (SVM) algorithm and artificial neural network approach (ANN) for classification of arrhythmias in ECG signal is presented in [5]. Deep learning method for active

classification of electrocardiogram signals was applied in the research described in [6], while the clustering method for QRS complexes classification was applied in [7].

Measurement of ECG and heart rate (HR) during daily activity is a potential tool for early diagnosis of cardiac diseases and may provide individualized guidance to exercise and physical training. This project aims at identifying ECG and HR parameters useful for differentiating normal and abnormal patterns during prolonged, high intensity endurance exercise.

## II. THE DATASET AND SOFTWARE

The database consisted of 3158 ten-second ECG recordings. After rejecting participants for whom some of the recordings were missing, 996 complete sets of 3 recordings were obtained. The collection was further reduced by cases of erroneous ECG segmentation. Further analysis was conducted for 989 participants (2967 ECG recordings). The data were processed and analyzed using Python programming language with packages: BioSPPy, SciPy, and scikit-learn.

## III. DATA PRE-PROCESSING AND FEATURE EXTRACTION

The dataset provided 8-channel ECG recordings, containing signals from leads I, II, and six precordial leads. In this project, only lead-I signal was analyzed. The channel of interest was extracted and subjected to pre-processing and measurements. The procedure aimed at visualization of changes in the ECG signal over the three days and extraction of features relevant for comparison of data obtained from different participants.

### A. Data pre-processing

The lead-I ECG signal was subjected to filtering to suppress high-frequency noise and remove baseline drift using bandpass Finite Impulse Response (FIR) filter with cutoff frequencies of 3 and 45 Hz. Next, locations of R-peaks were detected applying Engelse-Zeelenberg approach modified by Lourenco et al. [8]. For singular cases in which this method failed to reliably identify the peaks (less than 3 peaks found in a 10-s recording), the detection was repeated with Christov method [9]. The identified R-peaks were used as reference during extraction of heartbeat templates, defined in a time

Fig. 1. ECG key points detection - exemplary results.

window of 0.3 s. before and 0.4 s. after the spike. Algorithms implemented in the `BioSPPy` package were used.

Finally, heartbeat templates extracted from a single recording were averaged to improve signal-to-noise ratio [10]. Additionally, parameters referring to the heart rate (mean duration and standard deviation of RR intervals) were derived.

### B. Heartbeat templates measurements

In order to measure the ECG waveforms, methods for searching key points (peaks of P, Q, R, S, and T waves, as well as onsets and endpoints of some of them) in the heartbeat templates were developed. The location of R-peak in the signal was fixed at time 0.0 s (see Fig. 1). P wave top was defined as a maximum before the occurrence of R, excluding 0.05 s directly preceding the latter. Mirror-reflected procedure was applied for determining the top of the T wave. The Q and S points were found as local minima within a fixed, short time window before and after the R. The S wave endpoint was defined as a point where the positive slope after S is <90% of its value at S. Onsets and endpoints of P and T waves were found following the idea described by Laguna et al. [11]. Exemplary results of the ECG key point search are presented in Fig. 1. Each subplot presents an averaged heartbeat template for the respective day of measurements for the same participant. The points were used to measure intervals and amplitudes of ECG signals. For estimation of amplitudes, the level of Q was regarded as the baseline. ST elevation was defined as difference in amplitude between the endpoint of the S wave and the onset of the T wave.

### C. Morphological comparison of heartbeat templates

A set of parameters was derived from comparison of morphology of the extracted heartbeats, either a full set of beats from one signal or a set of 3 averaged beats from the 3 days for a given participant. To exclude correlation changes stemming from heart rate variation between the days, processing was done on QRS complexes, whose shape did not exhibit any heart-rate dependency. A basic measure to compare the heartbeats is Pearson  $r$  coefficient. Its value was computed for every pair of heartbeats within the analyzed set. To ensure that exclusively the shape of the beats is compared, with no influence of residual baseline drift, the coefficient was calculated using first differences of the signals.

Another aspect in beat contour analysis is the idea of morphological classification [12], [13]. QRS complexes from the

1st day were iteratively compared using Pearson  $r$  coefficient. Similar peaks were grouped into a class; if similarity threshold was exceeded, a new class was created. Beats within each class were averaged to serve as templates for comparison with signals from the 2nd and 3rd day. Beats from days 2 and 3 were assigned to this of the 1st day classes to which they were the most similar. In case Pearson coefficient for a beat and each of the classes' templates was below the threshold, the beat was considered an outlier.

### D. Features definition

Ten ECG features were derived from the measurements using the above described approaches:

- Shape coefficient of P wave - ratio of height of the wave to its width; the used features expressed change in this value from day 1 to day 2 or 3 ( $P\_shape\_12$  and  $P\_shape\_13$  respectively).
- Difference in duration of QT interval on day 2 or 3 with respect to day 1 ( $QT\_12$  and  $QT\_13$  respectively).
- Difference in duration of RR interval on day two or three with respect to day 1 ( $RR\_12$  and  $RR\_13$  respectively).
- Change (difference) in mean correlation of heartbeat templates from the 2nd or 3rd recording with respect to correlation in the 1st day ( $correlation\_12$  and  $correlation\_13$  respectively).
- Maximal ST elevation ( $max\_ST\_elev$ ) - maximum from values measured on the three days. ST elevation itself, not necessarily its change from day to day, should be regarded as an alarming ECG feature. [14]
- Percentage of morphological outliers - percentage of beats from days 2 and 3 not matching any beat class defined in day 1 for the given participant (expressed with relation to total number of beats from the three days), as defined in the previous section ( $morph\_outliers$ ).

Features based on differences between days are defined by subtracting value on day 2 or 3 from value on day 1. Positive values of these features indicate a decrease with respect to day 1 (shorter intervals or decline in correlation).

## IV. FEATURE SET ANALYSIS

Analysis of the derived set of features was performed by unsupervised clustering. Clustering on the entire dataset tends to yield one or more larger clusters and a few 'far outliers' groups, containing points significantly separated from the majority. Therefore a two-stage procedure was developed: after first-attempt analysis and clustering, the outliers' clusters (containing <10% of the total number of observations) were removed and the analysis was repeated to reveal structure of the majority clusters. Each of the two stages consisted of two main elements: principal component analysis (PCA) and K-means clustering combined with silhouette analysis.

### A. Principal Component Analysis

PCA is a statistical operation aimed at reduction of dimensionality of the clustering data [15], frequently applied prior to K-means clustering. It allows reducing computational effort by

decreasing number of dimensions to be analyzed and suppressing possible correlation between the original features [16]. PCA was applied after data normalization on both stages of the analysis. Six principal components, explaining 80% of the data variance, were retained. The data mapped on the PC space was passed to clustering and silhouette analysis.

### B. Clustering with Silhouette Analysis

Since no prior assumptions on the structure of the data were made, and the K-means clustering requires specified number of clusters as an input, silhouette analysis was launched on the dataset. It allows validating consistency of computed clusters by comparing cohesion of each sample and its separation from other clusters. The resulting silhouette score is a fraction between -1 and 1, where 1 represents good sample classification and -1 indicates that the sample might have been assigned to an improper cluster. Average silhouette score of all samples allows assessing general consistency and validity of the clustering [17]. Silhouette analysis on the PC-transformed data was performed for number of clusters ranging from 2 to 7 to choose the one with highest average score. K-means clustering with the chosen number of clusters was applied to the dataset mapped to the reduced PC space. The result was presented and analyzed graphically in the PC and the original feature space for both processing stages.

## V. RESULTS AND DISCUSSION

The results of clustering in the original feature space and PC space are presented in scatter plot of observations in two dimensions of the feature space (Fig. 2-5). The results of PCA are shown as bar plots of components' eigenvectors (Fig. 6).

In the first stage of the analysis, the majority (over 90%) of observations were assigned to cluster 1, while the other two clusters are smaller (Fig. 2 and 3). Cluster 2 is separated from the other two with respect to the PCs 4 and 5 (Fig. 2a), defined mainly by percentage of morphological outliers and ST elevation (Fig. 6a). As confirmed by Fig. 3a, this cluster is composed of the observations with high values for morphological outliers percentage, while in most cases the values are close to 0. Cluster 0 in PC 4&5 projection is overlapped partially with clusters 1 and 2. However, it is clearly separated when observed from PCs 1 and 3, exhibiting high dependence on beat correlation (Fig. 3b). Analysis of respective projection of the data reveals majority of the points being concentrated around the (0,0) point, indicating little change in intra-recording beat correlation between the days. For some participants - assigned to cluster 0 - correlation on both the 2nd and 3rd day was considerably high when compared to day 1. This is typically not accompanied by increased percentage of morphological outliers since the latter uses day 1 as a reference. Since the clusters 0 and 2 encompassed minor portion of the observations (1.2% and 4.8% respectively), they were excluded from further analysis. The second stage of the procedure was conducted on the points originally assigned to cluster 1. In second phase results, the three major clusters (0, 1, and 4) can be discriminated by looking i.a. at principal

Fig. 2. Result of clustering on the full dataset, in the PC space - projection on: (a) PCs 4 and 5; (b) PCs 1 and 3. (normalized).

Fig. 3. Result of clustering on the full dataset, in the original feature space - projection on: (a) QT interval difference (days 1 and 2) and percentage of morphological outliers; (b) correlation difference-related features.

components 1 and 4 (Fig. 4a), dependent on maximal ST elevation and features related to QT and RR interval (Fig. 5a). Clusters 2, 3, and 6, can be distinguished by projection onto PCs 2 and 3, defined predominantly by features associated with shape of the P wave, correlation, and morphological outliers percentage (Fig. 6 and Fig. 4b). Statistical significance of the latter was slightly lower than in the first stage of the analysis (considering its contribution to the first two PCs); however, it is still one of main components differentiating cluster 2 from others (as shown in Fig. 5b). This is particularly interesting when compared to correlation representation of the clustering result (Fig. 5c). Cluster 2 is constituted by points for which decreased correlation was indeed observed, but predominantly either on day 2 or 3; rarely on both days. On the other hand, closer look at the P shape allows discriminating cluster 3 (Fig. 5e). For participants belonging to this cluster, P wave was flattened (lower height-to-width ratio) in days 2 and 3 with respect to day 1. The change in shape was more prominent than observed in the other groups. Finally, cluster 5 is distinctly separated with respect to PCs 5 and 6 (Fig. 4c). It was not reflected in any of the first components due to relatively small size of this cluster (ca. 0.5% of all observations), which diminishes its impact on the total variance of the dataset. Original features that contribute the most to this component include those related

with QT and RR intervals. As presented in Fig. 5d, decrease in duration of QT interval is in general correlated with increase in RR interval. For cluster 5, however, this trend does not apply. Further detailed investigation is needed to determine whether the phenomenon is a question of improper key point localization or a sign of potential cardiac issue.

## VI. CONCLUSION

The NEEDED study focuses on characterization patterns associated with a prolonged endurance exercise. One of its major goals is identification of parameters related to ECG and heart rate which could be used to distinguish between regular and deviated heart performance. Several potentially discriminative features were recognized. Further investigation and validation with additional data is needed to verify their relevance in detection of electrocardiophysiological abnormalities.

The study was conducted using 2 stage clustering and principal component analysis. It was found that no single feature or principal component would provide separation between all the clusters globally. Each cluster could be described by a combination of two to four features making it distinguishable. Determination of features defining the partition was facilitated by analysis of eigenvectors of the principal components. However, PCA is only based on variance of the dataset, which is not equivalent to separation between clusters. Discriminative features are always reflected in high values in PCs' eigenvectors, but the reverse is not always true.

The presented method produces hierarchical structure of clusters. This allows 2-level investigation of the data structure, with separate insight in huge discrepancies and more subtle trends. Furthermore, the hierarchy is also followed in analysis of statistical significance of the features. Combined with additional data, it could be used in differentiation between natural groups among the population and allow early detection of certain cardiac abnormalities.

Future works include a fusion of time-domain and frequency-domain analysis of the ECG data. The new dataset will be supplemented with information of i.a. patients' age, gender, the race completion time, and possibly indication of medical condition. This will allow to verify the significance of the ECG features derived and investigated in this paper.

**Abstract**—Code review is a key tool for quality assurance in software development. It is intended to find coding mistakes overlooked during development phase and lower risk of bugs in final product. In large and complex projects accurate code review is a challenging task. As code review depends on individual reviewer predisposition there is certain margin of source code changes that is not checked as it should. In this paper we propose machine learning approach for pointing project artifacts that are significantly at risk of failure. Planning and adjusting quality assurance (QA) activities could strongly benefit from accurate estimation of software areas endangered by defects. Extended code review could be directed there. The proposed approach has been evaluated for feasibility on large medical software project. Significant work was done to extract features from heterogeneous production data, leading to good predictive model. Our preliminary research results were considered worthy of implementation in the company where the research has been conducted, thus opening the opportunities for the continuation of the studies.

### I. INTRODUCTION

DEFINING QA processes is a challenging task for organizations developing software-intensive systems. QA efforts could strongly benefit from accurate estimation of error prone project areas. Taking into account relative cost of fixing software defects based on time of detection, any improvements in early development stage are worth the effort (Fig. 1). The National Institute of Standards and Technology (NIST) estimates that code fixes performed after release can result in 30 times the cost of fixes performed during the design phase [1]. Additional costs may include a significant loss of productivity and confidence. The NIST report also indicates, that involving programmers in tracking and correcting their own errors, by reviewing code before run time testing improves their programming skills. Curhan states that “some types of defects have a much higher costs to fix due to the customer impact and the time needed to fix them or the wide distribution of the software in which they are embedded” [2]. Adam Kolawa [3] defines error as a human mistake and a defect as a fault, bug, inaccuracy, or lack of expected functionality in a project artifact. Broad definition of defects, thus includes problems such as contradicting requirements, design oversights or coding bugs. With proper

processes for requirements and design review in place, when building prediction model we are focusing on coding problems only. In fact, every software moved to production contains defects, although many are not detected yet. Thus, undeniable increase of corrections costs for subsequent project stages lead to conclusion that major effort should be put in the earliest possible phases of software production process. We assume that best place to focus is code review stage, a place in the process, when we have a chance to eliminate the problems at its genesis (Fig. 2) McIntosh et. al. [4] summarized their case study with statement: “Components with higher review coverage tend to have fewer post-release defects”. Their analysis also indicates that “Although review coverage is negatively associated with software quality in our models, several defect-prone components have high coverage rates, suggesting that other properties of the code review process are at play.” In our situation, company with full code review coverage, still face relatively large number of defects reported.

We put the thesis, that with predicting code changes failures we can direct more focus on endangered areas, with additional code review, and have potential defects corrected before testing phase. That would significantly improve final software quality, with lower operational costs. Important part of this research is feature engineering that allows building reliable problem prediction model. There is also proposed approach for software development process with defect prevention mechanism, improving QA effectiveness in large and complex software projects. Particular attention is paid to having the research applicable in real life scenarios. Our preliminary research results were considered worthy of implementation in the company. The authors’ contribution to the work is feature set development, data mining from variety of sources, feature selection and building reliable prediction model. We explicitly define our goals aligned the objectives of company in Section 2. We explain how the results will be evaluated in Section 3. Data acquisition caveats and the data set are presented in Section 4. We present main challenges and taken approach to getting results in Section 5. We conclude with summary of our work and future suggestions in Section 6, followed by Appendix with list of all attributes acquired for this research.

This work was supported by SoftSystem Sp. z o.o.

## II. GOALS

The main objective in this work was to build problem predictor model that could be integrated into process of a large software project to support decisions and improve quality of final products. The paper is a case study on building *Rework* prediction system for one of the leading companies developing software for hospitals and medical laboratories around the world. Company established QA department over 15 years ago and employs highly qualified testing team working according to best industry standards. Along with manual testing there is also automated testing team that is continuously monitoring product quality. The company has been certified to the ISO 9001:2008 and ISO 13485:2012 standards [5]. With the requirements for a quality management system, specific to the medical devices industry, the company is expected to constantly improve quality management processes. A good example of such actions is implementing static code analysis process, which increased source code overall quality, but it has not had significant influence on number of defects in general. Company introduces changes

in processes on different organizational levels to improve quality, and our research is part of these endeavors.

Number of source code change reworks is constant for last three years (Fig. 3). This period will be a base for building a prediction model. Rework stands for “change implemented by programmer that was rejected, qualified for correction either by code reviewer or testing team”. Software change can be rejected for multiple reasons and our analysis will focus on following categories:

- Source code review failed
  - Source changes rejected by programmer
  - Static code analysis problems detected
- Functional testing failed
  - Manual testing (change, integration, etc.)
  - Automated testing (acceptance, regression)

The expected problem detection moment is when the programmer completed the work. Ideally, the programmer who is implementing the change, reviews the code and corrects bugs that were introduced, before passing the finished work for code review by other programmer and testing. Also acceptable situation is when code reviewer (technical team leader) is able to track down the problems and move the implementation back for corrections. Our goal is to support this flow of events. The complete change called “an issue” consists of functional requirements, design documents and files that were modified and submitted to Apache Subversion (SVN), a software versioning and revision control system. In this work we consider reworks as individual files, that were submitted to SVN after rejection of the whole change. The assumption was made, that these files are “reworked” and, they require additional changes or corrections. That is not true for every instance but acceptable for purpose of building the model in this research.

The company requested to have reliable information which source code changes require extensive code review. Information about records with increased risk should be delivered as soon as programmer completes the work and marks the task as ready for review. To guide development

Fig 3. Rejected code changes vs. correct changes, in years 2014-2016, monthly

teams, our model should be able to classify particular file changes either *Correct* or *Rework*.

### III. MODEL EVALUATION

Performance of the classifier is measured with Confusion Matrix, which is a table describing predictive ability of a classifier on test data set for which the true values are known, as in Table 1. *Rework* denotes positive value and *Correct* denotes negative value.  $T_p$ ,  $F_p$ ,  $T_n$ , and  $F_n$  denote the number of true positives, false positives, true negatives, and false negatives, respectively. Predictive ability of multiple models can be compared by measuring the area under receiver operational characteristics (AUROC) of each classifier [6]. Receiver operating characteristic (ROC) is a curve on two dimensional space where x axis is False Positive Rate (i.e.  $F_p/(F_p+F_n)$ ) while y axis is the True Positive Rate (i.e.  $T_p/(T_p+T_n)$ ). We measure True Positive Rate and False Positive Rate of the classifier and the set of attributes. Measurements are taken directly from Weka software. A perfect classifier's False Positive Rate is zero and True Positive Rate is one, thus the perfect classifier is a point on ROC curve. A completely random classifier would have equal true and false positive rates, therefore a random classifier is a diagonal line on the ROC curve. We expect any good classifier to be above the random curve and close to the perfect point (0.0, 1.0).

TABLE I.  
CONFUSION MATRIX FOR REWORK PREDICTOR

		Predicted	
		Correct (negative)	Rework (positive)
Actual	Correct (negative)	$T_n$	$F_p$
	Rework (positive)	$F_n$	$T_p$

Results of the classification can be said to be precise if the values are close to the average value of the quantity being measured, while the results can be said to be accurate if the values are close to the true value of the quantity being measured. Precision and accuracy are defined [7] as follows:

$$Precision = \frac{T_p}{T_p + F_p} \quad (1)$$

$$Accuracy = \frac{T_p + T_n}{T_p + F_p + T_n + F_n} \quad (2)$$

Sensitivity is the probability that a model will indicate *Reworks* among those which actually are *Reworks*:

$$Sensitivity = \frac{T_p}{T_p + F_n} \quad (3)$$

Specificity is the fraction of *Correct* records which will be qualified as *Correct*

$$Specificity = \frac{T_n}{T_n + F_p} \quad (4)$$

Sensitivity and specificity are characteristics of the model that does not depend on *Correct* and *Rework* proportions. Although in our situation significant classes imbalance has to be taken into consideration as there are only 17% *Reworks* in data. Thus, important variable in model evaluation is the prevalence of the *Reworks* in question. Prevalence is defined as the percent of instances in the test set that actually are *Reworks*.

$$Positive\ Prevalence = \frac{T_p + F_p}{T_p + F_p + T_n + F_n} \quad (5)$$

Development team would like to get answer to question: what is the chance that a file change classified as a *Rework* truly is a *Rework*? If classified record is in the second row of Table 1, what is the probability of being  $T_p$  as compared to  $F_p$ ? An answer to these questions would be Positive Predictive Value (PPV) and Negative Predictive Value (NPV). Both PPV and NPV are influenced by the positive prevalence of *Rework* instances in the test set. If we test in a high prevalence setting, it is more likely that instances qualified as *Rework* truly are *Reworks* than if the testing is performed in a set with low prevalence.

$$Positive\ Predictive\ Value = \frac{T_p}{T_p + F_p} \quad (6)$$

$$Negative\ Predictive\ Value = \frac{T_n}{T_n + F_n} \quad (7)$$

### IV. DATA

The data set used to build and test the model consists of files changes registered during development of medical laboratory software, between years 2014-2016. The data set contains 237128 observations and a large number of explanatory variables (20 nominal, 6 ordinal and 51 numeric) involved in assessing file change values. Data were collected from many data sources (project management database, issue tracker, requirements library, human resource management database, source control repository, and code metrics software) and consolidated into one data set. Each record is an individual file, changed in context of bigger entity which is a task. For each record (file change) there has been class assigned, appropriately *Correct* or *Rework*.

The combination of data from different systems was possible thanks to the processes that were introduced by the QA department and good integration of these systems. To commit changes to source control (in our case it was SVN), programmer should have created earlier and approved valid task number. SVN was configured in the way that changes with wrong task number were rejected. If a programmer passes valid task number, information about all changed files with change type (A- added, U – updated, D – deleted) and information about author are stored in issue tracker system. This way data about all revisions are stored in system.

The company uses proprietary system for development management called SoftDev.

To query data from the company systems related to development management we used SQL queries. For manipulating the data, we used Java JDMP [8] and Python Pandas [9] libraries. The data was stored in CSV (comma separated value) format. For basic data set, we have created collection of additional mining scripts that queried other systems (source control system (SVN), HR database, requirements library and code metrics software) for contextual data.

In our rework prediction research, large number of features has been collected and grouped into following five categories:

- Employee metrics – metrics containing information about author of file change. All attributes are time aware and are in reference when change was made. We measure for example experience in module(MX) affected by change, experience in sub-module (DMX) as well as experience in file (UEXP).
- Task metrics – set of metrics related to change request.
- Changed file metrics – attributes related to modified file.
- Change quantitative metrics – metrics of file change size.
- Source code metrics – metrics obtained from static code analysis using tool SourceMonitor [10].

All attributes description is available in the appendix.

Medical laboratory system that is subject of this research is developed in Java and .Net programming languages. Client part, Graphic User Interface (GUI) is built with .Net Windows Forms technology. Server part in Java implements logic, database operations, and exposes web-services for GUI. Most of coding tasks require changes in both .Net and Java classes. This limits the number of source code metrics only to those applicable to both technologies. The project is modular with about 4 million Java lines of code and 7 million .Net lines of code. All source code files for the analysis retrieved from source control repository took challenging 85 GB of disk space. This is caused by development running on several branch lines that are separated from main development for months or years. All these development lines were included in the research.

Acquired historical data (2014-2016), with only Java and .Net files has 237128 records, which gives around 300 files committed a day, where 17% was marked as a *Rework*. Learning from historical instances we could predict which changes will be *Reworked* and assign it for more extensive review (review could be done by additional programmers or architects). With 17% detected defects there is certain amount of overlooked problems that will be included in release version, but some of them could have been discovered if critical changes were reviewed more carefully. In defect prediction studies [11],[12], both process and source code metrics are used. We were not able to get satisfactory results with commonly used attributes as well as [13] and [14].

With company software development experts, we worked out long list of attributes that are worth including in prediction model. Apart from attributes commonly used in defect prediction practices, we tried to build other, like these describing employee metrics with experience per module (on different modularization levels), employee history in terms of failures, task complexity related to number of functional requirements or number of people involved in task coding. Final list contains 77 attributes.

## V. RESULTS

We used WEKA 3.8.1 [15] software package to build classifiers, select features and produce prediction reports with metrics described in section II. WEKA is an open-source package initiated by University of Waikato, with rich collection of machine learning algorithms for data mining tasks. The algorithms can be either applied directly to a data set or from the Java source code. Due to large data set in our research (223712 records with 77 attributes) we had to use distributed computing when evaluating different classifiers and subsets of attributes.

To reflect real use case for the system, we have trained classifier with 90% of all data and tested with remaining 10%. Assumption is that the model will be built with historical data for certain period, and new instances will be classified with it. Prediction model should be rebuilt every month. Taking into account software development process changes and experience with production cycle specifics we chose 3 years period as input for the model. Results of testing with models built for shorter periods confirmed this decision.

Performance of different classifiers and attribute sets, due to significant imbalance in class distribution, has to be done by measuring the AUROC of each classification [7]. From our experience in this research, the problem of attributes selection was a key aspect to obtain satisfactory results, which was also confirmed by [16], [17], and [18]. With appropriate attributes identified, the better accuracy could be achieved for a smaller sets of attributes with a simple appropriate classifier. We evaluated the following attribute selection algorithms:

- *CorrelationAttributeEval* which evaluates the worth of an attribute by measuring the correlation (Pearson's) between it and the class
- *PrincipalComponents* which performs a principal components analysis and transformation of the data
- *ReliefAttributeEval* which evaluates the worth of an attribute by repeatedly sampling an instance and considering the value of the given attribute for the nearest instance of the same and different class.
- *GainRatioAttributeEval* which evaluates the worth of an attribute by measuring the gain ratio with respect to the class
- *InfoGainAttributeEval* which evaluates the worth of an attribute by measuring the information gain with respect to the class

All these attribute selection methods were tested with Weka ranker which ranks attributes by their individual evaluations. Ranker was also used to find best number of attributes, evaluating in range of 15 to 65 attributes with step 6. Combination of 5 classification algorithms, attribute selection methods and number of attributes gave challenging number of 275 cases for grid search. Calculations were done with WEKA distributed computing, using company server resources. The best result has been achieved for Random Forest algorithm with 25 attributes selected with *InfoGainAttributeEval* algorithm.

Performance comparison of selected classifiers is presented in Table II. For chosen list of attributes the Random Forest algorithm provided the highest performance measure by means of AUROC (0.930). The results for other metrics are presented in Tables III-IV.

TABLE II.  
COMPARISON OF DIFFERENT CLASSIFIERS

Classification algorithm	Attribute selection algorithm	Number of attributes	AUROC
Random Forest	InfoGainAttributeEval	25	0.930
Bayes Net	GainRatioAttributeEval	60	0.816
C4.5	InfoGainAttributeEval	20	0.872
KNN	GainRatioAttributeEval	20	0.829
Naive Bayes	GainRatioAttributeEval	45	0.787

TABLE III.  
CONFUSION MATRIX FOR BEST PREDICTION MODEL

		Predicted	
		Correct (negative)	Rework (positive)
Actual	Correct (negative)	19755	543
	Rework (positive)	1290	2125

The interpretation of the results for development team is:

TABLE IV.  
BEST PREDICTION MODEL PERFORMANCE METRICS

Metric	Value
Precision	97.12 %
Accuracy	92.27 %
Sensitivity	62.23 %
Specificity	97.32 %
AUROC	0.930
Positive Prevalence	11.25 %
Positive Predictive Value	79.64 %
Negative Predictive Value	93.87 %

**If model classifies records as *Correct*, its confidence is 94%. Only 11% of all changed files have to be sent for extended code review, to hit 79% potential problems. Predictive model is able to recognize correctly 62% of all Reworks.**

We evaluated the classifier using 10 folds cross validation to find out that results are very close to those done in percentage split test. We take this as a confirmation, that prepared model is stable and ready for use in real life scenarios. List of all attributes mined in this research is available in Appendix, with best 25 preselected attributes, marked with a star (\*).

## VI. Conclusions

Our *Rework* prediction model will support QA activities with effective estimation of software areas that are at risk by mistakes introduced during source code changes. System will direct extended code review to these places. The proposed approach has been evaluated for feasibility on large medical software project and research results were considered worthy of implementation in the company where the research has been conducted. With very high precision (97.12 %) and accuracy (92.27 %), company should expect visible effects after implementation of the system build upon our research results. We show that by comparing AUROC values, Random Forest provides *Rework* prediction models with better predictive ability than other algorithms like Bayes Net, C4.5, KNN, and Naive Bayes. We believe that sophisticated mechanisms developed to collect the data for this research will be a base for subsequent analysis, and knowledge retrieved will support project management. Subjective medical software project is developed in multiple remote offices in different locations around the world, making the data set even more challenging and interesting from analytical point of view.

Next steps would include incorporating the prediction model into company regular operations and follow up on mechanisms to measure effectiveness of the implementation.

## APPENDIX

### Attributes collected from project management database:

- ISST* Problem category with possible values: Defect, Deficiency, Enhancement, Performance, Refactoring, Coding Standard, Demo, Custom scripts, Test Case, External – 3rd party
- ISSS* Severity of issue with possible values: Non Critical, Critical, Risk to Health
- ISSP* Priority of issue. Available values: 0-5 (Low - Urgent)
- HLE* Task coding time high level estimation in hours (\*)
- OFF* Employee office name

### Attributes collected from issue tracker system:

- CR* Task number. Generally task is created from issue and is assigned to programmer.

*IMPBY* Person who marked task as ‘Implemented’ (done). After this action task is passed to testing team.

*IMPD* Date when person marked task as ‘Implemented’

*SOLBY* Person who created solution for task. (Generally, it is more experienced person like architect or team leader)

*SOLT* This is set of 20 predefined values describing type of solution.

*ECH* Estimated hours for coding based on all details from task (\*)

*ACH* Actual hours spent on coding. (\*)

*NCMR* Number of commits for task (\*)

*NFCR* Number of file changed for task (\*)

*PINCR* Number of users who committed changes within task

*NAM* Number of affected modules (\*)

*NADM* Number of affected “dipper modules” (\*)

*NCSR* Number of .net files changed within task (\*)

*NJVR* Number of java files changed within task (\*)

*ASM* Number of affected files in the same module (\*)

*ASDM* Number of affected files in the same “dipper module” (\*)

*AOM* Number of affected files in other modules (\*)

*AODM* Number of affected files in “dipper modules” (\*)

#### **Data collected from issue tracker system on ‘file change level’:**

*CBY* Person who committed file change to source control system

*REV* Source control revision related to change

*OPT* File change operation: A – addition, D – deletion, U – update

*PAT* Absolute path to modified file in source control tree

*RPAT* Relative path to modified file

*BRA* Source control branch name

*PROJ* Project name of modified file

*MOD* Module name of modified file

*DMOD* Very big modules were divided it into small pieces called “dipper module”

*LAN* Coding language of modified file

*RWRK* This information stating if particular file change was good or was not. If at least one file was marked as rework, then related task was also marked as rework

*URE* This is information on how many reworks has person who committed particular change in his/her history. Attribute was calculated from the whole user history till commit date (\*)

*URYB* This is information on how many reworks has person who committed particular change over the last year (\*)

*NOFF* Number of commits of file within task (\*)

*PIIF* Number of people involved in file within task

#### **Attributes collected from source control (svn):**

*MCEXP* Sum of all modifications on file made by user who committed change till commit date

*TC* Sum of all modifications on file made by all users till commit date. This attribute may be treated as file age measures in changes.

*CGTC* File age categorized by expert into 8 categories

*UEXP* Contribution of committed user in file till commit date expressed in percentage

*CGUX* User Contribution categorized by expert into 6 categories

*NFUX* For 63 records we cannot establish user experience

*MMX* Sum of all modifications on module made by user who committed change till commit date (\*)

*DMMX* Sum of all modifications on “dipper module” made by user who committed change till commit date (\*)

*TMX* Sum of all modifications on module made by all users till commit date. This attribute may be treated as module age measures in changes (\*)

*TDX* Sum of all modifications on “dipper module” made by all users till commit date. This attribute may be treated as module age measures in changes (\*)

*MX* Contribution of committed user to module till commit date expressed in percentages (\*)

*DMX* Contribution of committed user to “dipper module” till commit date expressed in percentage (\*)

*CMX* User Contribution categorized by expert into 8 categories

*CDMX* Same as CMX but on “dipper module” level

*DIFI* Number of line insertions on a file in last commit

*DIFD* Number of line deletions on a file in last commit

*DIFC* Number of chunks on a file in last commit

*DIFER* For 60 records we cannot establish last commit size

*SDIFI* Sum of all line insertions per file per task

*SDIFD* Sum of all line deletions per file per task

*SDIFC* Sum of all chunks per file per task

*LFRD* Duration of the file change process measured in the number of revisions throughout the project (\*)

*LMP* How many days have elapsed since last modification of file in concrete svn branch

*LMRP* How many days have elapsed since last modification of file across all svn branches

*LMU* How many days have elapsed since last modification of file across all svn branches by user who committed this change

*DAISS* Number of requirements assigned to issue (\*)

*DACR* Number of requirements assigned to task (\*)

#### **Source code metrics for Java and .Net classes:**

*WBA* Average block depth for file

*WBB* Agerage complexity for file

*WBC* Number of lines of code

*WBD* Number of statements

*WBE* Number of statements per method

*WBF* Number of lines number of deepest block

*WBG* Number of lines of most complex method

*WBH* Maximum complexity

*WBI* For 3124 records we were not able to obtain metrics from file exported by SourceMonitor

*WBJ* For 9 records SourceMonitor throws an exception  
*WBK* For files that were deleted metrics were not calculated

**Abstract**—This paper presents a deep analysis of literature on the problems of optimization of parameters and structure of the neural networks and the basic disadvantages that are present in the observed algorithms and methods. As a result, there is suggested a new algorithm for neural network structure optimization, which is free of the major shortcomings of other algorithms. The paper describes a detailed description of the algorithm, its implementation and application for recognition problems.

## I. INTRODUCTION

THE unit of neural networks is widely used to solve various problems including recognition tasks. The existence of a method for automatic search of neural network optimal structure could provide an opportunity to get the structure of a neural network much faster, that would better suit the subject area and existing incoming data.

Since there are no well-defined procedures for selecting the parameters of a NN and its structure for a given application, finding the best parameters can be a case of trial and error.

There are many papers, like [1-3] for example, in which the authors arbitrarily choose the number of hidden layer neurons, the activation function, and number of hidden layers. In [4], networks were trained with 3 to 12 hidden neurons, and it was found that 9 was optimal for that specific problem. The GA had to be run 10 times, one for each of the network architectures.

Since selecting NN parameters is more of an art than a science, it is an ideal problem for the GA. The GA has been used in numerous different ways to select the architecture, prune, and train neural networks. In [5], a simple encoding scheme was used to optimize a multi-layer NN. The encoding scheme consisted of the number of neurons per layer, which is a key parameter of a neural network. Having too few neurons does not allow the neural network to reach

an acceptably low error, while having too many neurons limits the NN's ability to generalize.

Another important design consideration is deciding how many connections should exist between network layers. In [6], a genetic algorithm was used to determine the ideal amount of connectivity in a feed-forward network. The three choices were 30%, 70%, or 100% (fully-connected).

In general, it is beneficial to minimize the size of a NN to decrease learning time and allow for better generalization. A common process known as pruning is applied to neural networks after they have already been trained. Pruning a NN involves removing any unnecessary weighted synapses. In [7], a GA was used to prune a trained network. The genome consisted of one bit for each of the synapses in the network, with a '1' represented keeping the synapse, while a '0' represented removing the synapse. Each individual in the population represented a version of the original trained network with some of the synapses pruned (the ones with a gene of '0'). The GA was performed to find a pruned version of the trained network that had an acceptable error. Even though pruning reduces the size of a network, it requires a previously trained network. The algorithm developed in this research optimizes for size and error at the same time, finding a solution with minimum error and minimum number of neurons.

Another critical design decision, which is application-specific, is the selection of the activation function. Depending on the problem at hand, the selection of the correct activation function allows for faster learning and potentially a more accurate NN. In [8], a GA was used to determine which of several activation functions (linear, logsig, and tansig) were ideal for a breast cancer diagnosis application.

Another common use of GA is to find the optimal initial weights of back-propagation and other types of neural networks. As mentioned in [9], genetic algorithms are good for global optimization, while neural networks are good for local optimization. Using the combination of genetic algorithms to determine the initial weights and back propagation learning to further lower error takes advantage of both strengths and has been shown to avoid local minima in the error space of a given problem. Examining the specifics of the GA used in [1] shows the general way in

<sup>1</sup> Presented results of the research, which was carried out under the theme No. E-3/627/2016/DS, were funded by the subsidies on science granted by Polish Ministry of Science and Higher Education.

which many other research papers use GA to determine initial weights. In [1], this technique was used to train a NN to perform image restoration. The researchers used fitness based selection on a population of 100, with each gene representing one weight in the network that ranged from -1 to 1 as a floating point number. Dictated by the specifics of the problem, the structure of the neural network was fixed at nine input and one output node. The researchers arbitrarily chose five neurons for the only hidden layer in the network. To determine the fitness of an individual, the initial weights dictated by the genes are applied to a network which is trained using back propagation learning for a fixed number of epochs. Individuals with lower error were designated with a higher fitness value. In [9-10], this technique was used to train a sonar array azimuth control system and to monitor the wear of a cutting tool, respectively. In both cases, this approach was shown to produce better results than when using back-propagation exclusively. In [11], the performance of a two back propagation neural networks were compared: one with GA optimized initial weights and one without. The number of input, hidden, and output neurons were fixed at 6, 25, and 4, respectively. Other parameters such as learning rate and activation functions were also fixed so that the only differences between the two were the initial weights.

In [1, 10-12], each of the synaptic weights was encoded into the genome as a floating point number (at least 16 bits), making the genome very large. The algorithm developed in this research only encodes a random number seed, which decreases the search space by many orders of magnitude. Determining the initial values using the GA has improved the performance of non-back propagation networks as well. In [13], a GA was used to initialize the weights of a Wavelet Neural Network (WNN) to diagnose faulty piston compressors. WNNs have an input layer, a hidden layer with the wavelet activation function, and an output layer. Instead of using back propagation learning, these networks use the gradient descent learning algorithm. The structure of the network was fixed, with one gene for each weight and wavelet parameter. Using the GA was shown to produce lower error and escape local minima in the error space. Neural networks with feedback loops have also been improved with GA generated initial weights.

Genetic algorithms have also been used in the training process of neural networks, as an alternative to the back-propagation algorithm. In [14] and [15], genes represented encoded weight values, with one gene for each synapse in the neural network. It is shown in [16] that training a network using only the back-propagation algorithm takes more CPU cycles than training using only GA, but in the long run back-propagation will reach a more precise solution. In [17], the Improved Genetic Algorithm (IGA) was used to train a NN and shown to be superior to using a simple genetic algorithm to find initial values of a back propagation neural network. Each weight was encoded using a real number instead of a binary number, which avoided lack of accuracy inherent in binary encoding. Crossover was only performed on a random number of genes instead of all of them, and mutation was performed on a random digit

within a weight's real number. Since the genes weren't binary, the mutation performed a "reverse significance of 9" operation (for example 3 mutates to 6, 4 mutates to 5, and so on). The XOR problem was studied, and the IGA was shown to be both faster and produce lower error. Similar to [2], this algorithm requires a large genome since all the weights are encoded.

Previously, genetic algorithms were used to optimize a one layered network [18], which is too few to solve even moderately complex problems. Many other genetic algorithms were used to optimize neural networks with a set number of layers [1-2, 11, 13, 19-20]. The problem with this approach is that the GA would need to be run once for each of the different number of hidden layers. In [19], the Variable String Genetic Algorithm was used to determine both the initial weights of a feed forward NN as well as the number of neurons in the hidden layer to classify infrared aerial images. Even though the number of layers was fixed (input, hidden, and output), adjusting the number of neurons allowed the GA to search through different sized networks.

A wide range of algorithms is used to build the optimal neural network structure. The first of these algorithms is the tiled constructing algorithm [21]. The idea of the algorithm is to add new layers of neurons in a way that input training vectors that have different respective initial values, would have a different internal representation in the algorithm. Another prominent representative is the fast superstructure algorithm [22]. According to this algorithm new neurons are added between the output layers. The role of these neurons is the correction of the output neurons error. In general, a neural network that is based on this algorithm has the form of a binary tree.

In summary, the papers mentioned above studied genetic algorithms that were lacking in several ways:

1. They do not allow flexibility of the number of hidden layers and neurons.
2. They do not optimize for size.
3. They have very large genomes and therefore search spaces.

The algorithm described in this article addresses all of these issues. The main goal of this work is to analyze the structure optimization algorithm of neural network during its learning for the tasks of pattern recognition [23] and to implement the algorithm using program instruments.

## II. THE ALGORITHM OF STRUCTURAL OPTIMIZATION DURING LEARNING

Structural learning algorithm is used in multilayer networks and directs distribution networks and has an iterative nature: on each iteration it searches for the network structure that is better than the last one. Network search is performed by sorting all possible mutations of network and by selection and combination of the best ones (selection and crossing).

Consider the basic parameters of the algorithm.

Learning parameters:

- learning rate:  $\eta$ ;

- inertia coefficient:  $\mu$ ;
- damping weights coefficient:  $\varepsilon$ ;
- probability of hidden layer neuron activation:  $p_h$ ;
- probability of input layer neuron activation:  $p_i$ .

Structured learning parameters:

- initial number of neurons in the hidden layer;
- activation function for the hidden layer;
- activation function in the output layer;
- maximum number of mutations in the crossing;
- number of training epochs of the original network;
- number of training epochs in the iteration;
- acceptable mutation types;
- part of the training sample used for training.

### III. ELEMENTARY STRUCTURAL OPERATIONS ON NEURAL NETWORK

According to [24] the following basic structural operations on the network have been introduced:

- adding a synapse between two randomly selected unrelated network nodes or neurons – operation  $Syn_{ADD}$ ;
- removing the synapse between two randomly selected unrelated network nodes or neurons – operation  $Syn_{DEL}$ ;
- moving synapse between two randomly selected unrelated network nodes or neurons – operation  $Syn_{MOD}$ ;
- changing the activation function of the neuron to randomly selected neuron – operation  $A_{MOD}$ ;
- serialization of the node or the neuron – operations  $Ser_{NODE}$  and  $Ser_{NR}$ ;
- parallelization of the node or the neuron – operations  $Par_{NODE}$  and  $Par_{NR}$ ;
- adding a node or a neuron – operations  $Add_{NODE}$  and  $Add_{NR}$ ;
- create a new layer – operation  $L_{ADD}$ ;
- removing the layer NN – operation  $L_{DEL}$ .

The use or nonuse of described structural operations depends on the complexity of the task.

For recognition problems that will be described in this article operations (mutations) described in [25] are used.

### IV. ALGORITHM IMPLEMENTATION

Internally neural networks are presented as numeric matrix sequences of each layer weight except for the input one. In Fig.1 the matrix sequence for [2-3-2] network type is showed: hidden layer matrix 2x3 and output layer one 3x2.

Each element  $a_{ij}$  in matrix  $A_k$  equals to weight value between  $i$  and  $j$  network neurons.

For realization of different types of mutations, the operations on matrices are used. When adding a new neuron

Fig. 1 [2-3-2] Network internal realization example

to the layer a combination of adding operations of new matrix row and column is implemented. In Fig. 2, 3 and 4 the realization of neuron addition to the input, hidden and output layers has been presented.

Fig.2 Neuron addition to the input layer

Fig.3 Neuron addition to the hidden layer

Fig. 4 Neuron addition to the output layer

To extract neurons opposing operations are used. In Fig. 5 there is a realization of extraction of a second neuron in the hidden network.

Fig.5 Hidden layer neuron extraction.

When adding a new layer, the new weight's matrix insertion operation is performed.

Since some operations change matrices' structures, there is a certain difficulty in their combination. For example, when extracting the hidden layer  $O_3$  neuron in [2-3-2] network the  $O_4$  neuron in the resulting network will shift

one position and become  $O_3$  neuron; when adding new hidden layer, that contains 4 neurons in front of existing hidden layer, next layer will shift one position. When combining different mutations their step-by-step execution has to be done in a strict order, which depends on type and parameters of each mutation. In Listing 1 there is a code fragment implemented in Clojure [26], that executes combined mutation. At first the mutations that do not change structures - addition and extraction of connections, are executed, then the addition of new neurons and extraction of existing ones is executed; new layers are added at the end. Mutations which extract neurons, are executed in neuron number decrease order, similarly as layer addition - in new layer index decrease order.

```
(defmethod mutate ::combined
[net {:keys [mutations]}]
(let [grouped-ms (group-by :operation mutations)
      {add-node-ms ::add-node del-node-ms ::del-node
       layer-ms ::add-layer} grouped-ms
      safe-ms (mapcat grouped-ms [::identity ::add-
        edge ::del-edge])
      safe-del-node-ms (reverse
        (sort-by #(second (:deleted-node %)) del-node-ms))
      safe-layer-ms (reverse (sort-by :layer-pos layer-
        ms))]
  ms (concat safe-ms add-node-ms safe-del-node-ms
    safe-layer-ms)]
(reduce mutate net ms)))
```

Listing 1 - Code fragment implemented in Clojure, that executes combined mutation

One of the Clojure [8] benefits over other programming languages is usage of unchangeable data structures - collections and containers, the content of which cannot be changed. In return, while trying to add a new element to the collection the new substance of the collection will be created containing this element. The operation of creating a new collection is optimized this way: both objects will use the mutual part of collection. In Fig. 6 the result of adding object 5 to the end of array [.....] is showed. V denotes an old collection object, v2 denotes newly created collection object.

Fig.6 Principle of data structure work in Clojure

Programming with unchangeable data structure usage makes programs much easier to understand.

- program parallelization simplicity - unchangeable data can be used in parallel without any need to synchronize threads;
- no problems with memory leaks;
- caching simplicity;
- major memory economy in some cases.

Due to these characteristics of unchangeable structures the main part of an algorithms work is done in parallel with maximum computing resources usage.

The developed system has a client-server architecture. A system deployment diagram is showed in Fig. 7. In general the system consists of 2 parts:

- server application, which does neural network learning and implements structure optimization algorithm;
- client application, which implements GUI

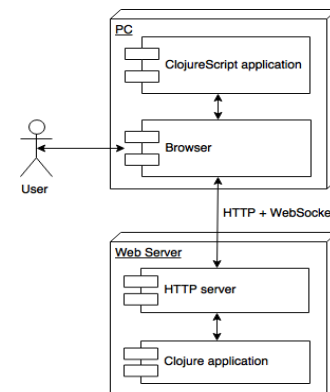

Fig.7 System deployment diagram

Clojure has been used to implement the server application. The Java platform [27] has been used as a runtime environment.

For the GUI implementation, the ClojureScript - Clojure dialect [26], executed in JavaScript, has been used.

## V. EXPERIMENTAL RESEARCH

The implemented program system is used to research problems of human face recognition. The face image database of Yale university was used as output data [28].

**Sampling** 10 different persons and 50 different images of each person were selected. Each image has been scaled to the size of 26x26 pixels and coded into 676-dimensional vector, the values of pixels' brightness were normalized to 0...1 range. Each output class representing a particular person was coded into a 10 element vector which contains 9 zeroes and a single 1 at a different index. The obtained 500 samples were randomly divided into training and testing sets 2:1.

In Fig. 8 the source images and images used for neural network learning are showed.

**Architecture of source network.** A network architecture which is shown in Fig. 9 was used to evaluate the work of the algorithm

Fig.8 Data set formation example

Fig.9 Image recognition network architecture

**Research of the algorithm.** The following training values and structural optimization settings have been used for SGD with weight decay regularization [29]:

- learning rate:  $\eta=0.002$ ;
- inertia coefficient:  $\mu=0.1$ ;
- damping weights coefficient:  $\varepsilon=0.1$ ;
- probability of hidden layer neuron activation:  $p_h=1$ ;
- probability of input layer neuron activation:  $p_i=1$ .

Selected parameters following algorithm:

- initial number of neurons in the hidden layer: 3;
- activation function for the hidden layer: ReLU[30];
- activation function in the output layer: softmax;
- maximum number of mutations in the crossing:  $M=50$ ;
- number of training epochs of the original network:  $T_0=100$ ;
- number of training epochs in the iteration:  $T_i=5$ ;
- acceptable mutation types: adding and removing synapses;
- part of the training sample used for training: 1;
- type of cost function: cross-entropy [31].

During 40 iterations of the algorithm 300 extractions and 128 additions of synapses were carried out. In Fig.10 and Fig. 11 the dependency of price and precision values of classification from amount of implemented learning epochs has been presented. Received values are shown in Table 1.

Due to connections' optimization structure we could lower false classification percentage to 4.2% on testing set.

An experiment has also been made in which  $T_i=3$ , which is shown in Fig. 12 and Fig. 13.

During 100 iterations of the algorithm 645 extractions and 457 additions of synapses were carried out. We could lower the false recognition percentage from 7.8 to 6.0 on testing set. The result is shown in Table 2.

TABLE 1 THE RESULTING ACCURACY OF IMAGE CLASSIFICATION FOR  $T_i=5$

Type NN	Training, %	Testing, %
Common	97.59	93.41
Optimized	98.19	95.80

Fig.13 Price value for image classification for  $T_i=3$

## VI. CONCLUSION

The problem of a structural optimization algorithm implementation was considered in this article, and the possible appliance of this algorithm in an image recognition problems was analyzed.

Due to the optimisation structure of connections we could lower the false classification percentage to 4.2% in the testing set and also we could lower the false recognition percentage from 7.8 to 6.0 in the testing set. The proposed algorithm has flexibility in the number of hidden layers, neurons and links.

The obtained results prove the efficiency of the proposed algorithm for using with recognition problems.
